
Line 98: `"""Signed-16 master value, signed-24 Q15 momentum, and deployment format."""` This is executable documentation attached to the class MasterTensor, which handles master tensor. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 100: `master: np.ndarray` Inside the class MasterTensor, which handles master tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are master: the value named 'master' in this block; ndarray: the value named 'ndarray' in this block.

Line 101: `velocity_q15: np.ndarray` Inside the class MasterTensor, which handles master tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are velocity_q15: the momentum history retained by the SGD optimizer; ndarray: the value named 'ndarray' in this block.

Line 102: `fractional_bits: int` Inside the class MasterTensor, which handles master tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are fractional_bits: the value named 'fractional bits' in this block.

Line 103: `deploy_minimum: int` Inside the class MasterTensor, which handles master tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are deploy_minimum: the value named 'deploy minimum' in this block.

Line 104: `deploy_maximum: int` Inside the class MasterTensor, which handles master tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are deploy_maximum: the value named 'deploy maximum' in this block.

Line 106: `def __post_init__(self) -> None:` This starts function ___post_init___. Its indented body performs post init as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 107: `master = np.asarray(self.master)` This assigns 'np.asarray(self.master)' to 'master ' in host memory. Here master means the value named 'master' in this block. The important operands are asarray: the value named 'asarray' in this block; master: the value named 'master' in this block. Context: the function ___post_init___, which handles post init.

Line 108: `velocity = np.asarray(self.velocity_q15)` This assigns 'np.asarray(self.velocity_q15)' to 'velocity ' in host memory. Here velocity means the momentum history retained by the SGD optimizer. The important operands are asarray: the value named 'asarray' in this block; velocity_q15: the momentum history retained by the SGD optimizer. Context: the function ___post_init___, which handles post init.

Line 109: `if not np.issubdtype(master.dtype, np.integer) or not np.issubdtype(` This line opens or closes a multi-line Python expression inside the function ___post_init___, which handles post init; the neighboring lines supply its arguments or elements.

Line 110: `velocity.dtype, np.integer` Inside the function ___post_init___, which handles post init, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are velocity: the momentum history retained by the SGD optimizer; dtype: the value named 'dtype' in this block; integer: the value named 'integer' in this block.

Line 111: `):` Inside the function ___post_init___, which handles post init, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 112: `raise ValueError("master and velocity tensors must contain integers")` This rejects an invalid state by raising ‘ValueError("master and velocity tensors must contain integers")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 113: `if master.shape != velocity.shape or master.size == 0:` This executes the following indented host-code branch only when ‘master.shape != velocity.shape or master.size == 0‘ is true. The important operands are master: the value named ’master’ in this block; shape: the value named ’shape’ in this block; velocity: the momentum history retained by the SGD optimizer. Context: the function ___post_init___, which handles post init.

Line 114: `raise ValueError("master and velocity tensors must share a nonempty shape")` This rejects an invalid state by raising ‘ValueError("master and velocity tensors must share a nonempty shape")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 115: `if np.any(master < -(1 << 15)) or np.any(master > (1 << 15) - 1):` This executes the following indented host-code branch only when ‘np.any(master < -(1 << 15)) or np.any(master > (1 << 15) - 1)‘ is true. The important operands are any: the value named ’any’ in this block; master: the value named ’master’ in this block; or: the value named ’or’ in this block. Context: the function ___post_init___, which handles post init.

Line 116: `raise ValueError("master tensor must fit signed 16-bit")` This rejects an invalid state by raising ‘ValueError("master tensor must fit signed 16-bit")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 117: `if np.any(velocity < -(1 << 23)) or np.any(velocity > (1 << 23) - 1):` This executes the following indented host-code branch only when ‘np.any(velocity < -(1 << 23)) or np.any(velocity > (1 << 23) - 1)‘ is true. The important operands are any: the value named ’any’ in this block; velocity: the momentum history retained by the SGD optimizer; or: the value named ’or’ in this block. Context: the function ___post_init___, which handles post init.

Line 118: `raise ValueError("master velocity must fit signed 24-bit")` This rejects an invalid state by raising ‘ValueError("master velocity must fit signed 24-bit")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 119: `self.master = master.astype(np.int16, copy=False)` This assigns ‘master.astype(np.int16, copy=False)‘ to ‘self.master ‘ in host memory. Here master means the value named ’master’ in this block. The important operands are master: the value named ’master’ in this block; astype: the value named ’astype’ in this block; int16: the value named ’int16’ in this block. Context: the function ___post_init___, which handles post init.

Line 120: `self.velocity_q15 = velocity.astype(np.int32, copy=False)` This assigns ‘velocity.astype(np.int32, copy=False)‘ to ‘self.velocity_q15 ‘ in host memory. Here velocity_q15 means the momentum history retained by the SGD optimizer. The important operands are velocity: the momentum history retained by the SGD optimizer; astype: the value named ’astype’ in this block; int32: the value named ’int32’ in this block. Context: the function ___post_init___, which handles post init.

Line 121: `if not 0 <= self.fractional_bits <= 14:` This executes the following indented host-code branch only when ‘not 0 <= self.fractional_bits <= 14‘ is true. The important operands are not: the value named ’not’ in this block; fractional_bits: the value named ’fractional bits’ in this block. Context: the function ___post_init___, which handles post init.

Line 122: `raise ValueError("master fractional bits must be in [0,14]")` This rejects an invalid state by raising ‘ValueError("master fractional bits must be in [0,14]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 123: `if self.deploy_minimum > self.deploy_maximum:` This executes the following indented host-code branch only when ‘self.deploy_minimum > self.deploy_maximum‘ is true. The important operands are deploy_minimum: the value named ’deploy minimum’ in this block; deploy_maximum: the value named ’deploy maximum’ in this block. Context: the function ___post_init___, which handles post init.

Line 124: `raise ValueError("deployment clamp is inverted")` This rejects an invalid state by raising ‘ValueError("deployment clamp is inverted")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 127: `def _padded_lanes(values: Sequence[int], fill: int = 0) -> tuple[int, ...]:` This starts function _padded_lanes. Its indented body performs padded lanes as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 128: `lanes = tuple(map(int, values))` This assigns ‘tuple(map(int, values))‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are tuple: the value named ’tuple’ in this block; map: the value named ’map’ in this block; values: the value named ’values’ in this block. Context: the function _padded_lanes, which handles padded lanes.

Line 129: `if len(lanes) > VECTOR_LANES:` This executes the following indented host-code branch only when ‘len(lanes) > VECTOR_LANES‘ is true. The important operands are len: the value named ’len’ in this block; lanes: one parallel arithmetic element within a vector or tensor datapath; VECTOR_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function _padded_lanes, which handles padded lanes.

Line 130: `raise ValueError("a vector chunk cannot exceed eight lanes")` This rejects an invalid state by raising ‘ValueError("a vector chunk cannot exceed eight lanes")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 131: `return lanes + (int(fill),) * (VECTOR_LANES - len(lanes))` This returns ‘lanes + (int(fill),) * (VECTOR_LANES - len(lanes))‘ to the caller of the function _padded_lanes, which handles padded lanes, ending this invocation. The important operands are lanes: one parallel arithmetic element within a vector or tensor datapath; fill: the value named ’fill’ in this block; VECTOR_LANES: one parallel arithmetic element within a vector or tensor datapath.

Line 134: `def execute_vector_tensor(` This starts function execute_vector_tensor. Its indented body performs execute vector tensor as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 135: `driver: FullTrainingDriver,` Inside the function execute_vector_tensor, which handles execute vector tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named ’driver’ in this block; FullTrainingDriver: the value named ’full training driver’ in this block.

Line 136: `operation: VectorOperation,` Inside the function execute_vector_tensor, which handles execute vector tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block.

Line 137: `operand_a,` Inside the function execute_vector_tensor, which handles execute vector tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are operand_a: the value named ’operand a’ in this block.

Line 138: `operand_b=None,` This assigns ‘None,‘ to ‘operand_b‘ in host memory. Here operand_b means the value named ’operand b’ in this block. The important operands are None: the value named ’none’ in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 139: `*,` Inside the function execute_vector_tensor, which handles execute vector tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 140: `multiplier_q15: int = 0,` This assigns ‘0,‘ to ‘multiplier_q15‘ in host memory. Here multiplier_q15 means the value named ’multiplier q15’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 141: `right_shift: int = 0,` This assigns ‘0,‘ to ‘right_shift‘ in host memory. Here right_shift means the value named ’right shift’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 142: `output_zero_point: int = 0,` This assigns ‘0,‘ to ‘output_zero_point‘ in host memory. Here output_zero_point means the integer code representing real numeric zero in affine quantization. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 143: `threshold: int = 0,` This assigns ‘0,‘ to ‘threshold‘ in host memory. Here threshold means the membrane level at which a neuron emits a spike. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 144: `surrogate_window: int = 0,` This assigns ‘0,‘ to ‘surrogate_window‘ in host memory. Here surrogate_window means the value named ’surrogate window’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 145: `clamp_minimum: int = -(1 << 31),` This assigns ‘-(1 << 31),‘ to ‘clamp_minimum‘ in host memory. Here clamp_minimum means the value named ’clamp minimum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 146: `clamp_maximum: int = (1 << 31) - 1,` This assigns ‘(1 << 31) - 1,‘ to ‘clamp_maximum‘ in host memory. Here clamp_maximum means the value named ’clamp maximum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 147: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 148: `) -> np.ndarray:` Inside the function execute_vector_tensor, which handles execute vector tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are ndarray: the value named ’ndarray’ in this block.

Line 149: `"""Apply one vector command to every element using descriptor batching."""` This is executable documentation attached to the function execute_vector_tensor, which handles execute vector tensor. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 151: `a = np.asarray(operand_a, dtype=np.int64)` This assigns ‘np.asarray(operand_a, dtype=np.int64)‘ to ‘a ‘ in host memory. Here a means the value named ’a’ in this block. The important operands are asarray: the value named ’asarray’ in this block; operand_a: the value named ’operand a’ in this block; dtype: the value named ’dtype’ in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 152: `b = np.zeros_like(a) if operand_b is None else np.asarray(operand_b, dtype=np.int64)` This assigns ‘np.zeros_like(a) if operand_b is None else np.asarray(operand_b, dtype=np.int64)‘ to ‘b ‘ in host memory. Here b means the value named ’b’ in this block. The important operands are zeros_like: the value named ’zeros like’ in this block; a: the value named ’a’ in this block; operand_b: the value named ’operand b’ in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 153: `if a.shape != b.shape:` This executes the following indented host-code branch only when ‘a.shape != b.shape‘ is true. The important operands are a: the value named ’a’ in this block; shape: the value named ’shape’ in this block; b: the value named ’b’ in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 154: `raise ValueError("vector operands must share a shape")` This rejects an invalid state by raising ‘ValueError("vector operands must share a shape")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 155: `for name, value in (("operand_a", a), ("operand_b", b)):` This iterates name, value over ‘(("operand_a", a), ("operand_b", b))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_vector_tensor, which handles execute vector tensor.

Line 156: `if value.size and (` This line opens or closes a multi-line Python expression inside the function execute_vector_tensor, which handles execute vector tensor; the neighboring lines supply its arguments or elements.

Line 157: `value.min() < -(1 << 31) or value.max() > (1 << 31) - 1` Inside the function execute_vector_tensor, which handles execute vector tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are value: the value named ’value’ in this block; min: the value named ’min’ in this block; or: the value named ’or’ in this block.

Line 158: `):` Inside the function execute_vector_tensor, which handles execute vector tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 159: `raise OverflowError(f"{name} does not fit signed 32-bit lanes")` This rejects an invalid state by raising ‘OverflowError(f"{name} does not fit signed 32-bit lanes")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 160: `if a.size == 0:` This executes the following indented host-code branch only when ‘a.size == 0‘ is true. The important operands are a: the value named ’a’ in this block; size: the value named ’size’ in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 161: `return np.empty(a.shape, dtype=np.int64)` This returns ‘np.empty(a.shape, dtype=np.int64)‘ to the caller of the function execute_vector_tensor, which handles execute vector tensor, ending this invocation. The important operands are empty: the value named ’empty’ in this block; a: the value named ’a’ in this block; shape: the value named ’shape’ in this block.

Line 162: `command = vector_command(` This statement continues through source line 169; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘vector_command(int(operation), multiplier_q15=multiplier_q15, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operation: the value named ’operation’ in this block; multiplier_q15: the value named ’multiplier q15’ in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 163: `int(operation),` This is continuation line 2 of the 8-line logical statement that begins at source line 162. Its exact fragment is ‘int(operation),‘. The important operands are operation: the value named ’operation’ in this block. Read together, the complete operation is: This assigns ‘vector_command(int(operation), multiplier_q15=multiplier_q15, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape,

mode, and numeric parameters; operation: the value named 'operation' in this block; multiplier_q15: the value named 'multiplier q15' in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 164: `multiplier_q15=multiplier_q15,` This is continuation line 3 of the 8-line logical statement that begins at source line 162. Its exact fragment is 'multiplier_q15=multiplier_q15,'. The important operands are multiplier_q15: the value named 'multiplier q15' in this block. Read together, the complete operation is: This assigns 'vector_command(int(operation), multiplier_q15=multiplier_q15, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operation: the value named 'operation' in this block; multiplier_q15: the value named 'multiplier q15' in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 165: `right_shift=right_shift,` This is continuation line 4 of the 8-line logical statement that begins at source line 162. Its exact fragment is 'right_shift=right_shift,'. The important operands are right_shift: the value named 'right shift' in this block. Read together, the complete operation is: This assigns 'vector_command(int(operation), multiplier_q15=multiplier_q15, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operation: the value named 'operation' in this block; multiplier_q15: the value named 'multiplier q15' in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 166: `output_zero_point=output_zero_point,` This is continuation line 5 of the 8-line logical statement that begins at source line 162. Its exact fragment is 'output_zero_point=output_zero_point,'. The important operands are output_zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This assigns 'vector_command(int(operation), multiplier_q15=multiplier_q15, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operation: the value named 'operation' in this block; multiplier_q15: the value named 'multiplier q15' in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 167: `threshold=threshold,` This is continuation line 6 of the 8-line logical statement that begins at source line 162. Its exact fragment is 'threshold=threshold,'. The important operands are threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This assigns 'vector_command(int(operation), multiplier_q15=multiplier_q15, right_shift=right_shift, output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operation: the value named 'operation' in this block; multiplier_q15: the value named 'multiplier q15' in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 168: `surrogate_window=surrogate_window,` This is continuation line 7 of the 8-line logical statement that begins at source line 162. Its exact fragment is 'surrogate_window=surrogate_window,'. The important operands are surrogate_window: the value named 'surrogate window' in this block. Read together, the complete operation is: This assigns 'vector_command(int(operation), multiplier_q15=multiplier_q15, right_shift=right_shift, output_zero_point=output_zero_po threshold=threshold, surrogate_window=surrogate_window,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operation: the value named 'operation' in this block; multiplier_q15: the value named 'multiplier q15' in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 169: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 162. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'vector_command(int(operation), multiplier_q15=multiplier_q15, right_shift=right_shift,

output_zero_point=output_zero_point, threshold=threshold, surrogate_window=surrogate_window,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operation: the value named 'operation' in this block; multiplier_q15: the value named 'multiplier q15' in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 170: `flat_a = a.reshape(-1)` This assigns ‘a.reshape(-1)‘ to ‘flat_a ‘ in host memory. Here flat_a means the value named 'flat a' in this block. The important operands are a: the value named 'a' in this block; reshape: the value named 'reshape' in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 171: `flat_b = b.reshape(-1)` This assigns ‘b.reshape(-1)‘ to ‘flat_b ‘ in host memory. Here flat_b means the value named 'flat b' in this block. The important operands are b: the value named 'b' in this block; reshape: the value named 'reshape' in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 172: `records: list[ProgramRecord] = []` This assigns ‘[]‘ to ‘records‘ in host memory. Here records means the number of descriptor records accepted since program start. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 173: `counts: list[int] = []` This assigns ‘[]‘ to ‘counts‘ in host memory. Here counts means the value named 'counts' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 174: `for start in range(0, flat_a.size, VECTOR_LANES):` This iterates start over ‘range(0, flat_a.size, VECTOR_LANES)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_vector_tensor, which handles execute vector tensor.

Line 175: `stop = min(start + VECTOR_LANES, flat_a.size)` This assigns ‘min(start + VECTOR_LANES, flat_a.size)‘ to ‘stop ‘ in host memory. Here stop means the value named 'stop' in this block. The important operands are min: the value named 'min' in this block; start: the value named 'start' in this block; VECTOR_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 176: `count = stop - start` This assigns ‘stop - start‘ to ‘count ‘ in host memory. Here count means the value named 'count' in this block. The important operands are stop: the value named 'stop' in this block; start: the value named 'start' in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 177: `records.append(ProgramRecord(` This statement continues through source line 186; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(flat_a[start:stop]), _padded_lanes(flat_b[start:stop]), clamp_minimum=clamp_mini clamp_maximum=clamp_maximum,), 4,)‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 178: `command,` This is continuation line 2 of the 10-line logical statement that begins at source line 177. Its exact fragment is ‘command,‘. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(flat_a[start:stop]), _padded_lanes(flat_b[start:stop]), clamp_minimum=clamp_r clamp_maximum=clamp_maximum,), 4,)‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 179: `pack_vector_beats(` This is continuation line 3 of the 10-line logical statement that begins at source line 177. Its exact fragment is ‘pack_vector_beats(‘. The important operands are pack_vector_beats: the value named 'pack vector beats' in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(

command, pack_vector_beats(_padded_lanes(flat_a[start:stop]), _padded_lanes(flat_b[start:stop]), clamp_minimum=clamp_m
clamp_maximum=clamp_maximum,), 4,)‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 180: `_padded_lanes(flat_a[start:stop]),` This is continuation line 4 of the 10-line logical statement that begins at source line 177. Its exact fragment is ‘_padded_lanes(flat_a[start:stop]),‘. The important operands are _padded_lanes: one parallel arithmetic element within a vector or tensor datapath; flat_a: the value named ’flat a’ in this block; start: the value named ’start’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(flat_a[start:stop]), _padded_lanes(flat_b[start:stop]), clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 181: `_padded_lanes(flat_b[start:stop]),` This is continuation line 5 of the 10-line logical statement that begins at source line 177. Its exact fragment is ‘_padded_lanes(flat_b[start:stop]),‘. The important operands are _padded_lanes: one parallel arithmetic element within a vector or tensor datapath; flat_b: the value named ’flat b’ in this block; start: the value named ’start’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(flat_a[start:stop]), _padded_lanes(flat_b[start:stop]), clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 182: `clamp_minimum=clamp_minimum,` This is continuation line 6 of the 10-line logical statement that begins at source line 177. Its exact fragment is ‘clamp_minimum=clamp_minimum,‘. The important operands are clamp_minimum: the value named ’clamp minimum’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(flat_a[start:stop]), _padded_lanes(flat_b[
clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 183: `clamp_maximum=clamp_maximum,` This is continuation line 7 of the 10-line logical statement that begins at source line 177. Its exact fragment is ‘clamp_maximum=clamp_maximum,‘. The important operands are clamp_maximum: the value named ’clamp maximum’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(flat_a[start:stop]), _padded_lanes(flat_b[
clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 184: `),` This is continuation line 8 of the 10-line logical statement that begins at source line 177. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(flat_a[start:stop]), _padded_lanes(flat_b[start:stop]), clamp_minimum=clamp_minimum, clamp_maximum=cla
), 4,)‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 185: `4,` This is continuation line 9 of the 10-line logical statement that begins at source line 177. Its exact fragment is ‘4,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(flat_a[start:stop]), _padded_lanes(flat_b[start:stop]), clamp_minimum=clamp_minimum, clamp_maximum=cla
), 4,)‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 186: `))` This is continuation line 10 of the 10-line logical statement that begins at source line 177. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(flat_a[start:stop]), _padded_lanes(flat_b[start:stop]), clamp_minimum=clamp_minimum, clamp_maximum=cla), 4,)‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 187: `counts.append(count)` This calls ‘counts.append‘ with ‘count‘ inside the function execute_vector_tensor, which handles execute vector tensor. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 188: `words = driver.execute_program(records, timeout_seconds=timeout_seconds)` This assigns ‘driver.execute_pr timeout_seconds=timeout_seconds)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 189: `if len(words) != 4 * len(records):` This executes the following indented host-code branch only when ‘len(words) != 4 * len(records)‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block; records: the number of descriptor records accepted since program start. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 190: `raise RuntimeError(` This statement continues through source line 192; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘RuntimeError(f"vector program returned {len(words)} beats; expected {4 * len(records)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 191: `f"vector program returned {len(words)} beats; expected {4 * len(records)}"` This is continuation line 2 of the 3-line logical statement that begins at source line 190. Its exact fragment is ‘f"vector program returned {len(words)} beats; expected {4 * len(records)}"‘. The important operands are f: the value named ’f’ in this block; vector: the value named ’vector’ in this block; program: the value named ’program’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"vector program returned {len(words)} beats; expected {4 * len(records)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 192: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 190. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"vector program returned {len(words)} beats; expected {4 * len(records)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 193: `result = np.empty(flat_a.size, dtype=np.int64)` This assigns ‘np.empty(flat_a.size, dtype=np.int64)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are empty: the value named ’empty’ in this block; flat_a: the value named ’flat a’ in this block; size: the value named ’size’ in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 194: `cursor = 0` This assigns ‘0‘ to ‘cursor ‘ in host memory. Here cursor means the value named ’cursor’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 195: `for record_index, count in enumerate(counts):` This iterates record_index, count over ‘enumerate(counts)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_vector_tensor, which handles execute vector tensor.

Line 196: `lanes = unpack_vector_result(words[4 * record_index:4 * record_index + 4])` This assigns ‘unpack_vector_result(words[4 * record_index:4 * record_index + 4])‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are unpack_vector_result: the value named ’unpack vector result’ in this block; words: the value named ’words’ in this block; record_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 197: `result[cursor:cursor + count] = lanes[:count]` This assigns ‘lanes[:count]‘ to ‘result[cursor‘ in host memory. Here result means the value named ’result’ in this block. The important operands are lanes: one parallel arithmetic element within a vector or tensor datapath; count: the value named ’count’ in this block. Context: the function execute_vector_tensor, which handles execute vector tensor.

Line 198: `cursor += count` Inside the function execute_vector_tensor, which handles execute vector tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are cursor: the value named ’cursor’ in this block; count: the value named ’count’ in this block.

Line 199: `return result.reshape(a.shape)` This returns ‘result.reshape(a.shape)‘ to the caller of the function execute_vector_tensor, which handles execute vector tensor, ending this invocation. The important operands are result: the value named ’result’ in this block; reshape: the value named ’reshape’ in this block; a: the value named ’a’ in this block.

Line 202: `def execute_power_of_two_scale(` This starts function execute_power_of_two_scale. Its indented body performs execute power of two scale as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 203: `driver: FullTrainingDriver,` Inside the function execute_power_of_two_scale, which handles execute power of two scale, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named ’driver’ in this block; FullTrainingDriver: the value named ’full training driver’ in this block.

Line 204: `values,` Inside the function execute_power_of_two_scale, which handles execute power of two scale, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are values: the value named ’values’ in this block.

Line 205: `power: int,` Inside the function execute_power_of_two_scale, which handles execute power of two scale, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are power: the value named ’power’ in this block.

Line 206: `*,` Inside the function execute_power_of_two_scale, which handles execute power of two scale, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 207: `clamp_minimum: int = -(1 << 31),` This assigns ‘-(1 << 31),‘ to ‘clamp_minimum‘ in host memory. Here clamp_minimum means the value named ’clamp minimum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 208: `clamp_maximum: int = (1 << 31) - 1,` This assigns ‘(1 << 31) - 1,‘ to ‘clamp_maximum‘ in host memory. Here clamp_maximum means the value named ’clamp maximum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 209: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 210: `) -> np.ndarray:` Inside the function execute_power_of_two_scale, which handles execute power of two scale, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are ndarray: the value named 'ndarray' in this block.

Line 211: `"""Multiply by "2**power" with exact fabric round-to-nearest shifts."""` This is executable documentation attached to the function execute_power_of_two_scale, which handles execute power of two scale. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 213: `result = np.asarray(values, dtype=np.int64)` This assigns 'np.asarray(values, dtype=np.int64)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are asarray: the value named 'asarray' in this block; values: the value named 'values' in this block; dtype: the value named 'dtype' in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 214: `remaining = int(power)` This assigns 'int(power)' to 'remaining ' in host memory. Here remaining means the value named 'remaining' in this block. The important operands are power: the value named 'power' in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 215: `while remaining:` This repeats the following host-code block while 'remaining' remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 216: `step = min(remaining, 14) if remaining > 0 else max(remaining, -16)` This assigns 'min(remaining, 14) if remaining > 0 else max(remaining, -16)' to 'step ' in host memory. Here step means the value named 'step' in this block. The important operands are min: the value named 'min' in this block; remaining: the value named 'remaining' in this block; max: the value named 'max' in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 217: `result = execute_vector_tensor(` This statement continues through source line 226; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_vector_tensor(driver, VectorOperation.FLEX_REQUANTIZE, result, multiplier_q15=1 << 14, right_shift=-step - 1, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum, timeout_seconds=timeout_seconds,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 218: `driver,` This is continuation line 2 of the 10-line logical statement that begins at source line 217. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.FLEX_REQUANTIZE, result, multiplier_q15=1 << 14, right_shift=-step - 1, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum, timeout_seconds=timeout_seconds,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 219: `VectorOperation.FLEX_REQUANTIZE,` This is continuation line 3 of the 10-line logical statement that begins at source line 217. Its exact fragment is 'VectorOperation.FLEX_REQUANTIZE,'. The important operands are VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide

accumulated result back into a bounded activation code. Read together, the complete operation is: This assigns ‘execute_vector_tensor(driver, VectorOperation.FLEX_REQUANTIZE, result, multiplier_q15=1 << 14, right_shift=-step - 1, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum, timeout_seconds=timeout_seconds,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 220: `result,` This is continuation line 4 of the 10-line logical statement that begins at source line 217. Its exact fragment is ‘result,‘. The important operands are result: the value named ’result’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(driver, VectorOperation.FLEX_REQUANTIZE, result, multiplier_q15=1 << 14, right_shift=-step - 1, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum, timeout_seconds=timeout_seconds,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 221: `multiplier_q15=1 << 14,` This is continuation line 5 of the 10-line logical statement that begins at source line 217. Its exact fragment is ‘multiplier_q15=1 << 14,‘. The important operands are multiplier_q15: the value named ’multiplier q15’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(driver, VectorOperation.FLEX_REQUANTIZE, result, multiplier_q15=1 << 14, right_shift=-step - 1, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum, timeout_seconds=timeout_seconds,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 222: `right_shift=-step - 1,` This is continuation line 6 of the 10-line logical statement that begins at source line 217. Its exact fragment is ‘right_shift=-step - 1,‘. The important operands are right_shift: the value named ’right shift’ in this block; step: the value named ’step’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(driver, VectorOperation.FLEX_REQUANTIZE, result, multiplier_q15=1 << 14, right_shift=-step - 1, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum, timeout_seconds=timeout_seconds,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 223: `clamp_minimum=clamp_minimum,` This is continuation line 7 of the 10-line logical statement that begins at source line 217. Its exact fragment is ‘clamp_minimum=clamp_minimum,‘. The important operands are clamp_minimum: the value named ’clamp minimum’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(driver, VectorOperation.FLEX_REQUANTIZE, result, multiplier_q15=1 << 14, right_shift=-step - 1, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum, timeout_seconds=timeout_seconds,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 224: `clamp_maximum=clamp_maximum,` This is continuation line 8 of the 10-line logical statement that begins at source line 217. Its exact fragment is ‘clamp_maximum=clamp_maximum,‘. The important operands are clamp_maximum: the value named ’clamp maximum’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(driver, VectorOperation.FLEX_REQUANTIZE, result, multiplier_q15=1 << 14, right_shift=-step - 1, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum, timeout_seconds=timeout_seconds,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 225: `timeout_seconds=timeout_seconds,` This is continuation line 9 of the 10-line logical statement that begins at source line 217. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.FLEX_REQUANTIZE, result, multiplier_q15=1 << 14, right_shift=-step - 1, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum, timeout_seconds=timeout_seconds,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 226: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 217. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.FLEX_REQUANTIZE, result, multiplier_q15=1 << 14, right_shift=-step - 1, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum, timeout_seconds=timeout_seconds,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_power_of_two_scale, which handles execute power of two scale.

Line 227: `remaining -= step` Inside the function execute_power_of_two_scale, which handles execute power of two scale, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are remaining: the value named 'remaining' in this block; step: the value named 'step' in this block.

Line 228: `return result` This returns 'result' to the caller of the function execute_power_of_two_scale, which handles execute power of two scale, ending this invocation. The important operands are result: the value named 'result' in this block.

Line 231: `def normalize_gradient_s16(` This starts function normalize_gradient_s16. Its indented body performs normalize gradient s16 as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 232: `driver: FullTrainingDriver,` Inside the function normalize_gradient_s16, which handles normalize gradient s16, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named 'driver' in this block; FullTrainingDriver: the value named 'full training driver' in this block.

Line 233: `gradient: BlockGradient,` Inside the function normalize_gradient_s16, which handles normalize gradient s16, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 234: `*,` Inside the function normalize_gradient_s16, which handles normalize gradient s16, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 235: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 236: `) -> BlockGradient:` Inside the function normalize_gradient_s16, which handles normalize gradient s16, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter.

Line 237: `"""Right-shift a block only as much as required for signed-16 matrix input."""` This is executable documentation attached to the function normalize_gradient_s16, which handles normalize gradient s16. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 239: `values = gradient.values` This assigns ‘gradient.values‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 240: `maximum = int(np.abs(values).max(initial=0))` This assigns ‘int(np.abs(values).max(initial=0))‘ to ‘maximum ‘ in host memory. Here maximum means the value named ’maximum’ in this block. The important operands are abs: the value named ’abs’ in this block; values: the value named ’values’ in this block; max: the value named ’max’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 241: `shift = 0` This assigns ‘0‘ to ‘shift ‘ in host memory. Here shift means the value named ’shift’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 242: `while maximum > 32767:` This repeats the following host-code block while ‘maximum $>$ 32767‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 243: `maximum = (maximum + 1) // 2` This assigns ‘(maximum + 1) // 2‘ to ‘maximum ‘ in host memory. Here maximum means the value named ’maximum’ in this block. The important operands are maximum: the value named ’maximum’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 244: `shift += 1` Inside the function normalize_gradient_s16, which handles normalize gradient s16, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are shift: the value named ’shift’ in this block.

Line 245: `if shift == 0:` This executes the following indented host-code branch only when ‘shift == 0‘ is true. The important operands are shift: the value named ’shift’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 246: `return BlockGradient(values.astype(np.int64, copy=False), gradient.exponent)` This returns ‘BlockGradient(values.astype(np.int64, copy=False), gradient.exponent)‘ to the caller of the function normalize_gradient_s16, which handles normalize gradient s16, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; astype: the value named ’astype’ in this block.

Line 247: `shifted = execute_power_of_two_scale(` This statement continues through source line 254; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_power_of_two_scale(driver, values, -shift, clamp_minimum=-32768, clamp_maximum=32767, timeout_seconds=timeout_seconds,)‘ to ‘shifted ‘ in host memory. Here shifted means the value named ’shifted’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 248: `driver,` This is continuation line 2 of the 8-line logical statement that begins at source line 247. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(driver, values, -shift, clamp_minimum=-32768, clamp_maximum=32767, timeout_seconds=timeout_seconds,)‘ to ‘shifted ‘ in host memory. Here shifted means the value named ’shifted’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 249: `values,` This is continuation line 3 of the 8-line logical statement that begins at source line 247. Its exact fragment is ‘values,‘. The important operands are values: the value named ’values’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(driver, values, -shift, clamp_minimum=-32768, clamp_maximum=32767, timeout_seconds=timeout_seconds,)‘ to ‘shifted ‘ in host memory. Here shifted means the value named ’shifted’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 250: `-shift,` This is continuation line 4 of the 8-line logical statement that begins at source line 247. Its exact fragment is ‘-shift,‘. The important operands are shift: the value named ’shift’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(driver, values, -shift, clamp_minimum=-32768, clamp_maximum=32767, timeout_seconds=timeout_seconds,)‘ to ‘shifted ‘ in host memory. Here shifted means the value named ’shifted’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 251: `clamp_minimum=-32768,` This is continuation line 5 of the 8-line logical statement that begins at source line 247. Its exact fragment is ‘clamp_minimum=-32768,‘. The important operands are clamp_minimum: the value named ’clamp minimum’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(driver, values, -shift, clamp_minimum=-32768, clamp_maximum=32767, timeout_seconds=timeout_seconds,)‘ to ‘shifted ‘ in host memory. Here shifted means the value named ’shifted’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 252: `clamp_maximum=32767,` This is continuation line 6 of the 8-line logical statement that begins at source line 247. Its exact fragment is ‘clamp_maximum=32767,‘. The important operands are clamp_maximum: the value named ’clamp maximum’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(driver, values, -shift, clamp_minimum=-32768, clamp_maximum=32767, timeout_seconds=timeout_seconds,)‘ to ‘shifted ‘ in host memory. Here shifted means the value named ’shifted’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 253: `timeout_seconds=timeout_seconds,` This is continuation line 7 of the 8-line logical statement that begins at source line 247. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(driver, values, -shift, clamp_minimum=-32768, clamp_maximum=32767, timeout_seconds=timeout_seconds,)‘ to ‘shifted ‘ in host memory. Here shifted means the value named ’shifted’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 254: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 247. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(driver, values, -shift, clamp_minimum=-32768, clamp_maximum=32767, timeout_seconds=timeout_seconds,)‘ to ‘shifted ‘ in host memory. Here shifted means the value named ’shifted’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function normalize_gradient_s16, which handles normalize gradient s16.

Line 255: `return BlockGradient(shifted, gradient.exponent + shift)` This returns ‘BlockGradient(shifted, gradient.exponent + shift)‘ to the caller of the function normalize_gradient_s16, which handles normalize gradient s16, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; shifted: the value named ’shifted’ in this block; gradient: the signed loss derivative used to update a learned parameter.

Line 258: `def add_block_gradients(` This starts function add_block_gradients. Its indented body performs add block gradients as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 259: `driver: FullTrainingDriver,` Inside the function add_block_gradients, which handles add block gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named 'driver' in this block; FullTrainingDriver: the value named 'full training driver' in this block.

Line 260: `left: BlockGradient,` Inside the function add_block_gradients, which handles add block gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are left: the value named 'left' in this block; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 261: `right: BlockGradient,` Inside the function add_block_gradients, which handles add block gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are right: the value named 'right' in this block; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 262: `*,` Inside the function add_block_gradients, which handles add block gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 263: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function add_block_gradients, which handles add block gradients.

Line 264: `) -> BlockGradient:` Inside the function add_block_gradients, which handles add block gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter.

Line 265: `"""Align two block exponents and add all lanes in programmable logic."""` This is executable documentation attached to the function add_block_gradients, which handles add block gradients. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 267: `if left.values.shape != right.values.shape:` This executes the following indented host-code branch only when 'left.values.shape != right.values.shape' is true. The important operands are left: the value named 'left' in this block; values: the value named 'values' in this block; shape: the value named 'shape' in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 268: `raise ValueError("gradient addends must share a shape")` This rejects an invalid state by raising 'ValueError("gradient addends must share a shape")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 269: `exponent = max(left.exponent, right.exponent)` This assigns 'max(left.exponent, right.exponent)' to 'exponent ' in host memory. Here exponent means the value named 'exponent' in this block. The important operands are max: the value named 'max' in this block; left: the value named 'left' in this block; exponent: the value named 'exponent' in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 270: `left_values = left.values` This assigns 'left.values' to 'left_values ' in host memory. Here left_values means the value named 'left values' in this block. The important operands are left: the value named 'left' in this block; values: the value named 'values' in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 271: `right_values = right.values` This assigns ‘right.values‘ to ‘right_values ‘ in host memory. Here right_values means the value named ’right values’ in this block. The important operands are right: the value named ’right’ in this block; values: the value named ’values’ in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 272: `if left.exponent != exponent:` This executes the following indented host-code branch only when ‘left.exponent != exponent‘ is true. The important operands are left: the value named ’left’ in this block; exponent: the value named ’exponent’ in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 273: `left_values = execute_power_of_two_scale(` This statement continues through source line 275; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_power_of_two_scale(driver, left_values, left.exponent - exponent, timeout_seconds=timeout_seconds)‘ to ‘left_values ‘ in host memory. Here left_values means the value named ’left values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; left_values: the value named ’left values’ in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 274: `driver, left_values, left.exponent - exponent,` This is continuation line 2 of the 3-line logical statement that begins at source line 273. Its exact fragment is ‘driver, left_values, left.exponent - exponent,‘. The important operands are driver: the value named ’driver’ in this block; left_values: the value named ’left values’ in this block; left: the value named ’left’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(driver, left_values, left.exponent - exponent, timeout_seconds=timeout_seconds)‘ to ‘left_values ‘ in host memory. Here left_values means the value named ’left values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; left_values: the value named ’left values’ in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 275: `timeout_seconds=timeout_seconds)` This is continuation line 3 of the 3-line logical statement that begins at source line 273. Its exact fragment is ‘timeout_seconds=timeout_seconds)‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(driver, left_values, left.exponent - exponent, timeout_seconds=timeout_seconds)‘ to ‘left_values ‘ in host memory. Here left_values means the value named ’left values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; left_values: the value named ’left values’ in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 276: `if right.exponent != exponent:` This executes the following indented host-code branch only when ‘right.exponent != exponent‘ is true. The important operands are right: the value named ’right’ in this block; exponent: the value named ’exponent’ in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 277: `right_values = execute_power_of_two_scale(` This statement continues through source line 279; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_power_of_two_scale(driver, right_values, right.exponent - exponent, timeout_seconds=timeout_seconds)‘ to ‘right_values ‘ in host memory. Here right_values means the value named ’right values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; right_values: the value named ’right values’ in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 278: `driver, right_values, right.exponent - exponent,` This is continuation line 2 of the 3-line logical statement that begins at source line 277. Its exact fragment is ‘driver, right_values, right.exponent - exponent,‘. The important operands are driver: the value named ’driver’ in this block; right_values: the value named ’right values’ in this block; right: the value named ’right’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(driver, right_values, right.exponent - exponent, timeout_seconds=timeout_seconds)‘ to ‘right_values ‘ in host memory. Here right_values means the value named ’right values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver:

the value named 'driver' in this block; right_values: the value named 'right values' in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 279: `timeout_seconds=timeout_seconds)` This is continuation line 3 of the 3-line logical statement that begins at source line 277. Its exact fragment is 'timeout_seconds=timeout_seconds)'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_power_of_two_scale(driver, right_values, right.exponent - exponent, timeout_seconds=timeout_seconds)' to 'right_values ' in host memory. Here right_values means the value named 'right values' in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block; right_values: the value named 'right values' in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 280: `result = execute_vector_tensor(` This statement continues through source line 286; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, left_values, right_values, timeout_seconds=timeout_seconds,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 281: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 280. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, left_values, right_values, timeout_seconds=timeout_seconds,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 282: `VectorOperation.ADD_SAT,` This is continuation line 3 of the 7-line logical statement that begins at source line 280. Its exact fragment is 'VectorOperation.ADD_SAT,'. The important operands are VectorOperation: the value named 'vector operation' in this block; ADD_SAT: the value named 'add sat' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, left_values, right_values, timeout_seconds=timeout_seconds,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 283: `left_values,` This is continuation line 4 of the 7-line logical statement that begins at source line 280. Its exact fragment is 'left_values,'. The important operands are left_values: the value named 'left values' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, left_values, right_values, timeout_seconds=timeout_seconds,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 284: `right_values,` This is continuation line 5 of the 7-line logical statement that begins at source line 280. Its exact fragment is 'right_values,'. The important operands are right_values: the value named 'right values' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, left_values, right_values, timeout_seconds=timeout_seconds,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 285: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 280. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'exe-

cute_vector_tensor(driver, VectorOperation.ADD_SAT, left_values, right_values, timeout_seconds=timeout_seconds,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 286: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 280. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘execute_vector_tensor(driver, VectorOperation.ADD_SAT, left_values, right_values, timeout_seconds=timeout_seconds,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function add_block_gradients, which handles add block gradients.

Line 287: `return BlockGradient(result, exponent)` This returns ‘BlockGradient(result, exponent)‘ to the caller of the function add_block_gradients, which handles add block gradients, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; result: the value named ’result’ in this block; exponent: the value named ’exponent’ in this block.

Line 290: `def _required_right_shift(bound: int, maximum: int) -> int:` This starts function _required_right_shift. Its indented body performs required right shift as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 291: `if bound < 0 or maximum <= 0:` This executes the following indented host-code branch only when ‘bound < 0 or maximum <= 0‘ is true. The important operands are bound: the value named ’bound’ in this block; or: the value named ’or’ in this block; maximum: the value named ’maximum’ in this block. Context: the function _required_right_shift, which handles required right shift.

Line 292: `raise ValueError("gradient bounds must be nonnegative with a positive limit")` This rejects an invalid state by raising ‘ValueError("gradient bounds must be nonnegative with a positive limit")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 293: `shift = 0` This assigns ‘0‘ to ‘shift ‘ in host memory. Here shift means the value named ’shift’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _required_right_shift, which handles required right shift.

Line 294: `while bound > maximum:` This repeats the following host-code block while ‘bound > maximum‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 295: `bound = (bound + 1) // 2` This assigns ‘(bound + 1) // 2‘ to ‘bound ‘ in host memory. Here bound means the value named ’bound’ in this block. The important operands are bound: the value named ’bound’ in this block. Context: the function _required_right_shift, which handles required right shift.

Line 296: `shift += 1` Inside the function _required_right_shift, which handles required right shift, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are shift: the value named ’shift’ in this block.

Line 297: `if shift > 31:` This executes the following indented host-code branch only when ‘shift > 31‘ is true. The important operands are shift: the value named ’shift’ in this block. Context: the function _required_right_shift, which handles required right shift.

Line 298: `raise OverflowError("a gradient reduction requires more than 31 shift bits")` This rejects an invalid state by raising ‘OverflowError("a gradient reduction requires more than 31 shift bits")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 299: `return shift` This returns ‘shift‘ to the caller of the function _required_right_shift, which handles required right shift, ending this invocation. The important operands are shift: the value named ’shift’ in this block.

Line 302: `def backward_requantize_projection(` This starts function backward_requantize_projection. Its indented body performs backward requantize projection as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 303: `driver: FullTrainingDriver,` Inside the function backward_requantize_projection, which handles backward requantize projection, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named ’driver’ in this block; FullTrainingDriver: the value named ’full training driver’ in this block.

Line 304: `output_gradient: BlockGradient,` Inside the function backward_requantize_projection, which handles backward requantize projection, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 305: `parameters: ProjectionParameters,` Inside the function backward_requantize_projection, which handles backward requantize projection, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are parameters: the value named ’parameters’ in this block; ProjectionParameters: the value named ’projection parameters’ in this block.

Line 306: `*,` Inside the function backward_requantize_projection, which handles backward requantize projection, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 307: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 308: `) -> BlockGradient:` Inside the function backward_requantize_projection, which handles backward requantize projection, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter.

Line 309: `"""Differentiate the exported per-channel folded-BN requantizer with STE."""` This is executable documentation attached to the function backward_requantize_projection, which handles backward requantize projection. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 311: `values = output_gradient.values` This assigns ‘output_gradient.values‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 312: `channels = parameters.weight_k_by_n.shape[1]` This assigns ‘parameters.weight_k_by_n.shape[1]‘ to ‘channels ‘ in host memory. Here channels means the value named ’channels’ in this block. The important operands are parameters: the value named ’parameters’ in this block; weight_k_by_n: a learned coefficient multiplied by an activation; shape: the value named ’shape’ in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 313: `if values.ndim != 2 or values.shape[1] != channels:` This executes the following indented host-code branch only when ‘values.ndim != 2 or values.shape[1] != channels‘ is true. The important operands are values: the value named ’values’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 314: `raise ValueError("projection output gradient must have shape [rows,channels]")` This rejects an invalid state by raising ‘ValueError("projection output gradient must have shape [rows,channels]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 315: `shifts = parameters.binary_point_shift.astype(np.int64)` This assigns ‘parameters.binary_point_shift.astype to ‘shifts ‘ in host memory. Here shifts means the value named ’shifts’ in this block. The important operands are parameters: the value named ’parameters’ in this block; binary_point_shift: the value named ’binary point shift’ in this block; astype: the value named ’astype’ in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 316: `multipliers = parameters.multiplier_q15.astype(np.int64)` This assigns ‘parameters.multiplier_q15.astype(np to ‘multipliers ‘ in host memory. Here multipliers means the value named ’multipliers’ in this block. The important operands are parameters: the value named ’parameters’ in this block; multiplier_q15: the value named ’multiplier q15’ in this block; astype: the value named ’astype’ in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 317: `boost_minimum = max(int(shift) - 15 for shift in shifts)` This assigns ‘max(int(shift) - 15 for shift in shifts)‘ to ‘boost_minimum ‘ in host memory. Here boost_minimum means the value named ’boost minimum’ in this block. The important operands are max: the value named ’max’ in this block; shift: the value named ’shift’ in this block; for: the value named ’for’ in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 318: `boost_maximum = min(int(shift) + 15 for shift in shifts)` This assigns ‘min(int(shift) + 15 for shift in shifts)‘ to ‘boost_maximum ‘ in host memory. Here boost_maximum means the value named ’boost maximum’ in this block. The important operands are min: the value named ’min’ in this block; shift: the value named ’shift’ in this block; for: the value named ’for’ in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 319: `selected_boost: int | None = None` This assigns ‘None‘ to ‘selected_boost‘ in host memory. Here selected_boost means the value named ’selected boost’ in this block. The important operands are None: the value named ’none’ in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 320: `for boost in range(boost_maximum, boost_minimum - 1, -1):` This iterates boost over ‘range(boost_maximum, boost_minimum - 1, -1)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function backward_requantize_projection, which handles backward requantize projection.

Line 321: `represented_maximum = 0` This assigns ‘0‘ to ‘represented_maximum ‘ in host memory. Here represented_maximum means the value named ’represented maximum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 322: `for channel in range(channels):` This iterates channel over ‘range(channels)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function backward_requantize_projection, which handles backward requantize projection.

Line 323: `product = values[:, channel] * int(multipliers[channel])` This assigns ‘values[:, channel] * int(multipliers[cha to ‘product ‘ in host memory. Here product means the value named ’product’ in this block. The important operands are values: the value named ’values’ in this block; channel: the value named ’channel’ in this block; multipliers: the

value named 'multipliers' in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 324: `represented = round_shift_signed(` This statement continues through source line 325; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'round_shift_signed(product, 15 + int(shifts[channel]) - boost)' to 'represented ' in host memory. Here represented means the value named 'represented' in this block. The important operands are round_shift_signed: the value named 'round shift signed' in this block; product: the value named 'product' in this block; shifts: the value named 'shifts' in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 325: `product, 15 + int(shifts[channel]) - boost)` This is continuation line 2 of the 2-line logical statement that begins at source line 324. Its exact fragment is 'product, 15 + int(shifts[channel]) - boost)'. The important operands are product: the value named 'product' in this block; shifts: the value named 'shifts' in this block; channel: the value named 'channel' in this block. Read together, the complete operation is: This assigns 'round_shift_signed(product, 15 + int(shifts[channel]) - boost)' to 'represented ' in host memory. Here represented means the value named 'represented' in this block. The important operands are round_shift_signed: the value named 'round shift signed' in this block; product: the value named 'product' in this block; shifts: the value named 'shifts' in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 326: `represented_maximum = max(` This statement continues through source line 327; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'max(represented_maximum, int(np.abs(represented).ma
to 'represented_maximum ' in host memory. Here represented_maximum means the value named 'represented maximum' in this block. The important operands are max: the value named 'max' in this block; represented_maximum: the value named 'represented maximum' in this block; abs: the value named 'abs' in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 327: `represented_maximum, int(np.abs(represented).max(initial=0)))` This is continuation line 2 of the 2-line logical statement that begins at source line 326. Its exact fragment is 'represented_maximum, int(np.abs(represented).max(init
The important operands are represented_maximum: the value named 'represented maximum' in this block; abs: the value named 'abs' in this block; represented: the value named 'represented' in this block. Read together, the complete operation is: This assigns 'max(represented_maximum, int(np.abs(represented).max(initial=0)))' to 'represented_maximum ' in host memory. Here represented_maximum means the value named 'represented maximum' in this block. The important operands are max: the value named 'max' in this block; represented_maximum: the value named 'represented maximum' in this block; abs: the value named 'abs' in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 328: `if represented_maximum <= 32767:` This executes the following indented host-code branch only when 'represented_maximum <= 32767' is true. The important operands are represented_maximum: the value named 'represented maximum' in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 329: `selected_boost = boost` This assigns 'boost' to 'selected_boost ' in host memory. Here selected_boost means the value named 'selected boost' in this block. The important operands are boost: the value named 'boost' in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 330: `break` Inside the function backward_requantize_projection, which handles backward requantize projection, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are break: the value named 'break' in this block.

Line 331: `if selected_boost is None:` This executes the following indented host-code branch only when 'selected_boost is None' is true. The important operands are selected_boost: the value named 'selected boost' in this block; is: the value named 'is' in this block; None: the value named 'none' in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 332: `raise OverflowError("projection derivative cannot be represented by signed-16 lanes")` This rejects an invalid state by raising ‘OverflowError("projection derivative cannot be represented by signed-16 lanes")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 334: `rows = values.shape[0]` This assigns ‘values.shape[0]‘ to ‘rows ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 335: `records: list[ProgramRecord] = []` This assigns ‘[]‘ to ‘records‘ in host memory. Here records means the number of descriptor records accepted since program start. The expression is a literal or structural operator and has no hidden software state. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 336: `bindings: list[tuple[int, int, int]] = []` This assigns ‘[]‘ to ‘bindings‘ in host memory. Here bindings means the value named ’bindings’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 337: `zeros = (0,) * VECTOR_LANES` This assigns ‘(0,) * VECTOR_LANES‘ to ‘zeros ‘ in host memory. Here zeros means the value named ’zeros’ in this block. The important operands are VECTOR_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 338: `for channel in range(channels):` This iterates channel over ‘range(channels)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function backward_requantize_projection, which handles backward requantize projection.

Line 339: `command = vector_command(` This statement continues through source line 343; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘vector_command(int(VectorOperation.FLEX_REQUA multiplier_q15=int(multipliers[channel]), right_shift=int(shifts[channel]) - selected_boost,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 340: `int(VectorOperation.FLEX_REQUANTIZE),` This is continuation line 2 of the 5-line logical statement that begins at source line 339. Its exact fragment is ‘int(VectorOperation.FLEX_REQUANTIZE),‘. The important operands are VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Read together, the complete operation is: This assigns ‘vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=int(multipliers[channel]), right_shift=int(shifts[channel]) - selected_boost,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 341: `multiplier_q15=int(multipliers[channel]),` This is continuation line 3 of the 5-line logical statement that begins at source line 339. Its exact fragment is ‘multiplier_q15=int(multipliers[channel]),‘. The important operands are multiplier_q15: the value named ’multiplier q15’ in this block; multipliers: the value named ’multipliers’ in this block; channel: the value named ’channel’ in this block. Read together, the complete operation is: This assigns ‘vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=int(multipliers[channel]), right_shift=int(shifts[channel]) - selected_boost,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command:

the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 342: `right_shift=int(shifts[channel]) - selected_boost,` This is continuation line 4 of the 5-line logical statement that begins at source line 339. Its exact fragment is 'right_shift=int(shifts[channel]) - selected_boost,'. The important operands are right_shift: the value named 'right shift' in this block; shifts: the value named 'shifts' in this block; channel: the value named 'channel' in this block. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=int(multipliers[channel]), right_shift=int(shifts[chan - selected_boost,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 343: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 339. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=int(multipliers[channel]), right_shift=int(shifts[channel]) - selected_boost,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 344: `for row_start in range(0, rows, VECTOR_LANES):` This iterates row_start over 'range(0, rows, VECTOR_LANES)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function backward_requantize_projection, which handles backward requantize projection.

Line 345: `row_stop = min(row_start + VECTOR_LANES, rows)` This assigns 'min(row_start + VECTOR_LANES, rows)' to 'row_stop ' in host memory. Here row_stop means one output-row position processed by the tensor tile. The important operands are min: the value named 'min' in this block; row_start: one output-row position processed by the tensor tile; VECTOR_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 346: `records.append(ProgramRecord(` This statement continues through source line 355; the explanation uses the complete expression rather than only the first visual fragment. This calls 'records.append' with 'ProgramRecord(command, pack_vector_beats(_padded_lanes(values[row_start:row_stop, channel]), zeros, clamp_minimum=-32768, clamp_maximum=32767,), 4,)' inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 347: `command,` This is continuation line 2 of the 10-line logical statement that begins at source line 346. Its exact fragment is 'command,'. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls 'records.append' with 'ProgramRecord(command, pack_vector_beats(_padded_lanes(values[row_start:row_stop, channel]), zeros, clamp_minimum=-32768, clamp_maximum=32767,), 4,)' inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 348: `pack_vector_beats(` This is continuation line 3 of the 10-line logical statement that begins at source line 346. Its exact fragment is 'pack_vector_beats('. The important operands are pack_vector_beats: the value named 'pack vector beats' in this block. Read together, the complete operation is: This calls 'records.append' with 'ProgramRecord(command, pack_vector_beats(_padded_lanes(values[row_start:row_stop, channel]), zeros, clamp_minimum=-32768,

clamp_maximum=32767,), 4,)‘ inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 349: `_padded_lanes(values[row_start:row_stop, channel]),` This is continuation line 4 of the 10-line logical statement that begins at source line 346. Its exact fragment is ‘_padded_lanes(values[row_start:row_stop, channel]),‘. The important operands are _padded_lanes: one parallel arithmetic element within a vector or tensor datapath; values: the value named ’values’ in this block; row_start: one output-row position processed by the tensor tile. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(values[row_start:row_stop, channel]), zeros, clamp_minimum=-32768, clamp_maximum=32767,), 4,)‘ inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 350: `zeros,` This is continuation line 5 of the 10-line logical statement that begins at source line 346. Its exact fragment is ‘zeros,‘. The important operands are zeros: the value named ’zeros’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(values[row_start:row channel]), zeros, clamp_minimum=-32768, clamp_maximum=32767,), 4,)‘ inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 351: `clamp_minimum=-32768,` This is continuation line 6 of the 10-line logical statement that begins at source line 346. Its exact fragment is ‘clamp_minimum=-32768,‘. The important operands are clamp_minimum: the value named ’clamp minimum’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(values[row_start:row_stop, channel]), zeros, clamp_minimum=-32768, clamp_maximum=32767,), 4,)‘ inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 352: `clamp_maximum=32767,` This is continuation line 7 of the 10-line logical statement that begins at source line 346. Its exact fragment is ‘clamp_maximum=32767,‘. The important operands are clamp_maximum: the value named ’clamp maximum’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(values[row_start:row_stop, channel]), zeros, clamp_minimum=-32768, clamp_maximum=32767,), 4,)‘ inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 353: `),` This is continuation line 8 of the 10-line logical statement that begins at source line 346. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(values[row_start:row_stop, channel]), zeros, clamp_minimum=-32768, clamp_maximum=32767,), 4,)‘ inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 354: `4,` This is continuation line 9 of the 10-line logical statement that begins at source line 346. Its exact fragment is ‘4,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(_padded_lanes(values[row_start:row_stop, channel]), zeros, clamp_minimum=-32768, clamp_maximum=32767,), 4,)‘ inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 355: `))` This is continuation line 10 of the 10-line logical statement that begins at source line 346. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(

_padded_lanes(values[row_start:row_stop, channel]), zeros, clamp_minimum=-32768, clamp_maximum=32767,), 4,)‘ inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 356: `bindings.append((row_start, row_stop, channel))` This calls ‘bindings.append‘ with ‘(row_start, row_stop, channel)‘ inside the function backward_requantize_projection, which handles backward requantize projection. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 357: `words = driver.execute_program(records, timeout_seconds=timeout_seconds)` This assigns ‘driver.execute_pr timeout_seconds=timeout_seconds)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 358: `if len(words) != 4 * len(records):` This executes the following indented host-code branch only when ‘len(words) != 4 * len(records)‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block; records: the number of descriptor records accepted since program start. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 359: `raise RuntimeError("projection derivative returned an invalid stream length")` This rejects an invalid state by raising ‘RuntimeError("projection derivative returned an invalid stream length")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 360: `result = np.zeros(values.shape, dtype=np.int64)` This assigns ‘np.zeros(values.shape, dtype=np.int64)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are zeros: the value named ’zeros’ in this block; values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 361: `for record_index, (row_start, row_stop, channel) in enumerate(bindings):` This iterates record_index, (row_start, row_stop, channel) over ‘enumerate(bindings)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function backward_requantize_projection, which handles backward requantize projection.

Line 362: `lanes = unpack_vector_result(words[4 * record_index:4 * record_index + 4])` This assigns ‘unpack_vector_result(words[4 * record_index:4 * record_index + 4])‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are unpack_vector_result: the value named ’unpack vector result’ in this block; words: the value named ’words’ in this block; record_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 363: `result[row_start:row_stop, channel] = lanes[:row_stop - row_start]` This assigns ‘lanes[:row_stop - row_start]‘ to ‘result[row_start‘ in host memory. Here result means the value named ’result’ in this block. The important operands are lanes: one parallel arithmetic element within a vector or tensor datapath; row_stop: one output-row position processed by the tensor tile; row_start: one output-row position processed by the tensor tile. Context: the function backward_requantize_projection, which handles backward requantize projection.

Line 364: `return BlockGradient(result, output_gradient.exponent - selected_boost)` This returns ‘BlockGradient(result, output_gradient.exponent - selected_boost)‘ to the caller of the function backward_requantize_projection, which handles backward requantize projection, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; result: the value named ’result’ in this block; output_gradient: the signed loss derivative used to update a learned parameter.

Line 367: `def execute_linear_backward_block(` This starts function execute_linear_backward_block. Its indented body performs execute linear backward block as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 368: `driver: FullTrainingDriver,` Inside the function execute_linear_backward_block, which handles execute linear backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named 'driver' in this block; FullTrainingDriver: the value named 'full training driver' in this block.

Line 369: `activations,` Inside the function execute_linear_backward_block, which handles execute linear backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 370: `weights,` Inside the function execute_linear_backward_block, which handles execute linear backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are weights: a learned coefficient multiplied by an activation.

Line 371: `output_gradient: BlockGradient,` Inside the function execute_linear_backward_block, which handles execute linear backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 372: `*,` Inside the function execute_linear_backward_block, which handles execute linear backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 373: `timeout_seconds: float = 120.0,` This assigns '120.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 374: `) -> tuple[BlockGradient, BlockGradient]:` Inside the function execute_linear_backward_block, which handles execute linear backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named 'tuple' in this block; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 375: `"""Run a block-floating matrix backward pass with proven saturation bounds."""` This is executable documentation attached to the function execute_linear_backward_block, which handles execute linear backward block. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 377: `x = np.asarray(activations, dtype=np.int64)` This assigns 'np.asarray(activations, dtype=np.int64)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are asarray: the value named 'asarray' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; dtype: the value named 'dtype' in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 378: `w = np.asarray(weights, dtype=np.int64)` This assigns ‘np.asarray(weights, dtype=np.int64)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are asarray: the value named ’asarray’ in this block; weights: a learned coefficient multiplied by an activation; dtype: the value named ’dtype’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 379: `if x.ndim != 2 or w.ndim != 2 or x.shape[1] != w.shape[0]:` This executes the following indented host-code branch only when ‘x.ndim != 2 or w.ndim != 2 or x.shape[1] != w.shape[0]‘ is true. The important operands are x: the value named ’x’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 380: `raise ValueError("linear backward operands do not align")` This rejects an invalid state by raising ‘ValueError("linear backward operands do not align")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 381: `if output_gradient.values.shape != (x.shape[0], w.shape[1]):` This executes the following indented host-code branch only when ‘output_gradient.values.shape != (x.shape[0], w.shape[1])‘ is true. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 382: `raise ValueError("linear output-gradient shape does not match Y=XW")` This rejects an invalid state by raising ‘ValueError("linear output-gradient shape does not match Y=XW")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 383: `dy = normalize_gradient_s16(` This statement continues through source line 384; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘normalize_gradient_s16(driver, output_gradient, timeout_seconds=timeout_seconds)‘ to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are normalize_gradient_s16: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 384: `driver, output_gradient, timeout_seconds=timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 383. Its exact fragment is ‘driver, output_gradient, timeout_seconds=timeout_seconds)‘. The important operands are driver: the value named ’driver’ in this block; output_gradient: the signed loss derivative used to update a learned parameter; timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘normalize_gradient_s16(driver, output_gradient, timeout_seconds=timeout_seconds)‘ to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are normalize_gradient_s16: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 385: `maximum_dy = int(np.abs(dy.values).max(initial=0))` This assigns ‘int(np.abs(dy.values).max(initial=0))‘ to ‘maximum_dy ‘ in host memory. Here maximum_dy means the value named ’maximum dy’ in this block. The important operands are abs: the value named ’abs’ in this block; dy: the value named ’dy’ in this block; values: the value named ’values’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 386: `maximum_x = int(np.abs(x).max(initial=0))` This assigns ‘int(np.abs(x).max(initial=0))‘ to ‘maximum_x ‘ in host memory. Here maximum_x means the value named ’maximum x’ in this block. The important operands are abs: the value named ’abs’ in this block; x: the value named ’x’ in this block; max: the value named ’max’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 387: `maximum_w = int(np.abs(w).max(initial=0))` This assigns ‘int(np.abs(w).max(initial=0))‘ to ‘maximum_w ‘ in host memory. Here maximum_w means the value named ’maximum w’ in this block. The important operands are abs: the value named ’abs’ in this block; w: the value named ’w’ in this block; max: the value named ’max’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 388: `dx_bound = w.shape[1] * maximum_dy * maximum_w` This assigns ‘w.shape[1] * maximum_dy * maximum_w‘ to ‘dx_bound ‘ in host memory. Here dx_bound means the value named ’dx bound’ in this block. The important operands are w: the value named ’w’ in this block; shape: the value named ’shape’ in this block; maximum_dy: the value named ’maximum dy’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 389: `dw_bound = x.shape[0] * maximum_x * maximum_dy` This assigns ‘x.shape[0] * maximum_x * maximum_dy‘ to ‘dw_bound ‘ in host memory. Here dw_bound means the value named ’dw bound’ in this block. The important operands are x: the value named ’x’ in this block; shape: the value named ’shape’ in this block; maximum_x: the value named ’maximum x’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 390: `dx_shift = _required_right_shift(dx_bound, (1 << 31) - 1)` This assigns ‘_required_right_shift(dx_bound, (1 << 31) - 1)‘ to ‘dx_shift ‘ in host memory. Here dx_shift means the value named ’dx shift’ in this block. The important operands are _required_right_shift: the value named ’required right shift’ in this block; dx_bound: the value named ’dx bound’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 391: `dw_shift = _required_right_shift(dw_bound, (1 << 23) - 1)` This assigns ‘_required_right_shift(dw_bound, (1 << 23) - 1)‘ to ‘dw_shift ‘ in host memory. Here dw_shift means the value named ’dw shift’ in this block. The important operands are _required_right_shift: the value named ’required right shift’ in this block; dw_bound: the value named ’dw bound’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 392: `program = compile_linear_backward(` This statement continues through source line 398; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compile_linear_backward(x, w, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 393: `x,` This is continuation line 2 of the 7-line logical statement that begins at source line 392. Its exact fragment is ‘x,‘. The important operands are x: the value named ’x’ in this block. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 394: `w,` This is continuation line 3 of the 7-line logical statement that begins at source line 392. Its exact fragment is ‘w,‘. The important operands are w: the value named ’w’ in this block. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 395: `dy.values,` This is continuation line 4 of the 7-line logical statement that begins at source line 392. Its exact fragment is ‘dy.values,‘. The important operands are dy: the value named ’dy’ in this block; values: the value named ’values’ in this block. Read together, the complete operation is: This assigns ‘compile_linear_backward(x,

w, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 396: `input_gradient_shift=dx_shift,` This is continuation line 5 of the 7-line logical statement that begins at source line 392. Its exact fragment is ‘input_gradient_shift=dx_shift,‘. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter; dx_shift: the value named ’dx shift’ in this block. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 397: `weight_gradient_shift=dw_shift,` This is continuation line 6 of the 7-line logical statement that begins at source line 392. Its exact fragment is ‘weight_gradient_shift=dw_shift,‘. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation; dw_shift: the value named ’dw shift’ in this block. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 398: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 392. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘compile_linear_backward(x, w, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_linear_backward: the value named ’compile linear backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 399: `dx, dw = program.execute_batched(driver, timeout_seconds=timeout_seconds)` This assigns ‘program.execute_batched(driver, timeout_seconds=timeout_seconds)‘ to ‘dx, dw ‘ in host memory. Here dx means the value named ’dx’ in this block. The important operands are program: the value named ’program’ in this block; execute_batched: the value named ’execute batched’ in this block; driver: the value named ’driver’ in this block. Context: the function execute_linear_backward_block, which handles execute linear backward block.

Line 400: `return (` This statement continues through source line 403; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘(BlockGradient(dx, dy.exponent + dx_shift), BlockGradient(dw, dy.exponent + dw_shift),)‘ to the caller of the function execute_linear_backward_block, which handles execute linear backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block.

Line 401: `BlockGradient(dx, dy.exponent + dx_shift),` This is continuation line 2 of the 4-line logical statement that begins at source line 400. Its exact fragment is ‘BlockGradient(dx, dy.exponent + dx_shift),‘. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block. Read together, the complete operation is: This returns ‘(BlockGradient(dx, dy.exponent + dx_shift), BlockGradient(dw, dy.exponent + dw_shift),)‘ to the caller of the function execute_linear_backward_block, which handles execute linear backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block.

Line 402: `BlockGradient(dw, dy.exponent + dw_shift),` This is continuation line 3 of the 4-line logical statement that begins at source line 400. Its exact fragment is ‘BlockGradient(dw, dy.exponent + dw_shift),‘. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dw: the value named ’dw’ in this block; dy: the value named ’dy’ in this block. Read together, the complete operation is: This returns ‘(

BlockGradient(dx, dy.exponent + dx_shift), BlockGradient(dw, dy.exponent + dw_shift),)‘ to the caller of the function execute_linear_backward_block, which handles execute linear backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named 'dx' in this block; dy: the value named 'dy' in this block.

Line 403: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 400. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘(BlockGradient(dx, dy.exponent + dx_shift), BlockGradient(dw, dy.exponent + dw_shift),)‘ to the caller of the function execute_linear_backward_block, which handles execute linear backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named 'dx' in this block; dy: the value named 'dy' in this block.

Line 406: `def execute_affine_backward_block(` This starts function execute_affine_backward_block. Its indented body performs execute affine backward block as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 407: `driver: FullTrainingDriver,` Inside the function execute_affine_backward_block, which handles execute affine backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named 'driver' in this block; FullTrainingDriver: the value named 'full training driver' in this block.

Line 408: `activations,` Inside the function execute_affine_backward_block, which handles execute affine backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 409: `weights,` Inside the function execute_affine_backward_block, which handles execute affine backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are weights: a learned coefficient multiplied by an activation.

Line 410: `bias,` Inside the function execute_affine_backward_block, which handles execute affine backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are bias: an additive learned offset applied after accumulation.

Line 411: `output_gradient: BlockGradient,` Inside the function execute_affine_backward_block, which handles execute affine backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 412: `*,` Inside the function execute_affine_backward_block, which handles execute affine backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 413: `timeout_seconds: float = 120.0,` This assigns ‘120.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 414: `) -> tuple[BlockGradient, ParameterGradient]:` Inside the function execute_affine_backward_block, which handles execute affine backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named 'tuple' in this block; BlockGradient: the signed loss derivative used to update a learned parameter; ParameterGradient: the signed loss derivative used to update a learned parameter.

Line 415: `"""Run dX, dW, and dB for Y=XW+b through the matrix backward array."""` This is executable documentation attached to the function execute_affine_backward_block, which handles execute affine backward block. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 417: `x = np.asarray(activations, dtype=np.int64)` This assigns 'np.asarray(activations, dtype=np.int64)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are asarray: the value named 'asarray' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; dtype: the value named 'dtype' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 418: `w = np.asarray(weights, dtype=np.int64)` This assigns 'np.asarray(weights, dtype=np.int64)' to 'w ' in host memory. Here w means the value named 'w' in this block. The important operands are asarray: the value named 'asarray' in this block; weights: a learned coefficient multiplied by an activation; dtype: the value named 'dtype' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 419: `b = np.asarray(bias, dtype=np.int64)` This assigns 'np.asarray(bias, dtype=np.int64)' to 'b ' in host memory. Here b means the value named 'b' in this block. The important operands are asarray: the value named 'asarray' in this block; bias: an additive learned offset applied after accumulation; dtype: the value named 'dtype' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 420: `if x.ndim != 2 or w.ndim != 2 or b.shape != (w.shape[1],):` This executes the following indented host-code branch only when 'x.ndim != 2 or w.ndim != 2 or b.shape != (w.shape[1],)' is true. The important operands are x: the value named 'x' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 421: `raise ValueError("affine operands have inconsistent shapes")` This rejects an invalid state by raising 'ValueError("affine operands have inconsistent shapes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 422: `if x.shape[1] != w.shape[0]:` This executes the following indented host-code branch only when 'x.shape[1] != w.shape[0]' is true. The important operands are x: the value named 'x' in this block; shape: the value named 'shape' in this block; w: the value named 'w' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 423: `raise ValueError("affine activation and weight dimensions do not align")` This rejects an invalid state by raising 'ValueError("affine activation and weight dimensions do not align")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 424: `dy = normalize_gradient_s16(` This statement continues through source line 425; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'normalize_gradient_s16(driver, output_gradient, timeout_seconds=timeout_seconds)' to 'dy ' in host memory. Here dy means the value named 'dy' in this block. The important operands are normalize_gradient_s16: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 425: `driver, output_gradient, timeout_seconds=timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 424. Its exact fragment is 'driver, output_gradient, timeout_seconds=timeout_seconds)'. The important operands are driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter; timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'normalize_gradient_s16(driver, output_gradient, timeout_seconds=timeout_seconds)' to 'dy ' in host memory. Here dy means the value named 'dy' in this block. The important operands are normalize_gradient_s16: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 426: `maximum_dy = int(np.abs(dy.values).max(initial=0))` This assigns 'int(np.abs(dy.values).max(initial=0))' to 'maximum_dy ' in host memory. Here maximum_dy means the value named 'maximum dy' in this block. The important operands are abs: the value named 'abs' in this block; dy: the value named 'dy' in this block; values: the value named 'values' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 427: `maximum_x = max(int(np.abs(x).max(initial=0)), 1)` This assigns 'max(int(np.abs(x).max(initial=0)), 1)' to 'maximum_x ' in host memory. Here maximum_x means the value named 'maximum x' in this block. The important operands are max: the value named 'max' in this block; abs: the value named 'abs' in this block; x: the value named 'x' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 428: `maximum_w = max(int(np.abs(w).max(initial=0)), int(np.abs(b).max(initial=0)))` This assigns 'max(int(np.abs(w).max(initial=0)), int(np.abs(b).max(initial=0)))' to 'maximum_w ' in host memory. Here maximum_w means the value named 'maximum w' in this block. The important operands are max: the value named 'max' in this block; abs: the value named 'abs' in this block; w: the value named 'w' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 429: `dx_bound = w.shape[1] * maximum_dy * maximum_w` This assigns 'w.shape[1] * maximum_dy * maximum_w' to 'dx_bound ' in host memory. Here dx_bound means the value named 'dx bound' in this block. The important operands are w: the value named 'w' in this block; shape: the value named 'shape' in this block; maximum_dy: the value named 'maximum dy' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 430: `dw_bound = x.shape[0] * maximum_x * maximum_dy` This assigns 'x.shape[0] * maximum_x * maximum_dy' to 'dw_bound ' in host memory. Here dw_bound means the value named 'dw bound' in this block. The important operands are x: the value named 'x' in this block; shape: the value named 'shape' in this block; maximum_x: the value named 'maximum x' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 431: `dx_shift = _required_right_shift(dx_bound, (1 << 31) - 1)` This assigns '_required_right_shift(dx_bound, (1 << 31) - 1)' to 'dx_shift ' in host memory. Here dx_shift means the value named 'dx shift' in this block. The important operands are _required_right_shift: the value named 'required right shift' in this block; dx_bound: the value named 'dx bound' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 432: `dw_shift = _required_right_shift(dw_bound, (1 << 23) - 1)` This assigns '_required_right_shift(dw_bound, (1 << 23) - 1)' to 'dw_shift ' in host memory. Here dw_shift means the value named 'dw shift' in this block. The important operands are _required_right_shift: the value named 'required right shift' in this block; dw_bound: the value named 'dw bound' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 433: `program = compile_affine_backward(` This statement continues through source line 440; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'compile_affine_backward(x, w, b, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here

program means the value named 'program' in this block. The important operands are compile_affine_backward: the value named 'compile affine backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 434: `x,` This is continuation line 2 of the 8-line logical statement that begins at source line 433. Its exact fragment is 'x,'. The important operands are x: the value named 'x' in this block. Read together, the complete operation is: This assigns 'compile_affine_backward(x, w, b, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_affine_backward: the value named 'compile affine backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 435: `w,` This is continuation line 3 of the 8-line logical statement that begins at source line 433. Its exact fragment is 'w,'. The important operands are w: the value named 'w' in this block. Read together, the complete operation is: This assigns 'compile_affine_backward(x, w, b, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_affine_backward: the value named 'compile affine backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 436: `b,` This is continuation line 4 of the 8-line logical statement that begins at source line 433. Its exact fragment is 'b,'. The important operands are b: the value named 'b' in this block. Read together, the complete operation is: This assigns 'compile_affine_backward(x, w, b, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_affine_backward: the value named 'compile affine backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 437: `dy.values,` This is continuation line 5 of the 8-line logical statement that begins at source line 433. Its exact fragment is 'dy.values,'. The important operands are dy: the value named 'dy' in this block; values: the value named 'values' in this block. Read together, the complete operation is: This assigns 'compile_affine_backward(x, w, b, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_affine_backward: the value named 'compile affine backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 438: `input_gradient_shift=dx_shift,` This is continuation line 6 of the 8-line logical statement that begins at source line 433. Its exact fragment is 'input_gradient_shift=dx_shift,'. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter; dx_shift: the value named 'dx shift' in this block. Read together, the complete operation is: This assigns 'compile_affine_backward(x, w, b, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_affine_backward: the value named 'compile affine backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 439: `weight_gradient_shift=dw_shift,` This is continuation line 7 of the 8-line logical statement that begins at source line 433. Its exact fragment is 'weight_gradient_shift=dw_shift,'. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation; dw_shift: the value named 'dw shift' in this block. Read together, the complete operation is: This assigns 'compile_affine_backward(x, w, b, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_affine_backward: the value named 'compile affine backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 440: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 433. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together,

the complete operation is: This assigns ‘compile_affine_backward(x, w, b, dy.values, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_affine_backward: the value named ’compile affine backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 441: `dx, dw, db = program.execute_batched(driver, timeout_seconds=timeout_seconds)` This assigns ‘program.execute_batched(driver, timeout_seconds=timeout_seconds)‘ to ‘dx, dw, db ‘ in host memory. Here dx means the value named ’dx’ in this block. The important operands are program: the value named ’program’ in this block; execute_batched: the value named ’execute batched’ in this block; driver: the value named ’driver’ in this block. Context: the function execute_affine_backward_block, which handles execute affine backward block.

Line 442: `return (` This statement continues through source line 448; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘(BlockGradient(dx, dy.exponent + dx_shift), ParameterGradient(BlockGradient(dw, dy.exponent + dw_shift), BlockGradient(db, dy.exponent + dw_shift),),)‘ to the caller of the function execute_affine_backward_block, which handles execute affine backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block.

Line 443: `BlockGradient(dx, dy.exponent + dx_shift),` This is continuation line 2 of the 7-line logical statement that begins at source line 442. Its exact fragment is ‘BlockGradient(dx, dy.exponent + dx_shift),‘. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block. Read together, the complete operation is: This returns ‘(BlockGradient(dx, dy.exponent + dx_shift), ParameterGradient(BlockGradient(dw, dy.exponent + dw_shift), BlockGradient(db, dy.exponent + dw_shift),),)‘ to the caller of the function execute_affine_backward_block, which handles execute affine backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block.

Line 444: `ParameterGradient(` This is continuation line 3 of the 7-line logical statement that begins at source line 442. Its exact fragment is ‘ParameterGradient(‘. The important operands are ParameterGradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This returns ‘(BlockGradient(dx, dy.exponent + dx_shift), ParameterGradient(BlockGradient(dw, dy.exponent + dw_shift), BlockGradient(db, dy.exponent + dw_shift),),)‘ to the caller of the function execute_affine_backward_block, which handles execute affine backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block.

Line 445: `BlockGradient(dw, dy.exponent + dw_shift),` This is continuation line 4 of the 7-line logical statement that begins at source line 442. Its exact fragment is ‘BlockGradient(dw, dy.exponent + dw_shift),‘. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dw: the value named ’dw’ in this block; dy: the value named ’dy’ in this block. Read together, the complete operation is: This returns ‘(BlockGradient(dx, dy.exponent + dx_shift), ParameterGradient(BlockGradient(dw, dy.exponent + dw_shift), BlockGradient(db, dy.exponent + dw_shift),),)‘ to the caller of the function execute_affine_backward_block, which handles execute affine backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block.

Line 446: `BlockGradient(db, dy.exponent + dw_shift),` This is continuation line 5 of the 7-line logical statement that begins at source line 442. Its exact fragment is ‘BlockGradient(db, dy.exponent + dw_shift),‘. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; db: the value named ’db’ in this block; dy: the value named ’dy’ in this block. Read together, the complete operation is: This returns ‘(BlockGradient(dx, dy.exponent + dx_shift), ParameterGradient(BlockGradient(dw, dy.exponent + dw_shift), BlockGradient(db, dy.exponent + dw_shift),),)‘ to the caller of the function execute_affine_backward_block, which handles execute affine backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block.

Line 447: `),` This is continuation line 6 of the 7-line logical statement that begins at source line 442. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together,

the complete operation is: This returns ‘(BlockGradient(dx, dy.exponent + dx_shift), ParameterGradient(BlockGradient(dw, dy.exponent + dw_shift), BlockGradient(db, dy.exponent + dw_shift),),)‘ to the caller of the function execute_affine_backward_block, which handles execute affine backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block.

Line 448: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 442. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘(BlockGradient(dx, dy.exponent + dx_shift), ParameterGradient(BlockGradient(dw, dy.exponent + dw_shift), BlockGradient(db, dy.exponent + dw_shift),),)‘ to the caller of the function execute_affine_backward_block, which handles execute affine backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named ’dx’ in this block; dy: the value named ’dy’ in this block.

Line 451: `def execute_conv2d_backward_block(` This starts function execute_conv2d_backward_block. Its indented body performs execute conv2d backward block as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 452: `driver: FullTrainingDriver,` Inside the function execute_conv2d_backward_block, which handles execute conv2d backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named ’driver’ in this block; FullTrainingDriver: the value named ’full training driver’ in this block.

Line 453: `activations,` Inside the function execute_conv2d_backward_block, which handles execute conv2d backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 454: `weights,` Inside the function execute_conv2d_backward_block, which handles execute conv2d backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are weights: a learned coefficient multiplied by an activation.

Line 455: `bias,` Inside the function execute_conv2d_backward_block, which handles execute conv2d backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are bias: an additive learned offset applied after accumulation.

Line 456: `output_gradient: BlockGradient,` Inside the function execute_conv2d_backward_block, which handles execute conv2d backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 457: `*,` Inside the function execute_conv2d_backward_block, which handles execute conv2d backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 458: `stride=1,` This assigns ‘1,‘ to ‘stride‘ in host memory. Here stride means the value named ’stride’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 459: `padding=0,` This assigns ‘0,‘ to ‘padding‘ in host memory. Here padding means the value named ’padding’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 460: `dilation=1,` This assigns ‘1,‘ to ‘dilation‘ in host memory. Here dilation means the value named ’dilation’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 461: `groups: int = 1,` This assigns ‘1,‘ to ‘groups‘ in host memory. Here groups means the value named ’groups’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 462: `timeout_seconds: float = 120.0,` This assigns ‘120.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 463: `) -> tuple[BlockGradient, ParameterGradient]:` Inside the function execute_conv2d_backward_block, which handles execute conv2d backward block, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named ’tuple’ in this block; BlockGradient: the signed loss derivative used to update a learned parameter; ParameterGradient: the signed loss derivative used to update a learned parameter.

Line 464: `"""Run grouped NCHW convolution dX/dW/dB with block-floating bounds."""` This is executable documentation attached to the function execute_conv2d_backward_block, which handles execute conv2d backward block. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 466: `x = np.asarray(activations, dtype=np.int64)` This assigns ‘np.asarray(activations, dtype=np.int64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are asarray: the value named ’asarray’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation; dtype: the value named ’dtype’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 467: `w = np.asarray(weights, dtype=np.int64)` This assigns ‘np.asarray(weights, dtype=np.int64)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are asarray: the value named ’asarray’ in this block; weights: a learned coefficient multiplied by an activation; dtype: the value named ’dtype’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 468: `b = np.asarray(bias, dtype=np.int64)` This assigns ‘np.asarray(bias, dtype=np.int64)‘ to ‘b ‘ in host memory. Here b means the value named ’b’ in this block. The important operands are asarray: the value named ’asarray’ in this block; bias: an additive learned offset applied after accumulation; dtype: the value named ’dtype’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 469: `dy = output_gradient.values` This assigns ‘output_gradient.values‘ to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 470: `if x.ndim != 4 or w.ndim != 4 or dy.ndim != 4:` This executes the following indented host-code branch only when ‘x.ndim != 4 or w.ndim != 4 or dy.ndim != 4‘ is true. The important operands are x: the value named ’x’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 471: `raise ValueError("convolution backward requires NCHW/OIHW tensors")` This rejects an invalid state by raising 'ValueError("convolution backward requires NCHW/OIHW tensors")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 472: `normalized = normalize_gradient_s16(` This statement continues through source line 473; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'normalize_gradient_s16(driver, output_gradient, timeout_seconds=timeout_seconds)' to 'normalized ' in host memory. Here normalized means the value named 'normalized' in this block. The important operands are normalize_gradient_s16: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 473: `driver, output_gradient, timeout_seconds=timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 472. Its exact fragment is 'driver, output_gradient, timeout_seconds=timeout_seconds)'. The important operands are driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter; timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'normalize_gradient_s16(driver, output_gradient, timeout_seconds=timeout_seconds)' to 'normalized ' in host memory. Here normalized means the value named 'normalized' in this block. The important operands are normalize_gradient_s16: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 474: `maximum_dy = int(np.abs(normalized.values).max(initial=0))` This assigns 'int(np.abs(normalized.values).max to 'maximum_dy ' in host memory. Here maximum_dy means the value named 'maximum dy' in this block. The important operands are abs: the value named 'abs' in this block; normalized: the value named 'normalized' in this block; values: the value named 'values' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 475: `maximum_x = max(int(np.abs(x).max(initial=0)), 1)` This assigns 'max(int(np.abs(x).max(initial=0)), 1)' to 'maximum_x ' in host memory. Here maximum_x means the value named 'maximum x' in this block. The important operands are max: the value named 'max' in this block; abs: the value named 'abs' in this block; x: the value named 'x' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 476: `maximum_w = int(np.abs(w).max(initial=0))` This assigns 'int(np.abs(w).max(initial=0))' to 'maximum_w ' in host memory. Here maximum_w means the value named 'maximum w' in this block. The important operands are abs: the value named 'abs' in this block; w: the value named 'w' in this block; max: the value named 'max' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 477: `output_channels_per_group = w.shape[0] // groups` This assigns 'w.shape[0] // groups' to 'output_channels_per ' in host memory. Here output_channels_per_group means the value named 'output channels per group' in this block. The important operands are w: the value named 'w' in this block; shape: the value named 'shape' in this block; groups: the value named 'groups' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 478: `kernel_elements = w.shape[2] * w.shape[3]` This assigns 'w.shape[2] * w.shape[3]' to 'kernel_elements ' in host memory. Here kernel_elements means the value named 'kernel elements' in this block. The important operands are w: the value named 'w' in this block; shape: the value named 'shape' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 479: `dx_bound = output_channels_per_group * kernel_elements * maximum_dy * maximum_w` This assigns 'output_channels_per_group * kernel_elements * maximum_dy * maximum_w' to 'dx_bound ' in host memory. Here dx_bound means the value named 'dx bound' in this block. The important operands are output_channels_per_group: the value named 'output channels per group' in this block; kernel_elements: the value named 'kernel elements' in this block; maximum_dy: the value named 'maximum dy' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 480: `reduction_rows = normalized.values.shape[0] * normalized.values.shape[2] * normalized.values.shape[` This assigns ‘normalized.values.shape[0] * normalized.values.shape[2] * normalized.values.shape[3]‘ to ‘reduction_rows ‘ in host memory. Here reduction_rows means one output-row position processed by the tensor tile. The important operands are normalized: the value named ’normalized’ in this block; values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 481: `dw_bound = reduction_rows * maximum_x * maximum_dy` This assigns ‘reduction_rows * maximum_x * maximum_dy‘ to ‘dw_bound ‘ in host memory. Here dw_bound means the value named ’dw bound’ in this block. The important operands are reduction_rows: one output-row position processed by the tensor tile; maximum_x: the value named ’maximum x’ in this block; maximum_dy: the value named ’maximum dy’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 482: `dx_shift = _required_right_shift(dx_bound, (1 << 31) - 1)` This assigns ‘_required_right_shift(dx_bound, (1 << 31) - 1)‘ to ‘dx_shift ‘ in host memory. Here dx_shift means the value named ’dx shift’ in this block. The important operands are _required_right_shift: the value named ’required right shift’ in this block; dx_bound: the value named ’dx bound’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 483: `dw_shift = _required_right_shift(dw_bound, (1 << 23) - 1)` This assigns ‘_required_right_shift(dw_bound, (1 << 23) - 1)‘ to ‘dw_shift ‘ in host memory. Here dw_shift means the value named ’dw shift’ in this block. The important operands are _required_right_shift: the value named ’required right shift’ in this block; dw_bound: the value named ’dw bound’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 484: `program = compile_conv2d_backward(` This statement continues through source line 495; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_conv2d_backward: the value named ’compile conv2d backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 485: `x,` This is continuation line 2 of the 12-line logical statement that begins at source line 484. Its exact fragment is ‘x,‘. The important operands are x: the value named ’x’ in this block. Read together, the complete operation is: This assigns ‘compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_conv2d_backward: the value named ’compile conv2d backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 486: `w,` This is continuation line 3 of the 12-line logical statement that begins at source line 484. Its exact fragment is ‘w,‘. The important operands are w: the value named ’w’ in this block. Read together, the complete operation is: This assigns ‘compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_conv2d_backward: the value named ’compile conv2d backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 487: `b,` This is continuation line 4 of the 12-line logical statement that begins at source line 484. Its exact fragment is ‘b,‘. The important operands are b: the value named ’b’ in this block. Read together, the complete operation is: This assigns ‘compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_conv2d_backward: the value named ’compile conv2d backward’ in this block; x: the value named ’x’ in this block; w: the value named ’w’ in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 488: `normalized.values,` This is continuation line 5 of the 12-line logical statement that begins at source line 484. Its exact fragment is 'normalized.values,'. The important operands are normalized: the value named 'normalized' in this block; values: the value named 'values' in this block. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 489: `stride=stride,` This is continuation line 6 of the 12-line logical statement that begins at source line 484. Its exact fragment is 'stride=stride,'. The important operands are stride: the value named 'stride' in this block. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 490: `padding=padding,` This is continuation line 7 of the 12-line logical statement that begins at source line 484. Its exact fragment is 'padding=padding,'. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_s)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 491: `dilation=dilation,` This is continuation line 8 of the 12-line logical statement that begins at source line 484. Its exact fragment is 'dilation=dilation,'. The important operands are dilation: the value named 'dilation' in this block. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 492: `groups=groups,` This is continuation line 9 of the 12-line logical statement that begins at source line 484. Its exact fragment is 'groups=groups,'. The important operands are groups: the value named 'groups' in this block. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 493: `input_gradient_shift=dx_shift,` This is continuation line 10 of the 12-line logical statement that begins at source line 484. Its exact fragment is 'input_gradient_shift=dx_shift,'. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter; dx_shift: the value named 'dx shift' in this block. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 494: `weight_gradient_shift=dw_shift,` This is continuation line 11 of the 12-line logical statement that begins at source line 484. Its exact fragment is 'weight_gradient_shift=dw_shift,'. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation; dw_shift: the value named 'dw shift' in this block. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_s)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 495: `)` This is continuation line 12 of the 12-line logical statement that begins at source line 484. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'compile_conv2d_backward(x, w, b, normalized.values, stride=stride, padding=padding, dilation=dilation, groups=groups, input_gradient_shift=dx_shift, weight_gradient_shift=dw_shift,)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block; x: the value named 'x' in this block; w: the value named 'w' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 496: `dx, dw, db = program.execute_batched(driver, timeout_seconds=timeout_seconds)` This assigns 'program.execute_batched(driver, timeout_seconds=timeout_seconds)' to 'dx, dw, db ' in host memory. Here dx means the value named 'dx' in this block. The important operands are program: the value named 'program' in this block; execute_batched: the value named 'execute batched' in this block; driver: the value named 'driver' in this block. Context: the function execute_conv2d_backward_block, which handles execute conv2d backward block.

Line 497: `return (` This statement continues through source line 503; the explanation uses the complete expression rather than only the first visual fragment. This returns '(BlockGradient(dx, normalized.exponent + dx_shift), ParameterGradient(BlockGradient(dw, normalized.exponent + dw_shift), BlockGradient(db, normalized.exponent + dw_shift),),)' to the caller of the function execute_conv2d_backward_block, which handles execute conv2d backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named 'dx' in this block; normalized: the value named 'normalized' in this block.

Line 498: `BlockGradient(dx, normalized.exponent + dx_shift),` This is continuation line 2 of the 7-line logical statement that begins at source line 497. Its exact fragment is 'BlockGradient(dx, normalized.exponent + dx_shift),'. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named 'dx' in this block; normalized: the value named 'normalized' in this block. Read together, the complete operation is: This returns '(BlockGradient(dx, normalized.exponent + dx_shift), ParameterGradient(BlockGradient(dw, normalized.exponent + dw_shift), BlockGradient(db, normalized.exponent + dw_shift),),)' to the caller of the function execute_conv2d_backward_block, which handles execute conv2d backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named 'dx' in this block; normalized: the value named 'normalized' in this block.

Line 499: `ParameterGradient(` This is continuation line 3 of the 7-line logical statement that begins at source line 497. Its exact fragment is 'ParameterGradient('. The important operands are ParameterGradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This returns '(BlockGradient(dx, normalized.exponent + dx_shift), ParameterGradient(BlockGradient(dw, normalized.exponent + dw_shift), BlockGradient(db, normalized.exponent + dw_shift),),)' to the caller of the function execute_conv2d_backward_block, which handles execute conv2d backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named 'dx' in this block; normalized: the value named 'normalized' in this block.

Line 500: `BlockGradient(dw, normalized.exponent + dw_shift),` This is continuation line 4 of the 7-line logical statement that begins at source line 497. Its exact fragment is 'BlockGradient(dw, normalized.exponent + dw_shift),'. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dw: the value named 'dw' in this block; normalized: the value named 'normalized' in this block. Read together, the complete operation

is: This returns ‘(BlockGradient(dx, normalized.exponent + dx_shift), ParameterGradient(BlockGradient(dw, normalized.exponent + dw_shift), BlockGradient(db, normalized.exponent + dw_shift),),)‘ to the caller of the function execute_conv2d_backward_block, which handles execute conv2d backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named 'dx' in this block; normalized: the value named 'normalized' in this block.

Line 501: `BlockGradient(db, normalized.exponent + dw_shift),` This is continuation line 5 of the 7-line logical statement that begins at source line 497. Its exact fragment is ‘BlockGradient(db, normalized.exponent + dw_shift),‘. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; db: the value named 'db' in this block; normalized: the value named 'normalized' in this block. Read together, the complete operation is: This returns ‘(BlockGradient(dx, normalized.exponent + dx_shift), ParameterGradient(BlockGradient(dw, normalized.exponent + dw_shift), BlockGradient(db, normalized.exponent + dw_shift),),)‘ to the caller of the function execute_conv2d_backward_block, which handles execute conv2d backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named 'dx' in this block; normalized: the value named 'normalized' in this block.

Line 502: `),` This is continuation line 6 of the 7-line logical statement that begins at source line 497. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘(BlockGradient(dx, normalized.exponent + dx_shift), ParameterGradient(BlockGradient(dw, normalized.exponent + dw_shift), BlockGradient(db, normalized.exponent + dw_shift),),)‘ to the caller of the function execute_conv2d_backward_block, which handles execute conv2d backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named 'dx' in this block; normalized: the value named 'normalized' in this block.

Line 503: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 497. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘(BlockGradient(dx, normalized.exponent + dx_shift), ParameterGradient(BlockGradient(dw, normalized.exponent + dw_shift), BlockGradient(db, normalized.exponent + dw_shift),),)‘ to the caller of the function execute_conv2d_backward_block, which handles execute conv2d backward block, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; dx: the value named 'dx' in this block; normalized: the value named 'normalized' in this block.

Line 506: `def execute_softmax_q15(` This starts function execute_softmax_q15. Its indented body performs execute softmax q15 as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 507: `driver: FullTrainingDriver,` Inside the function execute_softmax_q15, which handles execute softmax q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named 'driver' in this block; FullTrainingDriver: the value named 'full training driver' in this block.

Line 508: `logits,` Inside the function execute_softmax_q15, which handles execute softmax q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are logits: the ten unnormalized classifier scores used for argmax.

Line 509: `*,` Inside the function execute_softmax_q15, which handles execute softmax q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 510: `difference_shift: int,` Inside the function execute_softmax_q15, which handles execute softmax q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are difference_shift: the value named 'difference shift' in this block.

Line 511: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 512: `) -> np.ndarray:` Inside the function execute_softmax_q15, which handles execute softmax q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are ndarray: the value named 'ndarray' in this block.

Line 513: `"""Evaluate the hardware power-of-two softmax for each classifier row."""` This is executable documentation attached to the function execute_softmax_q15, which handles execute softmax q15. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 515: `scores = np.asarray(logits, dtype=np.int64)` This assigns 'np.asarray(logits, dtype=np.int64)' to 'scores ' in host memory. Here scores means the value named 'scores' in this block. The important operands are asarray: the value named 'asarray' in this block; logits: the ten unnormalized classifier scores used for argmax; dtype: the value named 'dtype' in this block. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 516: `if scores.ndim != 2 or not 1 <= scores.shape[1] <= 256:` This executes the following indented host-code branch only when 'scores.ndim != 2 or not 1 <= scores.shape[1] <= 256' is true. The important operands are scores: the value named 'scores' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 517: `raise ValueError("logits must have shape [batch,classes] with 1..256 classes")` This rejects an invalid state by raising 'ValueError("logits must have shape [batch,classes] with 1..256 classes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 518: `if scores.size and (scores.min() < -(1 << 23) or scores.max() > (1 << 23) - 1):` This executes the following indented host-code branch only when 'scores.size and (scores.min() < -(1 << 23) or scores.max() > (1 << 23) - 1)' is true. The important operands are scores: the value named 'scores' in this block; size: the value named 'size' in this block; and: the value named 'and' in this block. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 519: `raise OverflowError("softmax logits must fit signed 24-bit")` This rejects an invalid state by raising 'OverflowError("softmax logits must fit signed 24-bit")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 520: `records = tuple(` This statement continues through source line 527; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'tuple(ProgramRecord(log_softmax_command(scores.shape[1], difference_shift), pack_softmax_beats(tuple(map(int, row))), scores.shape[1],) for row in scores)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named 'tuple' in this block; ProgramRecord: the value named 'program record' in this block; log_softmax_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 521: `ProgramRecord(` This is continuation line 2 of the 8-line logical statement that begins at source line 520. Its exact fragment is 'ProgramRecord('. The important operands are ProgramRecord: the value named 'program record' in this block. Read together, the complete operation is: This assigns 'tuple(ProgramRecord(log_softmax_command(scores.shape[1], difference_shift), pack_softmax_beats(tuple(map(int, row))), scores.shape[1],) for row in scores)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named 'tuple' in this block; ProgramRecord: the value named 'program record' in this block; log_softmax_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 522: `log_softmax_command(scores.shape[1], difference_shift),` This is continuation line 3 of the 8-line logical statement that begins at source line 520. Its exact fragment is 'log_softmax_command(scores.shape[1], difference_shift),'. The important operands are log_softmax_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; scores: the value named 'scores' in this block; shape: the value named 'shape' in this block. Read together, the complete operation is: This assigns 'tuple(ProgramRecord(log_softmax_command(scores.shape[1], difference_shift), pack_softmax_beats(tuple(map(int, row))), scores.shape[1],) for row in scores)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named 'tuple' in this block; ProgramRecord: the value named 'program record' in this block; log_softmax_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 523: `pack_softmax_beats(tuple(map(int, row))),` This is continuation line 4 of the 8-line logical statement that begins at source line 520. Its exact fragment is 'pack_softmax_beats(tuple(map(int, row))),'. The important operands are pack_softmax_beats: the value named 'pack softmax beats' in this block; tuple: the value named 'tuple' in this block; map: the value named 'map' in this block. Read together, the complete operation is: This assigns 'tuple(ProgramRecord(log_softmax_command(scores.shape[1], difference_shift), pack_softmax_beats(tuple(map(int, row))), scores.shape[1],) for row in scores)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named 'tuple' in this block; ProgramRecord: the value named 'program record' in this block; log_softmax_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 524: `scores.shape[1],` This is continuation line 5 of the 8-line logical statement that begins at source line 520. Its exact fragment is 'scores.shape[1],'. The important operands are scores: the value named 'scores' in this block; shape: the value named 'shape' in this block. Read together, the complete operation is: This assigns 'tuple(ProgramRecord(log_softmax_command(scores.shape[1], difference_shift), pack_softmax_beats(tuple(map(int, row))), scores.shape[1],) for row in scores)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named 'tuple' in this block; ProgramRecord: the value named 'program record' in this block; log_softmax_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 525: `)` This is continuation line 6 of the 8-line logical statement that begins at source line 520. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'tuple(ProgramRecord(log_softmax_command(scores.shape[1], difference_shift), pack_softmax_beats(tuple(map(int, row))), scores.shape[1],) for row in scores)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named 'tuple' in this block; ProgramRecord: the value named 'program record' in this block; log_softmax_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 526: `for row in scores` This is continuation line 7 of the 8-line logical statement that begins at source line 520. Its exact fragment is 'for row in scores'. The important operands are for: the value named 'for' in this block; row: one output-row position processed by the tensor tile; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'tuple(ProgramRecord(log_softmax_command(scores.shape[1], difference_shift), pack_softmax_beats(tuple(map(int, row))), scores.shape[1],) for row in scores)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named 'tuple' in this block; ProgramRecord: the value named 'program record' in this block; log_softmax_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 527: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 520. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'tuple(ProgramRecord(log_softmax_command(scores.shape[1], difference_shift), pack_softmax_beats(tuple(map(int, row))), scores.shape[1],) for row in scores)' to 'records ' in host memory. Here records means the number of descriptor records accepted since program start. The important operands are tuple: the value named 'tuple' in this block; ProgramRecord: the value named 'program record' in this block;

log_softmax_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 528: `words = driver.execute_program(records, timeout_seconds=timeout_seconds)` This assigns ‘driver.execute_pr timeout_seconds=timeout_seconds)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 529: `if len(words) != scores.size:` This executes the following indented host-code branch only when ‘len(words) != scores.size‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block; scores: the value named ’scores’ in this block. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 530: `raise RuntimeError("softmax returned an invalid stream length")` This rejects an invalid state by raising ‘RuntimeError("softmax returned an invalid stream length")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 531: `probabilities = np.zeros(scores.shape, dtype=np.int64)` This assigns ‘np.zeros(scores.shape, dtype=np.int64) to ‘probabilities ‘ in host memory. Here probabilities means the value named ’probabilities’ in this block. The important operands are zeros: the value named ’zeros’ in this block; scores: the value named ’scores’ in this block; shape: the value named ’shape’ in this block. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 532: `for batch_index in range(scores.shape[0]):` This iterates batch_index over ‘range(scores.shape[0])‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_softmax_q15, which handles execute softmax q15.

Line 533: `for class_index in range(scores.shape[1]):` This iterates class_index over ‘range(scores.shape[1])‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_softmax_q15, which handles execute softmax q15.

Line 534: `probability, returned_index, final = unpack_softmax_result(` This statement continues through source line 536; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘unpack_softmax_result(words[batch_index * scores.shape[1] + class_index])‘ to ‘probability, returned_index, final ‘ in host memory. Here probability means the value named ’probability’ in this block. The important operands are unpack_softmax_result: the value named ’unpack softmax result’ in this block; words: the value named ’words’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 535: `words[batch_index * scores.shape[1] + class_index]` This is continuation line 2 of the 3-line logical statement that begins at source line 534. Its exact fragment is ‘words[batch_index * scores.shape[1] + class_index]‘. The important operands are words: the value named ’words’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; scores: the value named ’scores’ in this block. Read together, the complete operation is: This assigns ‘unpack_softmax_result(words[batch_index * scores.shape[1] + class_index])‘ to ‘probability, returned_index, final ‘ in host memory. Here probability means the value named ’probability’ in this block. The important operands are unpack_softmax_result: the value named ’unpack softmax result’ in this block; words: the value named ’words’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 536: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 534. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘unpack_softmax_result(words[batch_index * scores.shape[1] + class_index])‘ to ‘probability, returned_index, final ‘ in host memory. Here probability means the value named ’probability’ in this block. The important operands are unpack_softmax_result: the value named ’unpack softmax result’ in this block; words:

the value named 'words' in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 537: `if returned_index != class_index or final != (` This line opens or closes a multi-line Python expression inside the function execute_softmax_q15, which handles execute softmax q15; the neighboring lines supply its arguments or elements.

Line 538: `class_index == scores.shape[1] - 1` Inside the function execute_softmax_q15, which handles execute softmax q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are class_index: an integer selecting one tensor element, lane, bank, or state entry; scores: the value named 'scores' in this block; shape: the value named 'shape' in this block.

Line 539: `):` Inside the function execute_softmax_q15, which handles execute softmax q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 540: `raise RuntimeError("softmax result metadata is out of order")` This rejects an invalid state by raising 'RuntimeError("softmax result metadata is out of order")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 541: `probabilities[batch_index, class_index] = probability` This assigns 'probability' to 'probabilities[batch_index, class_index] ' in host memory. Here probabilities means the value named 'probabilities' in this block. The important operands are probability: the value named 'probability' in this block. Context: the function execute_softmax_q15, which handles execute softmax q15.

Line 542: `return probabilities` This returns 'probabilities' to the caller of the function execute_softmax_q15, which handles execute softmax q15, ending this invocation. The important operands are probabilities: the value named 'probabilities' in this block.

Line 545: `def execute_cross_entropy_gradient_q15(` This starts function execute_cross_entropy_gradient_q15. Its indented body performs execute cross entropy gradient q15 as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 546: `driver: FullTrainingDriver,` Inside the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named 'driver' in this block; FullTrainingDriver: the value named 'full training driver' in this block.

Line 547: `probabilities_q15,` Inside the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are probabilities_q15: the value named 'probabilities q15' in this block.

Line 548: `labels,` Inside the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are labels: the value named 'labels' in this block.

Line 549: `*,` Inside the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 550: `timeout_seconds:  float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 551: `)  -> BlockGradient:` Inside the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter.

Line 552: `"""Form batch-mean "probability - one_hot" entirely with vector RTL."""` This is executable documentation attached to the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 554: `probabilities = np.asarray(probabilities_q15, dtype=np.int64)` This assigns 'np.asarray(probabilities_q15, dtype=np.int64)' to 'probabilities ' in host memory. Here probabilities means the value named 'probabilities' in this block. The important operands are asarray: the value named 'asarray' in this block; probabilities_q15: the value named 'probabilities q15' in this block; dtype: the value named 'dtype' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 555: `targets = np.asarray(labels, dtype=np.int64)` This assigns 'np.asarray(labels, dtype=np.int64)' to 'targets ' in host memory. Here targets means the value named 'targets' in this block. The important operands are asarray: the value named 'asarray' in this block; labels: the value named 'labels' in this block; dtype: the value named 'dtype' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 556: `if probabilities.ndim != 2 or targets.shape != (probabilities.shape[0],):` This executes the following indented host-code branch only when 'probabilities.ndim != 2 or targets.shape != (probabilities.shape[0],)' is true. The important operands are probabilities: the value named 'probabilities' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 557: `raise ValueError("labels must contain one class index per probability row")` This rejects an invalid state by raising 'ValueError("labels must contain one class index per probability row")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 558: `if np.any(targets < 0) or np.any(targets >= probabilities.shape[1]):` This executes the following indented host-code branch only when 'np.any(targets < 0) or np.any(targets >= probabilities.shape[1])' is true. The important operands are any: the value named 'any' in this block; targets: the value named 'targets' in this block; or: the value named 'or' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 559: `raise ValueError("a target class is outside the classifier range")` This rejects an invalid state by raising 'ValueError("a target class is outside the classifier range")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 560: `correction = np.zeros(probabilities.shape, dtype=np.int64)` This assigns 'np.zeros(probabilities.shape, dtype=np.int64)' to 'correction ' in host memory. Here correction means the value named 'correction' in this block. The important operands are zeros: the value named 'zeros' in this block; probabilities: the value named 'probabilities' in this block; shape: the value named 'shape' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 561: `correction[np.arange(probabilities.shape[0]), targets] = -(1 << 15)` Inside the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are correction: the value named 'correction' in this block; arange: the value named 'arange' in this block; probabilities: the value named 'probabilities' in this block.

Line 562: `gradient = execute_vector_tensor(` This statement continues through source line 568; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, probabilities, correction, timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 563: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 562. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, probabilities, correction, timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 564: `VectorOperation.ADD_SAT,` This is continuation line 3 of the 7-line logical statement that begins at source line 562. Its exact fragment is 'VectorOperation.ADD_SAT,'. The important operands are VectorOperation: the value named 'vector operation' in this block; ADD_SAT: the value named 'add sat' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, probabilities, correction, timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 565: `probabilities,` This is continuation line 4 of the 7-line logical statement that begins at source line 562. Its exact fragment is 'probabilities,'. The important operands are probabilities: the value named 'probabilities' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, probabilities, correction, timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 566: `correction,` This is continuation line 5 of the 7-line logical statement that begins at source line 562. Its exact fragment is 'correction,'. The important operands are correction: the value named 'correction' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, probabilities, correction, timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 567: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 562. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, probabilities, correction, timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The

important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 568: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 562. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.ADD_SAT, probabilities, correction, timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 569: `if probabilities.shape[0] > 1:` This executes the following indented host-code branch only when 'probabilities.shape[0] > 1' is true. The important operands are probabilities: the value named 'probabilities' in this block; shape: the value named 'shape' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 570: `reciprocal_q15 = int(round((1 << 15) / probabilities.shape[0]))` This assigns 'int(round((1 << 15) / probabilities.shape[0]))' to 'reciprocal_q15 ' in host memory. Here reciprocal_q15 means the value named 'reciprocal q15' in this block. The important operands are round: the value named 'round' in this block; probabilities: the value named 'probabilities' in this block; shape: the value named 'shape' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 571: `gradient = execute_vector_tensor(` This statement continues through source line 577; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_vector_tensor(driver, VectorOperation.MULTIPLY_Q15, gradient, np.full(gradient.shape, reciprocal_q15, dtype=np.int64), timeout_seconds=timeout_sec)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 572: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 571. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.MULTIPLY_Q15, gradient, np.full(gradient.shape, reciprocal_q15, dtype=np.int64), timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 573: `VectorOperation.MULTIPLY_Q15,` This is continuation line 3 of the 7-line logical statement that begins at source line 571. Its exact fragment is 'VectorOperation.MULTIPLY_Q15,'. The important operands are VectorOperation: the value named 'vector operation' in this block; MULTIPLY_Q15: the value named 'multiply q15' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.MULTIPLY_Q15, gradient, np.full(gradient.shape, reciprocal_q15, dtype=np.int64), timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 574: `gradient,` This is continuation line 4 of the 7-line logical statement that begins at source line 571. Its exact fragment is 'gradient,'. The important operands are gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.MULTIPLY_Q15, gradient, np.full(gradient.shape, reciprocal_q15, dtype=np.int64), timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The

important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 575: `np.full(gradient.shape, reciprocal_q15, dtype=np.int64),` This is continuation line 5 of the 7-line logical statement that begins at source line 571. Its exact fragment is 'np.full(gradient.shape, reciprocal_q15, dtype=np.int64),'. The important operands are full: the value named 'full' in this block; gradient: the signed loss derivative used to update a learned parameter; shape: the value named 'shape' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.MULTIPLY_Q15, gradient, np.full(gradient.shape, reciprocal_q15, dtype=np.int64), timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 576: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 571. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.MULTIPLY_Q15, gradient, np.full(gradient.shape, reciprocal_q15, dtype=np.int64), timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 577: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 571. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.MULTIPLY_Q15, gradient, np.full(gradient.shape, reciprocal_q15, dtype=np.int64), timeout_seconds=timeout_seconds,)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15.

Line 578: `return BlockGradient(gradient, -15)` This returns 'BlockGradient(gradient, -15)' to the caller of the function execute_cross_entropy_gradient_q15, which handles execute cross entropy gradient q15, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter.

Line 581: `def _master_fractional_bits(values: np.ndarray, maximum_bits: int) -> int:` This starts function _master_fractional_bits. Its indented body performs master fractional bits as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 582: `maximum = int(np.abs(np.asarray(values, dtype=np.int64)).max(initial=0))` This assigns 'int(np.abs(np.asa dtype=np.int64)).max(initial=0))' to 'maximum ' in host memory. Here maximum means the value named 'maximum' in this block. The important operands are abs: the value named 'abs' in this block; asarray: the value named 'asarray' in this block; values: the value named 'values' in this block. Context: the function _master_fractional_bits, which handles master fractional bits.

Line 583: `fractional = 0` This assigns '0' to 'fractional ' in host memory. Here fractional means the value named 'fractional' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _master_fractional_bits, which handles master fractional bits.

Line 584: `while fractional < maximum_bits and maximum <= (32767 >> (fractional + 1)):` This repeats the following host-code block while ‘fractional < maximum_bits and maximum <= (32767 >> (fractional + 1))‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 585: `fractional += 1` Inside the function _master_fractional_bits, which handles master fractional bits, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are fractional: the value named 'fractional' in this block.

Line 586: `return fractional` This returns ‘fractional‘ to the caller of the function _master_fractional_bits, which handles master fractional bits, ending this invocation. The important operands are fractional: the value named 'fractional' in this block.

Line 589: `def execute_deploy_master(` This starts function execute_deploy_master. Its indented body performs execute deploy master as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 590: `driver: FullTrainingDriver,` Inside the function execute_deploy_master, which handles execute deploy master, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named 'driver' in this block; FullTrainingDriver: the value named 'full training driver' in this block.

Line 591: `tensor: MasterTensor,` Inside the function execute_deploy_master, which handles execute deploy master, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tensor: the value named 'tensor' in this block; MasterTensor: the value named 'master tensor' in this block.

Line 592: `*,` Inside the function execute_deploy_master, which handles execute deploy master, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 593: `timeout_seconds: float = 120.0,` This assigns ‘120.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_deploy_master, which handles execute deploy master.

Line 594: `) -> np.ndarray:` Inside the function execute_deploy_master, which handles execute deploy master, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are ndarray: the value named 'ndarray' in this block.

Line 595: `"""Round a signed-16 master tensor and clamp it to its deployment range."""` This is executable documentation attached to the function execute_deploy_master, which handles execute deploy master. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 597: `shifted = execute_power_of_two_scale(` This statement continues through source line 611; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_power_of_two_scale(driver, tensor.master, -tensor.fractional_bits, clamp_minimum=tensor.deploy_minimum, clamp_maximum=tensor.deploy_maxim timeout_seconds=timeout_seconds,) if tensor.fractional_bits else execute_vector_tensor(driver, VectorOperation.CLAMP, tensor.master, clamp_minimum=tensor.deploy_minimum, clamp_maximum=tensor.deploy_maximum, timeout_seconds=timeou)‘ to ‘shifted ‘ in host memory. Here shifted means the value named 'shifted' in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function execute_deploy_master, which handles execute deploy master.

Line 598: `driver,` This is continuation line 2 of the 15-line logical statement that begins at source line 597. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_power_of_two_scale(driver, tensor.master, -tensor.fractional_bits, clamp_minimum=tensor.deploy_minimum, clamp_maximum=tensor.deploy_maximum, timeout_seconds=timeout_seconds,) if tensor.fractional_bits else execute_vector_tensor(driver, VectorOperation.CLAMP, tensor.master, clamp_minimum=tensor.de clamp_maximum=tensor.deploy_maximum, timeout_seconds=timeout_seconds,)' to 'shifted ' in host memory. Here shifted means the value named 'shifted' in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function execute_deploy_master, which handles execute deploy master.

Line 599: `tensor.master,` This is continuation line 3 of the 15-line logical statement that begins at source line 597. Its exact fragment is 'tensor.master,'. The important operands are tensor: the value named 'tensor' in this block; master: the value named 'master' in this block. Read together, the complete operation is: This assigns 'execute_power_of_two_scale(driver, tensor.master, -tensor.fractional_bits, clamp_minimum=tensor.deploy_minimum, clamp_maximum=tensor.deploy_maximum, timeout_seconds=timeout_seconds,) if tensor.fractional_bits else execute_vector_tensor(driver, VectorOperation.CLAMP, tensor.master, clamp_minimum=tensor.deploy_minimum, clamp_maximu timeout_seconds=timeout_seconds,)' to 'shifted ' in host memory. Here shifted means the value named 'shifted' in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function execute_deploy_master, which handles execute deploy master.

Line 600: `-tensor.fractional_bits,` This is continuation line 4 of the 15-line logical statement that begins at source line 597. Its exact fragment is '-tensor.fractional_bits,'. The important operands are tensor: the value named 'tensor' in this block; fractional_bits: the value named 'fractional bits' in this block. Read together, the complete operation is: This assigns 'execute_power_of_two_scale(driver, tensor.master, -tensor.fractional_bits, clamp_minimum=tensor.deploy_minimum, clamp_maximum=tensor.deploy_maximum, timeout_seconds=timeout_seconds,) if tensor.fractional_bits else execute_vector_tensor(driver, VectorOperation.CLAMP, tensor.master, clamp_minimum=tensor.deploy_minimum, clamp_maximu timeout_seconds=timeout_seconds,)' to 'shifted ' in host memory. Here shifted means the value named 'shifted' in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function execute_deploy_master, which handles execute deploy master.

Line 601: `clamp_minimum=tensor.deploy_minimum,` This is continuation line 5 of the 15-line logical statement that begins at source line 597. Its exact fragment is 'clamp_minimum=tensor.deploy_minimum,'. The important operands are clamp_minimum: the value named 'clamp minimum' in this block; tensor: the value named 'tensor' in this block; deploy_minimum: the value named 'deploy minimum' in this block. Read together, the complete operation is: This assigns 'execute_power_of_two_scale(driver, tensor.master, -tensor.fractional_bits, clamp_minimum=tensor.deploy_minimum, clamp_maximum=tensor.deploy_maximum, timeout_seconds=timeout_seconds,) if tensor.fractional_bits else execute_vector_tensor(driver, VectorOperation.CLAMP, tensor.master, clamp_minimum=tensor.deploy_minimum, clamp_maximu timeout_seconds=timeout_seconds,)' to 'shifted ' in host memory. Here shifted means the value named 'shifted' in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function execute_deploy_master, which handles execute deploy master.

Line 602: `clamp_maximum=tensor.deploy_maximum,` This is continuation line 6 of the 15-line logical statement that begins at source line 597. Its exact fragment is 'clamp_maximum=tensor.deploy_maximum,'. The important operands are clamp_maximum: the value named 'clamp maximum' in this block; tensor: the value named 'tensor' in this block; deploy_maximum: the value named 'deploy maximum' in this block. Read together, the complete operation is: This assigns 'execute_power_of_two_scale(driver, tensor.master, -tensor.fractional_bits, clamp_minimum=tensor.deploy_minimum, clamp_maximum=tensor.deploy_maximum, timeout_seconds=timeout_seconds,) if tensor.fractional_bits else execute_vector_tensor(driver, VectorOperation.CLAMP, tensor.master, clamp_minimum=tensor.deploy_minimum, clamp_maximu timeout_seconds=timeout_seconds,)' to 'shifted ' in host memory. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function execute_deploy_master, which handles execute deploy master.

Line 612: `return shifted.astype(np.int64)` This returns 'shifted.astype(np.int64)' to the caller of the function execute_deploy_master, which handles execute deploy master, ending this invocation. The important operands are shifted: the value named 'shifted' in this block; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block.

Line 615: `def gradient_to_optimizer_q15(` This starts function gradient_to_optimizer_q15. Its indented body performs gradient to optimizer q15 as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 616: `driver: FullTrainingDriver,` Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named 'driver' in this block; FullTrainingDriver: the value named 'full training driver' in this block.

Line 617: `gradient: BlockGradient,` Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 618: `*,` Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 619: `clip_q15: int,` Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are clip_q15: the value named 'clip q15' in this block.

Line 620: `timeout_seconds: float = 120.0,` This assigns '120.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function gradient_to_optimizer_q15, which handles gradient to optimizer q15.

Line 621: `) -> np.ndarray:` Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are ndarray: the value named 'ndarray' in this block.

Line 622: `"""Convert a block gradient to Q15 and apply explicit fabric clipping."""` This is executable documentation attached to the function gradient_to_optimizer_q15, which handles gradient to optimizer q15. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 624: `if not 1 <= clip_q15 <= (1 << 23) - 1:` This executes the following indented host-code branch only when 'not 1 <= clip_q15 <= (1 << 23) - 1' is true. The important operands are not: the value named 'not' in this block; clip_q15: the value named 'clip q15' in this block. Context: the function gradient_to_optimizer_q15, which handles gradient to optimizer q15.

Line 625: `raise ValueError("clip_q15 must be in [1,8388607]")` This rejects an invalid state by raising 'ValueError("clip_q15 must be in [1,8388607]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 626: `scaled = execute_power_of_two_scale(` This statement continues through source line 631; the explanation uses the complete expression rather than only the first visual fragment. Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are scaled: the real-value spacing represented by one quantized integer step; execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block.

Line 627: `driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 626. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are scaled: the real-value spacing represented by one quantized integer step; execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block.

Line 628: `gradient.values,` This is continuation line 3 of the 6-line logical statement that begins at source line 626. Its exact fragment is 'gradient.values,'. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Read together, the complete operation is: Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are scaled: the real-value spacing represented by one quantized integer step; execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block.

Line 629: `gradient.exponent + 15,` This is continuation line 4 of the 6-line logical statement that begins at source line 626. Its exact fragment is 'gradient.exponent + 15,'. The important operands are gradient: the signed loss derivative used to update a learned parameter; exponent: the value named 'exponent' in this block. Read together, the complete operation is: Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are scaled: the real-value spacing represented by one quantized integer step; execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block.

Line 630: `timeout_seconds=timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 626. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are scaled: the real-value spacing represented by one quantized integer step; execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block.

Line 631: `) if gradient.exponent != -15 else gradient.values` This is continuation line 6 of the 6-line logical statement that begins at source line 626. Its exact fragment is ') if gradient.exponent != -15 else gradient.values'. The important operands are gradient: the signed loss derivative used to update a learned parameter; exponent: the value named 'exponent' in this block; values: the value named 'values' in this block. Read together, the complete operation is: Inside the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are scaled: the real-value spacing represented by one quantized integer step; execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block.

Line 632: `clipped = execute_vector_tensor(` This statement continues through source line 639; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_vector_tensor(driver, VectorOperation.CLAMP, scaled, clamp_minimum=-clip_q15, clamp_maximum=clip_q15, timeout_seconds=timeout_seconds,)' to 'clipped ' in host memory. Here clipped means the value named 'clipped' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function gradient_to_optimizer_q15, which handles gradient to optimizer q15.

Line 633: `driver,` This is continuation line 2 of the 8-line logical statement that begins at source line 632. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.CLAMP, scaled, clamp_minimum=-clip_q15, clamp_maximum=clip_q15, timeout_seconds=timeout_seconds,)' to 'clipped ' in host memory. Here clipped means the value named 'clipped' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function gradient_to_optimizer_q15, which handles gradient to optimizer q15.

Line 634: `VectorOperation.CLAMP,` This is continuation line 3 of the 8-line logical statement that begins at source line 632. Its exact fragment is 'VectorOperation.CLAMP,'. The important operands are VectorOperation: the value

named 'vector operation' in this block; CLAMP: the value named 'clamp' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.CLAMP, scaled, clamp_minimum=-clip_q15, clamp_maximum=clip_q15, timeout_seconds=timeout_seconds,)' to 'clipped ' in host memory. Here clipped means the value named 'clipped' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function gradient_to_optimizer_q15, which handles gradient to optimizer q15.

Line 635: `scaled,` This is continuation line 4 of the 8-line logical statement that begins at source line 632. Its exact fragment is 'scaled,'. The important operands are scaled: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.CLAMP, scaled, clamp_minimum=-clip_q15, clamp_maximum=clip_q15, timeout_seconds=timeout_seconds,)' to 'clipped ' in host memory. Here clipped means the value named 'clipped' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function gradient_to_optimizer_q15, which handles gradient to optimizer q15.

Line 636: `clamp_minimum=-clip_q15,` This is continuation line 5 of the 8-line logical statement that begins at source line 632. Its exact fragment is 'clamp_minimum=-clip_q15,'. The important operands are clamp_minimum: the value named 'clamp minimum' in this block; clip_q15: the value named 'clip q15' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.CLAMP, scaled, clamp_minimum=-clip_q15, clamp_maximum=clip_q15, timeout_seconds=timeout_seconds,)' to 'clipped ' in host memory. Here clipped means the value named 'clipped' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function gradient_to_optimizer_q15, which handles gradient to optimizer q15.

Line 637: `clamp_maximum=clip_q15,` This is continuation line 6 of the 8-line logical statement that begins at source line 632. Its exact fragment is 'clamp_maximum=clip_q15,'. The important operands are clamp_maximum: the value named 'clamp maximum' in this block; clip_q15: the value named 'clip q15' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.CLAMP, scaled, clamp_minimum=-clip_q15, clamp_maximum=clip_q15, timeout_seconds=timeout_seconds,)' to 'clipped ' in host memory. Here clipped means the value named 'clipped' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function gradient_to_optimizer_q15, which handles gradient to optimizer q15.

Line 638: `timeout_seconds=timeout_seconds,` This is continuation line 7 of the 8-line logical statement that begins at source line 632. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.CLAMP, scaled, clamp_minimum=-clip_q15, clamp_maximum=clip_q15, timeout_seconds=timeout_seconds,)' to 'clipped ' in host memory. Here clipped means the value named 'clipped' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function gradient_to_optimizer_q15, which handles gradient to optimizer q15.

Line 639: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 632. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_vector_tensor(driver, VectorOperation.CLAMP, scaled, clamp_minimum=-clip_q15, clamp_maximum=clip_q15, timeout_seconds=timeout_seconds,)' to 'clipped ' in host memory. Here clipped means the value named 'clipped' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function gradient_to_optimizer_q15, which handles gradient to optimizer q15.

Line 640: `return clipped.astype(np.int64)` This returns 'clipped.astype(np.int64)' to the caller of the function gradient_to_optimizer_q15, which handles gradient to optimizer q15, ending this invocation. The important operands are clipped: the value named 'clipped' in this block; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block.

Line 643: `class TrainableSpikingformerState:` This defines class TrainableSpikingformerState, which groups data and methods for trainable spikingformer state. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 644: `"""Mutable master parameters implementing the read-only archive interface."""` This is executable documentation attached to the class TrainableSpikingformerState, which handles trainable spikingformer state. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 646: `def __init__(self, archive: SpikingformerParameterArchive) -> None:` This starts function ___init___. Its indented body performs init as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 647: `self.manifest = archive.manifest` This assigns ‘archive.manifest‘ to ‘self.manifest ‘ in host memory. Here manifest means the value named 'manifest' in this block. The important operands are archive: the value named 'archive' in this block; manifest: the value named 'manifest' in this block. Context: the function ___init___, which handles init.

Line 648: `self.base_binary_sha256 = str(archive.manifest["binary_sha256"])` This assigns ‘str(archive.manifest["binary to ‘self.base_binary_sha256 ‘ in host memory. Here base_binary_sha256 means the value named 'base binary sha256' in this block. The important operands are str: the value named 'str' in this block; archive: the value named 'archive' in this block; manifest: the value named 'manifest' in this block. Context: the function ___init___, which handles init.

Line 649: `self._projection_static: dict[str, ProjectionParameters] = {}` This assigns ‘{}‘ to ‘self._projection_static in host memory. Here _projection_static means the value named 'projection static' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 650: `self._projection_weight: dict[str, MasterTensor] = {}` This assigns ‘{}‘ to ‘self._projection_weight‘ in host memory. Here _projection_weight means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 651: `self._projection_bias: dict[str, MasterTensor] = {}` This assigns ‘{}‘ to ‘self._projection_bias‘ in host memory. Here _projection_bias means an additive learned offset applied after accumulation. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 652: `self._deployed_projection_weight: dict[str, np.ndarray] = {}` This assigns ‘{}‘ to ‘self._deployed_projecti in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 653: `self._deployed_projection_bias: dict[str, np.ndarray] = {}` This assigns ‘{}‘ to ‘self._deployed_projection in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 654: `for name in archive.projection_names:` This iterates name over ‘archive.projection_names‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function ___init___, which handles init.

Line 655: `parameters = archive.projection(name)` This assigns ‘archive.projection(name)‘ to ‘parameters ‘ in host memory. Here parameters means the value named 'parameters' in this block. The important operands are archive: the value named 'archive' in this block; projection: the value named 'projection' in this block; name: the value named 'name' in this block. Context: the function ___init___, which handles init.

Line 656: `weight = parameters.weight_k_by_n.astype(np.int64)` This assigns ‘parameters.weight_k_by_n.astype(np.int64‘ to ‘weight ‘ in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are parameters: the value named ’parameters’ in this block; weight_k_by_n: a learned coefficient multiplied by an activation; astype: the value named ’astype’ in this block. Context: the function ___init___, which handles init.

Line 657: `bias = parameters.bias_q10.astype(np.int64)` This assigns ‘parameters.bias_q10.astype(np.int64)‘ to ‘bias ‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are parameters: the value named ’parameters’ in this block; bias_q10: an additive learned offset applied after accumulation; astype: the value named ’astype’ in this block. Context: the function ___init___, which handles init.

Line 658: `weight_fractional_bits = 8` This assigns ‘8‘ to ‘weight_fractional_bits ‘ in host memory. Here weight_fractional_b means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 659: `bias_fractional_bits = _master_fractional_bits(bias, 8)` This assigns ‘_master_fractional_bits(bias, 8)‘ to ‘bias_fractional_bits ‘ in host memory. Here bias_fractional_bits means an additive learned offset applied after accumulation. The important operands are _master_fractional_bits: the value named ’master fractional bits’ in this block; bias: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 660: `self._projection_static[name] = parameters` This assigns ‘parameters‘ to ‘self._projection_static[name] ‘ in host memory. Here _projection_static means the value named ’projection static’ in this block. The important operands are parameters: the value named ’parameters’ in this block. Context: the function ___init___, which handles init.

Line 661: `self._projection_weight[name] = MasterTensor(` This statement continues through source line 667; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘MasterTensor(weight << weight_fractional_bits, np.zeros(weight.shape, dtype=np.int64), weight_fractional_bits, -128, 127,)‘ to ‘self._projection_weight[name] ‘ in host memory. Here _projection_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; weight: a learned coefficient multiplied by an activation; weight_fractional_bits: a learned coefficient multiplied by an activation. Context: the function ___init___, which handles init.

Line 662: `weight << weight_fractional_bits,` This is continuation line 2 of the 7-line logical statement that begins at source line 661. Its exact fragment is ‘weight << weight_fractional_bits,‘. The important operands are weight: a learned coefficient multiplied by an activation; weight_fractional_bits: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘MasterTensor(weight << weight_fractional_bits, np.zeros(weight.shape, dtype=np.int64), weight_fractional_bits, -128, 127,)‘ to ‘self._projection_weight[name] ‘ in host memory. Here _projection_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; weight: a learned coefficient multiplied by an activation; weight_fractional_bits: a learned coefficient multiplied by an activation. Context: the function ___init___, which handles init.

Line 663: `np.zeros(weight.shape, dtype=np.int64),` This is continuation line 3 of the 7-line logical statement that begins at source line 661. Its exact fragment is ‘np.zeros(weight.shape, dtype=np.int64),‘. The important operands are zeros: the value named ’zeros’ in this block; weight: a learned coefficient multiplied by an activation; shape: the value named ’shape’ in this block. Read together, the complete operation is: This assigns ‘MasterTensor(weight << weight_fractional_bits, np.zeros(weight.shape, dtype=np.int64), weight_fractional_bits, -128, 127,)‘ to ‘self._projection_weight[n ‘ in host memory. Here _projection_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; weight: a learned coefficient multiplied by an activation; weight_fractional_bits: a learned coefficient multiplied by an activation. Context: the function ___init___, which handles init.

Line 664: `weight_fractional_bits,` This is continuation line 4 of the 7-line logical statement that begins at source line 661. Its exact fragment is ‘weight_fractional_bits,‘. The important operands are weight_fractional_bits:

a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘MasterTensor(weight << weight_fractional_bits, np.zeros(weight.shape, dtype=np.int64), weight_fractional_bits, -128, 127,)‘ to ‘self._projection_weight[name] ‘ in host memory. Here _projection_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; weight: a learned coefficient multiplied by an activation; weight_fractional_bits: a learned coefficient multiplied by an activation. Context: the function ___init___, which handles init.

Line 665: `-128,` This is continuation line 5 of the 7-line logical statement that begins at source line 661. Its exact fragment is ‘-128,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(weight << weight_fractional_bits, np.zeros(weight.shape, dtype=np.int64), weight_fractional_bits, -128, 127,)‘ to ‘self._projection_weight[name] ‘ in host memory. Here _projection_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; weight: a learned coefficient multiplied by an activation; weight_fractional_bits: a learned coefficient multiplied by an activation. Context: the function ___init___, which handles init.

Line 666: `127,` This is continuation line 6 of the 7-line logical statement that begins at source line 661. Its exact fragment is ‘127,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(weight << weight_fractional_bits, np.zeros(weight.shape, dtype=np.int64), weight_fractional_bits, -128, 127,)‘ to ‘self._projection_weight[name] ‘ in host memory. Here _projection_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; weight: a learned coefficient multiplied by an activation; weight_fractional_bits: a learned coefficient multiplied by an activation. Context: the function ___init___, which handles init.

Line 667: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 661. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(weight << weight_fractional_bits, np.zeros(weight.shape, dtype=np.int64), weight_fractional_bits, -128, 127,)‘ to ‘self._projection_weight[name] ‘ in host memory. Here _projection_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; weight: a learned coefficient multiplied by an activation; weight_fractional_bits: a learned coefficient multiplied by an activation. Context: the function ___init___, which handles init.

Line 668: `self._projection_bias[name] = MasterTensor(` This statement continues through source line 674; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘MasterTensor(bias << bias_fractional_bits, np.zeros(bias.shape, dtype=np.int64), bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)‘ to ‘self._projection_bias[name] ‘ in host memory. Here _projection_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named ’master tensor’ in this block; bias: an additive learned offset applied after accumulation; bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 669: `bias << bias_fractional_bits,` This is continuation line 2 of the 7-line logical statement that begins at source line 668. Its exact fragment is ‘bias << bias_fractional_bits,‘. The important operands are bias: an additive learned offset applied after accumulation; bias_fractional_bits: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns ‘MasterTensor(bias << bias_fractional_bits, np.zeros(bias.shape, dtype=np.int64), bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)‘ to ‘self._projection_bias[name] ‘ in host memory. Here _projection_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named ’master tensor’ in this block; bias: an additive learned offset applied after accumulation; bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 670: `np.zeros(bias.shape, dtype=np.int64),` This is continuation line 3 of the 7-line logical statement that begins at source line 668. Its exact fragment is ‘np.zeros(bias.shape, dtype=np.int64),‘. The important operands are zeros: the value named ’zeros’ in this block; bias: an additive learned offset applied after accumulation; shape: the value named ’shape’ in this block. Read together, the complete operation is: This assigns ‘MasterTensor(bias << bias_fractional_bits, np.zeros(bias.shape, dtype=np.int64), bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)‘ to ‘self._projection_bias[name] ‘ in host memory. Here _projection_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named ’master tensor’ in this block; bias: an additive learned offset applied

after accumulation; bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 671: `bias_fractional_bits,` This is continuation line 4 of the 7-line logical statement that begins at source line 668. Its exact fragment is 'bias_fractional_bits,'. The important operands are bias_fractional_bits: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'MasterTensor(bias << bias_fractional_bits, np.zeros(bias.shape, dtype=np.int64), bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)' to 'self._projection_bias[name] ' in host memory. Here _projection_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named 'master tensor' in this block; bias: an additive learned offset applied after accumulation; bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 672: `-(1 << 15),` This is continuation line 5 of the 7-line logical statement that begins at source line 668. Its exact fragment is '-(1 << 15),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'MasterTensor(bias << bias_fractional_bits, np.zeros(bias.shape, dtype=np.int64), bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)' to 'self._projection_bias[name] ' in host memory. Here _projection_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named 'master tensor' in this block; bias: an additive learned offset applied after accumulation; bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 673: `(1 << 15) - 1,` This is continuation line 6 of the 7-line logical statement that begins at source line 668. Its exact fragment is '(1 << 15) - 1,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'MasterTensor(bias << bias_fractional_bits, np.zeros(bias.shape, dtype=np.int64), bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)' to 'self._projection_bias[name] ' in host memory. Here _projection_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named 'master tensor' in this block; bias: an additive learned offset applied after accumulation; bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 674: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 668. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'MasterTensor(bias << bias_fractional_bits, np.zeros(bias.shape, dtype=np.int64), bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)' to 'self._projection_bias[name] ' in host memory. Here _projection_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named 'master tensor' in this block; bias: an additive learned offset applied after accumulation; bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 675: `self._deployed_projection_weight[name] = weight.astype(np.int8)` This assigns 'weight.astype(np.int8)' to 'self._deployed_projection_weight[name] ' in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are weight: a learned coefficient multiplied by an activation; astype: the value named 'astype' in this block; int8: the value named 'int8' in this block. Context: the function ___init___, which handles init.

Line 676: `self._deployed_projection_bias[name] = bias.astype(np.int64)` This assigns 'bias.astype(np.int64)' to 'self._deployed_projection_bias[name] ' in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are bias: an additive learned offset applied after accumulation; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Context: the function ___init___, which handles init.

Line 678: `head = archive.head` This assigns 'archive.head' to 'head ' in host memory. Here head means the value named 'head' in this block. The important operands are archive: the value named 'archive' in this block; head: the value named 'head' in this block. Context: the function ___init___, which handles init.

Line 679: `head_weight = head.weight_k_by_n.astype(np.int64)` This assigns ‘head.weight_k_by_n.astype(np.int64)‘ to ‘head_weight ‘ in host memory. Here head_weight means a learned coefficient multiplied by an activation. The important operands are head: the value named ’head’ in this block; weight_k_by_n: a learned coefficient multiplied by an activation; astype: the value named ’astype’ in this block. Context: the function ___init___, which handles init.

Line 680: `head_bias = head.bias_accumulator_units.astype(np.int64)` This assigns ‘head.bias_accumulator_units.astype to ‘head_bias ‘ in host memory. Here head_bias means an additive learned offset applied after accumulation. The important operands are head: the value named ’head’ in this block; bias_accumulator_units: an additive learned offset applied after accumulation; astype: the value named ’astype’ in this block. Context: the function ___init___, which handles init.

Line 681: `head_bias_fractional_bits = _master_fractional_bits(head_bias, 8)` This assigns ‘_master_fractional_bits(8)‘ to ‘head_bias_fractional_bits ‘ in host memory. Here head_bias_fractional_bits means an additive learned offset applied after accumulation. The important operands are _master_fractional_bits: the value named ’master fractional bits’ in this block; head_bias: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 682: `self._head_weight = MasterTensor(` This statement continues through source line 688; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘MasterTensor(head_weight << 8, np.zeros(head_weight.shape, dtype=np.int64), 8, -128, 127,)‘ to ‘self._head_weight ‘ in host memory. Here _head_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; head_weight: a learned coefficient multiplied by an activation; zeros: the value named ’zeros’ in this block. Context: the function ___init___, which handles init.

Line 683: `head_weight << 8,` This is continuation line 2 of the 7-line logical statement that begins at source line 682. Its exact fragment is ‘head_weight << 8,‘. The important operands are head_weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘MasterTensor(head_weight << 8, np.zeros(head_weight.shape, dtype=np.int64), 8, -128, 127,)‘ to ‘self._head_weight ‘ in host memory. Here _head_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; head_weight: a learned coefficient multiplied by an activation; zeros: the value named ’zeros’ in this block. Context: the function ___init___, which handles init.

Line 684: `np.zeros(head_weight.shape, dtype=np.int64),` This is continuation line 3 of the 7-line logical statement that begins at source line 682. Its exact fragment is ‘np.zeros(head_weight.shape, dtype=np.int64),‘. The important operands are zeros: the value named ’zeros’ in this block; head_weight: a learned coefficient multiplied by an activation; shape: the value named ’shape’ in this block. Read together, the complete operation is: This assigns ‘MasterTensor(head_weight << 8, np.zeros(head_weight.shape, dtype=np.int64), 8, -128, 127,)‘ to ‘self._head_weight ‘ in host memory. Here _head_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; head_weight: a learned coefficient multiplied by an activation; zeros: the value named ’zeros’ in this block. Context: the function ___init___, which handles init.

Line 685: `8,` This is continuation line 4 of the 7-line logical statement that begins at source line 682. Its exact fragment is ‘8,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(head_weight << 8, np.zeros(head_weight.shape, dtype=np.int64), 8, -128, 127,)‘ to ‘self._head_weight ‘ in host memory. Here _head_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; head_weight: a learned coefficient multiplied by an activation; zeros: the value named ’zeros’ in this block. Context: the function ___init___, which handles init.

Line 686: `-128,` This is continuation line 5 of the 7-line logical statement that begins at source line 682. Its exact fragment is ‘-128,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(head_weight << 8, np.zeros(head_weight.shape, dtype=np.int64), 8, -128, 127,)‘ to ‘self._head_weight ‘ in host memory. Here _head_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named ’master tensor’ in this block; head_weight: a learned coefficient multiplied by an activation; zeros: the value named ’zeros’ in this block. Context: the function ___init___, which handles init.

Line 687: `127,` This is continuation line 6 of the 7-line logical statement that begins at source line 682. Its exact fragment is '127,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'MasterTensor(head_weight << 8, np.zeros(head_weight.shape, dtype=np.int64), 8, -128, 127,)' to 'self._head_weight ' in host memory. Here _head_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named 'master tensor' in this block; head_weight: a learned coefficient multiplied by an activation; zeros: the value named 'zeros' in this block. Context: the function ___init___, which handles init.

Line 688: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 682. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'MasterTensor(head_weight << 8, np.zeros(head_weight.shape, dtype=np.int64), 8, -128, 127,)' to 'self._head_weight ' in host memory. Here _head_weight means a learned coefficient multiplied by an activation. The important operands are MasterTensor: the value named 'master tensor' in this block; head_weight: a learned coefficient multiplied by an activation; zeros: the value named 'zeros' in this block. Context: the function ___init___, which handles init.

Line 689: `self._head_bias = MasterTensor(` This statement continues through source line 695; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'MasterTensor(head_bias << head_bias_fractional_bits, np.zeros(head_bias.shape, dtype=np.int64), head_bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)' to 'self._head_bias ' in host memory. Here _head_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named 'master tensor' in this block; head_bias: an additive learned offset applied after accumulation; head_bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 690: `head_bias << head_bias_fractional_bits,` This is continuation line 2 of the 7-line logical statement that begins at source line 689. Its exact fragment is 'head_bias << head_bias_fractional_bits,'. The important operands are head_bias: an additive learned offset applied after accumulation; head_bias_fractional_bits: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'MasterTensor(head_bias << head_bias_fractional_bits, np.zeros(head_bias.shape, dtype=np.int64), head_bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)' to 'self._head_bias ' in host memory. Here _head_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named 'master tensor' in this block; head_bias: an additive learned offset applied after accumulation; head_bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 691: `np.zeros(head_bias.shape, dtype=np.int64),` This is continuation line 3 of the 7-line logical statement that begins at source line 689. Its exact fragment is 'np.zeros(head_bias.shape, dtype=np.int64),'. The important operands are zeros: the value named 'zeros' in this block; head_bias: an additive learned offset applied after accumulation; shape: the value named 'shape' in this block. Read together, the complete operation is: This assigns 'MasterTensor(head_bias << head_bias_fractional_bits, np.zeros(head_bias.shape, dtype=np.int64), head_bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)' to 'self._head_bias ' in host memory. Here _head_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named 'master tensor' in this block; head_bias: an additive learned offset applied after accumulation; head_bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 692: `head_bias_fractional_bits,` This is continuation line 4 of the 7-line logical statement that begins at source line 689. Its exact fragment is 'head_bias_fractional_bits,'. The important operands are head_bias_fractional_bits: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'MasterTensor(head_bias << head_bias_fractional_bits, np.zeros(head_bias.shape, dtype=np.int64), head_bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)' to 'self._head_bias ' in host memory. Here _head_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named 'master tensor' in this block; head_bias: an additive learned offset applied after accumulation; head_bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 693: `-(1 << 15),` This is continuation line 5 of the 7-line logical statement that begins at source line 689. Its exact fragment is '-(1 << 15),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'MasterTensor(head_bias << head_bias_fractional_bits,

np.zeros(head_bias.shape, dtype=np.int64), head_bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)‘ to ‘self._head_bias ‘ in host memory. Here _head_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named ’master tensor’ in this block; head_bias: an additive learned offset applied after accumulation; head_bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 694: `(1 << 15) - 1,` This is continuation line 6 of the 7-line logical statement that begins at source line 689. Its exact fragment is ‘(1 << 15) - 1,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(head_bias << head_bias_fractional_bits, np.zeros(head_bias.shape, dtype=np.int64), head_bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)‘ to ‘self._head_bias ‘ in host memory. Here _head_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named ’master tensor’ in this block; head_bias: an additive learned offset applied after accumulation; head_bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 695: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 689. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘MasterTensor(head_bias << head_bias_fractional_bits, np.zeros(head_bias.shape, dtype=np.int64), head_bias_fractional_bits, -(1 << 15), (1 << 15) - 1,)‘ to ‘self._head_bias ‘ in host memory. Here _head_bias means an additive learned offset applied after accumulation. The important operands are MasterTensor: the value named ’master tensor’ in this block; head_bias: an additive learned offset applied after accumulation; head_bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function ___init___, which handles init.

Line 696: `self._deployed_head_weight = head_weight.astype(np.int8)` This assigns ‘head_weight.astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are head_weight: a learned coefficient multiplied by an activation; astype: the value named ’astype’ in this block; int8: the value named ’int8’ in this block. Context: the function ___init___, which handles init.

Line 697: `self._deployed_head_bias = head_bias.astype(np.int64)` This assigns ‘head_bias.astype(np.int64)‘ to ‘self._deployed_head_bias ‘ in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are head_bias: an additive learned offset applied after accumulation; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Context: the function ___init___, which handles init.

Line 698: `self.optimizer_step = 0` This assigns ‘0‘ to ‘self.optimizer_step ‘ in host memory. Here optimizer_step means the value named ’optimizer step’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 700: `@property` This decorator changes how the following class or function is constructed. ‘@property‘ is applied at import time on the host and is part of the class TrainableSpikingformerState, which handles trainable spikingformer state; it creates no FPGA circuit by itself.

Line 701: `def projection_names(self) -> tuple[str, ...]:` This starts function projection_names. Its indented body performs projection names as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 702: `return tuple(self._projection_static)` This returns ‘tuple(self._projection_static)‘ to the caller of the function projection_names, which handles projection names, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; _projection_static: the value named ’projection static’ in this block.

Line 704: `def projection(self, name: str) -> ProjectionParameters:` This starts function projection. Its indented body performs projection as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 705: `static = self._projection_static[name]` This assigns ‘self._projection_static[name]‘ to ‘static ‘ in host memory. Here static means the value named ’static’ in this block. The important operands are _projection_static: the value named ’projection static’ in this block; name: the value named ’name’ in this block. Context: the function projection, which handles projection.

Line 706: `return ProjectionParameters(` This statement continues through source line 715; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘ProjectionParameters(static.name, self._deployed_projection_weight[name], self._deployed_projection_bias[name], static.multiplier_q15, static.binary_point_shift, static.compute_opcode, static.source_weight_shape, static.output_fractional_bits,)‘ to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; static: the value named ’static’ in this block; name: the value named ’name’ in this block.

Line 707: `static.name,` This is continuation line 2 of the 10-line logical statement that begins at source line 706. Its exact fragment is ‘static.name,‘. The important operands are static: the value named ’static’ in this block; name: the value named ’name’ in this block. Read together, the complete operation is: This returns ‘ProjectionParameters(static.name, self._deployed_projection_weight[name], self._deployed_projection_bias[name], static.multiplier_q15, static.binary_point_shift, static.compute_opcode, static.source_weight_shape, static.output_fractional_bits,)‘ to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; static: the value named ’static’ in this block; name: the value named ’name’ in this block.

Line 708: `self._deployed_projection_weight[name],` This is continuation line 3 of the 10-line logical statement that begins at source line 706. Its exact fragment is ‘self._deployed_projection_weight[name],‘. The important operands are _deployed_projection_weight: a learned coefficient multiplied by an activation; name: the value named ’name’ in this block. Read together, the complete operation is: This returns ‘ProjectionParameters(static.name, self._deployed_projection_weight[name], self._deployed_projection_bias[name], static.multiplier_q15, static.binary_point_shift, static.compute_opcode, static.source_weight_shape, static.output_fractional_bits,)‘ to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; static: the value named ’static’ in this block; name: the value named ’name’ in this block.

Line 709: `self._deployed_projection_bias[name],` This is continuation line 4 of the 10-line logical statement that begins at source line 706. Its exact fragment is ‘self._deployed_projection_bias[name],‘. The important operands are _deployed_projection_bias: an additive learned offset applied after accumulation; name: the value named ’name’ in this block. Read together, the complete operation is: This returns ‘ProjectionParameters(static.name, self._deployed_projection_weigh self._deployed_projection_bias[name], static.multiplier_q15, static.binary_point_shift, static.compute_opcode, static.source_wei static.output_fractional_bits,)‘ to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; static: the value named ’static’ in this block; name: the value named ’name’ in this block.

Line 710: `static.multiplier_q15,` This is continuation line 5 of the 10-line logical statement that begins at source line 706. Its exact fragment is ‘static.multiplier_q15,‘. The important operands are static: the value named ’static’ in this block; multiplier_q15: the value named ’multiplier q15’ in this block. Read together, the complete operation is: This returns ‘ProjectionParameters(static.name, self._deployed_projection_weight[name], self._deployed_projection_bias[name], static.multiplier_q15, static.binary_point_shift, static.compute_opcode, static.source_weight_shape, static.output_fractional_bi)‘ to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; static: the value named ’static’ in this block; name: the value named ’name’ in this block.

Line 711: `static.binary_point_shift,` This is continuation line 6 of the 10-line logical statement that begins at source line 706. Its exact fragment is ‘static.binary_point_shift,‘. The important operands are static: the value named ’static’ in this block; binary_point_shift: the value named ’binary point shift’ in this block. Read together, the complete operation is: This returns ‘ProjectionParameters(static.name, self._deployed_projection_weight[name], self._deployed_projection_bias[name], static.multiplier_q15, static.binary_point_shift, static.compute_opcode, static.source_wei static.output_fractional_bits,)‘ to the caller of the function projection, which handles projection, ending this invocation.

The important operands are ProjectionParameters: the value named 'projection parameters' in this block; static: the value named 'static' in this block; name: the value named 'name' in this block.

Line 712: `static.compute_opcode,` This is continuation line 7 of the 10-line logical statement that begins at source line 706. Its exact fragment is 'static.compute_opcode,'. The important operands are static: the value named 'static' in this block; compute_opcode: the value named 'compute opcode' in this block. Read together, the complete operation is: This returns 'ProjectionParameters(static.name, self._deployed_projection_weight[name], self._deployed_projection_bias[name], static.multiplier_q15, static.binary_point_shift, static.compute_opcode, static.source_weight_shape, static.output_fractional_bi)' to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; static: the value named 'static' in this block; name: the value named 'name' in this block.

Line 713: `static.source_weight_shape,` This is continuation line 8 of the 10-line logical statement that begins at source line 706. Its exact fragment is 'static.source_weight_shape,'. The important operands are static: the value named 'static' in this block; source_weight_shape: a learned coefficient multiplied by an activation. Read together, the complete operation is: This returns 'ProjectionParameters(static.name, self._deployed_projection_weight[name], self._deployed_projection_bias[name], static.multiplier_q15, static.binary_point_shift, static.compute_opcode, static.source_wei static.output_fractional_bits,)' to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; static: the value named 'static' in this block; name: the value named 'name' in this block.

Line 714: `static.output_fractional_bits,` This is continuation line 9 of the 10-line logical statement that begins at source line 706. Its exact fragment is 'static.output_fractional_bits,'. The important operands are static: the value named 'static' in this block; output_fractional_bits: the value named 'output fractional bits' in this block. Read together, the complete operation is: This returns 'ProjectionParameters(static.name, self._deployed_projection_weight[name], self._deployed_projection_bias[name], static.multiplier_q15, static.binary_point_shift, static.compute_opcode, static.source_wei static.output_fractional_bits,)' to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; static: the value named 'static' in this block; name: the value named 'name' in this block.

Line 715: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 706. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'ProjectionParameters(static.name, self._deployed_projection_weight[name], self._deployed_projection_bias[name], static.multiplier_q15, static.binary_point_shift, static.compute_opcode, static.source_wei static.output_fractional_bits,)' to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; static: the value named 'static' in this block; name: the value named 'name' in this block.

Line 717: `@property` This decorator changes how the following class or function is constructed. '@property' is applied at import time on the host and is part of the class TrainableSpikingformerState, which handles trainable spikingformer state; it creates no FPGA circuit by itself.

Line 718: `def head(self) -> HeadParameters:` This starts function head. Its indented body performs head as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 719: `return HeadParameters(self._deployed_head_weight, self._deployed_head_bias)` This returns 'HeadParameters(self._deployed_head_weight, self._deployed_head_bias)' to the caller of the function head, which handles head, ending this invocation. The important operands are HeadParameters: the value named 'head parameters' in this block; _deployed_head_weight: a learned coefficient multiplied by an activation; _deployed_head_bias: an additive learned offset applied after accumulation.

Line 721: `@staticmethod` This decorator changes how the following class or function is constructed. '@staticmethod' is applied at import time on the host and is part of the class TrainableSpikingformerState, which handles trainable spikingformer state; it creates no FPGA circuit by itself.

Line 722: `def _optimizer_coefficients(` This starts function _optimizer_coefficients. Its indented body performs optimizer coefficients as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 723: `tensor: MasterTensor,` Inside the function _optimizer_coefficients, which handles optimizer coefficients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tensor: the value named 'tensor' in this block; MasterTensor: the value named 'master tensor' in this block.

Line 724: `learning_rate: float,` Inside the function _optimizer_coefficients, which handles optimizer coefficients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude; float: the value named 'float' in this block.

Line 725: `momentum: float,` Inside the function _optimizer_coefficients, which handles optimizer coefficients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are momentum: the value named 'momentum' in this block; float: the value named 'float' in this block.

Line 726: `weight_decay: float,` Inside the function _optimizer_coefficients, which handles optimizer coefficients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are weight_decay: a learned coefficient multiplied by an activation; float: the value named 'float' in this block.

Line 727: `) -> tuple[int, int, int, int]:` Inside the function _optimizer_coefficients, which handles optimizer coefficients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named 'tuple' in this block.

Line 728: `if not 0.0 <= learning_rate:` This executes the following indented host-code branch only when ‘not 0.0 <= learning_rate‘ is true. The important operands are not: the value named 'not' in this block; learning_rate: the fixed-point multiplier controlling update magnitude. Context: the function _optimizer_coefficients, which handles optimizer coefficients.

Line 729: `raise ValueError("learning_rate must be nonnegative")` This rejects an invalid state by raising ‘ValueError("learning_rate must be nonnegative")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 730: `if not 0.0 <= momentum <= 1.0 or not 0.0 <= weight_decay:` This executes the following indented host-code branch only when ‘not 0.0 <= momentum <= 1.0 or not 0.0 <= weight_decay‘ is true. The important operands are not: the value named 'not' in this block; momentum: the value named 'momentum' in this block; or: the value named 'or' in this block. Context: the function _optimizer_coefficients, which handles optimizer coefficients.

Line 731: `raise ValueError("momentum must be in [0,1] and weight_decay nonnegative")` This rejects an invalid state by raising ‘ValueError("momentum must be in [0,1] and weight_decay nonnegative")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 732: `learning_rate_q16 = int(round(learning_rate * (1 << 16)))` This assigns ‘int(round(learning_rate * (1 << 16)))‘ to ‘learning_rate_q16 ‘ in host memory. Here learning_rate_q16 means the fixed-point multiplier controlling update magnitude. The important operands are round: the value named 'round' in this block; learning_rate: the fixed-point multiplier controlling update magnitude. Context: the function _optimizer_coefficients, which handles optimizer coefficients.

Line 733: `momentum_q16 = int(round(momentum * (1 << 16)))` This assigns ‘int(round(momentum * (1 << 16)))‘ to ‘momentum_q16 ‘ in host memory. Here momentum_q16 means the value named ’momentum q16’ in this block. The important operands are round: the value named ’round’ in this block; momentum: the value named ’momentum’ in this block. Context: the function _optimizer_coefficients, which handles optimizer coefficients.

Line 734: `decay_q16 = int(round(weight_decay * (1 << (31 - tensor.fractional_bits))))` This assigns ‘int(round(wei * (1 << (31 - tensor.fractional_bits))))‘ to ‘decay_q16 ‘ in host memory. Here decay_q16 means the value named ’decay q16’ in this block. The important operands are round: the value named ’round’ in this block; weight_decay: a learned coefficient multiplied by an activation; tensor: the value named ’tensor’ in this block. Context: the function _optimizer_coefficients, which handles optimizer coefficients.

Line 735: `update_right_shift = 31 - tensor.fractional_bits` This assigns ‘31 - tensor.fractional_bits‘ to ‘update_right_shift ‘ in host memory. Here update_right_shift means the value named ’update right shift’ in this block. The important operands are tensor: the value named ’tensor’ in this block; fractional_bits: the value named ’fractional bits’ in this block. Context: the function _optimizer_coefficients, which handles optimizer coefficients.

Line 736: `if learning_rate > 0.0 and learning_rate_q16 == 0:` This executes the following indented host-code branch only when ‘learning_rate > 0.0 and learning_rate_q16 == 0‘ is true. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude; and: the value named ’and’ in this block; learning_rate_q16: the fixed-point multiplier controlling update magnitude. Context: the function _optimizer_coefficients, which handles optimizer coefficients.

Line 737: `raise ValueError("learning_rate is below the Q16 optimizer resolution")` This rejects an invalid state by raising ‘ValueError("learning_rate is below the Q16 optimizer resolution")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 738: `if learning_rate_q16 > 131071:` This executes the following indented host-code branch only when ‘learning_rate_q16 > 131071‘ is true. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude. Context: the function _optimizer_coefficients, which handles optimizer coefficients.

Line 739: `raise OverflowError("Q16 learning rate exceeds the RTL field")` This rejects an invalid state by raising ‘OverflowError("Q16 learning rate exceeds the RTL field")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 740: `if momentum_q16 > 65536 or decay_q16 > 65536:` This executes the following indented host-code branch only when ‘momentum_q16 > 65536 or decay_q16 > 65536‘ is true. The important operands are momentum_q16: the value named ’momentum q16’ in this block; or: the value named ’or’ in this block; decay_q16: the value named ’decay q16’ in this block. Context: the function _optimizer_coefficients, which handles optimizer coefficients.

Line 741: `raise OverflowError("momentum or master-format weight decay exceeds the RTL field")` This rejects an invalid state by raising ‘OverflowError("momentum or master-format weight decay exceeds the RTL field")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 742: `return learning_rate_q16, momentum_q16, decay_q16, update_right_shift` This returns ‘learning_rate_q16, momentum_q16, decay_q16, update_right_shift‘ to the caller of the function _optimizer_coefficients, which handles optimizer coefficients, ending this invocation. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude; momentum_q16: the value named ’momentum q16’ in this block; decay_q16: the value named ’decay q16’ in this block.

Line 744: `def _update_tensor(` This starts function _update_tensor. Its indented body performs update tensor as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 745: `self,` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 746: `driver: FullTrainingDriver,` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named 'driver' in this block; FullTrainingDriver: the value named 'full training driver' in this block.

Line 747: `tensor: MasterTensor,` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tensor: the value named 'tensor' in this block; MasterTensor: the value named 'master tensor' in this block.

Line 748: `gradient: BlockGradient,` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 749: `*,` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 750: `learning_rate: float,` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude; float: the value named 'float' in this block.

Line 751: `momentum: float,` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are momentum: the value named 'momentum' in this block; float: the value named 'float' in this block.

Line 752: `weight_decay: float,` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are weight_decay: a learned coefficient multiplied by an activation; float: the value named 'float' in this block.

Line 753: `gradient_clip_q15: int,` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are gradient_clip_q15: the signed loss derivative used to update a learned parameter.

Line 754: `timeout_seconds: float,` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; float: the value named 'float' in this block.

Line 755: `) -> np.ndarray:` Inside the function _update_tensor, which handles update tensor, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are ndarray: the value named 'ndarray' in this block.

Line 756: `if gradient.values.shape != tensor.master.shape:` This executes the following indented host-code branch only when ‘gradient.values.shape != tensor.master.shape‘ is true. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function _update_tensor, which handles update tensor.

Line 757: `raise ValueError("parameter gradient shape does not match its master tensor")` This rejects an invalid state by raising ‘ValueError("parameter gradient shape does not match its master tensor")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 758: `gradient_q15 = gradient_to_optimizer_q15(` This statement continues through source line 763; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘gradient_to_optimizer_q15(driver, gradient, clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘gradient_q15 ‘ in host memory. Here gradient_q15 means the signed loss derivative used to update a learned parameter. The important operands are gradient_to_optimizer_q15: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; gradient: the signed loss derivative used to update a learned parameter. Context: the function _update_tensor, which handles update tensor.

Line 759: `driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 758. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘gradient_to_optimizer_q15(driver, gradient, clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘gradient_q15 ‘ in host memory. Here gradient_q15 means the signed loss derivative used to update a learned parameter. The important operands are gradient_to_optimizer_q15: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; gradient: the signed loss derivative used to update a learned parameter. Context: the function _update_tensor, which handles update tensor.

Line 760: `gradient,` This is continuation line 3 of the 6-line logical statement that begins at source line 758. Its exact fragment is ‘gradient,‘. The important operands are gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘gradient_to_optimizer_q15(driver, gradient, clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘gradient_q15 ‘ in host memory. Here gradient_q15 means the signed loss derivative used to update a learned parameter. The important operands are gradient_to_optimizer_q15: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; gradient: the signed loss derivative used to update a learned parameter. Context: the function _update_tensor, which handles update tensor.

Line 761: `clip_q15=gradient_clip_q15,` This is continuation line 4 of the 6-line logical statement that begins at source line 758. Its exact fragment is ‘clip_q15=gradient_clip_q15,‘. The important operands are clip_q15: the value named ’clip q15’ in this block; gradient_clip_q15: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘gradient_to_optimizer_q15(driver, gradient, clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘gradient_q15 ‘ in host memory. Here gradient_q15 means the signed loss derivative used to update a learned parameter. The important operands are gradient_to_optimizer_q15: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; gradient: the signed loss derivative used to update a learned parameter. Context: the function _update_tensor, which handles update tensor.

Line 762: `timeout_seconds=timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 758. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘gradient_to_optimizer_q15(driver, gradient, clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘gradient_q15 ‘ in host memory. Here gradient_q15 means the signed loss derivative used to update a learned parameter. The important operands are gradient_to_optimizer_q15: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; gradient: the signed loss derivative used to update a learned parameter. Context: the function _update_tensor, which handles update tensor.

Line 763: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 758. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘gradient_to_optimizer_q15(driver, gradient, clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘gradient_q15 ‘ in host memory. Here gradient_q15 means the signed loss

derivative used to update a learned parameter. The important operands are gradient_to_optimizer_q15: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; gradient: the signed loss derivative used to update a learned parameter. Context: the function _update_tensor, which handles update tensor.

Line 764: `coefficients = self._optimizer_coefficients(` This statement continues through source line 765; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._optimizer_coefficients(tensor, learning_rate, momentum, weight_decay)' to 'coefficients ' in host memory. Here coefficients means the value named 'coefficients' in this block. The important operands are _optimizer_coefficients: the value named 'optimizer coefficients' in this block; tensor: the value named 'tensor' in this block; learning_rate: the fixed-point multiplier controlling update magnitude. Context: the function _update_tensor, which handles update tensor.

Line 765: `tensor, learning_rate, momentum, weight_decay)` This is continuation line 2 of the 2-line logical statement that begins at source line 764. Its exact fragment is 'tensor, learning_rate, momentum, weight_decay)'. The important operands are tensor: the value named 'tensor' in this block; learning_rate: the fixed-point multiplier controlling update magnitude; momentum: the value named 'momentum' in this block. Read together, the complete operation is: This assigns 'self._optimizer_coefficients(tensor, learning_rate, momentum, weight_decay)' to 'coefficients ' in host memory. Here coefficients means the value named 'coefficients' in this block. The important operands are _optimizer_coefficients: the value named 'optimizer coefficients' in this block; tensor: the value named 'tensor' in this block; learning_rate: the fixed-point multiplier controlling update magnitude. Context: the function _update_tensor, which handles update tensor.

Line 766: `next_master, next_velocity = execute_sgdw_update(` This statement continues through source line 776; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[2], update_right_shift=coefficients[3], timeout_seconds=timeout_se)' to 'next_master, next_velocity ' in host memory. Here next_master means the value named 'next master' in this block. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function _update_tensor, which handles update tensor.

Line 767: `driver,` This is continuation line 2 of the 11-line logical statement that begins at source line 766. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[2], update_right_shift=coefficients timeout_seconds=timeout_seconds,)' to 'next_master, next_velocity ' in host memory. Here next_master means the value named 'next master' in this block. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function _update_tensor, which handles update tensor.

Line 768: `tensor.master,` This is continuation line 3 of the 11-line logical statement that begins at source line 766. Its exact fragment is 'tensor.master,'. The important operands are tensor: the value named 'tensor' in this block; master: the value named 'master' in this block. Read together, the complete operation is: This assigns 'execute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[2], update_right_shift=coefficients[3], timeout_seconds=timeout_seconds,)' to 'next_master, next_velocity ' in host memory. Here next_master means the value named 'next master' in this block. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function _update_tensor, which handles update tensor.

Line 769: `gradient_q15,` This is continuation line 4 of the 11-line logical statement that begins at source line 766. Its exact fragment is 'gradient_q15,'. The important operands are gradient_q15: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'execute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[2], update_right_shift=coefficients[3], timeout_seconds=timeout_seconds,)' to 'next_master, next_velocity ' in host memory. Here next_master means the value named 'next master' in this block. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; driver: the value named

'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function _update_tensor, which handles update tensor.

Line 770: `tensor.velocity_q15,` This is continuation line 5 of the 11-line logical statement that begins at source line 766. Its exact fragment is 'tensor.velocity_q15,'. The important operands are tensor: the value named 'tensor' in this block; velocity_q15: the momentum history retained by the SGD optimizer. Read together, the complete operation is: This assigns 'execute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[2], update_right_shift=coefficients[timeout_seconds=timeout_seconds,)' to 'next_master, next_velocity ' in host memory. Here next_master means the value named 'next master' in this block. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function _update_tensor, which handles update tensor.

Line 771: `learning_rate_q16=coefficients[0],` This is continuation line 6 of the 11-line logical statement that begins at source line 766. Its exact fragment is 'learning_rate_q16=coefficients[0],'. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude; coefficients: the value named 'coefficients' in this block. Read together, the complete operation is: This assigns 'execute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[update_right_shift=coefficients[3], timeout_seconds=timeout_seconds,)' to 'next_master, next_velocity ' in host memory. Here next_master means the value named 'next master' in this block. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function _update_tensor, which handles update tensor.

Line 772: `momentum_q16=coefficients[1],` This is continuation line 7 of the 11-line logical statement that begins at source line 766. Its exact fragment is 'momentum_q16=coefficients[1],'. The important operands are momentum_q16: the value named 'momentum q16' in this block; coefficients: the value named 'coefficients' in this block. Read together, the complete operation is: This assigns 'execute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[2], update_right_shift=coeffic timeout_seconds=timeout_seconds,)' to 'next_master, next_velocity ' in host memory. Here next_master means the value named 'next master' in this block. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function _update_tensor, which handles update tensor.

Line 773: `weight_decay_q16=coefficients[2],` This is continuation line 8 of the 11-line logical statement that begins at source line 766. Its exact fragment is 'weight_decay_q16=coefficients[2],'. The important operands are weight_decay_q16: a learned coefficient multiplied by an activation; coefficients: the value named 'coefficients' in this block. Read together, the complete operation is: This assigns 'execute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[update_right_shift=coefficients[3], timeout_seconds=timeout_seconds,)' to 'next_master, next_velocity ' in host memory. Here next_master means the value named 'next master' in this block. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function _update_tensor, which handles update tensor.

Line 774: `update_right_shift=coefficients[3],` This is continuation line 9 of the 11-line logical statement that begins at source line 766. Its exact fragment is 'update_right_shift=coefficients[3],'. The important operands are update_right_shift: the value named 'update right shift' in this block; coefficients: the value named 'coefficients' in this block. Read together, the complete operation is: This assigns 'execute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[update_right_shift=coefficients[3], timeout_seconds=timeout_seconds,)' to 'next_master, next_velocity ' in host memory. Here next_master means the value named 'next master' in this block. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block; driver: the value named 'driver' in this block; tensor: the value named 'tensor' in this block. Context: the function _update_tensor, which handles update tensor.

Line 775: `timeout_seconds=timeout_seconds,` This is continuation line 10 of the 11-line logical statement that begins at source line 766. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'ex-

ecute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[2], update_right_shift=coefficients[3], timeout_seconds=timeout_se)‘ to ‘next_master, next_velocity ‘ in host memory. Here next_master means the value named ’next master’ in this block. The important operands are execute_sgdw_update: the value named ’execute sgdw update’ in this block; driver: the value named ’driver’ in this block; tensor: the value named ’tensor’ in this block. Context: the function _update_tensor, which handles update tensor.

Line 776: `)` This is continuation line 11 of the 11-line logical statement that begins at source line 766. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘execute_sgdw_update(driver, tensor.master, gradient_q15, tensor.velocity_q15, learning_rate_q16=coefficients[0], momentum_q16=coefficients[1], weight_decay_q16=coefficients[2], update_right_shift=coefficients[timeout_seconds=timeout_seconds,)‘ to ‘next_master, next_velocity ‘ in host memory. Here next_master means the value named ’next master’ in this block. The important operands are execute_sgdw_update: the value named ’execute sgdw update’ in this block; driver: the value named ’driver’ in this block; tensor: the value named ’tensor’ in this block. Context: the function _update_tensor, which handles update tensor.

Line 777: `tensor.master = next_master.astype(np.int16)` This assigns ‘next_master.astype(np.int16)‘ to ‘tensor.master ‘ in host memory. Here master means the value named ’master’ in this block. The important operands are next_master: the value named ’next master’ in this block; astype: the value named ’astype’ in this block; int16: the value named ’int16’ in this block. Context: the function _update_tensor, which handles update tensor.

Line 778: `tensor.velocity_q15 = next_velocity.astype(np.int32)` This assigns ‘next_velocity.astype(np.int32)‘ to ‘tensor.velocity_q15 ‘ in host memory. Here velocity_q15 means the momentum history retained by the SGD optimizer. The important operands are next_velocity: the momentum history retained by the SGD optimizer; astype: the value named ’astype’ in this block; int32: the value named ’int32’ in this block. Context: the function _update_tensor, which handles update tensor.

Line 779: `return execute_deploy_master(driver, tensor, timeout_seconds=timeout_seconds)` This returns ‘execute_deploy_master(driver, tensor, timeout_seconds=timeout_seconds)‘ to the caller of the function _update_tensor, which handles update tensor, ending this invocation. The important operands are execute_deploy_master: the value named ’execute deploy master’ in this block; driver: the value named ’driver’ in this block; tensor: the value named ’tensor’ in this block.

Line 781: `def apply_gradients(` This starts function apply_gradients. Its indented body performs apply gradients as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 782: `self,` Inside the function apply_gradients, which handles apply gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 783: `driver: FullTrainingDriver,` Inside the function apply_gradients, which handles apply gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named ’driver’ in this block; FullTrainingDriver: the value named ’full training driver’ in this block.

Line 784: `gradients: Mapping[str, ParameterGradient],` Inside the function apply_gradients, which handles apply gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are gradients: the signed loss derivative used to update a learned parameter; Mapping: the value named ’mapping’ in this block; str: the value named ’str’ in this block.

Line 785: `*,` Inside the function apply_gradients, which handles apply gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 786: `learning_rate: float,` Inside the function apply_gradients, which handles apply gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude; float: the value named 'float' in this block.

Line 787: `momentum: float = 0.9,` This assigns '0.9,' to 'momentum' in host memory. Here momentum means the value named 'momentum' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function apply_gradients, which handles apply gradients.

Line 788: `weight_decay: float = 5e-4,` This assigns '5e-4,' to 'weight_decay' in host memory. Here weight_decay means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function apply_gradients, which handles apply gradients.

Line 789: `gradient_clip_q15: int = 4 << 15,` This assigns '4 << 15,' to 'gradient_clip_q15' in host memory. Here gradient_clip_q15 means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function apply_gradients, which handles apply gradients.

Line 790: `timeout_seconds: float = 120.0,` This assigns '120.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function apply_gradients, which handles apply gradients.

Line 791: `) -> None:` Inside the function apply_gradients, which handles apply gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are None: the value named 'none' in this block.

Line 792: `"""Update every projection and classifier coefficient through RTL SGDW."""` This is executable documentation attached to the function apply_gradients, which handles apply gradients. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 794: `expected = set(self.projection_names) | {"head"}` This assigns 'set(self.projection_names) | {"head"}' to 'expected ' in host memory. Here expected means the value named 'expected' in this block. The important operands are set: the value named 'set' in this block; projection_names: the value named 'projection names' in this block; head: the value named 'head' in this block. Context: the function apply_gradients, which handles apply gradients.

Line 795: `if set(gradients) != expected:` This executes the following indented host-code branch only when 'set(gradients) != expected' is true. The important operands are set: the value named 'set' in this block; gradients: the signed loss derivative used to update a learned parameter; expected: the value named 'expected' in this block. Context: the function apply_gradients, which handles apply gradients.

Line 796: `missing = sorted(expected - set(gradients))` This assigns 'sorted(expected - set(gradients))' to 'missing ' in host memory. Here missing means the value named 'missing' in this block. The important operands are sorted: the value named 'sorted' in this block; expected: the value named 'expected' in this block; set: the value named 'set' in this block. Context: the function apply_gradients, which handles apply gradients.

Line 797: `extra = sorted(set(gradients) - expected)` This assigns 'sorted(set(gradients) - expected)' to 'extra ' in host memory. Here extra means the value named 'extra' in this block. The important operands are sorted: the value named 'sorted' in this block; set: the value named 'set' in this block; gradients: the signed loss derivative used to update a learned parameter. Context: the function apply_gradients, which handles apply gradients.

Line 798: `raise ValueError(f"parameter-gradient coverage mismatch: missing={missing}, extra={extra}")` This rejects an invalid state by raising 'ValueError(f"parameter-gradient coverage mismatch: missing={missing}, extra={extra}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 799: `for name in self.projection_names:` This iterates name over ‘self.projection_names‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function apply_gradients, which handles apply gradients.

Line 800: `gradient = gradients[name]` This assigns ‘gradients[name]‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are gradients: the signed loss derivative used to update a learned parameter; name: the value named ’name’ in this block. Context: the function apply_gradients, which handles apply gradients.

Line 801: `self._deployed_projection_weight[name] = self._update_tensor(` This statement continues through source line 810; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._update_tensor(driver, self._projection_weight[name], gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_projection_weight[name] ‘ in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 802: `driver,` This is continuation line 2 of the 10-line logical statement that begins at source line 801. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_weight[name], gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_projection_weight[name] ‘ in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 803: `self._projection_weight[name],` This is continuation line 3 of the 10-line logical statement that begins at source line 801. Its exact fragment is ‘self._projection_weight[name],‘. The important operands are _projection_weight: a learned coefficient multiplied by an activation; name: the value named ’name’ in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_weight[name], gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_projection_weight[name] ‘ in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 804: `gradient.weight,` This is continuation line 4 of the 10-line logical statement that begins at source line 801. Its exact fragment is ‘gradient.weight,‘. The important operands are gradient: the signed loss derivative used to update a learned parameter; weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_weight[name], gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconc).astype(np.int8)‘ to ‘self._deployed_projection_weight[name] ‘ in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 805: `learning_rate=learning_rate,` This is continuation line 5 of the 10-line logical statement that begins at source line 801. Its exact fragment is ‘learning_rate=learning_rate,‘. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_weight[name], gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_projection_weight[name] ‘ in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named

'update tensor' in this block; driver: the value named 'driver' in this block; _projection_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 806: `momentum=momentum,` This is continuation line 6 of the 10-line logical statement that begins at source line 801. Its exact fragment is 'momentum=momentum,'. The important operands are momentum: the value named 'momentum' in this block. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._projection_weight[nam gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradien timeout_seconds=timeout_seconds,).astype(np.int8)' to 'self._deployed_projection_weight[name] ' in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _projection_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 807: `weight_decay=weight_decay,` This is continuation line 7 of the 10-line logical statement that begins at source line 801. Its exact fragment is 'weight_decay=weight_decay,'. The important operands are weight_decay: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._projection_weight[name], gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weig gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)' to 'self._deployed_projection_weig ' in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _projection_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 808: `gradient_clip_q15=gradient_clip_q15,` This is continuation line 8 of the 10-line logical statement that begins at source line 801. Its exact fragment is 'gradient_clip_q15=gradient_clip_q15,'. The important operands are gradient_clip_q15: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._projection_weight[name], gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_secon).astype(np.int8)' to 'self._deployed_projection_weight[name] ' in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _projection_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 809: `timeout_seconds=timeout_seconds,` This is continuation line 9 of the 10-line logical statement that begins at source line 801. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._projection_weight[name], gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)' to 'self._deployed_projection_weight[name] ' in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _projection_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 810: `).astype(np.int8)` This is continuation line 10 of the 10-line logical statement that begins at source line 801. Its exact fragment is ').astype(np.int8)'. The important operands are astype: the value named 'astype' in this block; int8: the value named 'int8' in this block. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._projection_weight[name], gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weig gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)' to 'self._deployed_projection_weig ' in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _projection_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 811: `self._deployed_projection_bias[name] = self._update_tensor(` This statement continues through source line 820; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._update_tensor(driver, self._projection_bias[name], gradient.bias, learning_rate=learning_rate, momen-

tum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘self._deployed_projection_bias[name] ‘ in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 812: `driver,` This is continuation line 2 of the 10-line logical statement that begins at source line 811. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_bias[name], gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=t)‘ to ‘self._deployed_projection_bias[name] ‘ in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 813: `self._projection_bias[name],` This is continuation line 3 of the 10-line logical statement that begins at source line 811. Its exact fragment is ‘self._projection_bias[name],‘. The important operands are _projection_bias: an additive learned offset applied after accumulation; name: the value named ’name’ in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_bias[name], gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=t)‘ to ‘self._deployed_projection_bias[name] ‘ in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 814: `gradient.bias,` This is continuation line 4 of the 10-line logical statement that begins at source line 811. Its exact fragment is ‘gradient.bias,‘. The important operands are gradient: the signed loss derivative used to update a learned parameter; bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_bias[name], gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘self._deployed_projection_bias[name] ‘ in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 815: `learning_rate=learning_rate,` This is continuation line 5 of the 10-line logical statement that begins at source line 811. Its exact fragment is ‘learning_rate=learning_rate,‘. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_bias[name], gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘self._deployed_projection_bias[name] ‘ in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 816: `momentum=momentum,` This is continuation line 6 of the 10-line logical statement that begins at source line 811. Its exact fragment is ‘momentum=momentum,‘. The important operands are momentum: the value named ’momentum’ in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_bias[name], gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘self._deployed_projection_bias[name] ‘ in host memory. Here _deployed_projection_bia means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 817: `weight_decay=0.0,` This is continuation line 7 of the 10-line logical statement that begins at source line 811. Its exact fragment is ‘weight_decay=0.0,‘. The important operands are weight_decay: a learned coeffi-

cient multiplied by an activation. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_bias[name], gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘self._deployed_projection_bias[name] ‘ in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 818: `gradient_clip_q15=gradient_clip_q15,` This is continuation line 8 of the 10-line logical statement that begins at source line 811. Its exact fragment is ‘gradient_clip_q15=gradient_clip_q15,‘. The important operands are gradient_clip_q15: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_bias[name], gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘self._deployed_projection_bias[name] ‘ in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 819: `timeout_seconds=timeout_seconds,` This is continuation line 9 of the 10-line logical statement that begins at source line 811. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_bias[name], gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘self._deployed_projection_bias[name] ‘ in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 820: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 811. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._projection_bias[name], gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=t)‘ to ‘self._deployed_projection_bias[name] ‘ in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _projection_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 821: `head_gradient = gradients["head"]` This assigns ‘gradients["head"]‘ to ‘head_gradient ‘ in host memory. Here head_gradient means the signed loss derivative used to update a learned parameter. The important operands are gradients: the signed loss derivative used to update a learned parameter; head: the value named ’head’ in this block. Context: the function apply_gradients, which handles apply gradients.

Line 822: `self._deployed_head_weight = self._update_tensor(` This statement continues through source line 831; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._update_tensor(driver, self._head_weight, head_gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_d gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 823: `driver,` This is continuation line 2 of the 10-line logical statement that begins at source line 822. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_weight, head_gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15,

timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 824: `self._head_weight,` This is continuation line 3 of the 10-line logical statement that begins at source line 822. Its exact fragment is ‘self._head_weight,‘. The important operands are _head_weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_weight, head_gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 825: `head_gradient.weight,` This is continuation line 4 of the 10-line logical statement that begins at source line 822. Its exact fragment is ‘head_gradient.weight,‘. The important operands are head_gradient: the signed loss derivative used to update a learned parameter; weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_weight, head_gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 826: `learning_rate=learning_rate,` This is continuation line 5 of the 10-line logical statement that begins at source line 822. Its exact fragment is ‘learning_rate=learning_rate,‘. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_weight, head_gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 827: `momentum=momentum,` This is continuation line 6 of the 10-line logical statement that begins at source line 822. Its exact fragment is ‘momentum=momentum,‘. The important operands are momentum: the value named 'momentum' in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_weight, head_gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=g timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 828: `weight_decay=weight_decay,` This is continuation line 7 of the 10-line logical statement that begins at source line 822. Its exact fragment is ‘weight_decay=weight_decay,‘. The important operands are weight_decay: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_weight, head_gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_d gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 829: `gradient_clip_q15=gradient_clip_q15,` This is continuation line 8 of the 10-line logical statement that begins at source line 822. Its exact fragment is ‘gradient_clip_q15=gradient_clip_q15,‘. The important operands are gra-

dient_clip_q15: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_weight, head_gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 830: `timeout_seconds=timeout_seconds,` This is continuation line 9 of the 10-line logical statement that begins at source line 822. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_weight, head_gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 831: `).astype(np.int8)` This is continuation line 10 of the 10-line logical statement that begins at source line 822. Its exact fragment is ‘).astype(np.int8)‘. The important operands are astype: the value named ’astype’ in this block; int8: the value named ’int8’ in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_weight, head_gradient.weight, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_d gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,).astype(np.int8)‘ to ‘self._deployed_head_weight ‘ in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function apply_gradients, which handles apply gradients.

Line 832: `self._deployed_head_bias = self._update_tensor(` This statement continues through source line 841; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._update_tensor(driver, self._head_bias, head_gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘self._deployed_head_bias ‘ in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 833: `driver,` This is continuation line 2 of the 10-line logical statement that begins at source line 832. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_bias, head_gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=t)‘ to ‘self._deployed_head_bias ‘ in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 834: `self._head_bias,` This is continuation line 3 of the 10-line logical statement that begins at source line 832. Its exact fragment is ‘self._head_bias,‘. The important operands are _head_bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns ‘self._update_tensor(driver, self._head_bias, head_gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)‘ to ‘self._deployed_head_bias ‘ in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named ’update tensor’ in this block; driver: the value named ’driver’ in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 835: `head_gradient.bias,` This is continuation line 4 of the 10-line logical statement that begins at source line 832. Its exact fragment is 'head_gradient.bias,'. The important operands are head_gradient: the signed loss derivative used to update a learned parameter; bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._head_bias, head_gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=t)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 836: `learning_rate=learning_rate,` This is continuation line 5 of the 10-line logical statement that begins at source line 832. Its exact fragment is 'learning_rate=learning_rate,'. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._head_bias, head_gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 837: `momentum=momentum,` This is continuation line 6 of the 10-line logical statement that begins at source line 832. Its exact fragment is 'momentum=momentum,'. The important operands are momentum: the value named 'momentum' in this block. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._head_bias, head_gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_ timeout_seconds=timeout_seconds,)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 838: `weight_decay=0.0,` This is continuation line 7 of the 10-line logical statement that begins at source line 832. Its exact fragment is 'weight_decay=0.0,'. The important operands are weight_decay: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._head_bias, head_gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 839: `gradient_clip_q15=gradient_clip_q15,` This is continuation line 8 of the 10-line logical statement that begins at source line 832. Its exact fragment is 'gradient_clip_q15=gradient_clip_q15,'. The important operands are gradient_clip_q15: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._head_bias, head_gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 840: `timeout_seconds=timeout_seconds,` This is continuation line 9 of the 10-line logical statement that begins at source line 832. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._head_bias, head_gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in

this block; _head_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 841: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 832. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self._update_tensor(driver, self._head_bias, head_gradient.bias, learning_rate=learning_rate, momentum=momentum, weight_decay=0.0, gradient_clip_q15=gradient_clip_q15, timeout_seconds=timeout_seconds,)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are _update_tensor: the value named 'update tensor' in this block; driver: the value named 'driver' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function apply_gradients, which handles apply gradients.

Line 842: `self.optimizer_step += 1` Inside the function apply_gradients, which handles apply gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are optimizer_step: the value named 'optimizer step' in this block.

Line 844: `def _checkpoint_tensors(self) -> dict[str, np.ndarray]:` This starts function _checkpoint_tensors. Its indented body performs checkpoint tensors as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 845: `tensors: dict[str, np.ndarray] = {}` This assigns '{}' to 'tensors' in host memory. Here tensors means the value named 'tensors' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _checkpoint_tensors, which handles checkpoint tensors.

Line 846: `for index, name in enumerate(self.projection_names):` This iterates index, name over 'enumerate(self.projection_names)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _checkpoint_tensors, which handles checkpoint tensors.

Line 847: `for kind, tensor in (` This line opens or closes a multi-line Python expression inside the function _checkpoint_tensors, which handles checkpoint tensors; the neighboring lines supply its arguments or elements.

Line 848: `("weight", self._projection_weight[name]),` Inside the function _checkpoint_tensors, which handles checkpoint tensors, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are weight: a learned coefficient multiplied by an activation; _projection_weight: a learned coefficient multiplied by an activation; name: the value named 'name' in this block.

Line 849: `("bias", self._projection_bias[name]),` Inside the function _checkpoint_tensors, which handles checkpoint tensors, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are bias: an additive learned offset applied after accumulation; _projection_bias: an additive learned offset applied after accumulation; name: the value named 'name' in this block.

Line 850: `):` Inside the function _checkpoint_tensors, which handles checkpoint tensors, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 851: `prefix = f"projection_{index}_{kind}"` This assigns 'f"projection_{index}_{kind}"' to 'prefix ' in host memory. Here prefix means the value named 'prefix' in this block. The important operands are f: the value named 'f' in this block; projection_: the value named 'projection' in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function _checkpoint_tensors, which handles checkpoint tensors.

Line 852: `tensors[f"{prefix}_master"] = tensor.master` Inside the function _checkpoint_tensors, which handles checkpoint tensors, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tensors: the value named 'tensors' in this block; f: the value named 'f' in this block; prefix: the value named 'prefix' in this block.

Line 853: `tensors[f"{prefix}_velocity"] = tensor.velocity_q15` Inside the function _checkpoint_tensors, which handles checkpoint tensors, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tensors: the value named 'tensors' in this block; f: the value named 'f' in this block; prefix: the value named 'prefix' in this block.

Line 854: `tensors["head_weight_master"] = self._head_weight.master` Inside the function _checkpoint_tensors, which handles checkpoint tensors, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tensors: the value named 'tensors' in this block; head_weight_master: a learned coefficient multiplied by an activation; _head_weight: a learned coefficient multiplied by an activation.

Line 855: `tensors["head_weight_velocity"] = self._head_weight.velocity_q15` Inside the function _checkpoint_tensors, which handles checkpoint tensors, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tensors: the value named 'tensors' in this block; head_weight_velocity: a learned coefficient multiplied by an activation; _head_weight: a learned coefficient multiplied by an activation.

Line 856: `tensors["head_bias_master"] = self._head_bias.master` Inside the function _checkpoint_tensors, which handles checkpoint tensors, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tensors: the value named 'tensors' in this block; head_bias_master: an additive learned offset applied after accumulation; _head_bias: an additive learned offset applied after accumulation.

Line 857: `tensors["head_bias_velocity"] = self._head_bias.velocity_q15` Inside the function _checkpoint_tensors, which handles checkpoint tensors, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tensors: the value named 'tensors' in this block; head_bias_velocity: an additive learned offset applied after accumulation; _head_bias: an additive learned offset applied after accumulation.

Line 858: `return tensors` This returns ‘tensors‘ to the caller of the function _checkpoint_tensors, which handles checkpoint tensors, ending this invocation. The important operands are tensors: the value named 'tensors' in this block.

Line 860: `def save_checkpoint(` This starts function save_checkpoint. Its indented body performs save checkpoint as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 861: `self,` Inside the function save_checkpoint, which handles save checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 862: `path: str | Path,` Inside the function save_checkpoint, which handles save checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are path: the value named 'path' in this block; str: the value named 'str' in this block; Path: the value named 'path' in this block.

Line 863: `*,` Inside the function save_checkpoint, which handles save checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 864: `epoch: int,` Inside the function save_checkpoint, which handles save checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are epoch: the value named 'epoch' in this block.

Line 865: `batch_index: int,` Inside the function save_checkpoint, which handles save checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 866: `best_accuracy_percent: float,` Inside the function save_checkpoint, which handles save checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are best_accuracy_percent: the value named 'best accuracy percent' in this block; float: the value named 'float' in this block.

Line 867: `extra: Mapping[str, Any] | None = None,` This assigns 'None,' to 'extra' in host memory. Here extra means the value named 'extra' in this block. The important operands are None: the value named 'none' in this block. Context: the function save_checkpoint, which handles save checkpoint.

Line 868: `) -> str:` Inside the function save_checkpoint, which handles save checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are str: the value named 'str' in this block.

Line 869: `"""Atomically save complete masters, momentum, and resume coordinates."""` This is executable documentation attached to the function save_checkpoint, which handles save checkpoint. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 871: `target = Path(path).expanduser().resolve()` This assigns 'Path(path).expanduser().resolve()' to 'target ' in host memory. Here target means the value named 'target' in this block. The important operands are Path: the value named 'path' in this block; path: the value named 'path' in this block; expanduser: the value named 'expanduser' in this block. Context: the function save_checkpoint, which handles save checkpoint.

Line 872: `target.parent.mkdir(parents=True, exist_ok=True)` This calls 'target.parent.mkdir' with 'parents=True, exist_ok=True' inside the function save_checkpoint, which handles save checkpoint. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 873: `metadata = {` This statement continues through source line 891; the explanation uses the complete expression rather than only the first visual fragment. This assigns '{ "format": CHECKPOINT_FORMAT, "state_format": MASTER_FORMAT, "base_binary_sha256": self.base_binary_sha256, "projection_names": list(self.projection_names), "projection_weight_fractional_bits": [self._projection_weight[name].fractional_bits for name in self.projection_names], "projection_bias_fractional_bits": [self._projection_bias[name].fractional_bits for name in self.projection_names], "head_weight_fractional_bits": self._head_weight.fractional_bits, "head_bias_fractional_bits": self._head_bias.fractional_bits, "optimizer_step": self.optimizer_step, "epoch": int(epoch), "batch_index": int(batch_index), "best_accuracy_percent": float(best_accuracy_percent), "extra": dict(extra or {}), }' to 'metadata ' in host memory. Here metadata means the value named 'metadata' in this block. The important operands are format: the value named 'format' in this block; CHECKPOINT_FORMAT: the value named 'checkpoint format' in this block; state_format: the finite-state-machine phase retained in flip-flops. Context: the function save_checkpoint, which handles save checkpoint.

Line 874: `"format": CHECKPOINT_FORMAT,` This is continuation line 2 of the 19-line logical statement that begins at source line 873. Its exact fragment is '"format": CHECKPOINT_FORMAT,'. The important operands are format: the value named 'format' in this block; CHECKPOINT_FORMAT: the value named 'checkpoint format' in this block. Read together, the complete operation is: This assigns '{ "format": CHECKPOINT_FORMAT, "state_format": MASTER_FORMAT, "base_binary_sha256": self.base_binary_sha256, "projection_names": list(self.projection_names), "projection_weight_fractional_bits": [self._projection_weight[name].fractional_bits for name in self.projection_names], "projection_bias_fractional_bits": [self._projection_bias[name].fractional_bits for name in self.projection_names], "head_weight_fractional_bits": self._head_weight.fractional_bits, "head_bias_fractional_bits": self._head_bias.fractional_bits,

"optimizer_step": self.optimizer_step, "epoch": int(epoch), "batch_index": int(batch_index), "best_accuracy_percent": float(best_accuracy_percent), "extra": dict(extra or {}), }‘ to ‘metadata ‘ in host memory. Here metadata means the value named ’metadata’ in this block. The important operands are format: the value named ’format’ in this block; CHECKPOINT_FORMAT: the value named ’checkpoint format’ in this block; state_format: the finite-state-machine phase retained in flip-flops. Context: the function save_checkpoint, which handles save checkpoint.

Line 875: `"state_format": MASTER_FORMAT,` This is continuation line 3 of the 19-line logical statement that begins at source line 873. Its exact fragment is ‘"state_format": MASTER_FORMAT,‘. The important operands are state_format: the finite-state-machine phase retained in flip-flops; MASTER_FORMAT: the value named ’master format’ in this block. Read together, the complete operation is: This assigns ‘{ "format": CHECKPOINT_FORMAT, "state_format": MASTER_FORMAT, "base_binary_sha256": self.base_binary_sha256, "projection_names": list(self.projection_ "projection_weight_fractional_bits": [self._projection_weight[name].fractional_bits for name in self.projection_names], "projection_bias_fractional_bits": [self._projection_bias[name].fractional_bits for name in self.projection_names], "head_weight_fractional_bits": self._head_weight.fractional_bits, "head_bias_fractional_bits": self._head_bias.fractional_bits, "optimizer_step": self.optimizer_step, "epoch": int(epoch), "batch_index": int(batch_index), "best_accuracy_percent": float(best_accuracy_percent), "extra": dict(extra or {}), }‘ to ‘metadata ‘ in host memory. Here metadata means the value named ’metadata’ in this block. The important operands are format: the value named ’format’ in this block; CHECKPOINT_FORMAT: the value named ’checkpoint format’ in this block; state_format: the finite-state-machine phase retained in flip-flops. Context: the function save_checkpoint, which handles save checkpoint.

Line 876: `"base_binary_sha256": self.base_binary_sha256,` This is continuation line 4 of the 19-line logical statement that begins at source line 873. Its exact fragment is ‘"base_binary_sha256": self.base_binary_sha256,‘. The important operands are base_binary_sha256: the value named ’base binary sha256’ in this block. Read together, the complete operation is: This assigns ‘{ "format": CHECKPOINT_FORMAT, "state_format": MASTER_FORMAT, "base_binary_sha256": self.base_binary_sha256, "projection_names": list(self.projection_names), "projection_weight_fractional_ [self._projection_weight[name].fractional_bits for name in self.projection_names], "projection_bias_fractional_bits": [self._projection_bias[name].fractional_bits for name in self.projection_names], "head_weight_fractional_bits": self._head_weight "head_bias_fractional_bits": self._head_bias.fractional_bits, "optimizer_step": self.optimizer_step, "epoch": int(epoch), "batch_index": int(batch_index), "best_accuracy_percent": float(best_accuracy_percent), "extra": dict(extra or {}), }‘ to ‘metadata ‘ in host memory. Here metadata means the value named ’metadata’ in this block. The important operands are format: the value named ’format’ in this block; CHECKPOINT_FORMAT: the value named ’checkpoint format’ in this block; state_format: the finite-state-machine phase retained in flip-flops. Context: the function save_checkpoint, which handles save checkpoint.

Line 877: `"projection_names": list(self.projection_names),` This is continuation line 5 of the 19-line logical statement that begins at source line 873. Its exact fragment is ‘"projection_names": list(self.projection_names),‘. The important operands are projection_names: the value named ’projection names’ in this block; list: the value named ’list’ in this block. Read together, the complete operation is: This assigns ‘{ "format": CHECKPOINT_FORMAT, "state_format": MASTER_FORMAT, "base_binary_sha256": self.base_binary_sha256, "projection_names": list(self.projection_ "projection_weight_fractional_bits": [self._projection_weight[name].fractional_bits for name in self.projection_names], "projection_bias_fractional_bits": [self._projection_bias[name].fractional_bits for name in self.projection_names], "head_weight_fractional_bits": self._head_weight.fractional_bits, "head_bias_fractional_bits": self._head_bias.fractional_bits, "optimizer_step": self.optimizer_step, "epoch": int(epoch), "batch_index": int(batch_index), "best_accuracy_percent": float(best_accuracy_percent), "extra": dict(extra or {}), }‘ to ‘metadata ‘ in host memory. Here metadata means the value named ’metadata’ in this block. The important operands are format: the value named ’format’ in this block; CHECKPOINT_FORMAT: the value named ’checkpoint format’ in this block; state_format: the finite-state-machine phase retained in flip-flops. Context: the function save_checkpoint, which handles save checkpoint.

Line 878: `"projection_weight_fractional_bits": [` This is continuation line 6 of the 19-line logical statement that begins at source line 873. Its exact fragment is ‘"projection_weight_fractional_bits": [‘. The important operands are projection_weight_fractional_bits: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘{ "format": CHECKPOINT_FORMAT, "state_format": MASTER_FORMAT, "base_binary_sha256": self.base_binary_sha256, "projection_names": list(self.projection_names), "projection_weight_fractional_ [self._projection_weight[name].fractional_bits for name in self.projection_names], "projection_bias_fractional_bits": [self._projection_bias[name].fractional_bits for name in self.projection_names], "head_weight_fractional_bits": self._head_weight "head_bias_fractional_bits": self._head_bias.fractional_bits, "optimizer_step": self.optimizer_step, "epoch": int(epoch), "batch_index": int(batch_index), "best_accuracy_percent": float(best_accuracy_percent), "extra": dict(extra or {}), }‘

to ‘metadata ‘ in host memory. Here metadata means the value named ’metadata’ in this block. The important operands are format: the value named ’format’ in this block; CHECKPOINT_FORMAT: the value named ’checkpoint format’ in this block; state_format: the finite-state-machine phase retained in flip-flops. Context: the function save_checkpoint, which handles save checkpoint.

Line 879: `self._projection_weight[name].fractional_bits for name in self.projection_names` This is continuation line 7 of the 19-line logical statement that begins at source line 873. Its exact fragment is ‘self._projection_weight[name].fra for name in self.projection_names‘. The important operands are _projection_weight: a learned coefficient multiplied by an activation; name: the value named ’name’ in this block; fractional_bits: the value named ’fractional bits’ in this block. Read together, the complete operation is: This assigns ‘{ "format": CHECKPOINT_FORMAT, "state_format": MASTER_FORMAT, "base_binary_sha256": self.base_binary_sha256, "projection_names": list(self.projection_names), "projection_weight_fractional_bits": [self._projection_weight[name].fractional_bits for name in self.projection_names], "projection_bias_fractional_bits": [self._projection_bias[name].fractional_bits for name in self.projection_names], "head_weight_fractional_bits": self._head_weight.fractional_bits, "head_bias_fractional_bits": self._head_bias.fractional_bits, "optimizer_step": self.optimizer_step, "epoch": int(epoch), "batch_index": int(batch_index), "best_accuracy_percent": float(best_accuracy_percent), "extra": dict(extra or {}), }‘ to ‘metadata ‘ in host memory. Here metadata means the value named ’metadata’ in this block. The important operands are format: the value named ’format’ in this block; CHECKPOINT_FORMAT: the value named ’checkpoint format’ in this block; state_format: the finite-state-machine phase retained in flip-flops. Context: the function save_checkpoint, which handles save checkpoint.

Line 880: `],` This is continuation line 8 of the 19-line logical statement that begins at source line 873. Its exact fragment is ‘],‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "format": CHECKPOINT_FORMAT, "state_format": MASTER_FORMAT, "base_binary_sha256": self.base_binary_sha256, "projection_names": list(self.projection_names), "projection_weight_fractional_ [self._projection_weight[name].fractional_bits for name in self.projection_names], "projection_bias_fractional_bits": [self._projection_bias[name].fractional_bits for name in self.projection_names], "head_weight_fractional_bits": self._head_weight "head_bias_fractional_bits": self._head_bias.fractional_bits, "optimizer_step": self.optimizer_step, "epoch": int(epoch), "batch_index": int(batch_index), "best_accuracy_percent": float(best_accuracy_percent), "extra": dict(extra or {}), }‘ to ‘metadata ‘ in host memory. Here metadata means the value named ’metadata’ in this block. The important operands are format: the value named ’format’ in this block; CHECKPOINT_FORMAT: the value named ’checkpoint format’ in this block; state_format: the finite-state-machine phase retained in flip-flops. Context: the function save_checkpoint, which handles save checkpoint.

Line 881: `"projection_bias_fractional_bits": [` This is continuation line 9 of the 19-line logical statement that begins at source line 873. Its exact fragment is ‘"projection_bias_fractional_bits": [‘. The important operands are projection_bias_fractional_bits: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns ‘{ "format": CHECKPOINT_FORMAT, "state_format": MASTER_FORMAT, "base_binary_sha256": self.base_binary_sha256, "projection_names": list(self.projection_names), "projection_weight_fractional_bits": [self._projection for name in self.projection_names], "projection_bias_fractional_bits": [self._projection_bias[name].fractional_bits for name in self.projection_names], "head_weight_fractional_bits": self._head_weight.fractional_bits, "head_bias_fractional_bits": self._head_bias.fractional_bits, "optimizer_step": self.optimizer_step, "epoch": int(epoch), "batch_index": int(batch_index), "best_accuracy_percent": float(best_accuracy_percent), "extra": dict(extra or {}), }‘ to ‘metadata ‘ in host memory. Context: the function save_checkpoint, which handles save checkpoint.

Line 891: `}` This is continuation line 19 of the 19-line logical statement that begins at source line 873. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '{ "format": CHECKPOINT_FORMAT, "state_format": MASTER_FORMAT, "base_binary_sha256": self.base_binary_sha256, "projection_names": list(self.projection_names), "projection_weight_fractional_ [self._projection_weight[name].fractional_bits for name in self.projection_names], "projection_bias_fractional_bits": [self._projection_bias[name].fractional_bits for name in self.projection_names], "head_weight_fractional_bits": self._head_weight "head_bias_fractional_bits": self._head_bias.fractional_bits, "optimizer_step": self.optimizer_step, "epoch": int(epoch), "batch_index": int(batch_index), "best_accuracy_percent": float(best_accuracy_percent), "extra": dict(extra or {}), }' to 'metadata ' in host memory. Here metadata means the value named 'metadata' in this block. The important operands are format: the value named 'format' in this block; CHECKPOINT_FORMAT: the value named 'checkpoint format' in this block; state_format: the finite-state-machine phase retained in flip-flops. Context: the function save_checkpoint, which handles save checkpoint.

Line 892: `temporary = target.with_name(target.name + ".tmp")` This assigns 'target.with_name(target.name + ".tmp")' to 'temporary ' in host memory. Here temporary means the value named 'temporary' in this block. The important operands are target: the value named 'target' in this block; with_name: the value named 'with name' in this block; name: the value named 'name' in this block. Context: the function save_checkpoint, which handles save checkpoint.

Line 893: `payload = self._checkpoint_tensors()` This assigns 'self._checkpoint_tensors()' to 'payload ' in host memory. Here payload means stream data belonging to the current command. The important operands are _checkpoint_tensors: the value named 'checkpoint tensors' in this block. Context: the function save_checkpoint, which handles save checkpoint.

Line 894: `payload["metadata_json"] = np.asarray(` This statement continues through source line 895; the explanation uses the complete expression rather than only the first visual fragment. Inside the function save_checkpoint, which handles save checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are payload: stream data belonging to the current command; metadata_json: the value named 'metadata json' in this block; asarray: the value named 'asarray' in this block.

Line 895: `json.dumps(metadata, sort_keys=True, separators=(",", ":")))` This is continuation line 2 of the 2-line logical statement that begins at source line 894. Its exact fragment is 'json.dumps(metadata, sort_keys=True, separators=(",", ":")))'. The important operands are json: the value named 'json' in this block; dumps: the value named 'dumps' in this block; metadata: the value named 'metadata' in this block. Read together, the complete operation is: Inside the function save_checkpoint, which handles save checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are payload: stream data belonging to the current command; metadata_json: the value named 'metadata json' in this block; asarray: the value named 'asarray' in this block.

Line 896: `with temporary.open("wb") as stream:` This opens a managed resource scope for 'temporary.open("wb") as stream' so files, tracing, or temporary state are finalized even if the function save_checkpoint, which handles save checkpoint raises an error.

Line 897: `np.savez_compressed(stream, **payload)` This calls 'np.savez_compressed' with 'stream, **payload' inside the function save_checkpoint, which handles save checkpoint. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 898: `stream.flush()` This calls 'stream.flush' with " inside the function save_checkpoint, which handles save checkpoint. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 899: `os.fsync(stream.fileno())` This calls 'os.fsync' with 'stream.fileno()' inside the function save_checkpoint, which handles save checkpoint. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 900: `os.replace(temporary, target)` This calls ‘os.replace‘ with ‘temporary, target‘ inside the function save_checkpoint, which handles save checkpoint. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 901: `return hashlib.sha256(target.read_bytes()).hexdigest()` This returns ‘hashlib.sha256(target.read_bytes()).he to the caller of the function save_checkpoint, which handles save checkpoint, ending this invocation. The important operands are hashlib: the value named ’hashlib’ in this block; sha256: the value named ’sha256’ in this block; target: the value named ’target’ in this block.

Line 903: `def load_checkpoint(self, path: str | Path) -> Mapping[str, Any]:` This starts function load_checkpoint. Its indented body performs load checkpoint as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 904: `"""Restore one complete checkpoint only after all metadata validates."""` This is executable documentation attached to the function load_checkpoint, which handles load checkpoint. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 906: `source = Path(path).expanduser().resolve()` This assigns ‘Path(path).expanduser().resolve()‘ to ‘source ‘ in host memory. Here source means the value named ’source’ in this block. The important operands are Path: the value named ’path’ in this block; path: the value named ’path’ in this block; expanduser: the value named ’expanduser’ in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 907: `with np.load(source, allow_pickle=False) as archive:` This opens a managed resource scope for ‘np.load(source, allow_pickle=False) as archive‘ so files, tracing, or temporary state are finalized even if the function load_checkpoint, which handles load checkpoint raises an error.

Line 908: `metadata = json.loads(str(archive["metadata_json"]))` This assigns ‘json.loads(str(archive["metadata_json"])) to ‘metadata ‘ in host memory. Here metadata means the value named ’metadata’ in this block. The important operands are json: the value named ’json’ in this block; loads: the value named ’loads’ in this block; str: the value named ’str’ in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 909: `if metadata.get("format") != CHECKPOINT_FORMAT:` This executes the following indented host-code branch only when ‘metadata.get("format") != CHECKPOINT_FORMAT‘ is true. The important operands are metadata: the value named ’metadata’ in this block; get: the value named ’get’ in this block; format: the value named ’format’ in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 910: `raise ValueError("unsupported training checkpoint format")` This rejects an invalid state by raising ‘ValueError("unsupported training checkpoint format")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 911: `if metadata.get("base_binary_sha256") != self.base_binary_sha256:` This executes the following indented host-code branch only when ‘metadata.get("base_binary_sha256") != self.base_binary_sha256‘ is true. The important operands are metadata: the value named ’metadata’ in this block; get: the value named ’get’ in this block; base_binary_sha256: the value named ’base binary sha256’ in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 912: `raise ValueError("checkpoint was initialized from a different parameter binary")` This rejects an invalid state by raising ‘ValueError("checkpoint was initialized from a different parameter binary")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 913: `if tuple(metadata.get("projection_names", ())) != self.projection_names:` This executes the following indented host-code branch only when ‘tuple(metadata.get("projection_names", ())) != self.projection_names‘ is true. The important operands are tuple: the value named ’tuple’ in this block; metadata: the value named ’metadata’ in this block; get: the value named ’get’ in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 914: `raise ValueError("checkpoint projection order does not match this graph")` This rejects an invalid state by raising 'ValueError("checkpoint projection order does not match this graph")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 915: `expected_weight_fractional = [` This statement continues through source line 917; the explanation uses the complete expression rather than only the first visual fragment. This assigns '[self._projection_weight[name].fractional_bits for name in self.projection_names]' to 'expected_weight_fractional ' in host memory. Here expected_weight_fractional means a learned coefficient multiplied by an activation. The important operands are _projection_weight: a learned coefficient multiplied by an activation; name: the value named 'name' in this block; fractional_bits: the value named 'fractional bits' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 916: `self._projection_weight[name].fractional_bits for name in self.projection_names` This is continuation line 2 of the 3-line logical statement that begins at source line 915. Its exact fragment is 'self._projection_weight[name].frac for name in self.projection_names'. The important operands are _projection_weight: a learned coefficient multiplied by an activation; name: the value named 'name' in this block; fractional_bits: the value named 'fractional bits' in this block. Read together, the complete operation is: This assigns '[self._projection_weight[name].fractional_bits for name in self.projection_names]' to 'expected_weight_fractional ' in host memory. Here expected_weight_fractional means a learned coefficient multiplied by an activation. The important operands are _projection_weight: a learned coefficient multiplied by an activation; name: the value named 'name' in this block; fractional_bits: the value named 'fractional bits' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 917: `]` This is continuation line 3 of the 3-line logical statement that begins at source line 915. Its exact fragment is ']'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '[self._projection_weight[name].fractional_bits for name in self.projection_names]' to 'expected_weight_fractional ' in host memory. Here expected_weight_fractional means a learned coefficient multiplied by an activation. The important operands are _projection_weight: a learned coefficient multiplied by an activation; name: the value named 'name' in this block; fractional_bits: the value named 'fractional bits' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 918: `expected_bias_fractional = [` This statement continues through source line 920; the explanation uses the complete expression rather than only the first visual fragment. This assigns '[self._projection_bias[name].fractional_bits for name in self.projection_names]' to 'expected_bias_fractional ' in host memory. Here expected_bias_fractional means an additive learned offset applied after accumulation. The important operands are _projection_bias: an additive learned offset applied after accumulation; name: the value named 'name' in this block; fractional_bits: the value named 'fractional bits' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 919: `self._projection_bias[name].fractional_bits for name in self.projection_names` This is continuation line 2 of the 3-line logical statement that begins at source line 918. Its exact fragment is 'self._projection_bias[name].fractional for name in self.projection_names'. The important operands are _projection_bias: an additive learned offset applied after accumulation; name: the value named 'name' in this block; fractional_bits: the value named 'fractional bits' in this block. Read together, the complete operation is: This assigns '[self._projection_bias[name].fractional_bits for name in self.projection_names]' to 'expected_bias_fractional ' in host memory. Here expected_bias_fractional means an additive learned offset applied after accumulation. The important operands are _projection_bias: an additive learned offset applied after accumulation; name: the value named 'name' in this block; fractional_bits: the value named 'fractional bits' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 920: `]` This is continuation line 3 of the 3-line logical statement that begins at source line 918. Its exact fragment is ']'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '[self._projection_bias[name].fractional_bits for name in self.projection_names]' to 'expected_bias_fractional ' in host memory. Here expected_bias_fractional means an additive learned offset applied after accumulation. The important operands are _projection_bias: an additive learned offset applied after accumulation; name: the value named 'name' in this block; fractional_bits: the value named 'fractional bits' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 921: `if metadata.get("projection_weight_fractional_bits") != expected_weight_fractional:` This executes the following indented host-code branch only when 'metadata.get("projection_weight_fractional_bits") != ex-

pected_weight_fractional‘ is true. The important operands are metadata: the value named 'metadata' in this block; get: the value named 'get' in this block; projection_weight_fractional_bits: a learned coefficient multiplied by an activation. Context: the function load_checkpoint, which handles load checkpoint.

Line 922: `raise ValueError("checkpoint projection weight Q formats do not match")` This rejects an invalid state by raising ‘ValueError("checkpoint projection weight Q formats do not match")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 923: `if metadata.get("projection_bias_fractional_bits") != expected_bias_fractional:` This executes the following indented host-code branch only when ‘metadata.get("projection_bias_fractional_bits") != expected_bias_fracti is true. The important operands are metadata: the value named 'metadata' in this block; get: the value named 'get' in this block; projection_bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 924: `raise ValueError("checkpoint projection bias Q formats do not match")` This rejects an invalid state by raising ‘ValueError("checkpoint projection bias Q formats do not match")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 925: `if int(metadata.get("head_weight_fractional_bits", -1)) != self._head_weight.fractional_bits:` This executes the following indented host-code branch only when ‘int(metadata.get("head_weight_fractional_bits", -1)) != self._head_weight.fractional_bits‘ is true. The important operands are metadata: the value named 'metadata' in this block; get: the value named 'get' in this block; head_weight_fractional_bits: a learned coefficient multiplied by an activation. Context: the function load_checkpoint, which handles load checkpoint.

Line 926: `raise ValueError("checkpoint head weight Q format does not match")` This rejects an invalid state by raising ‘ValueError("checkpoint head weight Q format does not match")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 927: `if int(metadata.get("head_bias_fractional_bits", -1)) != self._head_bias.fractional_bits:` This executes the following indented host-code branch only when ‘int(metadata.get("head_bias_fractional_bits", -1)) != self._head_bias.fractional_bits‘ is true. The important operands are metadata: the value named 'metadata' in this block; get: the value named 'get' in this block; head_bias_fractional_bits: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 928: `raise ValueError("checkpoint head bias Q format does not match")` This rejects an invalid state by raising ‘ValueError("checkpoint head bias Q format does not match")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 929: `staged: list[tuple[MasterTensor, np.ndarray, np.ndarray]] = []` This assigns ‘[]‘ to ‘staged‘ in host memory. Here staged means the value named 'staged' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function load_checkpoint, which handles load checkpoint.

Line 930: `for index, name in enumerate(self.projection_names):` This iterates index, name over ‘enumerate(self.projection_names)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function load_checkpoint, which handles load checkpoint.

Line 931: `for kind, tensor in (` This line opens or closes a multi-line Python expression inside the function load_checkpoint, which handles load checkpoint; the neighboring lines supply its arguments or elements.

Line 932: `("weight", self._projection_weight[name]),` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are weight: a learned coefficient multiplied by an activation; _projection_weight: a learned coefficient multiplied by an activation; name: the value named 'name' in this block.

Line 933: `("bias", self._projection_bias[name]),` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are bias: an additive learned offset applied after accumulation; _projection_bias: an additive learned offset applied after accumulation; name: the value named 'name' in this block.

Line 934: `):` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 935: `prefix = f"projection_{index}_{kind}"` This assigns ‘f"projection_{index}_{kind}"‘ to ‘prefix ‘ in host memory. Here prefix means the value named 'prefix' in this block. The important operands are f: the value named 'f' in this block; projection_: the value named 'projection' in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function load_checkpoint, which handles load checkpoint.

Line 936: `master = np.asarray(archive[f"{prefix}_master"], dtype=np.int64)` This assigns ‘np.asarray(archive[f"{prefix dtype=np.int64)‘ to ‘master ‘ in host memory. Here master means the value named 'master' in this block. The important operands are asarray: the value named 'asarray' in this block; archive: the value named 'archive' in this block; f: the value named 'f' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 937: `velocity = np.asarray(archive[f"{prefix}_velocity"], dtype=np.int64)` This assigns ‘np.asarray(archive[f"{ dtype=np.int64)‘ to ‘velocity ‘ in host memory. Here velocity means the momentum history retained by the SGD optimizer. The important operands are asarray: the value named 'asarray' in this block; archive: the value named 'archive' in this block; f: the value named 'f' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 938: `if master.shape != tensor.master.shape or velocity.shape != tensor.master.shape:` This executes the following indented host-code branch only when ‘master.shape != tensor.master.shape or velocity.shape != tensor.master.shape‘ is true. The important operands are master: the value named 'master' in this block; shape: the value named 'shape' in this block; tensor: the value named 'tensor' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 939: `raise ValueError(f"checkpoint tensor shape mismatch for {name} {kind}")` This rejects an invalid state by raising ‘ValueError(f"checkpoint tensor shape mismatch for {name} {kind}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 940: `if (np.any(master < -(1 << 15)) or np.any(master > (1 << 15) - 1)` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are any: the value named 'any' in this block; master: the value named 'master' in this block; or: the value named 'or' in this block.

Line 941: `or np.any(velocity < -(1 << 23))` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are or: the value named 'or' in this block; any: the value named 'any' in this block; velocity: the momentum history retained by the SGD optimizer.

Line 942: `or np.any(velocity > (1 << 23) - 1)):` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are or: the value named 'or' in this block; any: the value named 'any' in this block; velocity: the momentum history retained by the SGD optimizer.

Line 943: `raise ValueError(f"checkpoint tensor range mismatch for {name} {kind}")` This rejects an invalid state by raising ‘ValueError(f"checkpoint tensor range mismatch for {name} {kind}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 944: `staged.append((tensor, master.copy(), velocity.copy()))` This calls ‘staged.append‘ with ‘(tensor, master.copy(), velocity.copy())‘ inside the function load_checkpoint, which handles load checkpoint. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 945: `for prefix, tensor in (` This line opens or closes a multi-line Python expression inside the function load_checkpoint, which handles load checkpoint; the neighboring lines supply its arguments or elements.

Line 946: `("head_weight", self._head_weight),` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are head_weight: a learned coefficient multiplied by an activation; _head_weight: a learned coefficient multiplied by an activation.

Line 947: `("head_bias", self._head_bias),` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are head_bias: an additive learned offset applied after accumulation; _head_bias: an additive learned offset applied after accumulation.

Line 948: `):` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 949: `master = np.asarray(archive[f"{prefix}_master"], dtype=np.int64)` This assigns ‘np.asarray(archive[f"{prefix dtype=np.int64)‘ to ‘master ‘ in host memory. Here master means the value named ’master’ in this block. The important operands are asarray: the value named ’asarray’ in this block; archive: the value named ’archive’ in this block; f: the value named ’f’ in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 950: `velocity = np.asarray(archive[f"{prefix}_velocity"], dtype=np.int64)` This assigns ‘np.asarray(archive[f"{ dtype=np.int64)‘ to ‘velocity ‘ in host memory. Here velocity means the momentum history retained by the SGD optimizer. The important operands are asarray: the value named ’asarray’ in this block; archive: the value named ’archive’ in this block; f: the value named ’f’ in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 951: `if master.shape != tensor.master.shape or velocity.shape != tensor.master.shape:` This executes the following indented host-code branch only when ‘master.shape != tensor.master.shape or velocity.shape != tensor.master.shape‘ is true. The important operands are master: the value named ’master’ in this block; shape: the value named ’shape’ in this block; tensor: the value named ’tensor’ in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 952: `raise ValueError(f"checkpoint tensor shape mismatch for {prefix}")` This rejects an invalid state by raising ‘ValueError(f"checkpoint tensor shape mismatch for {prefix}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 953: `if (np.any(master < -(1 << 15)) or np.any(master > (1 << 15) - 1)` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are any: the value named ’any’ in this block; master: the value named ’master’ in this block; or: the value named ’or’ in this block.

Line 954: `or np.any(velocity < -(1 << 23))` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are or: the value named ’or’ in this block; any: the value named ’any’ in this block; velocity: the momentum history retained by the SGD optimizer.

Line 955: `or np.any(velocity > (1 << 23) - 1)):` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are or: the value named 'or' in this block; any: the value named 'any' in this block; velocity: the momentum history retained by the SGD optimizer.

Line 956: `raise ValueError(f"checkpoint tensor range mismatch for {prefix}")` This rejects an invalid state by raising 'ValueError(f"checkpoint tensor range mismatch for {prefix}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 957: `staged.append((tensor, master.copy(), velocity.copy()))` This calls 'staged.append' with '(tensor, master.copy(), velocity.copy())' inside the function load_checkpoint, which handles load checkpoint. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 958: `for tensor, master, velocity in staged:` This iterates tensor, master, velocity over 'staged'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function load_checkpoint, which handles load checkpoint.

Line 959: `tensor.master = master.astype(np.int16)` This assigns 'master.astype(np.int16)' to 'tensor.master ' in host memory. Here master means the value named 'master' in this block. The important operands are master: the value named 'master' in this block; astype: the value named 'astype' in this block; int16: the value named 'int16' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 960: `tensor.velocity_q15 = velocity.astype(np.int32)` This assigns 'velocity.astype(np.int32)' to 'tensor.velocity_q15 ' in host memory. Here velocity_q15 means the momentum history retained by the SGD optimizer. The important operands are velocity: the momentum history retained by the SGD optimizer; astype: the value named 'astype' in this block; int32: the value named 'int32' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 961: `self.optimizer_step = int(metadata["optimizer_step"])` This assigns 'int(metadata["optimizer_step"])' to 'self.optimizer_step ' in host memory. Here optimizer_step means the value named 'optimizer step' in this block. The important operands are metadata: the value named 'metadata' in this block; optimizer_step: the value named 'optimizer step' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 962: `for name in self.projection_names:` This iterates name over 'self.projection_names'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function load_checkpoint, which handles load checkpoint.

Line 963: `weight = self._projection_weight[name]` This assigns 'self._projection_weight[name]' to 'weight ' in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are _projection_weight: a learned coefficient multiplied by an activation; name: the value named 'name' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 964: `bias = self._projection_bias[name]` This assigns 'self._projection_bias[name]' to 'bias ' in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are _projection_bias: an additive learned offset applied after accumulation; name: the value named 'name' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 965: `self._deployed_projection_weight[name] = np.clip(` This statement continues through source line 967; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.clip(round_shift_signed(weight.master, weight.fractional_bits), -128, 127).astype(np.int8)' to 'self._deployed_projection_weight[name ' in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; weight: a learned coefficient multiplied by an activation. Context: the function load_checkpoint, which handles load checkpoint.

Line 966: `round_shift_signed(weight.master, weight.fractional_bits), -128, 127` This is continuation line 2 of the 3-line logical statement that begins at source line 965. Its exact fragment is 'round_shift_signed(weight.master, weight.fractional_bits), -128, 127'. The important operands are round_shift_signed: the value named 'round shift signed' in this block; weight: a learned coefficient multiplied by an activation; master: the value named 'master' in this block. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(weight.master, weight.fractional_bits), -128, 127).astype(np.int8)' to 'self._deployed_projection_weight[name] ' in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; weight: a learned coefficient multiplied by an activation. Context: the function load_checkpoint, which handles load checkpoint.

Line 967: `).astype(np.int8)` This is continuation line 3 of the 3-line logical statement that begins at source line 965. Its exact fragment is ').astype(np.int8)'. The important operands are astype: the value named 'astype' in this block; int8: the value named 'int8' in this block. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(weight.master, weight.fractional_bits), -128, 127).astype(np.int8)' to 'self._deployed_projection_weight[name ' in host memory. Here _deployed_projection_weight means a learned coefficient multiplied by an activation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; weight: a learned coefficient multiplied by an activation. Context: the function load_checkpoint, which handles load checkpoint.

Line 968: `self._deployed_projection_bias[name] = np.clip(` This statement continues through source line 972; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.clip(round_shift_signed(bia bias.fractional_bits), -(1 << 15), (1 << 15) - 1,).astype(np.int64)' to 'self._deployed_projection_bias[name] ' in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; bias: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 969: `round_shift_signed(bias.master, bias.fractional_bits),` This is continuation line 2 of the 5-line logical statement that begins at source line 968. Its exact fragment is 'round_shift_signed(bias.master, bias.fractional_bits),'. The important operands are round_shift_signed: the value named 'round shift signed' in this block; bias: an additive learned offset applied after accumulation; master: the value named 'master' in this block. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(bias.master, bias.fractional_bits), -(1 << 15), (1 << 15) - 1,).astype(np.int64)' to 'self._deployed_projection_bias[name] ' in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; bias: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 970: `-(1 << 15),` This is continuation line 3 of the 5-line logical statement that begins at source line 968. Its exact fragment is '-(1 << 15),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(bias.master, bias.fractional_bits), -(1 << 15), (1 << 15) - 1,).astype(np.int64)' to 'self._deployed_projection_bias[name] ' in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; bias: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 971: `(1 << 15) - 1,` This is continuation line 4 of the 5-line logical statement that begins at source line 968. Its exact fragment is '(1 << 15) - 1,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(bias.master, bias.fractional_bits), -(1 << 15), (1 << 15) - 1,).astype(np.int64)' to 'self._deployed_projection_bias[name] ' in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; bias: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 972: `).astype(np.int64)` This is continuation line 5 of the 5-line logical statement that begins at source line 968. Its exact fragment is ').astype(np.int64)'. The important operands are astype: the value named 'astype'

in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(bias.master, bias.fractional_bits), -(1 << 15), (1 << 15) - 1,).astype(np.int64)' to 'self._deployed_projection_bias[name] ' in host memory. Here _deployed_projection_bias means an additive learned offset applied after accumulation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; bias: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 973: `self._deployed_head_weight = np.clip(` This statement continues through source line 977; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.clip(round_shift_signed(self._head_we self._head_weight.fractional_bits), -128, 127,).astype(np.int8)' to 'self._deployed_head_weight ' in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function load_checkpoint, which handles load checkpoint.

Line 974: `round_shift_signed(self._head_weight.master, self._head_weight.fractional_bits),` This is continuation line 2 of the 5-line logical statement that begins at source line 973. Its exact fragment is 'round_shift_signed(self._head_we self._head_weight.fractional_bits),'. The important operands are round_shift_signed: the value named 'round shift signed' in this block; _head_weight: a learned coefficient multiplied by an activation; master: the value named 'master' in this block. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(self._head_weight.master, self._head_weight.fractional_bits), -128, 127,).astype(np.int8)' to 'self._deployed_head_weight ' in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function load_checkpoint, which handles load checkpoint.

Line 975: `-128,` This is continuation line 3 of the 5-line logical statement that begins at source line 973. Its exact fragment is '-128,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(self._head_weight.master, self._head_weight.fractional_bits), -128, 127,).astype(np.int8)' to 'self._deployed_head_weight ' in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function load_checkpoint, which handles load checkpoint.

Line 976: `127,` This is continuation line 4 of the 5-line logical statement that begins at source line 973. Its exact fragment is '127,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(self._head_weight.master, self._head_weight.fractional_bits), -128, 127,).astype(np.int8)' to 'self._deployed_head_weight ' in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function load_checkpoint, which handles load checkpoint.

Line 977: `).astype(np.int8)` This is continuation line 5 of the 5-line logical statement that begins at source line 973. Its exact fragment is ').astype(np.int8)'. The important operands are astype: the value named 'astype' in this block; int8: the value named 'int8' in this block. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(self._head_weight.master, self._head_weight.fractional_bits), -128, 127,).astype(np.int8)' to 'self._deployed_ ' in host memory. Here _deployed_head_weight means a learned coefficient multiplied by an activation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; _head_weight: a learned coefficient multiplied by an activation. Context: the function load_checkpoint, which handles load checkpoint.

Line 978: `self._deployed_head_bias = np.clip(` This statement continues through source line 982; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.clip(round_shift_signed(self._head_bias.m self._head_bias.fractional_bits), -(1 << 15), (1 << 15) - 1,).astype(np.int64)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 979: `round_shift_signed(self._head_bias.master, self._head_bias.fractional_bits),` This is continuation line 2 of the 5-line logical statement that begins at source line 978. Its exact fragment is 'round_shift_signed(self._head_bias.m self._head_bias.fractional_bits),'. The important operands are round_shift_signed: the value named 'round shift signed' in this block; _head_bias: an additive learned offset applied after accumulation; master: the value named 'master' in this block. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(self._head_bias.master, self._head_bias.fractional_bits), -(1 << 15), (1 << 15) - 1,).astype(np.int64)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 980: `-(1 << 15),` This is continuation line 3 of the 5-line logical statement that begins at source line 978. Its exact fragment is '-(1 << 15),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(self._head_bias.master, self._head_bias.fractional_bits), -(1 << 15), (1 << 15) - 1,).astype(np.int64)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 981: `(1 << 15) - 1,` This is continuation line 4 of the 5-line logical statement that begins at source line 978. Its exact fragment is '(1 << 15) - 1,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(self._head_bias.master, self._head_bias.fractional_bits), -(1 << 15), (1 << 15) - 1,).astype(np.int64)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 982: `).astype(np.int64)` This is continuation line 5 of the 5-line logical statement that begins at source line 978. Its exact fragment is ').astype(np.int64)'. The important operands are astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'np.clip(round_shift_signed(self._head_bias.master, self._head_bias.fractional_bits), -(1 << 15), (1 << 15) - 1,).astype(np.int64)' to 'self._deployed_head_bias ' in host memory. Here _deployed_head_bias means an additive learned offset applied after accumulation. The important operands are clip: the value named 'clip' in this block; round_shift_signed: the value named 'round shift signed' in this block; _head_bias: an additive learned offset applied after accumulation. Context: the function load_checkpoint, which handles load checkpoint.

Line 983: `return metadata` This returns 'metadata' to the caller of the function load_checkpoint, which handles load checkpoint, ending this invocation. The important operands are metadata: the value named 'metadata' in this block.

Line 986: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 987: `class LifTraceCache:` This defines class LifTraceCache, which groups data and methods for lif trace cache. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 988: `"""Forward values retained for one exact hard-reset LIF reverse pass."""` This is executable documentation attached to the class LifTraceCache, which handles lif trace cache. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 990: `input_q10: np.ndarray` Inside the class LifTraceCache, which handles lif trace cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are input_q10: the value named 'input q10' in this block; ndarray: the value named 'ndarray' in this block.

Line 991: `spikes: np.ndarray` Inside the class LifTraceCache, which handles lif trace cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are spikes: a binary event produced when a neuron crosses its threshold; ndarray: the value named 'ndarray' in this block.

Line 992: `pre_reset_membrane: np.ndarray` Inside the class LifTraceCache, which handles lif trace cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; ndarray: the value named 'ndarray' in this block.

Line 993: `threshold_q10: int` Inside the class LifTraceCache, which handles lif trace cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are threshold_q10: the membrane level at which a neuron emits a spike.

Line 996: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 997: `class TokenizerLayerCache:` This defines class TokenizerLayerCache, which groups data and methods for tokenizer layer cache. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 998: `"""One tokenizer projection and the LIF/pool operators that precede it."""` This is executable documentation attached to the class TokenizerLayerCache, which handles tokenizer layer cache. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1000: `index: int` Inside the class TokenizerLayerCache, which handles tokenizer layer cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry.

Line 1001: `projection_input: np.ndarray` Inside the class TokenizerLayerCache, which handles tokenizer layer cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are projection_input: the value named 'projection input' in this block; ndarray: the value named 'ndarray' in this block.

Line 1002: `projection_output: np.ndarray` Inside the class TokenizerLayerCache, which handles tokenizer layer cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are projection_output: the value named 'projection output' in this block; ndarray: the value named 'ndarray' in this block.

Line 1003: `lif: LifTraceCache | None` Inside the class TokenizerLayerCache, which handles tokenizer layer cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are lif: the value named 'lif' in this block; LifTraceCache: the value named 'lif trace cache' in this block; None: the value named 'none' in this block.

Line 1004: `pooled: bool` Inside the class TokenizerLayerCache, which handles tokenizer layer cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are pooled: the value named 'pooled' in this block; bool: the value named 'bool' in this block.

Line 1007: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 1008: `class AttentionCache:` This defines class AttentionCache, which groups data and methods for attention cache. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1009: `"""All state needed to reverse one spike-driven self-attention branch."""` This is executable documentation attached to the class AttentionCache, which handles attention cache. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1011: `block_index: int` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are block_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 1012: `input_shape: tuple[int, ...]` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are input_shape: the value named 'input shape' in this block; tuple: the value named 'tuple' in this block.

Line 1013: `projection_lif: LifTraceCache` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are projection_lif: the value named 'projection lif' in this block; LifTraceCache: the value named 'lif trace cache' in this block.

Line 1014: `token_spikes: np.ndarray` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are token_spikes: a binary event produced when a neuron crosses its threshold; ndarray: the value named 'ndarray' in this block.

Line 1015: `query_lif: LifTraceCache` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are query_lif: the value named 'query lif' in this block; LifTraceCache: the value named 'lif trace cache' in this block.

Line 1016: `key_lif: LifTraceCache` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are key_lif: the value named 'key lif' in this block; LifTraceCache: the value named 'lif trace cache' in this block.

Line 1017: `value_lif: LifTraceCache` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are value_lif: the value named 'value lif' in this block; LifTraceCache: the value named 'lif trace cache' in this block.

Line 1018: `query_heads: np.ndarray` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are query_heads: the value named 'query heads' in this block; ndarray: the value named 'ndarray' in this block.

Line 1019: `key_heads: np.ndarray` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are key_heads: the value named 'key heads' in this block; ndarray: the value named 'ndarray' in this block.

Line 1020: `value_heads: np.ndarray` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are value_heads: the value named 'value heads' in this block; ndarray: the value named 'ndarray' in this block.

Line 1021: `scores: np.ndarray` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are scores: the value named 'scores' in this block; ndarray: the value named 'ndarray' in this block.

Line 1022: `attention_values: np.ndarray` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are attention_values: the value named 'attention values' in this block; ndarray: the value named 'ndarray' in this block.

Line 1023: `attention_lif: LifTraceCache` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are attention_lif: the value named 'attention lif' in this block; LifTraceCache: the value named 'lif trace cache' in this block.

Line 1024: `projection_input: np.ndarray` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are projection_input: the value named 'projection input' in this block; ndarray: the value named 'ndarray' in this block.

Line 1025: `output: np.ndarray` Inside the class AttentionCache, which handles attention cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output: the value named 'output' in this block; ndarray: the value named 'ndarray' in this block.

Line 1028: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 1029: `class MlpCache:` This defines class MlpCache, which groups data and methods for mlp cache. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1030: `"""Forward state for the two learned MLP projections and their LIF nodes."""` This is executable documentation attached to the class MlpCache, which handles mlp cache. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1032: `block_index: int` Inside the class MlpCache, which handles mlp cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are block_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 1033: `input_shape: tuple[int, ...]` Inside the class MlpCache, which handles mlp cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are input_shape: the value named 'input shape' in this block; tuple: the value named 'tuple' in this block.

Line 1034: `input_lif: LifTraceCache` Inside the class MlpCache, which handles mlp cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are input_lif: the value named 'input lif' in this block; LifTraceCache: the value named 'lif trace cache' in this block.

Line 1035: `first_projection_input: np.ndarray` Inside the class MlpCache, which handles mlp cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are first_projection_input: the value named 'first projection input' in this block; ndarray: the value named 'ndarray' in this block.

Line 1036: `hidden_lif: LifTraceCache` Inside the class MlpCache, which handles mlp cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are hidden_lif: the value named 'hidden lif' in this block; LifTraceCache: the value named 'lif trace cache' in this block.

Line 1037: `second_projection_input: np.ndarray` Inside the class MlpCache, which handles mlp cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are second_projection_input: the value named 'second projection input' in this block; ndarray: the value named 'ndarray' in this block.

Line 1038: `output: np.ndarray` Inside the class MlpCache, which handles mlp cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output: the value named 'output' in this block; ndarray: the value named 'ndarray' in this block.

Line 1041: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 1042: `class TransformerBlockCache:` This defines class TransformerBlockCache, which groups data and methods for transformer block cache. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1043: `"""Attention, MLP, and the two residual values of one transformer block."""` This is executable documentation attached to the class TransformerBlockCache, which handles transformer block cache. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1045: `input_value: np.ndarray` Inside the class TransformerBlockCache, which handles transformer block cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are input_value: the value named 'input value' in this block; ndarray: the value named 'ndarray' in this block.

Line 1046: `attention: AttentionCache` Inside the class TransformerBlockCache, which handles transformer block cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are attention: the value named 'attention' in this block; AttentionCache: the value named 'attention cache' in this block.

Line 1047: `after_attention: np.ndarray` Inside the class TransformerBlockCache, which handles transformer block cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are after_attention: the value named 'after attention' in this block; ndarray: the value named 'ndarray' in this block.

Line 1048: `mlp: MlpCache` Inside the class TransformerBlockCache, which handles transformer block cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are mlp: the value named 'mlp' in this block; MlpCache: the value named 'mlp cache' in this block.

Line 1049: `output: np.ndarray` Inside the class TransformerBlockCache, which handles transformer block cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output: the value named 'output' in this block; ndarray: the value named 'ndarray' in this block.

Line 1052: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 1053: `class SpikingformerTrainingCache:` This defines class SpikingformerTrainingCache, which groups data and methods for spikingformer training cache. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1054: `"""Complete forward tape for one batch of the exported integer graph."""` This is executable documentation attached to the class SpikingformerTrainingCache, which handles spikingformer training cache. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1056: `normalized_image: np.ndarray` Inside the class SpikingformerTrainingCache, which handles spikingformer training cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are normalized_image: the value named 'normalized image' in this block; ndarray: the value named 'ndarray' in this block.

Line 1057: `image_u8: np.ndarray` Inside the class SpikingformerTrainingCache, which handles spikingformer training cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are image_u8: the value named 'image u8' in this block; ndarray: the value named 'ndarray' in this block.

Line 1058: `image_centered: np.ndarray` Inside the class SpikingformerTrainingCache, which handles spikingformer training cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are image_centered: the value named 'image centered' in this block; ndarray: the value named 'ndarray' in this block.

Line 1059: `tokenizer: tuple[TokenizerLayerCache, ...]` Inside the class SpikingformerTrainingCache, which handles spikingformer training cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tokenizer: the value named 'tokenizer' in this block; tuple: the value named 'tuple' in this block; TokenizerLayerCache: the value named 'tokenizer layer cache' in this block.

Line 1060: `blocks: tuple[TransformerBlockCache, ...]` Inside the class SpikingformerTrainingCache, which handles spikingformer training cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are blocks: the value named 'blocks' in this block; tuple: the value named 'tuple' in this block; TransformerBlockCache: the value named 'transformer block cache' in this block.

Line 1061: `final_value: np.ndarray` Inside the class SpikingformerTrainingCache, which handles spikingformer training cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are final_value: the value named 'final value' in this block; ndarray: the value named 'ndarray' in this block.

Line 1062: `head_preclip: np.ndarray` Inside the class SpikingformerTrainingCache, which handles spikingformer training cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are head_preclip: the value named 'head preclip' in this block; ndarray: the value named 'ndarray' in this block.

Line 1063: `head_input: np.ndarray` Inside the class SpikingformerTrainingCache, which handles spikingformer training cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are head_input: the value named 'head input' in this block; ndarray: the value named 'ndarray' in this block.

Line 1064: `logits_accumulator: np.ndarray` Inside the class SpikingformerTrainingCache, which handles spikingformer training cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are logits_accumulator: a widened running sum that prevents intermediate overflow; ndarray: the value named 'ndarray' in this block.

Line 1065: `logits: np.ndarray` Inside the class SpikingformerTrainingCache, which handles spikingformer training cache, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are logits: the ten unnormalized classifier scores used for argmax; ndarray: the value named 'ndarray' in this block.

Line 1068: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 1069: `class TrainingBackwardResult:` This defines class TrainingBackwardResult, which groups data and methods for training backward result. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1070: `"""Loss, classifier probabilities, all parameter gradients, and input dX."""` This is executable documentation attached to the class TrainingBackwardResult, which handles training backward result. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1072: `loss: float` Inside the class TrainingBackwardResult, which handles training backward result, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are loss: the value named 'loss' in this block; float: the value named 'float' in this block.

Line 1073: `probabilities_q15: np.ndarray` Inside the class TrainingBackwardResult, which handles training backward result, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are probabilities_q15: the value named 'probabilities q15' in this block; ndarray: the value named 'ndarray' in this block.

Line 1074: `predicted_class: np.ndarray` Inside the class TrainingBackwardResult, which handles training backward result, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are predicted_class: the value named 'predicted class' in this block; ndarray: the value named 'ndarray' in this block.

Line 1075: `parameter_gradients: Mapping[str, ParameterGradient]` Inside the class TrainingBackwardResult, which handles training backward result, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are parameter_gradients: the signed loss derivative used to update a learned parameter; Mapping: the value named 'mapping' in this block; str: the value named 'str' in this block.

Line 1076: `input_gradient: BlockGradient` Inside the class TrainingBackwardResult, which handles training backward result, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1079: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 1080: `class TrainingStepResult:` This defines class TrainingStepResult, which groups data and methods for training step result. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1081: `"""Observable result of one complete forward/backward/SGDW transaction."""` This is executable documentation attached to the class TrainingStepResult, which handles training step result. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1083: `loss: float` Inside the class TrainingStepResult, which handles training step result, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are loss: the value named 'loss' in this block; float: the value named 'float' in this block.

Line 1084: `probabilities_q15: np.ndarray` Inside the class TrainingStepResult, which handles training step result, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are probabilities_q15: the value named 'probabilities q15' in this block; ndarray: the value named 'ndarray' in this block.

Line 1085: `predicted_class: np.ndarray` Inside the class TrainingStepResult, which handles training step result, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are predicted_class: the value named 'predicted class' in this block; ndarray: the value named 'ndarray' in this block.

Line 1086: `optimizer_step: int` Inside the class TrainingStepResult, which handles training step result, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are optimizer_step: the value named 'optimizer step' in this block.

Line 1089: `class SpikingformerOnDeviceTrainer:` This defines class SpikingformerOnDeviceTrainer, which groups data and methods for spikingformer on device trainer. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1090: `"""Execute and train the complete exported Spikingformer graph on NeuraEdge."""` This is executable documentation attached to the class SpikingformerOnDeviceTrainer, which handles spikingformer on device trainer. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1092: `def __init__(` This starts function ___init___. Its indented body performs init as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1093: `self,` Inside the function ___init___, which handles init, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1094: `state: TrainableSpikingformerState,` Inside the function ___init___, which handles init, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are state: the finite-state-machine phase retained in flip-flops; TrainableSpikingformerState: the finite-state-machine phase retained in flip-flops.

Line 1095: `driver: FullTrainingDriver,` Inside the function ___init___, which handles init, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are driver: the value named 'driver' in this block; FullTrainingDriver: the value named 'full training driver' in this block.

Line 1096: `*,` Inside the function ___init___, which handles init, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1097: `transformer_blocks: int = 4,` This assigns '4,' to 'transformer_blocks' in host memory. Here transformer_blocks means the value named 'transformer blocks' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 1098: `attention_heads: int = 12,` This assigns '12,' to 'attention_heads' in host memory. Here attention_heads means the value named 'attention heads' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 1099: `timesteps: int = 4,` This assigns '4,' to 'timesteps' in host memory. Here timesteps means one discrete SNN update instant. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 1100: `input_shape: tuple[int, int, int] = (3, 32, 32),` This assigns '(3, 32, 32),' to 'input_shape' in host memory. Here input_shape means the value named 'input shape' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 1101: `layer_timeout_seconds: float = 120.0,` This assigns '120.0,' to 'layer_timeout_seconds' in host memory. Here layer_timeout_seconds means the value named 'layer timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 1102: `) -> None:` Inside the function ___init___, which handles init, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are None: the value named 'none' in this block.

Line 1103: `if transformer_blocks <= 0 or attention_heads <= 0 or timesteps <= 0:` This executes the following indented host-code branch only when ‘transformer_blocks <= 0 or attention_heads <= 0 or timesteps <= 0‘ is true. The important operands are transformer_blocks: the value named ’transformer blocks’ in this block; or: the value named ’or’ in this block; attention_heads: the value named ’attention heads’ in this block. Context: the function ___init___, which handles init.

Line 1104: `raise ValueError("block, head, and timestep counts must be positive")` This rejects an invalid state by raising ‘ValueError("block, head, and timestep counts must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1105: `if len(input_shape) != 3 or min(input_shape) <= 0:` This executes the following indented host-code branch only when ‘len(input_shape) != 3 or min(input_shape) <= 0‘ is true. The important operands are len: the value named ’len’ in this block; input_shape: the value named ’input shape’ in this block; or: the value named ’or’ in this block. Context: the function ___init___, which handles init.

Line 1106: `raise ValueError("input_shape must contain positive C,H,W dimensions")` This rejects an invalid state by raising ‘ValueError("input_shape must contain positive C,H,W dimensions")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1107: `if layer_timeout_seconds <= 0:` This executes the following indented host-code branch only when ‘layer_timeout_seconds <= 0‘ is true. The important operands are layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Context: the function ___init___, which handles init.

Line 1108: `raise ValueError("layer_timeout_seconds must be positive")` This rejects an invalid state by raising ‘ValueError("layer_timeout_seconds must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1109: `self.state = state` This assigns ‘state‘ to ‘self.state ‘ in host memory. Here state means the finite-state-machine phase retained in flip-flops. The important operands are state: the finite-state-machine phase retained in flip-flops. Context: the function ___init___, which handles init.

Line 1110: `self.driver = driver` This assigns ‘driver‘ to ‘self.driver ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are driver: the value named ’driver’ in this block. Context: the function ___init___, which handles init.

Line 1111: `self.projections = SpikingformerProjectionExecutor(state, driver)` This assigns ‘SpikingformerProjectionExecutor(state, driver)‘ to ‘self.projections ‘ in host memory. Here projections means the value named ’projections’ in this block. The important operands are SpikingformerProjectionExecutor: the value named ’spikingformer projection executor’ in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named ’driver’ in this block. Context: the function ___init___, which handles init.

Line 1112: `self.transformer_blocks = int(transformer_blocks)` This assigns ‘int(transformer_blocks)‘ to ‘self.transformer ‘ in host memory. Here transformer_blocks means the value named ’transformer blocks’ in this block. The important operands are transformer_blocks: the value named ’transformer blocks’ in this block. Context: the function ___init___, which handles init.

Line 1113: `self.attention_heads = int(attention_heads)` This assigns ‘int(attention_heads)‘ to ‘self.attention_heads ‘ in host memory. Here attention_heads means the value named ’attention heads’ in this block. The important operands are attention_heads: the value named ’attention heads’ in this block. Context: the function ___init___, which handles init.

Line 1114: `self.timesteps = int(timesteps)` This assigns ‘int(timesteps)‘ to ‘self.timesteps ‘ in host memory. Here timesteps means one discrete SNN update instant. The important operands are timesteps: one discrete SNN update instant. Context: the function ___init___, which handles init.

Line 1115: `self.input_shape = tuple(map(int, input_shape))` This assigns ‘tuple(map(int, input_shape))‘ to ‘self.input_shape ‘ in host memory. Here input_shape means the value named ’input shape’ in this block. The important operands are tuple: the value named ’tuple’ in this block; map: the value named ’map’ in this block; input_shape: the value named ’input shape’ in this block. Context: the function ___init___, which handles init.

Line 1116: `self.layer_timeout_seconds = float(layer_timeout_seconds)` This assigns ‘float(layer_timeout_seconds)‘ to ‘self.layer_timeout_seconds ‘ in host memory. Here layer_timeout_seconds means the value named ’layer timeout seconds’ in this block. The important operands are float: the value named ’float’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Context: the function ___init___, which handles init.

Line 1117: `self._surrogate_lut_loaded = False` This assigns ‘False‘ to ‘self._surrogate_lut_loaded ‘ in host memory. Here _surrogate_lut_loaded means the value named ’surrogate lut loaded’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 1118: `fixed = state.manifest.get("fixed_point")` This assigns ‘state.manifest.get("fixed_point")‘ to ‘fixed ‘ in host memory. Here fixed means the value named ’fixed’ in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; manifest: the value named ’manifest’ in this block; get: the value named ’get’ in this block. Context: the function ___init___, which handles init.

Line 1119: `if not isinstance(fixed, Mapping):` This executes the following indented host-code branch only when ‘not isinstance(fixed, Mapping)‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; fixed: the value named ’fixed’ in this block. Context: the function ___init___, which handles init.

Line 1120: `raise ValueError("trainable state has no fixed-point manifest")` This rejects an invalid state by raising ‘ValueError("trainable state has no fixed-point manifest")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1121: `self.fractional_bits = int(fixed["activation_fractional_bits"])` This assigns ‘int(fixed["activation_fracti
to ‘self.fractional_bits ‘ in host memory. Here fractional_bits means the value named ’fractional bits’ in this block. The important operands are fixed: the value named ’fixed’ in this block; activation_fractional_bits: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function ___init___, which handles init.

Line 1122: `self.fixed_scale = 1 << self.fractional_bits` This assigns ‘1 << self.fractional_bits‘ to ‘self.fixed_scale ‘ in host memory. Here fixed_scale means the real-value spacing represented by one quantized integer step. The important operands are fractional_bits: the value named ’fractional bits’ in this block. Context: the function ___init___, which handles init.

Line 1123: `if self.fixed_scale % 8:` This executes the following indented host-code branch only when ‘self.fixed_scale % 8‘ is true. The important operands are fixed_scale: the real-value spacing represented by one quantized integer step. Context: the function ___init___, which handles init.

Line 1124: `raise ValueError("attention scaling requires at least three activation fractional bits")` This rejects an invalid state by raising ‘ValueError("attention scaling requires at least three activation fractional bits")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1125: `attention_scale = self.fixed_scale // 8` This assigns ‘self.fixed_scale // 8‘ to ‘attention_scale ‘ in host memory. Here attention_scale means the real-value spacing represented by one quantized integer step. The important operands are fixed_scale: the real-value spacing represented by one quantized integer step. Context: the function ___init___, which handles init.

Line 1126: `if attention_scale <= 0 or attention_scale & (attention_scale - 1):` This executes the following indented host-code branch only when ‘attention_scale <= 0 or attention_scale & (attention_scale - 1)‘ is true. The important operands are attention_scale: the real-value spacing represented by one quantized integer step; or: the value named ’or’ in this block. Context: the function ___init___, which handles init.

Line 1127: `raise ValueError("attention scaling must be an exact power of two")` This rejects an invalid state by raising ‘ValueError("attention scaling must be an exact power of two")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1128: `self.attention_scale_shift = attention_scale.bit_length() - 1` This assigns ‘attention_scale.bit_length() - 1‘ to ‘self.attention_scale_shift ‘ in host memory. Here attention_scale_shift means the real-value spacing represented by one quantized integer step. The important operands are attention_scale: the real-value spacing represented by one quantized integer step; bit_length: the value named ’bit length’ in this block. Context: the function ___init___, which handles init.

Line 1129: `self.image_scale = float(fixed["image_input_scale"])` This assigns ‘float(fixed["image_input_scale"])‘ to ‘self.image_scale ‘ in host memory. Here image_scale means the real-value spacing represented by one quantized integer step. The important operands are float: the value named ’float’ in this block; fixed: the value named ’fixed’ in this block; image_input_scale: the real-value spacing represented by one quantized integer step. Context: the function ___init___, which handles init.

Line 1130: `self.image_zero_point = int(fixed["image_input_zero_point"])` This assigns ‘int(fixed["image_input_zero_
to ‘self.image_zero_point ‘ in host memory. Here image_zero_point means the integer code representing real numeric zero in affine quantization. The important operands are fixed: the value named ’fixed’ in this block; image_input_zero_point: the integer code representing real numeric zero in affine quantization. Context: the function ___init___, which handles init.

Line 1131: `self.head_activation_scale = float(fixed["head_activation_scale"])` This assigns ‘float(fixed["head_activa
to ‘self.head_activation_scale ‘ in host memory. Here head_activation_scale means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are float: the value named ’float’ in this block; fixed: the value named ’fixed’ in this block; head_activation_scale: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function ___init___, which handles init.

Line 1132: `required = {` This statement continues through source line 1139; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(self.transformer_blocks) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(self.transformer_blocks) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 1133: `*(f"patch_embed.block{index}" for index in range(5)),` This is continuation line 2 of the 8-line logical statement that begins at source line 1132. Its exact fragment is ‘*(f"patch_embed.block{index}" for index in range(5)),‘. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(self.transformer_blocks) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(self.transformer
for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 1134: `*(f"block.{block}.attn.{name}"` This is continuation line 3 of the 8-line logical statement that begins at source line 1132. Its exact fragment is ‘*(f"block.{block}.attn.{name}"‘. The important operands are f: the value named ’f’ in this block; block: the value named ’block’ in this block; attn: the value named ’attn’ in this block. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(self.transformer_blocks) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.f
for block in range(self.transformer_blocks) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 1135: `for block in range(self.transformer_blocks)` This is continuation line 4 of the 8-line logical statement that begins at source line 1132. Its exact fragment is ‘for block in range(self.transformer_blocks)‘. The important operands are for: the value named ’for’ in this block; block: the value named ’block’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(self.transformer_blocks) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(self.transformer_blocks) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 1136: `for name in ("q", "k", "v", "proj")),` This is continuation line 5 of the 8-line logical statement that begins at source line 1132. Its exact fragment is ‘for name in ("q", "k", "v", "proj")),‘. The important operands are for: the value named ’for’ in this block; name: the value named ’name’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(self.transformer_blocks) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(self.transformer_blocks) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 1137: `*(f"block.{block}.mlp.fc{layer}"` This is continuation line 6 of the 8-line logical statement that begins at source line 1132. Its exact fragment is ‘*(f"block.{block}.mlp.fc{layer}"‘. The important operands are f: the value named ’f’ in this block; block: the value named ’block’ in this block; mlp: the value named ’mlp’ in this block. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(self.transformer_blocks) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(self.transformer_blocks) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 1138: `for block in range(self.transformer_blocks) for layer in (1, 2)),` This is continuation line 7 of the 8-line logical statement that begins at source line 1132. Its exact fragment is ‘for block in range(self.transformer_blocks) for layer in (1, 2)),‘. The important operands are for: the value named ’for’ in this block; block: the value named ’block’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(self.transformer_blocks) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(self.transformer_blocks) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 1139: `}` This is continuation line 8 of the 8-line logical statement that begins at source line 1132. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(self.transformer_blocks) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(self.transformer_blocks) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 1140: `missing = required - set(state.projection_names)` This assigns ‘required - set(state.projection_names)‘ to ‘missing ‘ in host memory. Here missing means the value named ’missing’ in this block. The important operands are required: the value named ’required’ in this block; set: the value named ’set’ in this block; state: the finite-state-machine phase retained in flip-flops. Context: the function ___init___, which handles init.

Line 1141: `if missing:` This executes the following indented host-code branch only when ‘missing‘ is true. The important operands are missing: the value named ’missing’ in this block. Context: the function ___init___, which

handles init.

Line 1142: `raise ValueError(f"trainable state is missing projections: {sorted(missing)}")` This rejects an invalid state by raising ‘ValueError(f"trainable state is missing projections: {sorted(missing)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1143: `accumulator_scale = float(state.manifest["head"]["accumulator_scale"])` This assigns ‘float(state.manifes to ‘accumulator_scale ‘ in host memory. Here accumulator_scale means a widened running sum that prevents intermediate overflow. The important operands are float: the value named ’float’ in this block; state: the finite-state-machine phase retained in flip-flops; manifest: the value named ’manifest’ in this block. Context: the function ___init___, which handles init.

Line 1144: `ideal_difference = math.log(2.0) / accumulator_scale` This assigns ‘math.log(2.0) / accumulator_scale‘ to ‘ideal_difference ‘ in host memory. Here ideal_difference means the value named ’ideal difference’ in this block. The important operands are math: the value named ’math’ in this block; log: the value named ’log’ in this block; accumulator_scale: a widened running sum that prevents intermediate overflow. Context: the function ___init___, which handles init.

Line 1145: `self.softmax_difference_shift = int(round(math.log2(ideal_difference)))` This assigns ‘int(round(math.l to ‘self.softmax_difference_shift ‘ in host memory. Here softmax_difference_shift means the value named ’softmax difference shift’ in this block. The important operands are round: the value named ’round’ in this block; math: the value named ’math’ in this block; log2: the value named ’log2’ in this block. Context: the function ___init___, which handles init.

Line 1146: `if not 0 <= self.softmax_difference_shift <= 31:` This executes the following indented host-code branch only when ‘not 0 <= self.softmax_difference_shift <= 31‘ is true. The important operands are not: the value named ’not’ in this block; softmax_difference_shift: the value named ’softmax difference shift’ in this block. Context: the function ___init___, which handles init.

Line 1147: `raise ValueError("head accumulator scale is outside the hardware softmax range")` This rejects an invalid state by raising ‘ValueError("head accumulator scale is outside the hardware softmax range")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1149: `def _lif_trace(self, values: np.ndarray, *, threshold: float = 1.0) -> LifTraceCache:` This starts function _lif_trace. Its indented body performs lif trace as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1150: `threshold_q10 = int(round(threshold * self.fixed_scale))` This assigns ‘int(round(threshold * self.fixed_scale))‘ to ‘threshold_q10 ‘ in host memory. Here threshold_q10 means the membrane level at which a neuron emits a spike. The important operands are round: the value named ’round’ in this block; threshold: the membrane level at which a neuron emits a spike; fixed_scale: the real-value spacing represented by one quantized integer step. Context: the function _lif_trace, which handles lif trace.

Line 1151: `spikes, membrane = lif_sequence_with_trace_on_accelerator(` This statement continues through source line 1158; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘lif_sequence_with_trace_on_accelerator(self.driver, values, threshold_q10=threshold_q10, leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spikes, membrane ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the value named ’lif sequence with trace on accelerator’ in this block; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _lif_trace, which handles lif trace.

Line 1152: `self.driver,` This is continuation line 2 of the 8-line logical statement that begins at source line 1151. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read

together, the complete operation is: This assigns ‘lif_sequence_with_trace_on_accelerator(self.driver, values, threshold_q10=threshold_q10, leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spikes, membrane ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the value named ’lif sequence with trace on accelerator’ in this block; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _lif_trace, which handles lif trace.

Line 1153: `values,` This is continuation line 3 of the 8-line logical statement that begins at source line 1151. Its exact fragment is ‘values,‘. The important operands are values: the value named ’values’ in this block. Read together, the complete operation is: This assigns ‘lif_sequence_with_trace_on_accelerator(self.driver, values, threshold_q10=threshold_q10, leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spikes, membrane ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the value named ’lif sequence with trace on accelerator’ in this block; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _lif_trace, which handles lif trace.

Line 1154: `threshold_q10=threshold_q10,` This is continuation line 4 of the 8-line logical statement that begins at source line 1151. Its exact fragment is ‘threshold_q10=threshold_q10,‘. The important operands are threshold_q10: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This assigns ‘lif_sequence_with_trace_on_accelerator(self.driver, values, threshold_q10=threshold_q10, leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spikes, membrane ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the value named ’lif sequence with trace on accelerator’ in this block; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _lif_trace, which handles lif trace.

Line 1155: `leak_shift=1,` This is continuation line 5 of the 8-line logical statement that begins at source line 1151. Its exact fragment is ‘leak_shift=1,‘. The important operands are leak_shift: the retained fraction of prior membrane state. Read together, the complete operation is: This assigns ‘lif_sequence_with_trace_on_accelerator(self.driver, values, threshold_q10=threshold_q10, leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spikes, membrane ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the value named ’lif sequence with trace on accelerator’ in this block; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _lif_trace, which handles lif trace.

Line 1156: `reset_q10=0,` This is continuation line 6 of the 8-line logical statement that begins at source line 1151. Its exact fragment is ‘reset_q10=0,‘. The important operands are reset_q10: the value named ’reset q10’ in this block. Read together, the complete operation is: This assigns ‘lif_sequence_with_trace_on_accelerator(self.driver, values, threshold_q10=threshold_q10, leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spikes, membrane ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the value named ’lif sequence with trace on accelerator’ in this block; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _lif_trace, which handles lif trace.

Line 1157: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 7 of the 8-line logical statement that begins at source line 1151. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘lif_sequence_with_trace_on_ac self.driver, values, threshold_q10=threshold_q10, leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spikes, membrane ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the value named ’lif sequence with trace on accelerator’ in this block; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _lif_trace, which handles lif trace.

Line 1158: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 1151. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘lif_sequence_with_trace_on_accelerator(self.driver, values, threshold_q10=threshold_q10,

leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spikes, membrane ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif_sequence_with_trace_on_accelerator: the value named ’lif sequence with trace on accelerator’ in this block; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _lif_trace, which handles lif trace.

Line 1159: `return LifTraceCache(` This statement continues through source line 1164; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘LifTraceCache(np.asarray(values, dtype=np.int64), spikes, membrane, threshold_q10,)‘ to the caller of the function _lif_trace, which handles lif trace, ending this invocation. The important operands are LifTraceCache: the value named ’lif trace cache’ in this block; asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block.

Line 1160: `np.asarray(values, dtype=np.int64),` This is continuation line 2 of the 6-line logical statement that begins at source line 1159. Its exact fragment is ‘np.asarray(values, dtype=np.int64),‘. The important operands are asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block; dtype: the value named ’dtype’ in this block. Read together, the complete operation is: This returns ‘LifTraceCache(np.asarray(values, dtype=np.int64), spikes, membrane, threshold_q10,)‘ to the caller of the function _lif_trace, which handles lif trace, ending this invocation. The important operands are LifTraceCache: the value named ’lif trace cache’ in this block; asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block.

Line 1161: `spikes,` This is continuation line 3 of the 6-line logical statement that begins at source line 1159. Its exact fragment is ‘spikes,‘. The important operands are spikes: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This returns ‘LifTraceCache(np.asarray(values, dtype=np.int64), spikes, membrane, threshold_q10,)‘ to the caller of the function _lif_trace, which handles lif trace, ending this invocation. The important operands are LifTraceCache: the value named ’lif trace cache’ in this block; asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block.

Line 1162: `membrane,` This is continuation line 4 of the 6-line logical statement that begins at source line 1159. Its exact fragment is ‘membrane,‘. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This returns ‘LifTraceCache(np.asarray(values, dtype=np.int64), spikes, membrane, threshold_q10,)‘ to the caller of the function _lif_trace, which handles lif trace, ending this invocation. The important operands are LifTraceCache: the value named ’lif trace cache’ in this block; asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block.

Line 1163: `threshold_q10,` This is continuation line 5 of the 6-line logical statement that begins at source line 1159. Its exact fragment is ‘threshold_q10,‘. The important operands are threshold_q10: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This returns ‘LifTraceCache(np.asarray(values, dtype=np.int64), spikes, membrane, threshold_q10,)‘ to the caller of the function _lif_trace, which handles lif trace, ending this invocation. The important operands are LifTraceCache: the value named ’lif trace cache’ in this block; asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block.

Line 1164: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1159. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘LifTraceCache(np.asarray(values, dtype=np.int64), spikes, membrane, threshold_q10,)‘ to the caller of the function _lif_trace, which handles lif trace, ending this invocation. The important operands are LifTraceCache: the value named ’lif trace cache’ in this block; asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block.

Line 1166: `def _dynamic_binary_gemm(self, left: np.ndarray, right: np.ndarray) -> np.ndarray:` This starts function _dynamic_binary_gemm. Its indented body performs dynamic binary gemm as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1167: `return compile_spike_gemm(left, right).execute_batched(` This statement continues through source line 1168; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘compile_spike_gemm(left, right).execute_batched(self.driver, timeout_seconds=self.layer_timeout_seconds)‘ to the caller

of the function _dynamic_binary_gemm, which handles dynamic binary gemm, ending this invocation. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold; left: the value named 'left' in this block; right: the value named 'right' in this block.

Line 1168: `self.driver, timeout_seconds=self.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 1167. Its exact fragment is 'self.driver, timeout_seconds=self.layer_timeout_seconds)'. The important operands are driver: the value named 'driver' in this block; timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This returns 'compile_spike_gemm(left, right).execute_batched(self.driver, timeout_seconds=self.layer_timeout_seconds)' to the caller of the function _dynamic_binary_gemm, which handles dynamic binary gemm, ending this invocation. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold; left: the value named 'left' in this block; right: the value named 'right' in this block.

Line 1170: `def _dynamic_u8_gemm(self, left: np.ndarray, right: np.ndarray) -> np.ndarray:` This starts function _dynamic_u8_gemm. Its indented body performs dynamic u8 gemm as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1171: `return compile_u8_gemm(left, right).execute_batched(` This statement continues through source line 1172; the explanation uses the complete expression rather than only the first visual fragment. This returns 'compile_u8_gemm(left, right).execute_batched(self.driver, timeout_seconds=self.layer_timeout_seconds)' to the caller of the function _dynamic_u8_gemm, which handles dynamic u8 gemm, ending this invocation. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; left: the value named 'left' in this block; right: the value named 'right' in this block.

Line 1172: `self.driver, timeout_seconds=self.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 1171. Its exact fragment is 'self.driver, timeout_seconds=self.layer_timeout_seconds)'. The important operands are driver: the value named 'driver' in this block; timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This returns 'compile_u8_gemm(left, right).execute_batched(self.driver, timeout_seconds=self.layer_timeout_seconds)' to the caller of the function _dynamic_u8_gemm, which handles dynamic u8 gemm, ending this invocation. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; left: the value named 'left' in this block; right: the value named 'right' in this block.

Line 1174: `def _global_sum(self, value: np.ndarray) -> np.ndarray:` This starts function _global_sum. Its indented body performs global sum as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1175: `"""Reduce time and space through a pairwise fabric ADD tree."""` This is executable documentation attached to the function _global_sum, which handles global sum. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1177: `timesteps, batch, channels, height, width = value.shape` This assigns 'value.shape' to 'timesteps, batch, channels, height, width ' in host memory. Here timesteps means one discrete SNN update instant. The important operands are value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function _global_sum, which handles global sum.

Line 1178: `reduction = value.transpose(0, 3, 4, 1, 2).reshape(` This statement continues through source line 1179; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'value.transpose(0, 3, 4, 1, 2).reshape(timesteps * height * width, batch, channels)' to 'reduction ' in host memory. Here reduction means the value named 'reduction' in this block. The important operands are value: the value named 'value' in this block; transpose: the value named 'transpose' in this block; reshape: the value named 'reshape' in this block. Context: the function _global_sum, which handles global sum.

Line 1179: `timesteps * height * width, batch, channels)` This is continuation line 2 of the 2-line logical statement that begins at source line 1178. Its exact fragment is ‘timesteps * height * width, batch, channels)‘. The important operands are timesteps: one discrete SNN update instant; height: the value named ’height’ in this block; width: the value named ’width’ in this block. Read together, the complete operation is: This assigns ‘value.transpose(0, 3, 4, 1, 2).reshape(timesteps * height * width, batch, channels)‘ to ‘reduction ‘ in host memory. Here reduction means the value named ’reduction’ in this block. The important operands are value: the value named ’value’ in this block; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _global_sum, which handles global sum.

Line 1180: `conservative_bound = int(np.abs(reduction).max(initial=0)) * reduction.shape[0]` This assigns ‘int(np.abs(reduction).max(initial=0)) * reduction.shape[0]‘ to ‘conservative_bound ‘ in host memory. Here conservative_bound means the value named ’conservative bound’ in this block. The important operands are abs: the value named ’abs’ in this block; reduction: the value named ’reduction’ in this block; max: the value named ’max’ in this block. Context: the function _global_sum, which handles global sum.

Line 1181: `if conservative_bound > (1 << 31) - 1:` This executes the following indented host-code branch only when ‘conservative_bound > (1 << 31) - 1‘ is true. The important operands are conservative_bound: the value named ’conservative bound’ in this block. Context: the function _global_sum, which handles global sum.

Line 1182: `raise OverflowError("global pooling could saturate the signed-32 vector tree")` This rejects an invalid state by raising ‘OverflowError("global pooling could saturate the signed-32 vector tree")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1183: `candidates = [reduction[index] for index in range(reduction.shape[0])]` This assigns ‘[reduction[index] for index in range(reduction.shape[0])]‘ to ‘candidates ‘ in host memory. Here candidates means the value named ’candidates’ in this block. The important operands are reduction: the value named ’reduction’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named ’for’ in this block. Context: the function _global_sum, which handles global sum.

Line 1184: `while len(candidates) > 1:` This repeats the following host-code block while ‘len(candidates) > 1‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 1185: `reduced: list[np.ndarray] = []` This assigns ‘[]‘ to ‘reduced‘ in host memory. Here reduced means the value named ’reduced’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _global_sum, which handles global sum.

Line 1186: `for index in range(0, len(candidates) - 1, 2):` This iterates index over ‘range(0, len(candidates) - 1, 2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _global_sum, which handles global sum.

Line 1187: `reduced.append(execute_vector_tensor(` This statement continues through source line 1193; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘reduced.append‘ with ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=self.layer_)‘ inside the function _global_sum, which handles global sum. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1188: `self.driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1187. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This calls ‘reduced.append‘ with ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=self.layer_timeout_seconds,)‘ inside the function _global_sum, which handles global sum. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1189: `VectorOperation.ADD_SAT,` This is continuation line 3 of the 7-line logical statement that begins at source line 1187. Its exact fragment is 'VectorOperation.ADD_SAT,'. The important operands are VectorOperation: the value named 'vector operation' in this block; ADD_SAT: the value named 'add sat' in this block. Read together, the complete operation is: This calls 'reduced.append' with 'execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=self.layer_timeout_seconds,)' inside the function _global_sum, which handles global sum. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1190: `candidates[index],` This is continuation line 4 of the 7-line logical statement that begins at source line 1187. Its exact fragment is 'candidates[index],'. The important operands are candidates: the value named 'candidates' in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'reduced.append' with 'execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=self.layer_timeout_seconds,)' inside the function _global_sum, which handles global sum. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1191: `candidates[index + 1],` This is continuation line 5 of the 7-line logical statement that begins at source line 1187. Its exact fragment is 'candidates[index + 1],'. The important operands are candidates: the value named 'candidates' in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'reduced.append' with 'execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=self.layer_timeout_seconds,)' inside the function _global_sum, which handles global sum. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1192: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1187. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This calls 'reduced.append' with 'execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=self.layer_timeout_seconds,)' inside the function _global_sum, which handles global sum. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1193: `))` This is continuation line 7 of the 7-line logical statement that begins at source line 1187. Its exact fragment is '))'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'reduced.append' with 'execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=self.layer_timeout_seconds,)' inside the function _global_sum, which handles global sum. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1194: `if len(candidates) & 1:` This executes the following indented host-code branch only when 'len(candidates) & 1' is true. The important operands are len: the value named 'len' in this block; candidates: the value named 'candidates' in this block. Context: the function _global_sum, which handles global sum.

Line 1195: `reduced.append(candidates[-1])` This calls 'reduced.append' with 'candidates[-1]' inside the function _global_sum, which handles global sum. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1196: `candidates = reduced` This assigns 'reduced' to 'candidates ' in host memory. Here candidates means the value named 'candidates' in this block. The important operands are reduced: the value named 'reduced' in this block. Context: the function _global_sum, which handles global sum.

Line 1197: `return candidates[0]` This returns 'candidates[0]' to the caller of the function _global_sum, which handles global sum, ending this invocation. The important operands are candidates: the value named 'candidates' in this block.

Line 1199: `def _tokenizer_forward(` This starts function _tokenizer_forward. Its indented body performs tokenizer forward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1200: `self, image_u8: np.ndarray, image_centered: np.ndarray` Inside the function _tokenizer_forward, which handles tokenizer forward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are image_u8: the value named 'image u8' in this block; ndarray: the value named 'ndarray' in this block; image_centered: the value named 'image centered' in this block.

Line 1201: `) -> tuple[np.ndarray, tuple[TokenizerLayerCache, ...]]:` Inside the function _tokenizer_forward, which handles tokenizer forward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block; TokenizerLayerCache: the value named 'tokenizer layer cache' in this block.

Line 1202: `batch = image_u8.shape[0]` This assigns ‘image_u8.shape[0]‘ to ‘batch ‘ in host memory. Here batch means the value named 'batch' in this block. The important operands are image_u8: the value named 'image u8' in this block; shape: the value named 'shape' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1203: `first = self.projections.conv2d(` This statement continues through source line 1209; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeou)‘ to ‘first ‘ in host memory. Here first means the value named 'first' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1204: `"patch_embed.block0",` This is continuation line 2 of the 7-line logical statement that begins at source line 1203. Its exact fragment is ‘"patch_embed.block0",‘. The important operands are patch_embed: the value named 'patch embed' in this block; block0: the value named 'block0' in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘first ‘ in host memory. Here first means the value named 'first' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1205: `image_u8,` This is continuation line 3 of the 7-line logical statement that begins at source line 1203. Its exact fragment is ‘image_u8,‘. The important operands are image_u8: the value named 'image u8' in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘first ‘ in host memory. Here first means the value named 'first' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1206: `activation_zero_point=self.image_zero_point,` This is continuation line 4 of the 7-line logical statement that begins at source line 1203. Its exact fragment is ‘activation_zero_point=self.image_zero_point,‘. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation; image_zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This assigns ‘self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘first ‘ in host memory. Here first means the value named 'first' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1207: `padding=1,` This is continuation line 5 of the 7-line logical statement that begins at source line 1203. Its exact fragment is 'padding=1,'. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'first ' in host memory. Here first means the value named 'first' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1208: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1203. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeou)' to 'first ' in host memory. Here first means the value named 'first' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1209: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1203. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'first ' in host memory. Here first means the value named 'first' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1210: `caches: list[TokenizerLayerCache] = [` This statement continues through source line 1212; the explanation uses the complete expression rather than only the first visual fragment. This assigns '[TokenizerLayerCache(0, image_centered, first, None, False)]' to 'caches' in host memory. Here caches means the value named 'caches' in this block. The important operands are TokenizerLayerCache: the value named 'tokenizer layer cache' in this block; image_centered: the value named 'image centered' in this block; first: the value named 'first' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1211: `TokenizerLayerCache(0, image_centered, first, None, False)` This is continuation line 2 of the 3-line logical statement that begins at source line 1210. Its exact fragment is 'TokenizerLayerCache(0, image_centered, first, None, False)'. The important operands are TokenizerLayerCache: the value named 'tokenizer layer cache' in this block; image_centered: the value named 'image centered' in this block; first: the value named 'first' in this block. Read together, the complete operation is: This assigns '[TokenizerLayerCache(0, image_centered, first, None, False)]' to 'caches' in host memory. Here caches means the value named 'caches' in this block. The important operands are TokenizerLayerCache: the value named 'tokenizer layer cache' in this block; image_centered: the value named 'image centered' in this block; first: the value named 'first' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1212: `]` This is continuation line 3 of the 3-line logical statement that begins at source line 1210. Its exact fragment is ']'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '[TokenizerLayerCache(0, image_centered, first, None, False)]' to 'caches' in host memory. Here caches means the value named 'caches' in this block. The important operands are TokenizerLayerCache: the value named 'tokenizer layer cache' in this block; image_centered: the value named 'image centered' in this block; first: the value named 'first' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1213: `value = np.repeat(first[np.newaxis], self.timesteps, axis=0)` This assigns 'np.repeat(first[np.newaxis], self.timesteps, axis=0)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are repeat: the value named 'repeat' in this block; first: the value named 'first' in this block; newaxis: the value named 'newaxis' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1214: `for index in (1, 2, 3, 4):` This iterates index over ‘(1, 2, 3, 4)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _tokenizer_forward, which handles tokenizer forward.

Line 1215: `lif = self._lif_trace(value)` This assigns ‘self._lif_trace(value)‘ to ‘lif ‘ in host memory. Here lif means the value named ’lif’ in this block. The important operands are _lif_trace: the value named ’lif trace’ in this block; value: the value named ’value’ in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1216: `flat_spikes = lif.spikes.reshape(-1, *lif.spikes.shape[2:])` This assigns ‘lif.spikes.reshape(-1, *lif.spikes.shape[2:])‘ to ‘flat_spikes ‘ in host memory. Here flat_spikes means a binary event produced when a neuron crosses its threshold. The important operands are lif: the value named ’lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1217: `if index >= 3:` This executes the following indented host-code branch only when ‘index >= 3‘ is true. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1218: `projection_input = binary_max_pool2d_on_accelerator(` This statement continues through source line 1222; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘binary_max_pool2d_on_accelerator(self.driver, flat_spikes, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projection_input ‘ in host memory. Here projection_input means the value named ’projection input’ in this block. The important operands are binary_max_pool2d_on_accelerator: the value named ’binary max pool2d on accelerator’ in this block; driver: the value named ’driver’ in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1219: `self.driver,` This is continuation line 2 of the 5-line logical statement that begins at source line 1218. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘binary_max_pool2d_on_accelerator(self.driver, flat_spikes, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projection_input ‘ in host memory. Here projection_input means the value named ’projection input’ in this block. The important operands are binary_max_pool2d_on_accelerator: the value named ’binary max pool2d on accelerator’ in this block; driver: the value named ’driver’ in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1220: `flat_spikes,` This is continuation line 3 of the 5-line logical statement that begins at source line 1218. Its exact fragment is ‘flat_spikes,‘. The important operands are flat_spikes: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns ‘binary_max_pool2d_on_accelerator(self.driver, flat_spikes, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projection_input ‘ in host memory. Here projection_input means the value named ’projection input’ in this block. The important operands are binary_max_pool2d_on_accelerato the value named ’binary max pool2d on accelerator’ in this block; driver: the value named ’driver’ in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1221: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 4 of the 5-line logical statement that begins at source line 1218. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘binary_max_pool2d_on_accelerator(self.driver, flat_spikes, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projection_input ‘ in host memory. Here projection_input means the value named ’projection input’ in this block. The important operands are binary_max_pool2d_on_accelerator: the value named ’binary max pool2d on accelerator’ in this block; driver: the value named ’driver’ in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1222: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 1218. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘binary_max_pool2d_on_accelerator(self.driver, flat_spikes, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projection_input ‘ in host memory. Here projection_input means the value named ’projection input’ in this block. The important operands are binary_max_pool2d_on_accelerator: the value named ’binary max pool2d on accelerator’ in this block; driver: the value named ’driver’ in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1223: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function _tokenizer_forward, which handles tokenizer forward.

Line 1224: `projection_input = flat_spikes` This assigns ‘flat_spikes‘ to ‘projection_input ‘ in host memory. Here projection_input means the value named ’projection input’ in this block. The important operands are flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1225: `projected = self.projections.conv2d(` This statement continues through source line 1230; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", projection_input, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1226: `f"patch_embed.block{index}",` This is continuation line 2 of the 6-line logical statement that begins at source line 1225. Its exact fragment is ‘f"patch_embed.block{index}",‘. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", projection_input, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1227: `projection_input,` This is continuation line 3 of the 6-line logical statement that begins at source line 1225. Its exact fragment is ‘projection_input,‘. The important operands are projection_input: the value named ’projection input’ in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d(f"patch_embed.block{index projection_input, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1228: `padding=1,` This is continuation line 4 of the 6-line logical statement that begins at source line 1225. Its exact fragment is ‘padding=1,‘. The important operands are padding: the value named ’padding’ in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", projection_input, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1229: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1225. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", projection_input, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are

projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; f: the value named 'f' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1230: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1225. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self.projections.conv2d(f"patch_embed.block{index}", projection_input, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'projected ' in host memory. Here projected means the value named 'projected' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; f: the value named 'f' in this block. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1231: `caches.append(TokenizerLayerCache(` This statement continues through source line 1237; the explanation uses the complete expression rather than only the first visual fragment. This calls 'caches.append' with 'TokenizerLayerCache(index, projection_input, projected, lif, index >= 3,)' inside the function _tokenizer_forward, which handles tokenizer forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1232: `index,` This is continuation line 2 of the 7-line logical statement that begins at source line 1231. Its exact fragment is 'index,'. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'caches.append' with 'TokenizerLayerCache(index, projection_input, projected, lif, index >= 3,)' inside the function _tokenizer_forward, which handles tokenizer forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1233: `projection_input,` This is continuation line 3 of the 7-line logical statement that begins at source line 1231. Its exact fragment is 'projection_input,'. The important operands are projection_input: the value named 'projection input' in this block. Read together, the complete operation is: This calls 'caches.append' with 'TokenizerLayerCache(index, projection_input, projected, lif, index >= 3,)' inside the function _tokenizer_forward, which handles tokenizer forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1234: `projected,` This is continuation line 4 of the 7-line logical statement that begins at source line 1231. Its exact fragment is 'projected,'. The important operands are projected: the value named 'projected' in this block. Read together, the complete operation is: This calls 'caches.append' with 'TokenizerLayerCache(index, projection_input, projected, lif, index >= 3,)' inside the function _tokenizer_forward, which handles tokenizer forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1235: `lif,` This is continuation line 5 of the 7-line logical statement that begins at source line 1231. Its exact fragment is 'lif,'. The important operands are lif: the value named 'lif' in this block. Read together, the complete operation is: This calls 'caches.append' with 'TokenizerLayerCache(index, projection_input, projected, lif, index >= 3,)' inside the function _tokenizer_forward, which handles tokenizer forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1236: `index >= 3,` This is continuation line 6 of the 7-line logical statement that begins at source line 1231. Its exact fragment is 'index >= 3,'. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'caches.append' with 'TokenizerLayerCache(index, projection_input, projected, lif, index >= 3,)' inside the function _tokenizer_forward, which handles tokenizer forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1237: `))` This is continuation line 7 of the 7-line logical statement that begins at source line 1231. Its exact fragment is '))'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'caches.append' with 'TokenizerLayerCache(index, projection_input, projected, lif, index >= 3,)' inside the function _tokenizer_forward, which handles tokenizer forward. The call advances the

host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1238: `value = projected.reshape(` This statement continues through source line 1239; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘projected.reshape(self.timesteps, batch, *projected.shape[1:])‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are projected: the value named ’projected’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1239: `self.timesteps, batch, *projected.shape[1:])` This is continuation line 2 of the 2-line logical statement that begins at source line 1238. Its exact fragment is ‘self.timesteps, batch, *projected.shape[1:])‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; projected: the value named ’projected’ in this block. Read together, the complete operation is: This assigns ‘projected.reshape(self.timesteps, batch, *projected.shape[1:])‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are projected: the value named ’projected’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _tokenizer_forward, which handles tokenizer forward.

Line 1240: `return value, tuple(caches)` This returns ‘value, tuple(caches)‘ to the caller of the function _tokenizer_forward, which handles tokenizer forward, ending this invocation. The important operands are value: the value named ’value’ in this block; tuple: the value named ’tuple’ in this block; caches: the value named ’caches’ in this block.

Line 1242: `def _attention_forward(self, block_index: int, value: np.ndarray) -> AttentionCache:` This starts function _attention_forward. Its indented body performs attention forward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1243: `timesteps, batch, channels, height, width = value.shape` This assigns ‘value.shape‘ to ‘timesteps, batch, channels, height, width ‘ in host memory. Here timesteps means one discrete SNN update instant. The important operands are value: the value named ’value’ in this block; shape: the value named ’shape’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1244: `tokens = height * width` This assigns ‘height * width‘ to ‘tokens ‘ in host memory. Here tokens means the value named ’tokens’ in this block. The important operands are height: the value named ’height’ in this block; width: the value named ’width’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1245: `projection_lif = self._lif_trace(value)` This assigns ‘self._lif_trace(value)‘ to ‘projection_lif ‘ in host memory. Here projection_lif means the value named ’projection lif’ in this block. The important operands are _lif_trace: the value named ’lif trace’ in this block; value: the value named ’value’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1246: `token_spikes = projection_lif.spikes.reshape(` This statement continues through source line 1247; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘projection_lif.spikes.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2)‘ to ‘token_spikes ‘ in host memory. Here token_spikes means a binary event produced when a neuron crosses its threshold. The important operands are projection_lif: the value named ’projection lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1247: `timesteps, batch, channels, tokens).transpose(0, 1, 3, 2)` This is continuation line 2 of the 2-line logical statement that begins at source line 1246. Its exact fragment is ‘timesteps, batch, channels, tokens).transpose(0, 1, 3, 2)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This assigns ‘projection_lif.spikes.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2)‘ to ‘token_spikes ‘ in host memory. Here token_spikes means a binary event produced when a neuron crosses its threshold. The important operands are projection_lif: the value named ’projection lif’ in this block; spikes: a binary event produced when a neuron crosses its

threshold; reshape: the value named 'reshape' in this block. Context: the function _attention_forward, which handles attention forward.

Line 1248: `rows = token_spikes.reshape(timesteps * batch * tokens, channels)` This assigns 'token_spikes.reshape(tim * batch * tokens, channels)' to 'rows ' in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are token_spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _attention_forward, which handles attention forward.

Line 1249: `prefix = f"block.{block_index}.attn"` This assigns 'f"block.{block_index}.attn"' to 'prefix ' in host memory. Here prefix means the value named 'prefix' in this block. The important operands are f: the value named 'f' in this block; block: the value named 'block' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function _attention_forward, which handles attention forward.

Line 1251: `def projected_lif(name: str) -> LifTraceCache:` This starts function projected_lif. Its indented body performs projected lif as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1252: `projected = self.projections.matrix(` This statement continues through source line 1254; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self.projections.matrix(f"{prefix}.{name}", rows, timeout_seconds=self.layer_timeout_seconds)' to 'projected ' in host memory. Here projected means the value named 'projected' in this block. The important operands are projections: the value named 'projections' in this block; matrix: the value named 'matrix' in this block; f: the value named 'f' in this block. Context: the function projected_lif, which handles projected lif.

Line 1253: `f"{prefix}.{name}", rows,` This is continuation line 2 of the 3-line logical statement that begins at source line 1252. Its exact fragment is 'f"{prefix}.{name}", rows,'. The important operands are f: the value named 'f' in this block; prefix: the value named 'prefix' in this block; name: the value named 'name' in this block. Read together, the complete operation is: This assigns 'self.projections.matrix(f"{prefix}.{name}", rows, timeout_seconds=self.layer_timeout_seconds to 'projected ' in host memory. Here projected means the value named 'projected' in this block. The important operands are projections: the value named 'projections' in this block; matrix: the value named 'matrix' in this block; f: the value named 'f' in this block. Context: the function projected_lif, which handles projected lif.

Line 1254: `timeout_seconds=self.layer_timeout_seconds)` This is continuation line 3 of the 3-line logical statement that begins at source line 1252. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds)'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'self.projections.matrix(f"{prefix}.{name}", rows, timeout_seconds=self.layer_timeout_seconds)' to 'projected ' in host memory. Here projected means the value named 'projected' in this block. The important operands are projections: the value named 'projections' in this block; matrix: the value named 'matrix' in this block; f: the value named 'f' in this block. Context: the function projected_lif, which handles projected lif.

Line 1255: `shaped = projected.reshape(timesteps, batch, tokens, channels)` This assigns 'projected.reshape(timesteps batch, tokens, channels)' to 'shaped ' in host memory. Here shaped means the value named 'shaped' in this block. The important operands are projected: the value named 'projected' in this block; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function projected_lif, which handles projected lif.

Line 1256: `return self._lif_trace(shaped)` This returns 'self._lif_trace(shaped)' to the caller of the function projected_lif, which handles projected lif, ending this invocation. The important operands are _lif_trace: the value named 'lif trace' in this block; shaped: the value named 'shaped' in this block.

Line 1258: `query_lif = projected_lif("q")` This assigns 'projected_lif("q")' to 'query_lif ' in host memory. Here query_lif means the value named 'query lif' in this block. The important operands are projected_lif: the value named 'projected lif' in this block; q: the value named 'q' in this block. Context: the function _attention_forward, which handles attention forward.

Line 1259: `key_lif = projected_lif("k")` This assigns ‘projected_lif("k")‘ to ‘key_lif ‘ in host memory. Here key_lif means the value named ’key lif’ in this block. The important operands are projected_lif: the value named ’projected lif’ in this block; k: the value named ’k’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1260: `value_lif = projected_lif("v")` This assigns ‘projected_lif("v")‘ to ‘value_lif ‘ in host memory. Here value_lif means the value named ’value lif’ in this block. The important operands are projected_lif: the value named ’projected lif’ in this block; v: the value named ’v’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1261: `if channels % self.attention_heads:` This executes the following indented host-code branch only when ‘channels % self.attention_heads‘ is true. The important operands are channels: the value named ’channels’ in this block; attention_heads: the value named ’attention heads’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1262: `raise ValueError("attention channels must divide evenly into the head count")` This rejects an invalid state by raising ‘ValueError("attention channels must divide evenly into the head count")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1263: `head_dim = channels // self.attention_heads` This assigns ‘channels // self.attention_heads‘ to ‘head_dim ‘ in host memory. Here head_dim means the value named ’head dim’ in this block. The important operands are channels: the value named ’channels’ in this block; attention_heads: the value named ’attention heads’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1265: `def heads(spikes: np.ndarray) -> np.ndarray:` This starts function heads. Its indented body performs heads as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1266: `return spikes.reshape(` This statement continues through source line 1268; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘spikes.reshape(timesteps, batch, tokens, self.attention_heads, head_dim).transpose(0, 1, 3, 2, 4)‘ to the caller of the function heads, which handles heads, ending this invocation. The important operands are spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant.

Line 1267: `timesteps, batch, tokens, self.attention_heads, head_dim` This is continuation line 2 of the 3-line logical statement that begins at source line 1266. Its exact fragment is ‘timesteps, batch, tokens, self.attention_heads, head_dim‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; tokens: the value named ’tokens’ in this block. Read together, the complete operation is: This returns ‘spikes.reshape(timesteps, batch, tokens, self.attention_heads, head_dim).transpose(0, 1, 3, 2, 4)‘ to the caller of the function heads, which handles heads, ending this invocation. The important operands are spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant.

Line 1268: `).transpose(0, 1, 3, 2, 4)` This is continuation line 3 of the 3-line logical statement that begins at source line 1266. Its exact fragment is ‘).transpose(0, 1, 3, 2, 4)‘. The important operands are transpose: the value named ’transpose’ in this block. Read together, the complete operation is: This returns ‘spikes.reshape(timesteps, batch, tokens, self.attention_heads, head_dim).transpose(0, 1, 3, 2, 4)‘ to the caller of the function heads, which handles heads, ending this invocation. The important operands are spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant.

Line 1270: `query_heads = heads(query_lif.spikes)` This assigns ‘heads(query_lif.spikes)‘ to ‘query_heads ‘ in host memory. Here query_heads means the value named ’query heads’ in this block. The important operands are heads: the value named ’heads’ in this block; query_lif: the value named ’query lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold. Context: the function _attention_forward, which handles attention forward.

Line 1271: `key_heads = heads(key_lif.spikes)` This assigns ‘heads(key_lif.spikes)‘ to ‘key_heads ‘ in host memory. Here key_heads means the value named ’key heads’ in this block. The important operands are heads: the value named ’heads’ in this block; key_lif: the value named ’key lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold. Context: the function _attention_forward, which handles attention forward.

Line 1272: `value_heads = heads(value_lif.spikes)` This assigns ‘heads(value_lif.spikes)‘ to ‘value_heads ‘ in host memory. Here value_heads means the value named ’value heads’ in this block. The important operands are heads: the value named ’heads’ in this block; value_lif: the value named ’value lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold. Context: the function _attention_forward, which handles attention forward.

Line 1273: `scores = np.empty(` This statement continues through source line 1276; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.empty((timesteps, batch, self.attention_heads, tokens, tokens), dtype=np.int64,)‘ to ‘scores ‘ in host memory. Here scores means the value named ’scores’ in this block. The important operands are empty: the value named ’empty’ in this block; timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1274: `(timesteps, batch, self.attention_heads, tokens, tokens),` This is continuation line 2 of the 4-line logical statement that begins at source line 1273. Its exact fragment is ‘(timesteps, batch, self.attention_heads, tokens, tokens),‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; attention_heads: the value named ’attention heads’ in this block. Read together, the complete operation is: This assigns ‘np.empty((timesteps, batch, self.attention_heads, tokens, tokens), dtype=np.int64,)‘ to ‘scores ‘ in host memory. Here scores means the value named ’scores’ in this block. The important operands are empty: the value named ’empty’ in this block; timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1275: `dtype=np.int64,` This is continuation line 3 of the 4-line logical statement that begins at source line 1273. Its exact fragment is ‘dtype=np.int64,‘. The important operands are dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This assigns ‘np.empty((timesteps, batch, self.attention_heads, tokens, tokens), dtype=np.int64,)‘ to ‘scores ‘ in host memory. Here scores means the value named ’scores’ in this block. The important operands are empty: the value named ’empty’ in this block; timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1276: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1273. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.empty((timesteps, batch, self.attention_heads, tokens, tokens), dtype=np.int64,)‘ to ‘scores ‘ in host memory. Here scores means the value named ’scores’ in this block. The important operands are empty: the value named ’empty’ in this block; timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1277: `attention_values = np.empty(` This statement continues through source line 1280; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.empty((timesteps, batch, self.attention_heads, tokens, head_dim), dtype=np.int64,)‘ to ‘attention_values ‘ in host memory. Here attention_values means the value named ’attention values’ in this block. The important operands are empty: the value named ’empty’ in this block; timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1278: `(timesteps, batch, self.attention_heads, tokens, head_dim),` This is continuation line 2 of the 4-line logical statement that begins at source line 1277. Its exact fragment is ‘(timesteps, batch, self.attention_heads, tokens, head_dim),‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; attention_heads: the value named ’attention heads’ in this block. Read together, the complete operation is: This assigns ‘np.empty((timesteps, batch, self.attention_heads, tokens, head_dim), dtype=np.int64,)‘ to ‘attention_values ‘ in host memory. Here attention_values means the value named ’attention values’ in this block. The important operands are empty: the value named ’empty’ in this block; timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1279: `dtype=np.int64,` This is continuation line 3 of the 4-line logical statement that begins at source line 1277. Its exact fragment is 'dtype=np.int64,'. The important operands are dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'np.empty((timesteps, batch, self.attention_heads, tokens, head_dim), dtype=np.int64,)' to 'attention_values ' in host memory. Here attention_values means the value named 'attention values' in this block. The important operands are empty: the value named 'empty' in this block; timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block. Context: the function _attention_forward, which handles attention forward.

Line 1280: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1277. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.empty((timesteps, batch, self.attention_heads, tokens, head_dim), dtype=np.int64,)' to 'attention_values ' in host memory. Here attention_values means the value named 'attention values' in this block. The important operands are empty: the value named 'empty' in this block; timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block. Context: the function _attention_forward, which handles attention forward.

Line 1281: `for timestep in range(timesteps):` This iterates timestep over 'range(timesteps)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _attention_forward, which handles attention forward.

Line 1282: `for batch_index in range(batch):` This iterates batch_index over 'range(batch)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _attention_forward, which handles attention forward.

Line 1283: `for head in range(self.attention_heads):` This iterates head over 'range(self.attention_heads)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _attention_forward, which handles attention forward.

Line 1284: `score = self._dynamic_binary_gemm(` This statement continues through source line 1287; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._dynamic_binary_gemm(query_heads[timestep, batch_index, head], key_heads[timestep, batch_index, head].T,)' to 'score ' in host memory. Here score means the value named 'score' in this block. The important operands are _dynamic_binary_gemm: the value named 'dynamic binary gemm' in this block; query_heads: the value named 'query heads' in this block; timestep: one discrete SNN update instant. Context: the function _attention_forward, which handles attention forward.

Line 1285: `query_heads[timestep, batch_index, head],` This is continuation line 2 of the 4-line logical statement that begins at source line 1284. Its exact fragment is 'query_heads[timestep, batch_index, head],'. The important operands are query_heads: the value named 'query heads' in this block; timestep: one discrete SNN update instant; batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns 'self._dynamic_binary_gemm(query_heads[timestep, batch_index, head], key_heads[timestep, batch_index, head].T,)' to 'score ' in host memory. Here score means the value named 'score' in this block. The important operands are _dynamic_binary_gemm: the value named 'dynamic binary gemm' in this block; query_heads: the value named 'query heads' in this block; timestep: one discrete SNN update instant. Context: the function _attention_forward, which handles attention forward.

Line 1286: `key_heads[timestep, batch_index, head].T,` This is continuation line 3 of the 4-line logical statement that begins at source line 1284. Its exact fragment is 'key_heads[timestep, batch_index, head].T,'. The important operands are key_heads: the value named 'key heads' in this block; timestep: one discrete SNN update instant; batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns 'self._dynamic_binary_gemm(query_heads[timestep, batch_index, head], key_heads[timestep, batch_index, head].T,)' to 'score ' in host memory. Here score means the value named 'score' in this block. The important operands are _dynamic_binary_gemm: the value named 'dynamic binary gemm' in this block; query_heads: the value named 'query heads' in this block; timestep: one discrete SNN update instant. Context: the function _attention_forward, which handles attention forward.

Line 1287: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1284. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self._dynamic_binary_gemm(query_heads[timestep, batch_index, head], key_heads[timestep, batch_index, head].T,)' to 'score ' in host memory. Here score means the value named 'score' in this block. The important operands are _dynamic_binary_gemm: the value named 'dynamic binary gemm' in this block; query_heads: the value named 'query heads' in this block; timestep: one discrete SNN update instant. Context: the function _attention_forward, which handles attention forward.

Line 1288: `if score.min() < 0 or score.max() > 255:` This executes the following indented host-code branch only when 'score.min() $<$ 0 or score.max() $>$ 255' is true. The important operands are score: the value named 'score' in this block; min: the value named 'min' in this block; or: the value named 'or' in this block. Context: the function _attention_forward, which handles attention forward.

Line 1289: `raise OverflowError("binary QK score exceeds the unsigned AV contract")` This rejects an invalid state by raising 'OverflowError("binary QK score exceeds the unsigned AV contract")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1290: `scores[timestep, batch_index, head] = score` This assigns 'score' to 'scores[timestep, batch_index, head] ' in host memory. Here scores means the value named 'scores' in this block. The important operands are score: the value named 'score' in this block. Context: the function _attention_forward, which handles attention forward.

Line 1291: `attention_values[timestep, batch_index, head] = self._dynamic_u8_gemm(` This statement continues through source line 1294; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._dynamic_u8_gemm(score.astype(np.uint8), value_heads[timestep, batch_index, head].astype(np.uint8),)' to 'attention_values[timestep, batch_index, head] ' in host memory. Here attention_values means the value named 'attention values' in this block. The important operands are _dynamic_u8_gemm: the value named 'dynamic u8 gemm' in this block; score: the value named 'score' in this block; astype: the value named 'astype' in this block. Context: the function _attention_forward, which handles attention forward.

Line 1292: `score.astype(np.uint8),` This is continuation line 2 of the 4-line logical statement that begins at source line 1291. Its exact fragment is 'score.astype(np.uint8),'. The important operands are score: the value named 'score' in this block; astype: the value named 'astype' in this block; uint8: the value named 'uint8' in this block. Read together, the complete operation is: This assigns 'self._dynamic_u8_gemm(score.astype(np.uint8), value_heads[timestep, batch_index, head].astype(np.uint8),)' to 'attention_values[timestep, batch_index, head] ' in host memory. Here attention_values means the value named 'attention values' in this block. The important operands are _dynamic_u8_gemm: the value named 'dynamic u8 gemm' in this block; score: the value named 'score' in this block; astype: the value named 'astype' in this block. Context: the function _attention_forward, which handles attention forward.

Line 1293: `value_heads[timestep, batch_index, head].astype(np.uint8),` This is continuation line 3 of the 4-line logical statement that begins at source line 1291. The important operands are _dynamic_u8_gemm: the value named 'dynamic u8 gemm' in this block; score: the value named 'score' in this block; astype: the value named 'astype' in this block. Context: the function _attention_forward, which handles attention forward.

Line 1295: `attention_q10 = attention_values * (1 << self.attention_scale_shift)` This assigns ‘attention_values * (1 << self.attention_scale_shift)‘ to ‘attention_q10 ‘ in host memory. Here attention_q10 means the value named ’attention q10’ in this block. The important operands are attention_values: the value named ’attention values’ in this block; attention_scale_shift: the real-value spacing represented by one quantized integer step. Context: the function _attention_forward, which handles attention forward.

Line 1296: `merged = attention_q10.transpose(0, 1, 2, 4, 3).reshape(` This statement continues through source line 1297; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘attention_q10.transpose(0, 1, 2, 4, 3).reshape(timesteps, batch, channels, tokens)‘ to ‘merged ‘ in host memory. Here merged means the value named ’merged’ in this block. The important operands are attention_q10: the value named ’attention q10’ in this block; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1297: `timesteps, batch, channels, tokens)` This is continuation line 2 of the 2-line logical statement that begins at source line 1296. Its exact fragment is ‘timesteps, batch, channels, tokens)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This assigns ‘attention_q10.transpose(0, 1, 2, 4, 3).reshape(timesteps, batch, channels, tokens)‘ to ‘merged ‘ in host memory. Here merged means the value named ’merged’ in this block. The important operands are attention_q10: the value named ’attention q10’ in this block; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1298: `attention_lif = self._lif_trace(merged, threshold=0.5)` This assigns ‘self._lif_trace(merged, threshold=0.5)‘ to ‘attention_lif ‘ in host memory. Here attention_lif means the value named ’attention lif’ in this block. The important operands are _lif_trace: the value named ’lif trace’ in this block; merged: the value named ’merged’ in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function _attention_forward, which handles attention forward.

Line 1299: `projection_input = attention_lif.spikes.transpose(0, 1, 3, 2).reshape(` This statement continues through source line 1300; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘attention_lif.spikes.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)‘ to ‘projection_input ‘ in host memory. Here projection_input means the value named ’projection input’ in this block. The important operands are attention_lif: the value named ’attention lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold; transpose: the value named ’transpose’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1300: `timesteps * batch * tokens, channels)` This is continuation line 2 of the 2-line logical statement that begins at source line 1299. Its exact fragment is ‘timesteps * batch * tokens, channels)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; tokens: the value named ’tokens’ in this block. Read together, the complete operation is: This assigns ‘attention_lif.spikes.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)‘ to ‘projection_input ‘ in host memory. Here projection_input means the value named ’projection input’ in this block. The important operands are attention_lif: the value named ’attention lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold; transpose: the value named ’transpose’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1301: `output_rows = self.projections.matrix(` This statement continues through source line 1305; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self.projections.matrix(f"{prefix}.proj", projection_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1302: `f"{prefix}.proj",` This is continuation line 2 of the 5-line logical statement that begins at source line 1301. Its exact fragment is ‘f"{prefix}.proj",‘. The important operands are f: the value named ’f’ in this block; prefix: the value named ’prefix’ in this block; proj: the value named ’proj’ in this block. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"{prefix}.proj", projection_input, timeout_seconds=self.layer_timeout_seconds,

)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1303: `projection_input,` This is continuation line 3 of the 5-line logical statement that begins at source line 1301. Its exact fragment is ‘projection_input,‘. The important operands are projection_input: the value named ’projection input’ in this block. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"{prefix}.proj", projection_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1304: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 4 of the 5-line logical statement that begins at source line 1301. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"{prefix}.proj", projection_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1305: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 1301. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"{prefix}.proj", projection_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _attention_forward, which handles attention forward.

Line 1306: `output = output_rows.reshape(` This statement continues through source line 1308; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘output_rows.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(timesteps, batch, channels, height, width)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are output_rows: one output-row position processed by the tensor tile; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_forward, which handles attention forward.

Line 1307: `timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(` This is continuation line 2 of the 3-line logical statement that begins at source line 1306. Its exact fragment is ‘timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; tokens: the value named ’tokens’ in this block. Read together, the complete operation is: This assigns ‘output_rows.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(timesteps, batch, channels, height, width)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are output_rows: one output-row position processed by the tensor tile; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_forward, which handles attention forward.

Line 1308: `timesteps, batch, channels, height, width)` This is continuation line 3 of the 3-line logical statement that begins at source line 1306. Its exact fragment is ‘timesteps, batch, channels, height, width)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This assigns ‘output_rows.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(timesteps, batch, channels, height, width)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are output_rows: one output-row position processed by the tensor tile; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_forward, which handles attention forward.

Line 1309: `return AttentionCache(` This statement continues through source line 1325; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named ’attention cache’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named ’tuple’ in this block.

Line 1310: `block_index,` This is continuation line 2 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘block_index,‘. The important operands are block_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named ’attention cache’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named ’tuple’ in this block.

Line 1311: `tuple(value.shape),` This is continuation line 3 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘tuple(value.shape),‘. The important operands are tuple: the value named ’tuple’ in this block; value: the value named ’value’ in this block; shape: the value named ’shape’ in this block. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named ’attention cache’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named ’tuple’ in this block.

Line 1312: `projection_lif,` This is continuation line 4 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘projection_lif,‘. The important operands are projection_lif: the value named ’projection lif’ in this block. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named ’attention cache’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named ’tuple’ in this block.

Line 1313: `token_spikes,` This is continuation line 5 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘token_spikes,‘. The important operands are token_spikes: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named ’attention cache’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named ’tuple’ in this block.

Line 1314: `query_lif,` This is continuation line 6 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘query_lif,‘. The important operands are query_lif: the value named ’query lif’ in this block. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named ’attention cache’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named ’tuple’ in this block.

Line 1315: `key_lif,` This is continuation line 7 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘key_lif,‘. The important operands are key_lif: the value named ’key lif’ in this block. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes,

query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1316: `value_lif,` This is continuation line 8 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘value_lif,‘. The important operands are value_lif: the value named 'value lif' in this block. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1317: `query_heads,` This is continuation line 9 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘query_heads,‘. The important operands are query_heads: the value named 'query heads' in this block. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1318: `key_heads,` This is continuation line 10 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘key_heads,‘. The important operands are key_heads: the value named 'key heads' in this block. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1319: `value_heads,` This is continuation line 11 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘value_heads,‘. The important operands are value_heads: the value named 'value heads' in this block. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1320: `scores,` This is continuation line 12 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘scores,‘. The important operands are scores: the value named 'scores' in this block. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1321: `attention_values,` This is continuation line 13 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ‘attention_values,‘. The important operands are attention_values: the value named 'attention values' in this block. Read together, the complete operation is: This returns ‘AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)‘ to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1322: `attention_lif,` This is continuation line 14 of the 17-line logical statement that begins at source line 1309. Its exact fragment is 'attention_lif,'. The important operands are attention_lif: the value named 'attention lif' in this block. Read together, the complete operation is: This returns 'AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)' to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1323: `projection_input,` This is continuation line 15 of the 17-line logical statement that begins at source line 1309. Its exact fragment is 'projection_input,'. The important operands are projection_input: the value named 'projection input' in this block. Read together, the complete operation is: This returns 'AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)' to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1324: `output,` This is continuation line 16 of the 17-line logical statement that begins at source line 1309. Its exact fragment is 'output,'. The important operands are output: the value named 'output' in this block. Read together, the complete operation is: This returns 'AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)' to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1325: `)` This is continuation line 17 of the 17-line logical statement that begins at source line 1309. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'AttentionCache(block_index, tuple(value.shape), projection_lif, token_spikes, query_lif, key_lif, value_lif, query_heads, key_heads, value_heads, scores, attention_values, attention_lif, projection_input, output,)' to the caller of the function _attention_forward, which handles attention forward, ending this invocation. The important operands are AttentionCache: the value named 'attention cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1327: `def _mlp_forward(self, block_index: int, value: np.ndarray) -> MlpCache:` This starts function _mlp_forward. Its indented body performs mlp forward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1328: `timesteps, batch, channels, height, width = value.shape` This assigns 'value.shape' to 'timesteps, batch, channels, height, width ' in host memory. Here timesteps means one discrete SNN update instant. The important operands are value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1329: `tokens = height * width` This assigns 'height * width' to 'tokens ' in host memory. Here tokens means the value named 'tokens' in this block. The important operands are height: the value named 'height' in this block; width: the value named 'width' in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1330: `input_lif = self._lif_trace(value)` This assigns 'self._lif_trace(value)' to 'input_lif ' in host memory. Here input_lif means the value named 'input lif' in this block. The important operands are _lif_trace: the value named 'lif trace' in this block; value: the value named 'value' in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1331: `first_input = input_lif.spikes.reshape(` This statement continues through source line 1333; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'input_lif.spikes.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)' to 'first_input

‘ in host memory. Here first_input means the value named ’first input’ in this block. The important operands are input_lif: the value named ’input lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1332: `timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(` This is continuation line 2 of the 3-line logical statement that begins at source line 1331. Its exact fragment is ‘timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This assigns ‘input_lif.spikes.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)‘ to ‘first_input ‘ in host memory. Here first_input means the value named ’first input’ in this block. The important operands are input_lif: the value named ’input lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1333: `timesteps * batch * tokens, channels)` This is continuation line 3 of the 3-line logical statement that begins at source line 1331. Its exact fragment is ‘timesteps * batch * tokens, channels)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; tokens: the value named ’tokens’ in this block. Read together, the complete operation is: This assigns ‘input_lif.spikes.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)‘ to ‘first_input ‘ in host memory. Here first_input means the value named ’first input’ in this block. The important operands are input_lif: the value named ’input lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1334: `hidden_rows = self.projections.matrix(` This statement continues through source line 1338; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self.projections.matrix(f"block.{block_index}.mlp.fc1", first_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘hidden_rows ‘ in host memory. Here hidden_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1335: `f"block.{block_index}.mlp.fc1",` This is continuation line 2 of the 5-line logical statement that begins at source line 1334. Its exact fragment is ‘f"block.{block_index}.mlp.fc1",‘. The important operands are f: the value named ’f’ in this block; block: the value named ’block’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"block.{block_index}.mlp.fc1", first_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘hidden_rows ‘ in host memory. Here hidden_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1336: `first_input,` This is continuation line 3 of the 5-line logical statement that begins at source line 1334. Its exact fragment is ‘first_input,‘. The important operands are first_input: the value named ’first input’ in this block. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"block.{block_index}.mlp.fc1", first_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘hidden_rows ‘ in host memory. Here hidden_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1337: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 4 of the 5-line logical statement that begins at source line 1334. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"block.{block_index}.mlp.fc1", first_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘hidden_rows ‘ in host memory. Here hidden_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1338: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 1334. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self.projections.matrix(f"block.{block_index}.mlp.fc1", first_input, timeout_seconds=self.layer_timeout_seconds,)' to 'hidden_rows ' in host memory. Here hidden_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named 'projections' in this block; matrix: the value named 'matrix' in this block; f: the value named 'f' in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1339: `hidden_channels = hidden_rows.shape[1]` This assigns 'hidden_rows.shape[1]' to 'hidden_channels ' in host memory. Here hidden_channels means the value named 'hidden channels' in this block. The important operands are hidden_rows: one output-row position processed by the tensor tile; shape: the value named 'shape' in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1340: `hidden = hidden_rows.reshape(` This statement continues through source line 1341; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'hidden_rows.reshape(timesteps, batch, tokens, hidden_channels).transpose(0, 1, 3, 2)' to 'hidden ' in host memory. Here hidden means the value named 'hidden' in this block. The important operands are hidden_rows: one output-row position processed by the tensor tile; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _mlp_forward, which handles mlp forward.

Line 1341: `timesteps, batch, tokens, hidden_channels).transpose(0, 1, 3, 2)` This is continuation line 2 of the 2-line logical statement that begins at source line 1340. Its exact fragment is 'timesteps, batch, tokens, hidden_channels).transpose(0, 1, 3, 2)'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; tokens: the value named 'tokens' in this block. Read together, the complete operation is: This assigns 'hidden_rows.reshape(timesteps, batch, tokens, hidden_channels).transpose(0, 1, 3, 2)' to 'hidden ' in host memory. Here hidden means the value named 'hidden' in this block. The important operands are hidden_rows: one output-row position processed by the tensor tile; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _mlp_forward, which handles mlp forward.

Line 1342: `hidden_lif = self._lif_trace(hidden)` This assigns 'self._lif_trace(hidden)' to 'hidden_lif ' in host memory. Here hidden_lif means the value named 'hidden lif' in this block. The important operands are _lif_trace: the value named 'lif trace' in this block; hidden: the value named 'hidden' in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1343: `second_input = hidden_lif.spikes.transpose(0, 1, 3, 2).reshape(` This statement continues through source line 1344; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'hidden_lif.spikes.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, hidden_channels)' to 'second_input ' in host memory. Here second_input means the value named 'second input' in this block. The important operands are hidden_lif: the value named 'hidden lif' in this block; spikes: a binary event produced when a neuron crosses its threshold; transpose: the value named 'transpose' in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1344: `timesteps * batch * tokens, hidden_channels)` This is continuation line 2 of the 2-line logical statement that begins at source line 1343. Its exact fragment is 'timesteps * batch * tokens, hidden_channels)'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; tokens: the value named 'tokens' in this block. Read together, the complete operation is: This assigns 'hidden_lif.spikes.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, hidden_channels)' to 'second_input ' in host memory. Here second_input means the value named 'second input' in this block. The important operands are hidden_lif: the value named 'hidden lif' in this block; spikes: a binary event produced when a neuron crosses its threshold; transpose: the value named 'transpose' in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1345: `output_rows = self.projections.matrix(` This statement continues through source line 1349; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self.projections.matrix(f"block.{block_index}.mlp.fc2", second_input, timeout_seconds=self.layer_timeout_seconds,)' to 'output_rows ' in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named 'projections' in this block; matrix: the value named 'matrix' in this block; f: the value named 'f' in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1346: `f"block.{block_index}.mlp.fc2",` This is continuation line 2 of the 5-line logical statement that begins at source line 1345. Its exact fragment is ‘f"block.{block_index}.mlp.fc2",‘. The important operands are f: the value named ’f’ in this block; block: the value named ’block’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"block.{block_index}.mlp.fc2", second_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1347: `second_input,` This is continuation line 3 of the 5-line logical statement that begins at source line 1345. Its exact fragment is ‘second_input,‘. The important operands are second_input: the value named ’second input’ in this block. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"block.{block_index}.mlp.fc2", second_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1348: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 4 of the 5-line logical statement that begins at source line 1345. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"block.{block_index}.mlp.fc2", second_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1349: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 1345. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"block.{block_index}.mlp.fc2", second_input, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _mlp_forward, which handles mlp forward.

Line 1350: `output = output_rows.reshape(` This statement continues through source line 1352; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘output_rows.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(timesteps, batch, channels, height, width)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are output_rows: one output-row position processed by the tensor tile; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _mlp_forward, which handles mlp forward.

Line 1351: `timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(` This is continuation line 2 of the 3-line logical statement that begins at source line 1350. Its exact fragment is ‘timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; tokens: the value named ’tokens’ in this block. Read together, the complete operation is: This assigns ‘output_rows.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(timesteps, batch, channels, height, width)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are output_rows: one output-row position processed by the tensor tile; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _mlp_forward, which handles mlp forward.

Line 1352: `timesteps, batch, channels, height, width)` This is continuation line 3 of the 3-line logical statement that begins at source line 1350. Its exact fragment is ‘timesteps, batch, channels, height, width)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This assigns ‘output_rows.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(timesteps, batch, channels, height, width)‘ to ‘output ‘ in host memory.

Here output means the value named 'output' in this block. The important operands are output_rows: one output-row position processed by the tensor tile; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _mlp_forward, which handles mlp forward.

Line 1353: `return MlpCache(` This statement continues through source line 1361; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘MlpCache(block_index, tuple(value.shape), input_lif, first_input, hidden_lif, second_input, output,)‘ to the caller of the function _mlp_forward, which handles mlp forward, ending this invocation. The important operands are MlpCache: the value named 'mlp cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1354: `block_index,` This is continuation line 2 of the 9-line logical statement that begins at source line 1353. Its exact fragment is ‘block_index,‘. The important operands are block_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This returns ‘MlpCache(block_index, tuple(value.shape), input_lif, first_input, hidden_lif, second_input, output,)‘ to the caller of the function _mlp_forward, which handles mlp forward, ending this invocation. The important operands are MlpCache: the value named 'mlp cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1355: `tuple(value.shape),` This is continuation line 3 of the 9-line logical statement that begins at source line 1353. Its exact fragment is ‘tuple(value.shape),‘. The important operands are tuple: the value named 'tuple' in this block; value: the value named 'value' in this block; shape: the value named 'shape' in this block. Read together, the complete operation is: This returns ‘MlpCache(block_index, tuple(value.shape), input_lif, first_input, hidden_lif, second_input, output,)‘ to the caller of the function _mlp_forward, which handles mlp forward, ending this invocation. The important operands are MlpCache: the value named 'mlp cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1356: `input_lif,` This is continuation line 4 of the 9-line logical statement that begins at source line 1353. Its exact fragment is ‘input_lif,‘. The important operands are input_lif: the value named 'input lif' in this block. Read together, the complete operation is: This returns ‘MlpCache(block_index, tuple(value.shape), input_lif, first_input, hidden_lif, second_input, output,)‘ to the caller of the function _mlp_forward, which handles mlp forward, ending this invocation. The important operands are MlpCache: the value named 'mlp cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1357: `first_input,` This is continuation line 5 of the 9-line logical statement that begins at source line 1353. Its exact fragment is ‘first_input,‘. The important operands are first_input: the value named 'first input' in this block. Read together, the complete operation is: This returns ‘MlpCache(block_index, tuple(value.shape), input_lif, first_input, hidden_lif, second_input, output,)‘ to the caller of the function _mlp_forward, which handles mlp forward, ending this invocation. The important operands are MlpCache: the value named 'mlp cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1358: `hidden_lif,` This is continuation line 6 of the 9-line logical statement that begins at source line 1353. Its exact fragment is ‘hidden_lif,‘. The important operands are hidden_lif: the value named 'hidden lif' in this block. Read together, the complete operation is: This returns ‘MlpCache(block_index, tuple(value.shape), input_lif, first_input, hidden_lif, second_input, output,)‘ to the caller of the function _mlp_forward, which handles mlp forward, ending this invocation. The important operands are MlpCache: the value named 'mlp cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1359: `second_input,` This is continuation line 7 of the 9-line logical statement that begins at source line 1353. Its exact fragment is ‘second_input,‘. The important operands are second_input: the value named 'second input' in this block. Read together, the complete operation is: This returns ‘MlpCache(block_index, tuple(value.shape), input_lif, first_input, hidden_lif, second_input, output,)‘ to the caller of the function _mlp_forward, which handles mlp forward, ending this invocation. The important operands are MlpCache: the value named 'mlp cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1360: `output,` This is continuation line 8 of the 9-line logical statement that begins at source line 1353. Its exact fragment is 'output,'. The important operands are output: the value named 'output' in this block. Read together, the complete operation is: This returns 'MlpCache(block_index, tuple(value.shape), input_lif, first_input, hidden_lif, second_input, output,)' to the caller of the function _mlp_forward, which handles mlp forward, ending this invocation. The important operands are MlpCache: the value named 'mlp cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1361: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 1353. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'MlpCache(block_index, tuple(value.shape), input_lif, first_input, hidden_lif, second_input, output,)' to the caller of the function _mlp_forward, which handles mlp forward, ending this invocation. The important operands are MlpCache: the value named 'mlp cache' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; tuple: the value named 'tuple' in this block.

Line 1363: `def forward(self, normalized_image) -> SpikingformerTrainingCache:` This starts function forward. Its indented body performs forward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1364: `"""Run the full graph and retain every state required by reverse mode."""` This is executable documentation attached to the function forward, which handles forward. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1366: `image = np.asarray(normalized_image, dtype=np.float32)` This assigns 'np.asarray(normalized_image, dtype=np.float32)' to 'image ' in host memory. Here image means the value named 'image' in this block. The important operands are asarray: the value named 'asarray' in this block; normalized_image: the value named 'normalized image' in this block; dtype: the value named 'dtype' in this block. Context: the function forward, which handles forward.

Line 1367: `if image.ndim != 4 or tuple(image.shape[1:]) != self.input_shape or image.shape[0] == 0:` This executes the following indented host-code branch only when 'image.ndim != 4 or tuple(image.shape[1:]) != self.input_shape or image.shape[0] == 0' is true. The important operands are image: the value named 'image' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function forward, which handles forward.

Line 1368: `raise ValueError(f"input must have shape [batch,{','.join(map(str, self.input_shape))}]")` This rejects an invalid state by raising 'ValueError(f"input must have shape [batch,{','.join(map(str, self.input_shape))}]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1369: `image_u8 = np.rint(image / self.image_scale + self.image_zero_point)` This assigns 'np.rint(image / self.image_scale + self.image_zero_point)' to 'image_u8 ' in host memory. Here image_u8 means the value named 'image u8' in this block. The important operands are rint: the value named 'rint' in this block; image: the value named 'image' in this block; image_scale: the real-value spacing represented by one quantized integer step. Context: the function forward, which handles forward.

Line 1370: `image_u8 = np.clip(image_u8, 0, 255).astype(np.uint8)` This assigns 'np.clip(image_u8, 0, 255).astype(np.ui to 'image_u8 ' in host memory. Here image_u8 means the value named 'image u8' in this block. The important operands are clip: the value named 'clip' in this block; image_u8: the value named 'image u8' in this block; astype: the value named 'astype' in this block. Context: the function forward, which handles forward.

Line 1371: `image_centered = image_u8.astype(np.int64) - self.image_zero_point` This assigns 'image_u8.astype(np.in - self.image_zero_point' to 'image_centered ' in host memory. Here image_centered means the value named 'image centered' in this block. The important operands are image_u8: the value named 'image u8' in this block; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Context: the function forward, which handles forward.

Line 1372: `self.driver.execute_program(` This statement continues through source line 1375; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.driver.execute_program‘ with ‘ (ProgramRecord(clear_status_command()),), timeout_seconds=self.layer_timeout_seconds, ‘ inside the function forward, which handles forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1373: `(ProgramRecord(clear_status_command()),),` This is continuation line 2 of the 4-line logical statement that begins at source line 1372. Its exact fragment is ‘(ProgramRecord(clear_status_command()),),‘. The important operands are ProgramRecord: the value named ’program record’ in this block; clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘self.driver.execute_program‘ with ‘ (ProgramRecord(clear_status_command()),), timeout_seconds=self.layer_timeout_seconds, ‘ inside the function forward, which handles forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1374: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 3 of the 4-line logical statement that begins at source line 1372. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This calls ‘self.driver.execute_program‘ with ‘ (ProgramRecord(clear_status_command()),), timeout_seconds=self.layer_timeout_seconds, ‘ inside the function forward, which handles forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1375: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1372. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘self.driver.execute_program‘ with ‘ (ProgramRecord(clear_status_command()),), timeout_seconds=self.layer_timeout_seconds, ‘ inside the function forward, which handles forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1376: `value, tokenizer = self._tokenizer_forward(image_u8, image_centered)` This assigns ‘self._tokenizer_forw image_centered)‘ to ‘value, tokenizer ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are _tokenizer_forward: the value named ’tokenizer forward’ in this block; image_u8: the value named ’image u8’ in this block; image_centered: the value named ’image centered’ in this block. Context: the function forward, which handles forward.

Line 1377: `block_caches: list[TransformerBlockCache] = []` This assigns ‘[]‘ to ‘block_caches‘ in host memory. Here block_caches means the value named ’block caches’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function forward, which handles forward.

Line 1378: `for block_index in range(self.transformer_blocks):` This iterates block_index over ‘range(self.transformer_b Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function forward, which handles forward.

Line 1379: `block_input = value` This assigns ‘value‘ to ‘block_input ‘ in host memory. Here block_input means the value named ’block input’ in this block. The important operands are value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 1380: `attention = self._attention_forward(block_index, block_input)` This assigns ‘self._attention_forward(bloc block_input)‘ to ‘attention ‘ in host memory. Here attention means the value named ’attention’ in this block. The important operands are _attention_forward: the value named ’attention forward’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; block_input: the value named ’block input’ in this block. Context: the function forward, which handles forward.

Line 1381: `after_attention = execute_vector_tensor(` This statement continues through source line 1387; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, block_input, attention.output, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘after_attention ‘ in host memory. Here after_attention means the value named ’after attention’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1382: `self.driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1381. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, block_input, attention.output, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘after_attention ‘ in host memory. Here after_attention means the value named ’after attention’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1383: `VectorOperation.ADD_SAT,` This is continuation line 3 of the 7-line logical statement that begins at source line 1381. Its exact fragment is ‘VectorOperation.ADD_SAT,‘. The important operands are VectorOperation: the value named ’vector operation’ in this block; ADD_SAT: the value named ’add sat’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, block_input, attention.output, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘after_attention ‘ in host memory. Here after_attention means the value named ’after attention’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1384: `block_input,` This is continuation line 4 of the 7-line logical statement that begins at source line 1381. Its exact fragment is ‘block_input,‘. The important operands are block_input: the value named ’block input’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, block_input, attention.output, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘after_attention ‘ in host memory. Here after_attention means the value named ’after attention’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1385: `attention.output,` This is continuation line 5 of the 7-line logical statement that begins at source line 1381. Its exact fragment is ‘attention.output,‘. The important operands are attention: the value named ’attention’ in this block; output: the value named ’output’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, block_input, attention.output, timeout_seconds=self.layer_timeout_)‘ to ‘after_attention ‘ in host memory. Here after_attention means the value named ’after attention’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1386: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1381. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, block_input, attention.output, timeout_seconds=self.layer_timeout_)‘ to ‘after_attention ‘ in host memory. Here after_attention means the value named ’after attention’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1387: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1381. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete op-

eration is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, block_input, attention.output, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘after_attention ‘ in host memory. Here after_attention means the value named ’after attention’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1388: `mlp = self._mlp_forward(block_index, after_attention)` This assigns ‘self._mlp_forward(block_index, after_attention)‘ to ‘mlp ‘ in host memory. Here mlp means the value named ’mlp’ in this block. The important operands are _mlp_forward: the value named ’mlp forward’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; after_attention: the value named ’after attention’ in this block. Context: the function forward, which handles forward.

Line 1389: `value = execute_vector_tensor(` This statement continues through source line 1395; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, after_attention, mlp.output, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1390: `self.driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1389. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, after_attention, mlp.output, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1391: `VectorOperation.ADD_SAT,` This is continuation line 3 of the 7-line logical statement that begins at source line 1389. Its exact fragment is ‘VectorOperation.ADD_SAT,‘. The important operands are VectorOperation: the value named ’vector operation’ in this block; ADD_SAT: the value named ’add sat’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, after_attention, mlp.output, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1392: `after_attention,` This is continuation line 4 of the 7-line logical statement that begins at source line 1389. Its exact fragment is ‘after_attention,‘. The important operands are after_attention: the value named ’after attention’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, after_attention, mlp.output, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1393: `mlp.output,` This is continuation line 5 of the 7-line logical statement that begins at source line 1389. Its exact fragment is ‘mlp.output,‘. The important operands are mlp: the value named ’mlp’ in this block; output: the value named ’output’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, after_attention, mlp.output, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function forward, which handles forward.

Line 1394: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1389. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The

important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, after_attention, mlp.output, timeout_seconds=self.layer_timeout_s)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function forward, which handles forward.

Line 1395: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1389. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.ADD_SAT, after_attention, mlp.output, timeout_seconds=self.layer_timeout_seconds,)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function forward, which handles forward.

Line 1396: `block_caches.append(TransformerBlockCache(` This statement continues through source line 1397; the explanation uses the complete expression rather than only the first visual fragment. This calls 'block_caches.append' with 'TransformerBlockCache(block_input, attention, after_attention, mlp, value)' inside the function forward, which handles forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1397: `block_input, attention, after_attention, mlp, value))` This is continuation line 2 of the 2-line logical statement that begins at source line 1396. Its exact fragment is 'block_input, attention, after_attention, mlp, value))'. The important operands are block_input: the value named 'block input' in this block; attention: the value named 'attention' in this block; after_attention: the value named 'after attention' in this block. Read together, the complete operation is: This calls 'block_caches.append' with 'TransformerBlockCache(block_input, attention, after_attention, mlp, value)' inside the function forward, which handles forward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1399: `pooled_sum = self._global_sum(value.astype(np.int64))` This assigns 'self._global_sum(value.astype(np.int6 to 'pooled_sum ' in host memory. Here pooled_sum means the value named 'pooled sum' in this block. The important operands are _global_sum: the value named 'global sum' in this block; value: the value named 'value' in this block; astype: the value named 'astype' in this block. Context: the function forward, which handles forward.

Line 1400: `divisor = value.shape[0] * value.shape[3] * value.shape[4]` This assigns 'value.shape[0] * value.shape[3] * value.shape[4]' to 'divisor ' in host memory. Here divisor means the value named 'divisor' in this block. The important operands are value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function forward, which handles forward.

Line 1401: `denominator = divisor * self.fixed_scale * self.head_activation_scale` This assigns 'divisor * self.fixed_scale * self.head_activation_scale' to 'denominator ' in host memory. Here denominator means the value named 'denominator' in this block. The important operands are divisor: the value named 'divisor' in this block; fixed_scale: the real-value spacing represented by one quantized integer step; head_activation_scale: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function forward, which handles forward.

Line 1402: `rounded_denominator = int(round(denominator))` This assigns 'int(round(denominator))' to 'rounded_denomina ' in host memory. Here rounded_denominator means the value named 'rounded denominator' in this block. The important operands are round: the value named 'round' in this block; denominator: the value named 'denominator' in this block. Context: the function forward, which handles forward.

Line 1403: `if not math.isclose(denominator, rounded_denominator, rel_tol=0.0, abs_tol=1e-9):` This executes the following indented host-code branch only when 'not math.isclose(denominator, rounded_denominator, rel_tol=0.0, abs_tol=1e-9)' is true. The important operands are not: the value named 'not' in this block; math: the value named 'math' in this block; isclose: the value named 'isclose' in this block. Context: the function forward, which handles forward.

Line 1404: `raise ValueError("head pooling denominator is not an exact integer")` This rejects an invalid state by raising ‘ValueError("head pooling denominator is not an exact integer")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1405: `if rounded_denominator <= 0 or rounded_denominator & (rounded_denominator - 1):` This executes the following indented host-code branch only when ‘rounded_denominator <= 0 or rounded_denominator & (rounded_denominator - 1)‘ is true. The important operands are rounded_denominator: the value named ’rounded denominator’ in this block; or: the value named ’or’ in this block. Context: the function forward, which handles forward.

Line 1406: `raise ValueError("head pooling denominator must be a positive power of two")` This rejects an invalid state by raising ‘ValueError("head pooling denominator must be a positive power of two")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1407: `head_preclip = execute_power_of_two_scale(` This statement continues through source line 1412; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_power_of_two_scale(self.driver, pooled_sum, -(rounded_denominator.bit_length() - 1), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_preclip ‘ in host memory. Here head_preclip means the value named ’head preclip’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; pooled_sum: the value named ’pooled sum’ in this block. Context: the function forward, which handles forward.

Line 1408: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1407. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(self.driver, pooled_sum, -(rounded_denominator.bit_length() - 1), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_preclip ‘ in host memory. Here head_preclip means the value named ’head preclip’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; pooled_sum: the value named ’pooled sum’ in this block. Context: the function forward, which handles forward.

Line 1409: `pooled_sum,` This is continuation line 3 of the 6-line logical statement that begins at source line 1407. Its exact fragment is ‘pooled_sum,‘. The important operands are pooled_sum: the value named ’pooled sum’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(self.driver, pooled_sum, -(rounded_denominator.bit_length() - 1), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_preclip ‘ in host memory. Here head_preclip means the value named ’head preclip’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; pooled_sum: the value named ’pooled sum’ in this block. Context: the function forward, which handles forward.

Line 1410: `-(rounded_denominator.bit_length() - 1),` This is continuation line 4 of the 6-line logical statement that begins at source line 1407. Its exact fragment is ‘-(rounded_denominator.bit_length() - 1),‘. The important operands are rounded_denominator: the value named ’rounded denominator’ in this block; bit_length: the value named ’bit length’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(self.driver, pooled_sum, -(rounded_denominator.bit_length() - 1), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_preclip ‘ in host memory. Here head_preclip means the value named ’head preclip’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; pooled_sum: the value named ’pooled sum’ in this block. Context: the function forward, which handles forward.

Line 1411: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1407. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(self.driver, pooled_sum, -(rounded_denominator.bit_length() - 1), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_preclip ‘ in host memory. Here head_preclip means the value named ’head preclip’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step;

driver: the value named 'driver' in this block; pooled_sum: the value named 'pooled sum' in this block. Context: the function forward, which handles forward.

Line 1412: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1407. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_power_of_two_scale(self.driver, pooled_sum, -(rounded_denominator.bit_length() - 1), timeout_seconds=self.layer_timeout_seconds,)' to 'head_preclip ' in host memory. Here head_preclip means the value named 'head preclip' in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named 'driver' in this block; pooled_sum: the value named 'pooled sum' in this block. Context: the function forward, which handles forward.

Line 1413: `head_input = execute_vector_tensor(` This statement continues through source line 1420; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_vector_tensor(self.driver, VectorOperation.CLAMP, head_preclip, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_t)' to 'head_input ' in host memory. Here head_input means the value named 'head input' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function forward, which handles forward.

Line 1414: `self.driver,` This is continuation line 2 of the 8-line logical statement that begins at source line 1413. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.CLAMP, head_preclip, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_timeout_seconds,)' to 'head_input ' in host memory. Here head_input means the value named 'head input' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function forward, which handles forward.

Line 1415: `VectorOperation.CLAMP,` This is continuation line 3 of the 8-line logical statement that begins at source line 1413. Its exact fragment is 'VectorOperation.CLAMP,'. The important operands are VectorOperation: the value named 'vector operation' in this block; CLAMP: the value named 'clamp' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.CLAMP, head_preclip, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_timeout_seconds,)' to 'head_input ' in host memory. Here head_input means the value named 'head input' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function forward, which handles forward.

Line 1416: `head_preclip,` This is continuation line 4 of the 8-line logical statement that begins at source line 1413. Its exact fragment is 'head_preclip,'. Context: the function forward, which handles forward.

Line 1429: `logits_accumulator = head_program.execute_batched(` This statement continues through source line 1430; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘head_program.execute_b self.driver, timeout_seconds=self.layer_timeout_seconds)‘ to ‘logits_accumulator ‘ in host memory. Here logits_accumulator means a widened running sum that prevents intermediate overflow. The important operands are head_program: the value named ’head program’ in this block; execute_batched: the value named ’execute batched’ in this block; driver: the value named ’driver’ in this block. Context: the function forward, which handles forward.

Line 1430: `self.driver, timeout_seconds=self.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 1429. Its exact fragment is ‘self.driver, timeout_seconds=self.layer_timeout_seconds)‘. The important operands are driver: the value named ’driver’ in this block; timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘head_program.execute_batched(self.driver, timeout_seconds=self.layer_timeout_seconds)‘

to ‘logits_accumulator ‘ in host memory. Here logits_accumulator means a widened running sum that prevents intermediate overflow. The important operands are head_program: the value named ’head program’ in this block; execute_batched: the value named ’execute batched’ in this block; driver: the value named ’driver’ in this block. Context: the function forward, which handles forward.

Line 1431: `accumulator_scale = float(self.state.manifest["head"]["accumulator_scale"])` This assigns ‘float(self.sta
to ‘accumulator_scale ‘ in host memory. Here accumulator_scale means a widened running sum that prevents intermediate overflow. The important operands are float: the value named ’float’ in this block; state: the finite-state-machine phase retained in flip-flops; manifest: the value named ’manifest’ in this block. Context: the function forward, which handles forward.

Line 1432: `logits = logits_accumulator.astype(np.float64) * accumulator_scale` This assigns ‘logits_accumulator.asty
* accumulator_scale‘ to ‘logits ‘ in host memory. Here logits means the ten unnormalized classifier scores used for argmax. The important operands are logits_accumulator: a widened running sum that prevents intermediate overflow; astype: the value named ’astype’ in this block; float64: the value named ’float64’ in this block. Context: the function forward, which handles forward.

Line 1433: `return SpikingformerTrainingCache(` This statement continues through source line 1444; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1434: `image,` This is continuation line 2 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘image,‘. The important operands are image: the value named ’image’ in this block. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1435: `image_u8,` This is continuation line 3 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘image_u8,‘. The important operands are image_u8: the value named ’image u8’ in this block. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1436: `image_centered,` This is continuation line 4 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘image_centered,‘. The important operands are image_centered: the value named ’image centered’ in this block. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1437: `tokenizer,` This is continuation line 5 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘tokenizer,‘. The important operands are tokenizer: the value named ’tokenizer’ in this block. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1438: `tuple(block_caches),` This is continuation line 6 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘tuple(block_caches),‘. The important operands are tuple: the value named ’tuple’ in this block; block_caches: the value named ’block caches’ in this block. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1439: `value,` This is continuation line 7 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘value,‘. The important operands are value: the value named ’value’ in this block. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1440: `head_preclip,` This is continuation line 8 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘head_preclip,‘. The important operands are head_preclip: the value named ’head preclip’ in this block. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1441: `head_input,` This is continuation line 9 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘head_input,‘. The important operands are head_input: the value named ’head input’ in this block. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1442: `logits_accumulator,` This is continuation line 10 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘logits_accumulator,‘. The important operands are logits_accumulator: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1443: `logits,` This is continuation line 11 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘logits,‘. The important operands are logits: the ten unnormalized classifier scores used for argmax. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1444: `)` This is continuation line 12 of the 12-line logical statement that begins at source line 1433. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘SpikingformerTrainingCache(image, image_u8, image_centered, tokenizer, tuple(block_caches), value, head_preclip, head_input, logits_accumulator, logits,)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are SpikingformerTrainingCache: the value named ’spikingformer training cache’ in this block; image: the value named ’image’ in this block; image_u8: the value named ’image u8’ in this block.

Line 1446: `def _lif_backward(` This starts function _lif_backward. Its indented body performs lif backward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1447: `self, cache: LifTraceCache, output_gradient: BlockGradient` Inside the function _lif_backward, which handles lif backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are cache: the value named 'cache' in this block; LifTraceCache: the value named 'lif trace cache' in this block; output_gradient: the signed loss derivative used to update a learned parameter.

Line 1448: `) -> BlockGradient:` Inside the function _lif_backward, which handles lif backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1449: `if output_gradient.values.shape != cache.spikes.shape:` This executes the following indented host-code branch only when 'output_gradient.values.shape != cache.spikes.shape' is true. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block; shape: the value named 'shape' in this block. Context: the function _lif_backward, which handles lif backward.

Line 1450: `raise ValueError("LIF output gradient does not match its forward trace")` This rejects an invalid state by raising 'ValueError("LIF output gradient does not match its forward trace")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1451: `timesteps = cache.spikes.shape[0]` This assigns 'cache.spikes.shape[0]' to 'timesteps ' in host memory. Here timesteps means one discrete SNN update instant. The important operands are cache: the value named 'cache' in this block; spikes: a binary event produced when a neuron crosses its threshold; shape: the value named 'shape' in this block. Context: the function _lif_backward, which handles lif backward.

Line 1452: `membrane = cache.pre_reset_membrane.reshape(timesteps, -1)` This assigns 'cache.pre_reset_membrane.resha -1)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are cache: the value named 'cache' in this block; pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; reshape: the value named 'reshape' in this block. Context: the function _lif_backward, which handles lif backward.

Line 1453: `spikes = cache.spikes.reshape(timesteps, -1)` This assigns 'cache.spikes.reshape(timesteps, -1)' to 'spikes ' in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are cache: the value named 'cache' in this block; spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named 'reshape' in this block. Context: the function _lif_backward, which handles lif backward.

Line 1454: `gradient = output_gradient.values.reshape(timesteps, -1)` This assigns 'output_gradient.values.reshape(tim -1)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block; reshape: the value named 'reshape' in this block. Context: the function _lif_backward, which handles lif backward.

Line 1455: `input_gradient, _ = execute_lif_bptt(` This statement continues through source line 1465; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.frac - 5, 0), load_surrogate_table=not self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1456: `self.driver,` This is continuation line 2 of the 11-line logical statement that begins at source line 1455. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.fractional_bits - 5, 0), load_surrogate_table=not self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1457: `membrane,` This is continuation line 3 of the 11-line logical statement that begins at source line 1455. Its exact fragment is 'membrane,'. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.fractional_bits - 5, 0), load_surrogate_table=not self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1458: `spikes,` This is continuation line 4 of the 11-line logical statement that begins at source line 1455. Its exact fragment is 'spikes,'. The important operands are spikes: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.fractional_bits - 5, 0), load_surrogate_table=not self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1459: `gradient,` This is continuation line 5 of the 11-line logical statement that begins at source line 1455. Its exact fragment is 'gradient,'. The important operands are gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.fractional_bits - 5, 0), load_surrogate_table=not self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1460: `threshold=cache.threshold_q10,` This is continuation line 6 of the 11-line logical statement that begins at source line 1455. Its exact fragment is 'threshold=cache.threshold_q10,'. The important operands are threshold: the membrane level at which a neuron emits a spike; cache: the value named 'cache' in this block; threshold_q10: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.fractional_bits - 5, 0), load_surrogate_table=not self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1461: `reciprocal_tau_q15=1 << 14,` This is continuation line 7 of the 11-line logical statement that begins at source line 1455. Its exact fragment is 'reciprocal_tau_q15=1 << 14,'. The important operands are reciprocal_tau_q15: the value named 'reciprocal tau q15' in this block. Read together, the complete operation is: This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.fractional_bits - 5, 0), load_surrogate_table=not self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means

the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1462: `surrogate_address_shift=max(self.fractional_bits - 5, 0),` This is continuation line 8 of the 11-line logical statement that begins at source line 1455. Its exact fragment is 'surrogate_address_shift=max(self.fractional_bits - 5, 0),'. The important operands are surrogate_address_shift: the value named 'surrogate address shift' in this block; max: the value named 'max' in this block; fractional_bits: the value named 'fractional bits' in this block. Read together, the complete operation is: This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.fractional_bits - 5, 0), load_surrogate_table=not self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1463: `load_surrogate_table=not self._surrogate_lut_loaded,` This is continuation line 9 of the 11-line logical statement that begins at source line 1455. Its exact fragment is 'load_surrogate_table=not self._surrogate_lut_loaded,'. The important operands are load_surrogate_table: the value named 'load surrogate table' in this block; not: the value named 'not' in this block; _surrogate_lut_loaded: the value named 'surrogate lut loaded' in this block. Read together, the complete operation is: This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.fractional_bits - 5, 0), load_surrogate self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1464: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 10 of the 11-line logical statement that begins at source line 1455. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.fractional_bits - 5, 0), load_surrogate_table=not self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1465: `)` This is continuation line 11 of the 11-line logical statement that begins at source line 1455. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_lif_bptt(self.driver, membrane, spikes, gradient, threshold=cache.threshold_q10, reciprocal_tau_q15=1 << 14, surrogate_address_shift=max(self.fractional_bits - 5, 0), load_surrogate_table=not self._surrogate_lut_loaded, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, _ ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block; driver: the value named 'driver' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function _lif_backward, which handles lif backward.

Line 1466: `self._surrogate_lut_loaded = True` This assigns 'True' to 'self._surrogate_lut_loaded ' in host memory. Here _surrogate_lut_loaded means the value named 'surrogate lut loaded' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _lif_backward, which handles lif backward.

Line 1467: `return BlockGradient(` This statement continues through source line 1468; the explanation uses the complete expression rather than only the first visual fragment. This returns 'BlockGradient(input_gradient.reshape(cache.input_q10.sh

output_gradient.exponent)‘ to the caller of the function _lif_backward, which handles lif backward, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; input_gradient: the signed loss derivative used to update a learned parameter; reshape: the value named ’reshape’ in this block.

Line 1468: `input_gradient.reshape(cache.input_q10.shape), output_gradient.exponent)` This is continuation line 2 of the 2-line logical statement that begins at source line 1467. Its exact fragment is ‘input_gradient.reshape(cache.input_q
output_gradient.exponent)‘. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; reshape: the value named ’reshape’ in this block; cache: the value named ’cache’ in this block. Read together, the complete operation is: This returns ‘BlockGradient(input_gradient.reshape(cache.input_q10.shape), output_gradient.exponent)‘ to the caller of the function _lif_backward, which handles lif backward, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; input_gradient: the signed loss derivative used to update a learned parameter; reshape: the value named ’reshape’ in this block.

Line 1470: `def _bias_gradient(self, output_gradient: BlockGradient) -> BlockGradient:` This starts function _bias_gradient. Its indented body performs bias gradient as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1471: `if output_gradient.values.ndim != 2:` This executes the following indented host-code branch only when ‘output_gradient.values.ndim != 2‘ is true. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; ndim: the value named ’ndim’ in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1472: `raise ValueError("bias reduction expects a [rows,channels] gradient")` This rejects an invalid state by raising ‘ValueError("bias reduction expects a [rows,channels] gradient")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1473: `rows, channels = output_gradient.values.shape` This assigns ‘output_gradient.values.shape‘ to ‘rows, channels ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1474: `ones = np.ones((rows, 1), dtype=np.int64)` This assigns ‘np.ones((rows, 1), dtype=np.int64)‘ to ‘ones ‘ in host memory. Here ones means the value named ’ones’ in this block. The important operands are ones: the value named ’ones’ in this block; rows: one output-row position processed by the tensor tile; dtype: the value named ’dtype’ in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1475: `zeros = np.zeros((1, channels), dtype=np.int64)` This assigns ‘np.zeros((1, channels), dtype=np.int64)‘ to ‘zeros ‘ in host memory. Here zeros means the value named ’zeros’ in this block. The important operands are zeros: the value named ’zeros’ in this block; channels: the value named ’channels’ in this block; dtype: the value named ’dtype’ in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1476: `_, gradient = execute_linear_backward_block(` This statement continues through source line 1482; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_linear_backward_bloc
self.driver, ones, zeros, output_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘_, gradient ‘ in host memory. Here _ means the value named ” in this block. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; ones: the value named ’ones’ in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1477: `self.driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1476. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, ones, zeros, output_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘_, gradient ‘ in host memory. Here _ means the value named ”

in this block. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; ones: the value named 'ones' in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1478: `ones,` This is continuation line 3 of the 7-line logical statement that begins at source line 1476. Its exact fragment is 'ones,'. The important operands are ones: the value named 'ones' in this block. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, ones, zeros, output_gradient, timeout_seconds=self.layer_timeout_seconds,)' to '_, gradient ' in host memory. Here _ means the value named '' in this block. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; ones: the value named 'ones' in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1479: `zeros,` This is continuation line 4 of the 7-line logical statement that begins at source line 1476. Its exact fragment is 'zeros,'. The important operands are zeros: the value named 'zeros' in this block. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, ones, zeros, output_gradient, timeout_seconds=self.layer_timeout_seconds,)' to '_, gradient ' in host memory. Here _ means the value named '' in this block. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; ones: the value named 'ones' in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1480: `output_gradient,` This is continuation line 5 of the 7-line logical statement that begins at source line 1476. Its exact fragment is 'output_gradient,'. The important operands are output_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, ones, zeros, output_gradient, timeout_seconds=self.layer_timeout_seconds,)' to '_, gradient ' in host memory. Here _ means the value named '' in this block. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; ones: the value named 'ones' in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1481: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1476. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, ones, zeros, output_gradient, timeout_seconds=self.layer_timeout_seconds,)' to '_, gradient ' in host memory. Here _ means the value named '' in this block. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; ones: the value named 'ones' in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1482: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1476. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, ones, zeros, output_gradient, timeout_seconds=self.layer_timeout_seconds,)' to '_, gradient ' in host memory. Here _ means the value named '' in this block. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; ones: the value named 'ones' in this block. Context: the function _bias_gradient, which handles bias gradient.

Line 1483: `return BlockGradient(gradient.values.reshape(channels), gradient.exponent)` This returns 'BlockGradient(gradient.values.reshape(channels), gradient.exponent)' to the caller of the function _bias_gradient, which handles bias gradient, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block.

Line 1485: `def _projection_matrix_backward(` This starts function _projection_matrix_backward. Its indented body performs projection matrix backward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1486: `self,` Inside the function _projection_matrix_backward, which handles projection matrix backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1487: `name: str,` Inside the function _projection_matrix_backward, which handles projection matrix backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are name: the value named 'name' in this block; str: the value named 'str' in this block.

Line 1488: `activations: np.ndarray,` Inside the function _projection_matrix_backward, which handles projection matrix backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named 'ndarray' in this block.

Line 1489: `output_gradient: BlockGradient,` Inside the function _projection_matrix_backward, which handles projection matrix backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1490: `) -> tuple[BlockGradient, ParameterGradient]:` Inside the function _projection_matrix_backward, which handles projection matrix backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named 'tuple' in this block; BlockGradient: the signed loss derivative used to update a learned parameter; ParameterGradient: the signed loss derivative used to update a learned parameter.

Line 1491: `parameters = self.state.projection(name)` This assigns ‘self.state.projection(name)‘ to ‘parameters ‘ in host memory. Here parameters means the value named 'parameters' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; projection: the value named 'projection' in this block; name: the value named 'name' in this block. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1492: `scaled_gradient = backward_requantize_projection(` This statement continues through source line 1497; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘backward_requantize_projection(self.driver, output_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘scaled_gradient ‘ in host memory. Here scaled_gradient means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1493: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1492. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns ‘backward_requantize_projection(self.driver, output_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘scaled_gradient ‘ in host memory. Here scaled_gradient means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1494: `output_gradient,` This is continuation line 3 of the 6-line logical statement that begins at source line 1492. Its exact fragment is ‘output_gradient,‘. The important operands are output_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘backward_requantize_projection(self.driver, output_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘scaled_gradient ‘ in host

memory. Here scaled_gradient means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1495: `parameters,` This is continuation line 4 of the 6-line logical statement that begins at source line 1492. Its exact fragment is 'parameters,'. The important operands are parameters: the value named 'parameters' in this block. Read together, the complete operation is: This assigns 'backward_requantize_projection(self.driver, output_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)' to 'scaled_gradient ' in host memory. Here scaled_gradient means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1496: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1492. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'backward_requantize_projection(self.driver, output_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)' to 'scaled_gradient ' in host memory. Here scaled_gradient means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1497: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1492. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'backward_requantize_projection(self.driver, output_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)' to 'scaled_gradient ' in host memory. Here scaled_gradient means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1498: `input_gradient, weight_gradient = execute_linear_backward_block(` This statement continues through source line 1504; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_linear_backward_block(self.driver, activations, parameters.weight_k_by_n, scaled_gradient, timeout_seconds=self.layer_t)' to 'input_gradient, weight_gradient ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1499: `self.driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1498. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, activations, parameters.weight_k_by_n, scaled_gradient, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, weight_gradient ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1500: `activations,` This is continuation line 3 of the 7-line logical statement that begins at source line 1498. Its exact fragment is 'activations,'. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, activations, parameters.weight_k_by_n, scaled_gradient, timeout_seconds=self.layer_timeout_seconds,)'

to ‘input_gradient, weight_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1501: `parameters.weight_k_by_n,` This is continuation line 4 of the 7-line logical statement that begins at source line 1498. Its exact fragment is ‘parameters.weight_k_by_n,‘. The important operands are parameters: the value named ’parameters’ in this block; weight_k_by_n: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, activations, parameters.weight_k_by_n, scaled_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘input_gradient, weight_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1502: `scaled_gradient,` This is continuation line 5 of the 7-line logical statement that begins at source line 1498. Its exact fragment is ‘scaled_gradient,‘. The important operands are scaled_gradient: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, activations, parameters.weight_k_by_n, scaled_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘input_gradient, weight_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1503: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1498. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, activations, parameters.weight_k_by_n, scaled_gradient, timeout_seconds=self.layer_t)‘ to ‘input_gradient, weight_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1504: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1498. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, activations, parameters.weight_k_by_n, scaled_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘input_gradient, weight_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1505: `bias_gradient = self._bias_gradient(output_gradient)` This assigns ‘self._bias_gradient(output_gradient)‘ to ‘bias_gradient ‘ in host memory. Here bias_gradient means an additive learned offset applied after accumulation. The important operands are _bias_gradient: an additive learned offset applied after accumulation; output_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_matrix_backward, which handles projection matrix backward.

Line 1506: `return input_gradient, ParameterGradient(weight_gradient, bias_gradient)` This returns ‘input_gradient, ParameterGradient(weight_gradient, bias_gradient)‘ to the caller of the function _projection_matrix_backward, which handles projection matrix backward, ending this invocation. The important operands are input_gradient: the

signed loss derivative used to update a learned parameter; ParameterGradient: the signed loss derivative used to update a learned parameter; weight_gradient: a learned coefficient multiplied by an activation.

Line 1508: `def _projection_conv2d_backward(` This starts function _projection_conv2d_backward. Its indented body performs projection conv2d backward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1509: `self,` Inside the function _projection_conv2d_backward, which handles projection conv2d backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1510: `name: str,` Inside the function _projection_conv2d_backward, which handles projection conv2d backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are name: the value named 'name' in this block; str: the value named 'str' in this block.

Line 1511: `activations: np.ndarray,` Inside the function _projection_conv2d_backward, which handles projection conv2d backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named 'ndarray' in this block.

Line 1512: `output_gradient: BlockGradient,` Inside the function _projection_conv2d_backward, which handles projection conv2d backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1513: `*,` Inside the function _projection_conv2d_backward, which handles projection conv2d backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1514: `stride=1,` This assigns ‘1,‘ to ‘stride‘ in host memory. Here stride means the value named 'stride' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1515: `padding=0,` This assigns ‘0,‘ to ‘padding‘ in host memory. Here padding means the value named 'padding' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1516: `dilation=1,` This assigns ‘1,‘ to ‘dilation‘ in host memory. Here dilation means the value named 'dilation' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1517: `groups: int = 1,` This assigns ‘1,‘ to ‘groups‘ in host memory. Here groups means the value named 'groups' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1518: `) -> tuple[BlockGradient, ParameterGradient]:` Inside the function _projection_conv2d_backward, which handles projection conv2d backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named 'tuple' in this block; BlockGradient: the signed loss derivative used to update a learned parameter; ParameterGradient: the signed loss derivative used to update a learned parameter.

Line 1519: `parameters = self.state.projection(name)` This assigns ‘self.state.projection(name)‘ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; projection: the value named ’projection’ in this block; name: the value named ’name’ in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1520: `values = output_gradient.values` This assigns ‘output_gradient.values‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1521: `if values.ndim != 4:` This executes the following indented host-code branch only when ‘values.ndim != 4‘ is true. The important operands are values: the value named ’values’ in this block; ndim: the value named ’ndim’ in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1522: `raise ValueError("projection convolution gradient must be NCHW")` This rejects an invalid state by raising ‘ValueError("projection convolution gradient must be NCHW")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1523: `batch, channels, height, width = values.shape` This assigns ‘values.shape‘ to ‘batch, channels, height, width ‘ in host memory. Here batch means the value named ’batch’ in this block. The important operands are values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1524: `matrix_gradient = output_gradient.transpose(0, 2, 3, 1).reshape(` This statement continues through source line 1525; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘output_gradient.transpose(0, 2, 3, 1).reshape(batch * height * width, channels)‘ to ‘matrix_gradient ‘ in host memory. Here matrix_gradient means the signed loss derivative used to update a learned parameter. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1525: `batch * height * width, channels)` This is continuation line 2 of the 2-line logical statement that begins at source line 1524. Its exact fragment is ‘batch * height * width, channels)‘. The important operands are batch: the value named ’batch’ in this block; height: the value named ’height’ in this block; width: the value named ’width’ in this block. Read together, the complete operation is: This assigns ‘output_gradient.transpose(0, 2, 3, 1).reshape(batch * height * width, channels)‘ to ‘matrix_gradient ‘ in host memory. Here matrix_gradient means the signed loss derivative used to update a learned parameter. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1526: `scaled_matrix = backward_requantize_projection(` This statement continues through source line 1531; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘backward_requantize_projection(self.driver, matrix_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘scaled_matrix ‘ in host memory. Here scaled_matrix means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named ’driver’ in this block; matrix_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1527: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1526. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘backward_requantize_projection(self.driver, matrix_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘scaled_matrix ‘ in host memory. Here scaled_matrix means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection:

the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; matrix_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1528: `matrix_gradient,` This is continuation line 3 of the 6-line logical statement that begins at source line 1526. Its exact fragment is 'matrix_gradient,'. The important operands are matrix_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'backward_requantize_projection(self.driver, matrix_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)' to 'scaled_matrix ' in host memory. Here scaled_matrix means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; matrix_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1529: `parameters,` This is continuation line 4 of the 6-line logical statement that begins at source line 1526. Its exact fragment is 'parameters,'. The important operands are parameters: the value named 'parameters' in this block. Read together, the complete operation is: This assigns 'backward_requantize_projection(self.driver, matrix_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)' to 'scaled_matrix ' in host memory. Here scaled_matrix means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projectio the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; matrix_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1530: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1526. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'backward_requantize_projection(self.driver, matrix_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)' to 'scaled_matrix ' in host memory. Here scaled_matrix means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; matrix_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1531: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1526. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'backward_requantize_projection(self.driver, matrix_gradient, parameters, timeout_seconds=self.layer_timeout_seconds,)' to 'scaled_matrix ' in host memory. Here scaled_matrix means the real-value spacing represented by one quantized integer step. The important operands are backward_requantize_projection: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; matrix_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1532: `scaled_nchw = scaled_matrix.reshape(` This statement continues through source line 1533; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'scaled_matrix.reshape(batch, height, width, channels).transpose(0, 3, 1, 2)' to 'scaled_nchw ' in host memory. Here scaled_nchw means the real-value spacing represented by one quantized integer step. The important operands are scaled_matrix: the real-value spacing represented by one quantized integer step; reshape: the value named 'reshape' in this block; batch: the value named 'batch' in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1533: `batch, height, width, channels).transpose(0, 3, 1, 2)` This is continuation line 2 of the 2-line logical statement that begins at source line 1532. Its exact fragment is 'batch, height, width, channels).transpose(0, 3, 1, 2)'. The important operands are batch: the value named 'batch' in this block; height: the value named 'height' in this block; width: the value named 'width' in this block. Read together, the complete operation is: This assigns 'scaled_matrix.reshape(batch, height, width, channels).transpose(0, 3, 1, 2)' to 'scaled_nchw ' in host memory. Here scaled_nchw means the real-value spacing represented by one quantized integer step. The important operands are

scaled_matrix: the real-value spacing represented by one quantized integer step; reshape: the value named 'reshape' in this block; batch: the value named 'batch' in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1534: `weight_oihw = parameters.weight_k_by_n.T.reshape(parameters.source_weight_shape)` This assigns 'parameters.weight_k_by_n.T.reshape(parameters.source_weight_shape)' to 'weight_oihw ' in host memory. Here weight_oihw means a learned coefficient multiplied by an activation. The important operands are parameters: the value named 'parameters' in this block; weight_k_by_n: a learned coefficient multiplied by an activation; T: the value named 't' in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1535: `input_gradient, accumulator_parameter = execute_conv2d_backward_block(` This statement continues through source line 1546; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1536: `self.driver,` This is continuation line 2 of the 12-line logical statement that begins at source line 1535. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1537: `activations,` This is continuation line 3 of the 12-line logical statement that begins at source line 1535. Its exact fragment is 'activations,'. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1538: `weight_oihw,` This is continuation line 4 of the 12-line logical statement that begins at source line 1535. Its exact fragment is 'weight_oihw,'. The important operands are weight_oihw: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1539: `parameters.bias_q10,` This is continuation line 5 of the 12-line logical statement that begins at source line 1535. Its exact fragment is 'parameters.bias_q10,'. The important operands are parameters: the value named 'parameters' in this block; bias_q10: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative

used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1540: `scaled_nchw,` This is continuation line 6 of the 12-line logical statement that begins at source line 1535. Its exact fragment is 'scaled_nchw,'. The important operands are scaled_nchw: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1541: `stride=stride,` This is continuation line 7 of the 12-line logical statement that begins at source line 1535. Its exact fragment is 'stride=stride,'. The important operands are stride: the value named 'stride' in this block. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1542: `padding=padding,` This is continuation line 8 of the 12-line logical statement that begins at source line 1535. Its exact fragment is 'padding=padding,'. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1543: `dilation=dilation,` This is continuation line 9 of the 12-line logical statement that begins at source line 1535. Its exact fragment is 'dilation=dilation,'. The important operands are dilation: the value named 'dilation' in this block. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1544: `groups=groups,` This is continuation line 10 of the 12-line logical statement that begins at source line 1535. Its exact fragment is 'groups=groups,'. The important operands are groups: the value named 'groups' in this block. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1545: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 11 of the 12-line logical statement that begins at source line 1535. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1546: `)` This is continuation line 12 of the 12-line logical statement that begins at source line 1535. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_conv2d_backward_block(self.driver, activations, weight_oihw, parameters.bias_q10, scaled_nchw, stride=stride, padding=padding, dilation=dilation, groups=groups, timeout_seconds=self.layer_timeo)' to 'input_gradient, accumulator_parameter ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_conv2d_backward_block: the value named 'execute conv2d backward block' in this block; driver: the value named 'driver' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1547: `weight_gradient = accumulator_parameter.weight.values.reshape(` This statement continues through source line 1548; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'accumulator_parameter.weight.values.reshape(parameters.source_weight_shape[0], -1).T' to 'weight_gradient ' in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are accumulator_parameter: a widened running sum that prevents intermediate overflow; weight: a learned coefficient multiplied by an activation; values: the value named 'values' in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1548: `parameters.source_weight_shape[0], -1).T` This is continuation line 2 of the 2-line logical statement that begins at source line 1547. Its exact fragment is 'parameters.source_weight_shape[0], -1).T'. The important operands are parameters: the value named 'parameters' in this block; source_weight_shape: a learned coefficient multiplied by an activation; T: the value named 't' in this block. Read together, the complete operation is: This assigns 'accumulator_parameter.weight.values.reshape(parameters.source_weight_shape[0], -1).T' to 'weight_gradient ' in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are accumulator_parameter: a widened running sum that prevents intermediate overflow; weight: a learned coefficient multiplied by an activation; values: the value named 'values' in this block. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1549: `bias_gradient = self._bias_gradient(matrix_gradient)` This assigns 'self._bias_gradient(matrix_gradient)' to 'bias_gradient ' in host memory. Here bias_gradient means an additive learned offset applied after accumulation. The important operands are _bias_gradient: an additive learned offset applied after accumulation; matrix_gradient: the signed loss derivative used to update a learned parameter. Context: the function _projection_conv2d_backward, which handles projection conv2d backward.

Line 1550: `return input_gradient, ParameterGradient(` This statement continues through source line 1553; the explanation uses the complete expression rather than only the first visual fragment. This returns 'input_gradient, ParameterGradient(BlockGradient(weight_gradient, accumulator_parameter.weight.exponent), bias_gradient,)' to the caller of the function _projection_conv2d_backward, which handles projection conv2d backward, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; ParameterGradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1551: `BlockGradient(weight_gradient, accumulator_parameter.weight.exponent),` This is continuation line 2 of the 4-line logical statement that begins at source line 1550. Its exact fragment is 'BlockGradient(weight_gradient,

accumulator_parameter.weight.exponent),‘. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; weight_gradient: a learned coefficient multiplied by an activation; accumulator_parameter: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This returns ‘input_gradient, ParameterGradient(BlockGradient(weight_gradient, accumulator_parameter.weight.exponent), bias_gradient,)‘ to the caller of the function _projection_conv2d_backward, which handles projection conv2d backward, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; ParameterGradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1552: `bias_gradient,` This is continuation line 3 of the 4-line logical statement that begins at source line 1550. Its exact fragment is ‘bias_gradient,‘. The important operands are bias_gradient: an additive learned offset applied after accumulation. Read together, the complete operation is: This returns ‘input_gradient, ParameterGradient(BlockGradient(weight_gradient, accumulator_parameter.weight.exponent), bias_gradient,)‘ to the caller of the function _projection_conv2d_backward, which handles projection conv2d backward, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; ParameterGradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1553: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1550. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘input_gradient, ParameterGradient(BlockGradient(weight_gradient, accumulator_parameter.weight.exponent), bias_gradient,)‘ to the caller of the function _projection_conv2d_backward, which handles projection conv2d backward, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; ParameterGradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1555: `def _token_rows_gradient(` This starts function _token_rows_gradient. Its indented body performs token rows gradient as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1556: `self, gradient: BlockGradient, channels: int` Inside the function _token_rows_gradient, which handles token rows gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter; channels: the value named ’channels’ in this block.

Line 1557: `) -> BlockGradient:` Inside the function _token_rows_gradient, which handles token rows gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1558: `timesteps, batch, _, height, width = gradient.values.shape` This assigns ‘gradient.values.shape‘ to ‘timesteps, batch, _, height, width ‘ in host memory. Here timesteps means one discrete SNN update instant. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function _token_rows_gradient, which handles token rows gradient.

Line 1559: `tokens = height * width` This assigns ‘height * width‘ to ‘tokens ‘ in host memory. Here tokens means the value named ’tokens’ in this block. The important operands are height: the value named ’height’ in this block; width: the value named ’width’ in this block. Context: the function _token_rows_gradient, which handles token rows gradient.

Line 1560: `values = gradient.values.reshape(` This statement continues through source line 1562; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘gradient.values.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are gradient: the signed loss derivative

used to update a learned parameter; values: the value named 'values' in this block; reshape: the value named 'reshape' in this block. Context: the function _token_rows_gradient, which handles token rows gradient.

Line 1561: `timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(` This is continuation line 2 of the 3-line logical statement that begins at source line 1560. Its exact fragment is 'timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape('. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; channels: the value named 'channels' in this block. Read together, the complete operation is: This assigns 'gradient.values.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block; reshape: the value named 'reshape' in this block. Context: the function _token_rows_gradient, which handles token rows gradient.

Line 1562: `timesteps * batch * tokens, channels)` This is continuation line 3 of the 3-line logical statement that begins at source line 1560. Its exact fragment is 'timesteps * batch * tokens, channels)'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; tokens: the value named 'tokens' in this block. Read together, the complete operation is: This assigns 'gradient.values.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block; reshape: the value named 'reshape' in this block. Context: the function _token_rows_gradient, which handles token rows gradient.

Line 1563: `return BlockGradient(values, gradient.exponent)` This returns 'BlockGradient(values, gradient.exponent)' to the caller of the function _token_rows_gradient, which handles token rows gradient, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block; gradient: the signed loss derivative used to update a learned parameter.

Line 1565: `@staticmethod` This decorator changes how the following class or function is constructed. '@staticmethod' is applied at import time on the host and is part of the class SpikingformerOnDeviceTrainer, which handles spikingformer on device trainer; it creates no FPGA circuit by itself.

Line 1566: `def _rows_to_channel_first(` This starts function _rows_to_channel_first. Its indented body performs rows to channel first as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1567: `gradient: BlockGradient,` Inside the function _rows_to_channel_first, which handles rows to channel first, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1568: `shape: tuple[int, ...],` Inside the function _rows_to_channel_first, which handles rows to channel first, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are shape: the value named 'shape' in this block; tuple: the value named 'tuple' in this block.

Line 1569: `) -> BlockGradient:` Inside the function _rows_to_channel_first, which handles rows to channel first, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1570: `timesteps, batch, channels, height, width = shape` This assigns 'shape' to 'timesteps, batch, channels, height, width ' in host memory. Here timesteps means one discrete SNN update instant. The important operands are shape: the value named 'shape' in this block. Context: the function _rows_to_channel_first, which handles rows to channel first.

Line 1571: `tokens = height * width` This assigns ‘height * width‘ to ‘tokens ‘ in host memory. Here tokens means the value named ’tokens’ in this block. The important operands are height: the value named ’height’ in this block; width: the value named ’width’ in this block. Context: the function _rows_to_channel_first, which handles rows to channel first.

Line 1572: `values = gradient.values.reshape(` This statement continues through source line 1573; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘gradient.values.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(shape)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _rows_to_channel_first, which handles rows to channel first.

Line 1573: `timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(shape)` This is continuation line 2 of the 2-line logical statement that begins at source line 1572. Its exact fragment is ‘timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(shape)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; tokens: the value named ’tokens’ in this block. Read together, the complete operation is: This assigns ‘gradient.values.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(shape)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _rows_to_channel_first, which handles rows to channel first.

Line 1574: `return BlockGradient(values, gradient.exponent)` This returns ‘BlockGradient(values, gradient.exponent)‘ to the caller of the function _rows_to_channel_first, which handles rows to channel first, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; gradient: the signed loss derivative used to update a learned parameter.

Line 1576: `def _stack_disjoint_gradients(` This starts function _stack_disjoint_gradients. Its indented body performs stack disjoint gradients as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1577: `self,` Inside the function _stack_disjoint_gradients, which handles stack disjoint gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1578: `gradients: Sequence[BlockGradient],` Inside the function _stack_disjoint_gradients, which handles stack disjoint gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are gradients: the signed loss derivative used to update a learned parameter; Sequence: the value named ’sequence’ in this block; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1579: `shape: tuple[int, ...],` Inside the function _stack_disjoint_gradients, which handles stack disjoint gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are shape: the value named ’shape’ in this block; tuple: the value named ’tuple’ in this block.

Line 1580: `) -> BlockGradient:` Inside the function _stack_disjoint_gradients, which handles stack disjoint gradients, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1581: `if not gradients:` This executes the following indented host-code branch only when ‘not gradients‘ is true. The important operands are not: the value named ’not’ in this block; gradients: the signed loss derivative used to update a learned parameter. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1582: `raise ValueError("at least one gradient is required for stacking")` This rejects an invalid state by raising ‘ValueError("at least one gradient is required for stacking")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1583: `exponent = max(gradient.exponent for gradient in gradients)` This assigns ‘max(gradient.exponent for gradient in gradients)‘ to ‘exponent ‘ in host memory. Here exponent means the value named ’exponent’ in this block. The important operands are max: the value named ’max’ in this block; gradient: the signed loss derivative used to update a learned parameter; exponent: the value named ’exponent’ in this block. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1584: `aligned: list[np.ndarray] = []` This assigns ‘[]‘ to ‘aligned‘ in host memory. Here aligned means the value named ’aligned’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1585: `for gradient in gradients:` This iterates gradient over ‘gradients‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1586: `values = gradient.values` This assigns ‘gradient.values‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1587: `if gradient.exponent != exponent:` This executes the following indented host-code branch only when ‘gradient.exponent != exponent‘ is true. The important operands are gradient: the signed loss derivative used to update a learned parameter; exponent: the value named ’exponent’ in this block. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1588: `values = execute_power_of_two_scale(` This statement continues through source line 1593; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_power_of_two_scale(self.driver, values, gradient.exponent - exponent, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1589: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1588. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(self.driver, values, gradient.exponent - exponent, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1590: `values,` This is continuation line 3 of the 6-line logical statement that begins at source line 1588. Its exact fragment is ‘values,‘. The important operands are values: the value named ’values’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(self.driver, values, gradient.exponent - exponent, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1591: `gradient.exponent - exponent,` This is continuation line 4 of the 6-line logical statement that begins at source line 1588. Its exact fragment is ‘gradient.exponent - exponent,‘. The important operands are gradient: the signed loss derivative used to update a learned parameter; exponent: the value named ’exponent’ in this block. Read together,

the complete operation is: This assigns ‘execute_power_of_two_scale(self.driver, values, gradient.exponent - exponent, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1592: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1588. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(self.driver, values, gradient.exponent - exponent, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1593: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1588. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘execute_power_of_two_scale(self.driver, values, gradient.exponent - exponent, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are execute_power_of_two_scale: the real-value spacing represented by one quantized integer step; driver: the value named ’driver’ in this block; values: the value named ’values’ in this block. Context: the function _stack_disjoint_gradients, which handles stack disjoint gradients.

Line 1594: `aligned.append(values)` This calls ‘aligned.append‘ with ‘values‘ inside the function _stack_disjoint_gradients, which handles stack disjoint gradients. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1595: `return BlockGradient(np.stack(aligned).reshape(shape), exponent)` This returns ‘BlockGradient(np.stack(aligned).reshape(shape), exponent)‘ to the caller of the function _stack_disjoint_gradients, which handles stack disjoint gradients, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; stack: the value named ’stack’ in this block; aligned: the value named ’aligned’ in this block.

Line 1597: `def _gate_saturating_add_gradient(` This starts function _gate_saturating_add_gradient. Its indented body performs gate saturating add gradient as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1598: `self,` Inside the function _gate_saturating_add_gradient, which handles gate saturating add gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1599: `output_gradient: BlockGradient,` Inside the function _gate_saturating_add_gradient, which handles gate saturating add gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1600: `left: np.ndarray,` Inside the function _gate_saturating_add_gradient, which handles gate saturating add gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are left: the value named ’left’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 1601: `right: np.ndarray,` Inside the function _gate_saturating_add_gradient, which handles gate saturating add gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are right: the value named 'right' in this block; ndarray: the value named 'ndarray' in this block.

Line 1602: `) -> BlockGradient:` Inside the function _gate_saturating_add_gradient, which handles gate saturating add gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1603: `total = np.asarray(left, dtype=np.int64) + np.asarray(right, dtype=np.int64)` This assigns 'np.asarray(left, dtype=np.int64) + np.asarray(right, dtype=np.int64)' to 'total ' in host memory. Here total means the value named 'total' in this block. The important operands are asarray: the value named 'asarray' in this block; left: the value named 'left' in this block; dtype: the value named 'dtype' in this block. Context: the function _gate_saturating_add_gradient, which handles gate saturating add gradient.

Line 1604: `mask = ((total >= -(1 << 31)) & (total <= (1 << 31) - 1)).astype(np.int64)` Inside the function _gate_saturating_add_gradient, which handles gate saturating add gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are mask: the value named 'mask' in this block; total: the value named 'total' in this block; astype: the value named 'astype' in this block.

Line 1605: `gated = execute_vector_tensor(` This statement continues through source line 1611; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, mask, output_gradient.values, timeout_seconds=self.layer_timeout_seconds,)' to 'gated ' in host memory. Here gated means the value named 'gated' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function _gate_saturating_add_gradient, which handles gate saturating add gradient.

Line 1606: `self.driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1605. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, mask, output_gradient.values, timeout_seconds=self.layer_timeout_seconds,)' to 'gated ' in host memory. Here gated means the value named 'gated' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function _gate_saturating_add_gradient, which handles gate saturating add gradient.

Line 1607: `VectorOperation.SELECT_NONZERO,` This is continuation line 3 of the 7-line logical statement that begins at source line 1605. Its exact fragment is 'VectorOperation.SELECT_NONZERO,'. The important operands are VectorOperation: the value named 'vector operation' in this block; SELECT_NONZERO: the value named 'select nonzero' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, mask, output_gradient.values, timeout_seconds=self.layer_timeout_seconds,)' to 'gated ' in host memory. Here gated means the value named 'gated' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function _gate_saturating_add_gradient, which handles gate saturating add gradient.

Line 1608: `mask,` This is continuation line 4 of the 7-line logical statement that begins at source line 1605. Its exact fragment is 'mask,'. The important operands are mask: the value named 'mask' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, mask, output_gradient.values, timeout_seconds=self.layer_timeout_seconds,)' to 'gated ' in host memory. Here gated means the value named 'gated' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector

operation' in this block. Context: the function _gate_saturating_add_gradient, which handles gate saturating add gradient.

Line 1609: `output_gradient.values,` This is continuation line 5 of the 7-line logical statement that begins at source line 1605. Its exact fragment is 'output_gradient.values,'. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, mask, output_gradient.values, timeout_seconds=self.layer_timeout_seconds,)' to 'gated ' in host memory. Here gated means the value named 'gated' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function _gate_saturating_add_gradient, which handles gate saturating add gradient.

Line 1610: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1605. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, mask, output_gradient.values, timeout_seconds=self.laye)' to 'gated ' in host memory. Here gated means the value named 'gated' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function _gate_saturating_add_gradient, which handles gate saturating add gradient.

Line 1611: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1605. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, mask, output_gradient.values, timeout_seconds=self.layer_timeout_seconds,)' to 'gated ' in host memory. Here gated means the value named 'gated' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function _gate_saturating_add_gradient, which handles gate saturating add gradient.

Line 1612: `return BlockGradient(gated, output_gradient.exponent)` This returns 'BlockGradient(gated, output_gradient.exponent)' to the caller of the function _gate_saturating_add_gradient, which handles gate saturating add gradient, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gated: the value named 'gated' in this block; output_gradient: the signed loss derivative used to update a learned parameter.

Line 1614: `def _mlp_backward(` This starts function _mlp_backward. Its indented body performs mlp backward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1615: `self,` Inside the function _mlp_backward, which handles mlp backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1616: `cache: MlpCache,` Inside the function _mlp_backward, which handles mlp backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are cache: the value named 'cache' in this block; MlpCache: the value named 'mlp cache' in this block.

Line 1617: `output_gradient: BlockGradient,` Inside the function _mlp_backward, which handles mlp backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1618: `) -> tuple[BlockGradient, dict[str, ParameterGradient]]:` Inside the function _mlp_backward, which handles mlp backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named 'tuple' in this block; BlockGradient: the signed loss derivative used to update a learned parameter; dict: the value named 'dict' in this block.

Line 1619: `timesteps, batch, channels, height, width = cache.input_shape` This assigns 'cache.input_shape' to 'timesteps, batch, channels, height, width ' in host memory. Here timesteps means one discrete SNN update instant. The important operands are cache: the value named 'cache' in this block; input_shape: the value named 'input shape' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1620: `tokens = height * width` This assigns 'height * width' to 'tokens ' in host memory. Here tokens means the value named 'tokens' in this block. The important operands are height: the value named 'height' in this block; width: the value named 'width' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1621: `output_rows = self._token_rows_gradient(output_gradient, channels)` This assigns 'self._token_rows_grad channels)' to 'output_rows ' in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are _token_rows_gradient: the signed loss derivative used to update a learned parameter; output_gradient: the signed loss derivative used to update a learned parameter; channels: the value named 'channels' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1622: `second_name = f"block.{cache.block_index}.mlp.fc2"` This assigns 'f"block.{cache.block_index}.mlp.fc2"' to 'second_name ' in host memory. Here second_name means the value named 'second name' in this block. The important operands are f: the value named 'f' in this block; block: the value named 'block' in this block; cache: the value named 'cache' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1623: `hidden_spike_rows, second_parameter = self._projection_matrix_backward(` This statement continues through source line 1624; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._projection_matrix_backward(second_name, cache.second_projection_input, output_rows)' to 'hidden_spike_rows, second_parameter ' in host memory. Here hidden_spike_rows means a binary event produced when a neuron crosses its threshold. The important operands are _projection_matrix_backward: the value named 'projection matrix backward' in this block; second_name: the value named 'second name' in this block; cache: the value named 'cache' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1624: `second_name, cache.second_projection_input, output_rows)` This is continuation line 2 of the 2-line logical statement that begins at source line 1623. Its exact fragment is 'second_name, cache.second_projection_input, output_rows)'. The important operands are second_name: the value named 'second name' in this block; cache: the value named 'cache' in this block; second_projection_input: the value named 'second projection input' in this block. Read together, the complete operation is: This assigns 'self._projection_matrix_backward(second_name, cache.second_projection_input, output_rows)' to 'hidden_spike_rows, second_parameter ' in host memory. Here hidden_spike_rows means a binary event produced when a neuron crosses its threshold. The important operands are _projection_matrix_backward: the value named 'projection matrix backward' in this block; second_name: the value named 'second name' in this block; cache: the value named 'cache' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1625: `hidden_channels = cache.hidden_lif.spikes.shape[2]` This assigns 'cache.hidden_lif.spikes.shape[2]' to 'hidden_channels ' in host memory. Here hidden_channels means the value named 'hidden channels' in this block. The important operands are cache: the value named 'cache' in this block; hidden_lif: the value named 'hidden lif' in this block; spikes: a binary event produced when a neuron crosses its threshold. Context: the function _mlp_backward, which handles mlp backward.

Line 1626: `hidden_spike_gradient = hidden_spike_rows.reshape(` This statement continues through source line 1627; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'hidden_spike_rows.reshape(timesteps, batch, tokens, hidden_channels).transpose(0, 1, 3, 2)' to 'hidden_spike_gradient ' in host memory. Here hidden_spike_gradient means a binary event produced when a neuron crosses its threshold. The

important operands are hidden_spike_rows: a binary event produced when a neuron crosses its threshold; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _mlp_backward, which handles mlp backward.

Line 1627: `timesteps, batch, tokens, hidden_channels).transpose(0, 1, 3, 2)` This is continuation line 2 of the 2-line logical statement that begins at source line 1626. Its exact fragment is 'timesteps, batch, tokens, hidden_channels).transpose(0, 1, 3, 2)'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; tokens: the value named 'tokens' in this block. Read together, the complete operation is: This assigns 'hidden_spike_rows.reshape(timesteps, batch, tokens, hidden_channels).transpose(0, 1, 3, 2)' to 'hidden_spike_gradient ' in host memory. Here hidden_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are hidden_spike_rows: a binary event produced when a neuron crosses its threshold; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _mlp_backward, which handles mlp backward.

Line 1628: `hidden_gradient = self._lif_backward(` This statement continues through source line 1631; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._lif_backward(cache.hidden_lif, hidden_spike_gradient,)' to 'hidden_gradient ' in host memory. Here hidden_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named 'lif backward' in this block; cache: the value named 'cache' in this block; hidden_lif: the value named 'hidden lif' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1629: `cache.hidden_lif,` This is continuation line 2 of the 4-line logical statement that begins at source line 1628. Its exact fragment is 'cache.hidden_lif,'. The important operands are cache: the value named 'cache' in this block; hidden_lif: the value named 'hidden lif' in this block. Read together, the complete operation is: This assigns 'self._lif_backward(cache.hidden_lif, hidden_spike_gradient,)' to 'hidden_gradient ' in host memory. Here hidden_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named 'lif backward' in this block; cache: the value named 'cache' in this block; hidden_lif: the value named 'hidden lif' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1630: `hidden_spike_gradient,` This is continuation line 3 of the 4-line logical statement that begins at source line 1628. Its exact fragment is 'hidden_spike_gradient,'. The important operands are hidden_spike_gradient: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns 'self._lif_backward(cache.hidden_lif, hidden_spike_gradient,)' to 'hidden_gradient ' in host memory. Here hidden_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named 'lif backward' in this block; cache: the value named 'cache' in this block; hidden_lif: the value named 'hidden lif' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1631: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1628. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self._lif_backward(cache.hidden_lif, hidden_spike_gradient,)' to 'hidden_gradient ' in host memory. Here hidden_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named 'lif backward' in this block; cache: the value named 'cache' in this block; hidden_lif: the value named 'hidden lif' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1632: `hidden_rows = BlockGradient(` This statement continues through source line 1636; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'BlockGradient(hidden_gradient.values.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, hidden_channels), hidden_gradient.exponent,)' to 'hidden_rows ' in host memory. Here hidden_rows means one output-row position processed by the tensor tile. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; hidden_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1633: `hidden_gradient.values.transpose(0, 1, 3, 2).reshape(` This is continuation line 2 of the 5-line logical statement that begins at source line 1632. Its exact fragment is 'hidden_gradient.values.transpose(0, 1, 3, 2).reshape('. The important operands are hidden_gradient: the signed loss derivative used to update a learned parameter;

values: the value named 'values' in this block; transpose: the value named 'transpose' in this block. Read together, the complete operation is: This assigns 'BlockGradient(hidden_gradient.values.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, hidden_channels), hidden_gradient.exponent,)' to 'hidden_rows ' in host memory. Here hidden_rows means one output-row position processed by the tensor tile. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; hidden_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1634: `timesteps * batch * tokens, hidden_channels),` This is continuation line 3 of the 5-line logical statement that begins at source line 1632. Its exact fragment is 'timesteps * batch * tokens, hidden_channels),'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; tokens: the value named 'tokens' in this block. Read together, the complete operation is: This assigns 'BlockGradient(hidden_gradient.values.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, hidden_channels), hidden_gradient.exponent,)' to 'hidden_rows ' in host memory. Here hidden_rows means one output-row position processed by the tensor tile. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; hidden_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1635: `hidden_gradient.exponent,` This is continuation line 4 of the 5-line logical statement that begins at source line 1632. Its exact fragment is 'hidden_gradient.exponent,'. The important operands are hidden_gradient: the signed loss derivative used to update a learned parameter; exponent: the value named 'exponent' in this block. Read together, the complete operation is: This assigns 'BlockGradient(hidden_gradient.values.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, hidden_channels), hidden_gradient.exponent,)' to 'hidden_rows ' in host memory. Here hidden_rows means one output-row position processed by the tensor tile. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; hidden_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1636: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 1632. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'BlockGradient(hidden_gradient.values.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, hidden_channels), hidden_gradient.exponent,)' to 'hidden_rows ' in host memory. Here hidden_rows means one output-row position processed by the tensor tile. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; hidden_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1637: `first_name = f"block.{cache.block_index}.mlp.fc1"` This assigns 'f"block.{cache.block_index}.mlp.fc1"' to 'first_name ' in host memory. Here first_name means the active-low synchronous reset. The important operands are f: the value named 'f' in this block; block: the value named 'block' in this block; cache: the value named 'cache' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1638: `input_spike_rows, first_parameter = self._projection_matrix_backward(` This statement continues through source line 1639; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._projection_matrix_backward(first_name, cache.first_projection_input, hidden_rows)' to 'input_spike_rows, first_parameter ' in host memory. Here input_spike_rows means a binary event produced when a neuron crosses its threshold. The important operands are _projection_matrix_backward: the value named 'projection matrix backward' in this block; first_name: the active-low synchronous reset; cache: the value named 'cache' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1639: `first_name, cache.first_projection_input, hidden_rows)` This is continuation line 2 of the 2-line logical statement that begins at source line 1638. Its exact fragment is 'first_name, cache.first_projection_input, hidden_rows)'. The important operands are first_name: the active-low synchronous reset; cache: the value named 'cache' in this block; first_projection_input: the value named 'first projection input' in this block. Read together, the complete operation is: This assigns 'self._projection_matrix_backward(first_name, cache.first_projection_input, hidden_rows)' to 'input_spike_rows, first_parameter ' in host memory. Here input_spike_rows means a binary event produced when

a neuron crosses its threshold. The important operands are _projection_matrix_backward: the value named 'projection matrix backward' in this block; first_name: the active-low synchronous reset; cache: the value named 'cache' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1640: `input_spike_gradient = self._rows_to_channel_first(` This statement continues through source line 1641; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._rows_to_channel_first(input_spike_rows, cache.input_shape)' to 'input_spike_gradient ' in host memory. Here input_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are _rows_to_channel_first: one output-row position processed by the tensor tile; input_spike_rows: a binary event produced when a neuron crosses its threshold; cache: the value named 'cache' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1641: `input_spike_rows, cache.input_shape)` This is continuation line 2 of the 2-line logical statement that begins at source line 1640. Its exact fragment is 'input_spike_rows, cache.input_shape)'. The important operands are input_spike_rows: a binary event produced when a neuron crosses its threshold; cache: the value named 'cache' in this block; input_shape: the value named 'input shape' in this block. Read together, the complete operation is: This assigns 'self._rows_to_channel_first(input_spike_rows, cache.input_shape)' to 'input_spike_gradient ' in host memory. Here input_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are _rows_to_channel_first: one output-row position processed by the tensor tile; input_spike_rows: a binary event produced when a neuron crosses its threshold; cache: the value named 'cache' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1642: `input_gradient = self._lif_backward(cache.input_lif, input_spike_gradient)` This assigns 'self._lif_back input_spike_gradient)' to 'input_gradient ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named 'lif backward' in this block; cache: the value named 'cache' in this block; input_lif: the value named 'input lif' in this block. Context: the function _mlp_backward, which handles mlp backward.

Line 1643: `return input_gradient, {` This statement continues through source line 1646; the explanation uses the complete expression rather than only the first visual fragment. This returns 'input_gradient, { first_name: first_parameter, second_name: second_parameter, }' to the caller of the function _mlp_backward, which handles mlp backward, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; first_name: the active-low synchronous reset; first_parameter: the value named 'first parameter' in this block.

Line 1644: `first_name: first_parameter,` This is continuation line 2 of the 4-line logical statement that begins at source line 1643. Its exact fragment is 'first_name: first_parameter,'. The important operands are first_name: the active-low synchronous reset; first_parameter: the value named 'first parameter' in this block. Read together, the complete operation is: This returns 'input_gradient, { first_name: first_parameter, second_name: second_parameter, }' to the caller of the function _mlp_backward, which handles mlp backward, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; first_name: the active-low synchronous reset; first_parameter: the value named 'first parameter' in this block.

Line 1645: `second_name: second_parameter,` This is continuation line 3 of the 4-line logical statement that begins at source line 1643. Its exact fragment is 'second_name: second_parameter,'. The important operands are second_name: the value named 'second name' in this block; second_parameter: the value named 'second parameter' in this block. Read together, the complete operation is: This returns 'input_gradient, { first_name: first_parameter, second_name: second_parameter, }' to the caller of the function _mlp_backward, which handles mlp backward, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; first_name: the active-low synchronous reset; first_parameter: the value named 'first parameter' in this block.

Line 1646: `}` This is continuation line 4 of the 4-line logical statement that begins at source line 1643. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'input_gradient, { first_name: first_parameter, second_name: second_parameter, }' to the caller of the function _mlp_backward, which handles mlp backward, ending this invocation. The important

operands are input_gradient: the signed loss derivative used to update a learned parameter; first_name: the active-low synchronous reset; first_parameter: the value named 'first parameter' in this block.

Line 1648: `def _attention_backward(` This starts function _attention_backward. Its indented body performs attention backward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1649: `self,` Inside the function _attention_backward, which handles attention backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1650: `cache: AttentionCache,` Inside the function _attention_backward, which handles attention backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are cache: the value named 'cache' in this block; AttentionCache: the value named 'attention cache' in this block.

Line 1651: `output_gradient: BlockGradient,` Inside the function _attention_backward, which handles attention backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1652: `) -> tuple[BlockGradient, dict[str, ParameterGradient]]:` Inside the function _attention_backward, which handles attention backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named 'tuple' in this block; BlockGradient: the signed loss derivative used to update a learned parameter; dict: the value named 'dict' in this block.

Line 1653: `timesteps, batch, channels, height, width = cache.input_shape` This assigns 'cache.input_shape' to 'timesteps, batch, channels, height, width ' in host memory. Here timesteps means one discrete SNN update instant. The important operands are cache: the value named 'cache' in this block; input_shape: the value named 'input shape' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1654: `tokens = height * width` This assigns 'height * width' to 'tokens ' in host memory. Here tokens means the value named 'tokens' in this block. The important operands are height: the value named 'height' in this block; width: the value named 'width' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1655: `head_dim = channels // self.attention_heads` This assigns 'channels // self.attention_heads' to 'head_dim ' in host memory. Here head_dim means the value named 'head dim' in this block. The important operands are channels: the value named 'channels' in this block; attention_heads: the value named 'attention heads' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1656: `prefix = f"block.{cache.block_index}.attn"` This assigns 'f"block.{cache.block_index}.attn"' to 'prefix ' in host memory. Here prefix means the value named 'prefix' in this block. The important operands are f: the value named 'f' in this block; block: the value named 'block' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1657: `output_rows = self._token_rows_gradient(output_gradient, channels)` This assigns 'self._token_rows_grad channels)' to 'output_rows ' in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are _token_rows_gradient: the signed loss derivative used to update a learned parameter; output_gradient: the signed loss derivative used to update a learned parameter; channels: the value named 'channels' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1658: `attention_spike_rows, projection_parameter = self._projection_matrix_backward(` This statement continues through source line 1659; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._projection_matrix_backward(f"{prefix}.proj", cache.projection_input, output_rows)‘ to ‘attention_spike_rows, projection_parameter ‘ in host memory. Here attention_spike_rows means a binary event produced when a neuron crosses its threshold. The important operands are _projection_matrix_backward: the value named ’projection matrix backward’ in this block; f: the value named ’f’ in this block; prefix: the value named ’prefix’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1659: `f"{prefix}.proj", cache.projection_input, output_rows)` This is continuation line 2 of the 2-line logical statement that begins at source line 1658. Its exact fragment is ‘f"{prefix}.proj", cache.projection_input, output_rows)‘. The important operands are f: the value named ’f’ in this block; prefix: the value named ’prefix’ in this block; proj: the value named ’proj’ in this block. Read together, the complete operation is: This assigns ‘self._projection_matrix_backward(f"{prefix}.proj", cache.projection_input, output_rows)‘ to ‘attention_spike_rows, projection_parameter ‘ in host memory. Here attention_spike_rows means a binary event produced when a neuron crosses its threshold. The important operands are _projection_matrix_backward: the value named ’projection matrix backward’ in this block; f: the value named ’f’ in this block; prefix: the value named ’prefix’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1660: `attention_spike_gradient = BlockGradient(` This statement continues through source line 1664; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘BlockGradient(attention_spike_rows.values.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2), attention_spike_rows.exponent,)‘ to ‘attention_spike_gradient ‘ in host memory. Here attention_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; attention_spike_rows: a binary event produced when a neuron crosses its threshold; values: the value named ’values’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1661: `attention_spike_rows.values.reshape(` This is continuation line 2 of the 5-line logical statement that begins at source line 1660. Its exact fragment is ‘attention_spike_rows.values.reshape(‘. The important operands are attention_spike_rows: a binary event produced when a neuron crosses its threshold; values: the value named ’values’ in this block; reshape: the value named ’reshape’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(attention_spike_rows.values.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2), attention_spike_rows.exponent,)‘ to ‘attention_spike_gradient ‘ in host memory. Here attention_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; attention_spike_rows: a binary event produced when a neuron crosses its threshold; values: the value named ’values’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1662: `timesteps, batch, tokens, channels).transpose(0, 1, 3, 2),` This is continuation line 3 of the 5-line logical statement that begins at source line 1660. Its exact fragment is ‘timesteps, batch, tokens, channels).transpose(0, 1, 3, 2),‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; tokens: the value named ’tokens’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(attention_spike_rows.values.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2), attention_spike_rows.exponent,)‘ to ‘attention_spike_gradient ‘ in host memory. Here attention_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; attention_spike_rows: a binary event produced when a neuron crosses its threshold; values: the value named ’values’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1663: `attention_spike_rows.exponent,` This is continuation line 4 of the 5-line logical statement that begins at source line 1660. Its exact fragment is ‘attention_spike_rows.exponent,‘. The important operands are attention_spike_rows: a binary event produced when a neuron crosses its threshold; exponent: the value named ’exponent’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(attention_spike_rows.values.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2), attention_spike_rows.exponent,)‘ to ‘attention_spike_gradient ‘ in host memory. Here attention_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; attention_spike_rows: a binary event produced when a neuron crosses its threshold; values: the value named ’values’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1664: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 1660. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'BlockGradient(attention_spike_rows.values.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2), attention_spike_rows.exponent,)' to 'attention_spike_gradient ' in host memory. Here attention_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; attention_spike_rows: a binary event produced when a neuron crosses its threshold; values: the value named 'values' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1665: `merged_gradient = self._lif_backward(` This statement continues through source line 1666; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._lif_backward(cache.attention_lif, attention_spike_gradient)' to 'merged_gradient ' in host memory. Here merged_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named 'lif backward' in this block; cache: the value named 'cache' in this block; attention_lif: the value named 'attention lif' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1666: `cache.attention_lif, attention_spike_gradient)` This is continuation line 2 of the 2-line logical statement that begins at source line 1665. Its exact fragment is 'cache.attention_lif, attention_spike_gradient)'. The important operands are cache: the value named 'cache' in this block; attention_lif: the value named 'attention lif' in this block; attention_spike_gradient: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns 'self._lif_backward(cache.attention_lif, attention_spike_gradient)' to 'merged_gradient ' in host memory. Here merged_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named 'lif backward' in this block; cache: the value named 'cache' in this block; attention_lif: the value named 'attention lif' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1667: `attention_value_gradient = BlockGradient(` This statement continues through source line 1672; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'BlockGradient(merged_gradient.values.reshape(timesteps, batch, self.attention_heads, head_dim, tokens).transpose(0, 1, 2, 4, 3), merged_gradient.exponent + self.attention_scale_shift,)' to 'attention_value_gradient ' in host memory. Here attention_value_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; merged_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1668: `merged_gradient.values.reshape(` This is continuation line 2 of the 6-line logical statement that begins at source line 1667. Its exact fragment is 'merged_gradient.values.reshape('. The important operands are merged_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block; reshape: the value named 'reshape' in this block. Read together, the complete operation is: This assigns 'BlockGradient(merged_gradient.values.reshape(timesteps, batch, self.attention_heads, head_dim, tokens).transpose(0, 1, 2, 4, 3), merged_gradient.exponent + self.attention_scale_shift,)' to 'attention_value_gradient ' in host memory. Here attention_value_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; merged_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1669: `timesteps, batch, self.attention_heads, head_dim, tokens` This is continuation line 3 of the 6-line logical statement that begins at source line 1667. Its exact fragment is 'timesteps, batch, self.attention_heads, head_dim, tokens'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; attention_heads: the value named 'attention heads' in this block. Read together, the complete operation is: This assigns 'BlockGradient(merged_gradient.values.reshape(timesteps, batch, self.attention_heads, head_dim, tokens).transpose(0, 1, 2, 4, 3), merged_gradient.exponent + self.attention_scale_shift,)' to 'attention_value_gradient ' in host memory. Here attention_value_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; merged_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Line 1682: `cache.value_heads[timestep, batch_index, head],` This is continuation line 4 of the 11-line logical statement that begins at source line 1679. Its exact fragment is 'cache.value_heads[timestep, batch_index, head],'. The important operands are cache: the value named 'cache' in this block; value_heads: the value named 'value heads' in this block; timestep: one discrete SNN update instant. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, cache.scores[timestep, batch_index, head], cache.value_heads[timestep, batch_index, head], BlockGradient(attention_value_gradient.values[timestep, batch_index, head], attention_value_gradient.expo), timeout_seconds=self.layer_timeout_seconds,)' to 'score_gradient, value_gradient ' in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1683: `BlockGradient(` This is continuation line 5 of the 11-line logical statement that begins at source line 1679. Its exact fragment is 'BlockGradient('. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, cache.scores[timestep, batch_index, head], cache.value_heads[timestep, batch_index, head], BlockGradient(attention_value_gradient.values[timestep, batch_index, head], attention_value_gradient.exponent,), timeout_seconds=self.layer)' to 'score_gradient, value_gradient ' in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1684: `attention_value_gradient.values[` This is continuation line 6 of the 11-line logical statement that begins at source line 1679. Its exact fragment is 'attention_value_gradient.values['. The important operands are attention_value_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, cache.scores[timestep, batch_index, head], cache.value_heads[timestep, batch_index, head], BlockGradient(attention_value_gradi timestep, batch_index, head], attention_value_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)' to 'score_gradient, value_gradient ' in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1685: `timestep, batch_index, head],` This is continuation line 7 of the 11-line logical statement that begins at source line 1679. Its exact fragment is 'timestep, batch_index, head],'. The important operands are timestep: one discrete SNN update instant; batch_index: an integer selecting one tensor element, lane, bank, or state entry; head: the value named 'head' in this block. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, cache.scores[timestep, batch_index, head], cache.value_heads[timestep, batch_index, head], BlockGradient(attention_value_gradient.values[timestep, batch_index, head], attention_value_gradient.exponent,), timeout_seconds=self.layer)' to 'score_gradient, value_gradient ' in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1686: `attention_value_gradient.exponent,` This is continuation line 8 of the 11-line logical statement that begins at source line 1679. Its exact fragment is 'attention_value_gradient.exponent,'. The important operands are attention_value_gradient: the signed loss derivative used to update a learned parameter; exponent: the value named 'exponent' in this block. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, cache.scores[timestep, batch_index, head], cache.value_heads[timestep, batch_index, head], BlockGradient(attention_value_gradient.values[timestep, batch_index, head], attention_value_gradient.exponent,), timeout_seconds=self.layer)' to 'score_gradient, value_gradient ' in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1687: `),` This is continuation line 9 of the 11-line logical statement that begins at source line 1679. Its exact fragment is '),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, cache.scores[timestep, batch_index, head], cache.value_heads[timestep, batch_index, head], BlockGradient(attention_value_gradient.values[timestep, batch_index, head], attention_value_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)' to 'score_gradient, value_gradient ' in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1688: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 10 of the 11-line logical statement that begins at source line 1679. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, cache.scores[timestep, batch_index, head], cache.value_heads[timestep, batch_index, head], BlockGradient(attention_value_gradient.values[timestep, batch_index, head], attention_value_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)' to 'score_gradient, value_gradient ' in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1689: `)` This is continuation line 11 of the 11-line logical statement that begins at source line 1679. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, cache.scores[timestep, batch_index, head], cache.value_heads[timestep, batch_index, head], BlockGradient(attention_value_gradient.values[timestep, batch_index, head], attention_value_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)' to 'score_gradient, value_gradient ' in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1690: `score_parts.append(score_gradient)` This calls 'score_parts.append' with 'score_gradient' inside the function _attention_backward, which handles attention backward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1691: `value_parts.append(value_gradient)` This calls ‘value_parts.append‘ with ‘value_gradient‘ inside the function _attention_backward, which handles attention backward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1692: `score_gradient = self._stack_disjoint_gradients(` This statement continues through source line 1695; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._stack_disjoint_grad score_parts, (timesteps, batch, self.attention_heads, tokens, tokens),)‘ to ‘score_gradient ‘ in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; score_parts: the value named ’score parts’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1693: `score_parts,` This is continuation line 2 of the 4-line logical statement that begins at source line 1692. Its exact fragment is ‘score_parts,‘. The important operands are score_parts: the value named ’score parts’ in this block. Read together, the complete operation is: This assigns ‘self._stack_disjoint_gradients(score_parts, (timesteps, batch, self.attention_heads, tokens, tokens),)‘ to ‘score_gradient ‘ in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; score_parts: the value named ’score parts’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1694: `(timesteps, batch, self.attention_heads, tokens, tokens),` This is continuation line 3 of the 4-line logical statement that begins at source line 1692. Its exact fragment is ‘(timesteps, batch, self.attention_heads, tokens, tokens),‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; attention_heads: the value named ’attention heads’ in this block. Read together, the complete operation is: This assigns ‘self._stack_disjoint_gradients(score_parts, (timesteps, batch, self.attention_heads, tokens, tokens),)‘ to ‘score_gradient ‘ in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; score_parts: the value named ’score parts’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1695: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1692. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘self._stack_disjoint_gradients(score_parts, (timesteps, batch, self.attention_heads, tokens, tokens),)‘ to ‘score_gradient ‘ in host memory. Here score_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; score_parts: the value named ’score parts’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1696: `value_head_gradient = self._stack_disjoint_gradients(` This statement continues through source line 1699; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._stack_disjoint_gradients(value_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)‘ to ‘value_head_gradie ‘ in host memory. Here value_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; value_parts: the value named ’value parts’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1697: `value_parts,` This is continuation line 2 of the 4-line logical statement that begins at source line 1696. Its exact fragment is ‘value_parts,‘. The important operands are value_parts: the value named ’value parts’ in this block. Read together, the complete operation is: This assigns ‘self._stack_disjoint_gradients(value_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)‘ to ‘value_head_gradient ‘ in host memory. Here value_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; value_parts: the value named ’value parts’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1698: `(timesteps, batch, self.attention_heads, tokens, head_dim),` This is continuation line 3 of the 4-line logical statement that begins at source line 1696. Its exact fragment is '(timesteps, batch, self.attention_heads, tokens, head_dim),'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; attention_heads: the value named 'attention heads' in this block. Read together, the complete operation is: This assigns 'self._stack_disjoint_gradients(value_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)' to 'value_head_gradient ' in host memory. Here value_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; value_parts: the value named 'value parts' in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1699: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1696. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self._stack_disjoint_gradients(value_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)' to 'value_head_gradient ' in host memory. Here value_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; value_parts: the value named 'value parts' in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1701: `query_parts: list[BlockGradient] = []` This assigns '[]' to 'query_parts' in host memory. Here query_parts means the value named 'query parts' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _attention_backward, which handles attention backward.

Line 1702: `key_parts: list[BlockGradient] = []` This assigns '[]' to 'key_parts' in host memory. Here key_parts means the value named 'key parts' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _attention_backward, which handles attention backward.

Line 1703: `part_index = 0` This assigns '0' to 'part_index ' in host memory. Here part_index means an integer selecting one tensor element, lane, bank, or state entry. The expression is a literal or structural operator and has no hidden software state. Context: the function _attention_backward, which handles attention backward.

Line 1704: `for timestep in range(timesteps):` This iterates timestep over 'range(timesteps)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _attention_backward, which handles attention backward.

Line 1705: `for batch_index in range(batch):` This iterates batch_index over 'range(batch)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _attention_backward, which handles attention backward.

Line 1706: `for head in range(self.attention_heads):` This iterates head over 'range(self.attention_heads)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _attention_backward, which handles attention backward.

Line 1707: `query_gradient, transposed_key_gradient = execute_linear_backward_block(` This statement continues through source line 1716; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_linear_backward_block(self.driver, cache.query_heads[timestep, batch_index, head], cache.key_heads[timestep, batch_index, head].T, BlockGradient(score_gradient.values[timestep, batch_index, head], score_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)' to 'query_gradient, transposed_key_gradient ' in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1708: `self.driver,` This is continuation line 2 of the 10-line logical statement that begins at source line 1707. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_linear_backward_block(self.driver, cache.query_heads[timestep, batch_index,

head], cache.key_heads[timestep, batch_index, head].T, BlockGradient(score_gradient.values[timestep, batch_index, head], score_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘query_gradient, transposed_key_gradient ‘ in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; cache: the value named ’cache’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1709: `cache.query_heads[timestep, batch_index, head],` This is continuation line 3 of the 10-line logical statement that begins at source line 1707. Its exact fragment is ‘cache.query_heads[timestep, batch_index, head],‘. The important operands are cache: the value named ’cache’ in this block; query_heads: the value named ’query heads’ in this block; timestep: one discrete SNN update instant. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, cache.query_heads[timestep, batch_index, head], cache.key_heads[timestep, batch_index, head].T, BlockGradient(score_gradient.values[timestep, batch_index, head], score_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘query_gradient, transposed_key_gradient ‘ in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; cache: the value named ’cache’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1710: `cache.key_heads[timestep, batch_index, head].T,` This is continuation line 4 of the 10-line logical statement that begins at source line 1707. Its exact fragment is ‘cache.key_heads[timestep, batch_index, head].T,‘. The important operands are cache: the value named ’cache’ in this block; key_heads: the value named ’key heads’ in this block; timestep: one discrete SNN update instant. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, cache.query_heads[timestep, batch_index, head], cache.key_heads[timestep, batch_index, head].T, BlockGradient(score_gradient.values[timestep, batch_index, head], score_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘query_gradient, transposed_key_gradient ‘ in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; cache: the value named ’cache’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1711: `BlockGradient(` This is continuation line 5 of the 10-line logical statement that begins at source line 1707. Its exact fragment is ‘BlockGradient(‘. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, cache.query_heads[timestep, batch_index, head], cache.key_heads[timestep, batch_index, head].T, BlockGradient(score_gradient.values[timestep, batch_index, head], score_gradient.exponent,), timeout_seconds=self.layer_timeout_se)‘ to ‘query_gradient, transposed_key_gradient ‘ in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; cache: the value named ’cache’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1712: `score_gradient.values[timestep, batch_index, head],` This is continuation line 6 of the 10-line logical statement that begins at source line 1707. Its exact fragment is ‘score_gradient.values[timestep, batch_index, head],‘. The important operands are score_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; timestep: one discrete SNN update instant. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, cache.query_heads[timestep, batch_index, head], cache.key_heads[timestep, batch_index, head].T, BlockGradient(score_gradient.values[timestep, batch_index, head], score_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘query_gradient, transposed_key_gradient ‘ in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named ’execute linear backward block’ in this block; driver: the value named ’driver’ in this block; cache: the value named ’cache’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1713: `score_gradient.exponent,` This is continuation line 7 of the 10-line logical statement that begins at source line 1707. Its exact fragment is ‘score_gradient.exponent,‘. The important operands are score_gradient: the signed loss derivative used to update a learned parameter; exponent: the value named ’exponent’ in this block. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, cache.query_heads[timestep, batch_index,

head], cache.key_heads[timestep, batch_index, head].T, BlockGradient(score_gradient.values[timestep, batch_index, head], score_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘query_gradient, transposed_key_gradient ‘ in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1714: `),` This is continuation line 8 of the 10-line logical statement that begins at source line 1707. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, cache.query_heads[timestep, batch_index, head], cache.key_heads[timestep, batch_index, head].T, BlockGradient(score_gradient.values[timestep, batch_index, head], score_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘query_gradient, transposed_key_gradient ‘ in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1715: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 9 of the 10-line logical statement that begins at source line 1707. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, cache.query_heads[timestep, batch_index, head], cache.key_heads[timestep, batch_index, head].T, BlockGradient(score_gradient.values[timestep, batch_index, head], score_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘query_gradient, transposed_key_gradient ‘ in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1716: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 1707. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘execute_linear_backward_block(self.driver, cache.query_heads[timestep, batch_index, head], cache.key_heads[timestep, batch_index, head].T, BlockGradient(score_gradient.values[timestep, batch_index, head], score_gradient.exponent,), timeout_seconds=self.layer_timeout_seconds,)‘ to ‘query_gradient, transposed_key_gradient ‘ in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_linear_backward_block: the value named 'execute linear backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1717: `query_parts.append(query_gradient)` This calls ‘query_parts.append‘ with ‘query_gradient‘ inside the function _attention_backward, which handles attention backward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1718: `key_parts.append(BlockGradient(` This statement continues through source line 1721; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘key_parts.append‘ with ‘BlockGradient(transposed_key_gradient.values.T, transposed_key_gradient.exponent,)‘ inside the function _attention_backward, which handles attention backward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1719: `transposed_key_gradient.values.T,` This is continuation line 2 of the 4-line logical statement that begins at source line 1718. Its exact fragment is ‘transposed_key_gradient.values.T,‘. The important operands are transposed_key_gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block; T: the value named 't' in this block. Read together, the complete operation is: This calls ‘key_parts.append‘ with ‘BlockGradient(transposed_key_gradient.values.T, transposed_key_gradient.exponent,)‘ inside the function _attention_backward, which handles attention backward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1720: `transposed_key_gradient.exponent,` This is continuation line 3 of the 4-line logical statement that begins at source line 1718. Its exact fragment is 'transposed_key_gradient.exponent,'. The important operands are transposed_key_gradient: the signed loss derivative used to update a learned parameter; exponent: the value named 'exponent' in this block. Read together, the complete operation is: This calls 'key_parts.append' with 'BlockGradient(transposed_key_gradient.values.T, transposed_key_gradient.exponent,)' inside the function _attention_backward, which handles attention backward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1721: `))` This is continuation line 4 of the 4-line logical statement that begins at source line 1718. Its exact fragment is '))'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'key_parts.append' with 'BlockGradient(transposed_key_gradient.values.T, transposed_key_gradient.exponent,)' inside the function _attention_backward, which handles attention backward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1722: `part_index += 1` Inside the function _attention_backward, which handles attention backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are part_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 1723: `query_head_gradient = self._stack_disjoint_gradients(` This statement continues through source line 1726; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._stack_disjoint_gradients(query_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)' to 'query_head_gradie
' in host memory. Here query_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; query_parts: the value named 'query parts' in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1724: `query_parts,` This is continuation line 2 of the 4-line logical statement that begins at source line 1723. Its exact fragment is 'query_parts,'. Read together, the complete operation is: This assigns 'self._stack_disjoint_gradients(query_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)' to 'query_head_gradient ' in host memory. Here query_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; query_parts: the value named 'query parts' in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1725: `(timesteps, batch, self.attention_heads, tokens, head_dim),` This is continuation line 3 of the 4-line logical statement that begins at source line 1723. Its exact fragment is '(timesteps, batch, self.attention_heads, tokens, head_dim),'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; attention_heads: the value named 'attention heads' in this block. Read together, the complete operation is: This assigns 'self._stack_disjoint_gradients(query_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)' to 'query_head_gradient ' in host memory. Here query_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; query_parts: the value named 'query parts' in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1726: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1723. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self._stack_disjoint_gradients(query_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)' to 'query_head_gradient ' in host memory. Here query_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; query_parts: the value named 'query parts' in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1727: `key_head_gradient = self._stack_disjoint_gradients(` This statement continues through source line 1730; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._stack_disjoint_gradients(key_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)‘ to ‘key_head_gradient ‘ in host memory. Here key_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; key_parts: the value named ’key parts’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1728: `key_parts,` This is continuation line 2 of the 4-line logical statement that begins at source line 1727. Its exact fragment is ‘key_parts,‘. The important operands are key_parts: the value named ’key parts’ in this block. Read together, the complete operation is: This assigns ‘self._stack_disjoint_gradients(key_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)‘ to ‘key_head_gradient ‘ in host memory. Here key_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; key_parts: the value named ’key parts’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1729: `(timesteps, batch, self.attention_heads, tokens, head_dim),` This is continuation line 3 of the 4-line logical statement that begins at source line 1727. Its exact fragment is ‘(timesteps, batch, self.attention_heads, tokens, head_dim),‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; attention_heads: the value named ’attention heads’ in this block. Read together, the complete operation is: This assigns ‘self._stack_disjoint_gradients(key_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)‘ to ‘key_head_gradient ‘ in host memory. Here key_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; key_parts: the value named ’key parts’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1730: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1727. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘self._stack_disjoint_gradients(key_parts, (timesteps, batch, self.attention_heads, tokens, head_dim),)‘ to ‘key_head_gradient ‘ in host memory. Here key_head_gradient means the signed loss derivative used to update a learned parameter. The important operands are _stack_disjoint_gradients: the signed loss derivative used to update a learned parameter; key_parts: the value named ’key parts’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention_backward, which handles attention backward.

Line 1732: `def merge_heads(gradient: BlockGradient) -> BlockGradient:` This starts function merge_heads. Its indented body performs merge heads as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1733: `return BlockGradient(` This statement continues through source line 1737; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘BlockGradient(gradient.values.transpose(0, 1, 3, 2, 4).reshape(timesteps, batch, tokens, channels), gradient.exponent,)‘ to the caller of the function merge_heads, which handles merge heads, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block.

Line 1734: `gradient.values.transpose(0, 1, 3, 2, 4).reshape(` This is continuation line 2 of the 5-line logical statement that begins at source line 1733. Its exact fragment is ‘gradient.values.transpose(0, 1, 3, 2, 4).reshape(‘. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; transpose: the value named ’transpose’ in this block. Read together, the complete operation is: This returns ‘BlockGradient(gradient.values.transpose(0, 1, 3, 2, 4).reshape(timesteps, batch, tokens, channels), gradient.exponent,)‘ to the caller of the function merge_heads, which handles merge heads, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block.

Line 1735: `timesteps, batch, tokens, channels),` This is continuation line 3 of the 5-line logical statement that begins at source line 1733. Its exact fragment is 'timesteps, batch, tokens, channels),'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; tokens: the value named 'tokens' in this block. Read together, the complete operation is: This returns 'BlockGradient(gradient.values.transpose(0, 1, 3, 2, 4).reshape(timesteps, batch, tokens, channels), gradient.exponent,)' to the caller of the function merge_heads, which handles merge heads, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block.

Line 1736: `gradient.exponent,` This is continuation line 4 of the 5-line logical statement that begins at source line 1733. Its exact fragment is 'gradient.exponent,'. The important operands are gradient: the signed loss derivative used to update a learned parameter; exponent: the value named 'exponent' in this block. Read together, the complete operation is: This returns 'BlockGradient(gradient.values.transpose(0, 1, 3, 2, 4).reshape(timesteps, batch, tokens, channels), gradient.exponent,)' to the caller of the function merge_heads, which handles merge heads, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block.

Line 1737: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 1733. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'BlockGradient(gradient.values.transpose(0, 1, 3, 2, 4).reshape(timesteps, batch, tokens, channels), gradient.exponent,)' to the caller of the function merge_heads, which handles merge heads, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block.

Line 1739: `query_gradient = self._lif_backward(cache.query_lif, merge_heads(query_head_gradient))` This assigns 'self._lif_backward(cache.query_lif, merge_heads(query_head_gradient))' to 'query_gradient ' in host memory. Here query_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named 'lif backward' in this block; cache: the value named 'cache' in this block; query_lif: the value named 'query lif' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1740: `key_gradient = self._lif_backward(cache.key_lif, merge_heads(key_head_gradient))` This assigns 'self._lif_backward(cache.key_lif, merge_heads(key_head_gradient))' to 'key_gradient ' in host memory. Here key_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named 'lif backward' in this block; cache: the value named 'cache' in this block; key_lif: the value named 'key lif' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1741: `value_gradient = self._lif_backward(cache.value_lif, merge_heads(value_head_gradient))` This assigns 'self._lif_backward(cache.value_lif, merge_heads(value_head_gradient))' to 'value_gradient ' in host memory. Here value_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named 'lif backward' in this block; cache: the value named 'cache' in this block; value_lif: the value named 'value lif' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1742: `token_input = cache.token_spikes.reshape(timesteps * batch * tokens, channels)` This assigns 'cache.token_spikes.reshape(timesteps * batch * tokens, channels)' to 'token_input ' in host memory. Here token_input means the value named 'token input' in this block. The important operands are cache: the value named 'cache' in this block; token_spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named 'reshape' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1743: `branch_input_gradients: list[BlockGradient] = []` This assigns '[]' to 'branch_input_gradients' in host memory. Here branch_input_gradients means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function _attention_backward, which handles attention backward.

Line 1744: `parameters: dict[str, ParameterGradient] = {` This statement continues through source line 1746; the explanation uses the complete expression rather than only the first visual fragment. This assigns '{ f"{prefix}.proj":

projection_parameter, }‘ to ‘parameters‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are f: the value named ’f’ in this block; prefix: the value named ’prefix’ in this block; proj: the value named ’proj’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1745: `f"{prefix}.proj": projection_parameter,` This is continuation line 2 of the 3-line logical statement that begins at source line 1744. Its exact fragment is ‘f"{prefix}.proj": projection_parameter,‘. The important operands are f: the value named ’f’ in this block; prefix: the value named ’prefix’ in this block; proj: the value named ’proj’ in this block. Read together, the complete operation is: This assigns ‘{ f"{prefix}.proj": projection_parameter, }‘ to ‘parameters‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are f: the value named ’f’ in this block; prefix: the value named ’prefix’ in this block; proj: the value named ’proj’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1746: `}` This is continuation line 3 of the 3-line logical statement that begins at source line 1744. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ f"{prefix}.proj": projection_parameter, }‘ to ‘parameters‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are f: the value named ’f’ in this block; prefix: the value named ’prefix’ in this block; proj: the value named ’proj’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1747: `for name, gradient in (` This line opens or closes a multi-line Python expression inside the function _attention_backward, which handles attention backward; the neighboring lines supply its arguments or elements.

Line 1748: `("q", query_gradient),` Inside the function _attention_backward, which handles attention backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are q: the value named ’q’ in this block; query_gradient: the signed loss derivative used to update a learned parameter.

Line 1749: `("k", key_gradient),` Inside the function _attention_backward, which handles attention backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are k: the value named ’k’ in this block; key_gradient: the signed loss derivative used to update a learned parameter.

Line 1750: `("v", value_gradient),` Inside the function _attention_backward, which handles attention backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are v: the value named ’v’ in this block; value_gradient: the signed loss derivative used to update a learned parameter.

Line 1751: `):` Inside the function _attention_backward, which handles attention backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1752: `rows = BlockGradient(` This statement continues through source line 1755; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘BlockGradient(gradient.values.reshape(timesteps * batch * tokens, channels), gradient.exponent,)‘ to ‘rows ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1753: `gradient.values.reshape(timesteps * batch * tokens, channels),` This is continuation line 2 of the 4-line logical statement that begins at source line 1752. Its exact fragment is ‘gradient.values.reshape(timesteps * batch * tokens, channels),‘. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; reshape: the value named ’reshape’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(gradient.values.reshape(timesteps * batch * tokens, channels), gradient.exponent,)‘ to ‘rows ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter;

gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1754: `gradient.exponent,` This is continuation line 3 of the 4-line logical statement that begins at source line 1752. Its exact fragment is 'gradient.exponent,'. The important operands are gradient: the signed loss derivative used to update a learned parameter; exponent: the value named 'exponent' in this block. Read together, the complete operation is: This assigns 'BlockGradient(gradient.values.reshape(timesteps * batch * tokens, channels), gradient.exponent,)' to 'rows ' in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1755: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1752. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'BlockGradient(gradient.values.reshape(timesteps * batch * tokens, channels), gradient.exponent,)' to 'rows ' in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1756: `input_rows, parameter = self._projection_matrix_backward(` This statement continues through source line 1757; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._projection_matrix_backward(f"{prefix}.{name}", token_input, rows)' to 'input_rows, parameter ' in host memory. Here input_rows means one output-row position processed by the tensor tile. The important operands are _projection_matrix_backward: the value named 'projection matrix backward' in this block; f: the value named 'f' in this block; prefix: the value named 'prefix' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1757: `f"{prefix}.{name}", token_input, rows)` This is continuation line 2 of the 2-line logical statement that begins at source line 1756. Its exact fragment is 'f"{prefix}.{name}", token_input, rows)'. The important operands are f: the value named 'f' in this block; prefix: the value named 'prefix' in this block; name: the value named 'name' in this block. Read together, the complete operation is: This assigns 'self._projection_matrix_backward(f"{prefix}.{name}", token_input, rows)' to 'input_rows, parameter ' in host memory. Here input_rows means one output-row position processed by the tensor tile. The important operands are _projection_matrix_backward: the value named 'projection matrix backward' in this block; f: the value named 'f' in this block; prefix: the value named 'prefix' in this block. Context: the function _attention_backward, which handles attention backward.

Line 1758: `branch_input_gradients.append(input_rows)` This calls 'branch_input_gradients.append' with 'input_rows' inside the function _attention_backward, which handles attention backward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1759: `parameters[f"{prefix}.{name}"] = parameter` Inside the function _attention_backward, which handles attention backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are parameters: the value named 'parameters' in this block; f: the value named 'f' in this block; prefix: the value named 'prefix' in this block.

Line 1760: `token_gradient = add_block_gradients(` This statement continues through source line 1765; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'add_block_gradients(self.driver, branch_input_gradients[0], branch_input_gradients[1], timeout_seconds=self.layer_timeout_seconds,)' to 'token_gradient ' in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; branch_input_gradients: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1761: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1760. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'add_block_gradients(self.driver, branch_input_gradients[0], branch_input_gradients[1], timeout_seconds=self.layer_timeout_seconds,)' to 'token_gradient ' in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; branch_input_gradients: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1762: `branch_input_gradients[0],` This is continuation line 3 of the 6-line logical statement that begins at source line 1760. Its exact fragment is 'branch_input_gradients[0],'. The important operands are branch_input_gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'add_block_gradients(self.driver, branch_input_gradients[0], branch_input_gradients[1], timeout_seconds=self.layer_timeout_s)' to 'token_gradient ' in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; branch_input_gradients: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1763: `branch_input_gradients[1],` This is continuation line 4 of the 6-line logical statement that begins at source line 1760. Its exact fragment is 'branch_input_gradients[1],'. The important operands are branch_input_gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'add_block_gradients(self.driver, branch_input_gradients[0], branch_input_gradients[1], timeout_seconds=self.layer_timeout_s)' to 'token_gradient ' in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; branch_input_gradients: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1764: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1760. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'add_block_gradients(self.driver, branch_input_gradients[0], branch_input_gradients[1], timeout_seconds=self.layer_timeout_seconds,)' to 'token_gradient ' in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; branch_input_gradients: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1765: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1760. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'add_block_gradients(self.driver, branch_input_gradients[0], branch_input_gradients[1], timeout_seconds=self.layer_timeout_seconds,)' to 'token_gradient ' in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; branch_input_gradients: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1766: `token_gradient = add_block_gradients(` This statement continues through source line 1771; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'add_block_gradients(self.driver, token_gradient, branch_input_gradients[2], timeout_seconds=self.layer_timeout_seconds,)' to 'token_gradient ' in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; token_gradient: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1767: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1766. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together,

the complete operation is: This assigns ‘add_block_gradients(self.driver, token_gradient, branch_input_gradients[2], timeout_seconds=self.layer_timeout_seconds,)‘ to ‘token_gradient ‘ in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; token_gradient: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1768: `token_gradient,` This is continuation line 3 of the 6-line logical statement that begins at source line 1766. Its exact fragment is ‘token_gradient,‘. The important operands are token_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘add_block_gradients(self.driver, token_gradient, branch_input_gradients[2], timeout_seconds=self.layer_timeout_seconds,)‘ to ‘token_gradient ‘ in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; token_gradient: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1769: `branch_input_gradients[2],` This is continuation line 4 of the 6-line logical statement that begins at source line 1766. Its exact fragment is ‘branch_input_gradients[2],‘. The important operands are branch_input_gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘add_block_gradients(self.driver, token_gradient, branch_input_gradients[2], timeout_seconds=self.layer_timeout_seconds,)‘ to ‘token_gradient ‘ in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; token_gradient: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1770: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1766. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘add_block_gradients(self.driver, token_gradient, branch_input_gradients[2], timeout_seconds=self.layer_timeout_seconds,)‘ to ‘token_gradient ‘ in host memory. Here token_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; token_gradient: the signed loss derivative used to update a learned parameter. Context: the function _attention_backward, which handles attention backward.

Line 1771: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1766. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘add_block_gradients(self.driver, token_gradient, branch_input_gradients[2], timeout_seconds=self.layer_timeout_seconds,)‘ to ‘token_gradient ‘ in host memory. Line 1772: `projection_spike_gradient = self._rows_to_channel_first(` This statement continues through source line 1773; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._rows_to_channel_first(token_gradient, cache.input_shape)‘ to ‘projection_spike_gradient ‘ in host memory. Here projection_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are _rows_to_channel_first: one output-row position processed by the tensor tile; token_gradient: the signed loss derivative used to update a learned parameter; cache: the value named ’cache’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1773: `token_gradient, cache.input_shape)` This is continuation line 2 of the 2-line logical statement that begins at source line 1772. Its exact fragment is ‘token_gradient, cache.input_shape)‘. The important operands are token_gradient: the signed loss derivative used to update a learned parameter; cache: the value named ’cache’ in this block; input_shape: the value named ’input shape’ in this block. Read together, the complete operation is: This assigns

‘self._rows_to_channel_first(token_gradient, cache.input_shape)‘ to ‘projection_spike_gradient ‘ in host memory. Here projection_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are _rows_to_channel_first: one output-row position processed by the tensor tile; token_gradient: the signed loss derivative used to update a learned parameter; cache: the value named ’cache’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1774: `input_gradient = self._lif_backward(` This statement continues through source line 1775; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._lif_backward(cache.projection_lif, projection_spike_gradient)‘ to ‘input_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named ’lif backward’ in this block; cache: the value named ’cache’ in this block; projection_lif: the value named ’projection lif’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1775: `cache.projection_lif, projection_spike_gradient)` This is continuation line 2 of the 2-line logical statement that begins at source line 1774. Its exact fragment is ‘cache.projection_lif, projection_spike_gradient)‘. The important operands are cache: the value named ’cache’ in this block; projection_lif: the value named ’projection lif’ in this block; projection_spike_gradient: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns ‘self._lif_backward(cache.projection_lif, projection_spike_gradient)‘ to ‘input_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named ’lif backward’ in this block; cache: the value named ’cache’ in this block; projection_lif: the value named ’projection lif’ in this block. Context: the function _attention_backward, which handles attention backward.

Line 1776: `return input_gradient, parameters` This returns ‘input_gradient, parameters‘ to the caller of the function _attention_backward, which handles attention backward, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; parameters: the value named ’parameters’ in this block.

Line 1778: `def _block_backward(` This starts function _block_backward. Its indented body performs block backward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1779: `self,` Inside the function _block_backward, which handles block backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1780: `cache: TransformerBlockCache,` Inside the function _block_backward, which handles block backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are cache: the value named ’cache’ in this block; TransformerBlockCache: the value named ’transformer block cache’ in this block.

Line 1781: `output_gradient: BlockGradient,` Inside the function _block_backward, which handles block backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1782: `) -> tuple[BlockGradient, dict[str, ParameterGradient]]:` Inside the function _block_backward, which handles block backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named ’tuple’ in this block; BlockGradient: the signed loss derivative used to update a learned parameter; dict: the value named ’dict’ in this block.

Line 1783: `residual_two_gradient = self._gate_saturating_add_gradient(` This statement continues through source line 1784; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._gate_saturating_add_gradient(output_gradient, cache.after_attention, cache.mlp.output)‘ to ‘residual_two_gradient ‘ in host memory. Here residual_two_gradient means the signed loss derivative used to update a learned parameter. The important operands are _gate_saturating_add_gradient: the signed loss derivative used to update a learned parameter; output_gradient: the signed loss derivative used to update a learned parameter; cache: the value named ’cache’ in this block. Context: the function _block_backward, which handles block backward.

Line 1784: `output_gradient, cache.after_attention, cache.mlp.output)` This is continuation line 2 of the 2-line logical statement that begins at source line 1783. Its exact fragment is ‘output_gradient, cache.after_attention, cache.mlp.output)‘. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; cache: the value named ’cache’ in this block; after_attention: the value named ’after attention’ in this block. Read together, the complete operation is: This assigns ‘self._gate_saturating_add_gradient(output_gradient, cache.after_attention, cache.mlp.output)‘ to ‘residual_two_gradient ‘ in host memory. Here residual_two_gradient means the signed loss derivative used to update a learned parameter. The important operands are _gate_saturating_add_gradient: the signed loss derivative used to update a learned parameter; output_gradient: the signed loss derivative used to update a learned parameter; cache: the value named ’cache’ in this block. Context: the function _block_backward, which handles block backward.

Line 1785: `mlp_input_gradient, mlp_parameters = self._mlp_backward(` This statement continues through source line 1786; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._mlp_backward(cache.mlp, residual_two_gradient)‘ to ‘mlp_input_gradient, mlp_parameters ‘ in host memory. Here mlp_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _mlp_backward: the value named ’mlp backward’ in this block; cache: the value named ’cache’ in this block; mlp: the value named ’mlp’ in this block. Context: the function _block_backward, which handles block backward.

Line 1786: `cache.mlp, residual_two_gradient)` This is continuation line 2 of the 2-line logical statement that begins at source line 1785. Its exact fragment is ‘cache.mlp, residual_two_gradient)‘. The important operands are cache: the value named ’cache’ in this block; mlp: the value named ’mlp’ in this block; residual_two_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘self._mlp_backward(cache.mlp, residual_two_gradient)‘ to ‘mlp_input_gradient, mlp_parameters ‘ in host memory. Here mlp_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _mlp_backward: the value named ’mlp backward’ in this block; cache: the value named ’cache’ in this block; mlp: the value named ’mlp’ in this block. Context: the function _block_backward, which handles block backward.

Line 1787: `after_attention_gradient = add_block_gradients(` This statement continues through source line 1792; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘add_block_gradients(self.driver, residual_two_gradient, mlp_input_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘after_attention_grad ‘ in host memory. Here after_attention_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; residual_two_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1788: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1787. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘add_block_gradients(self.driver, residual_two_gradient, mlp_input_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘after_attention_gradient ‘ in host memory. Here after_attention_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; residual_two_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1789: `residual_two_gradient,` This is continuation line 3 of the 6-line logical statement that begins at source line 1787. Its exact fragment is ‘residual_two_gradient,‘. The important operands are residual_two_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘add_block_gradients(self.driver, residual_two_gradient, mlp_input_gradient, timeout_seconds=self.layer_timeout_seconds,

)‘ to ‘after_attention_gradient ‘ in host memory. Here after_attention_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; residual_two_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1790: `mlp_input_gradient,` This is continuation line 4 of the 6-line logical statement that begins at source line 1787. Its exact fragment is ‘mlp_input_gradient,‘. The important operands are mlp_input_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘add_block_gradients(self.driver, residual_two_gradient, mlp_input_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘after_attention_grad ‘ in host memory. Here after_attention_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; residual_two_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1791: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1787. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘add_block_gradients(self.driver, residual_two_gradient, mlp_input_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘after_attention_grad ‘ in host memory. Here after_attention_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; residual_two_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1792: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1787. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘add_block_gradients(self.driver, residual_two_gradient, mlp_input_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘after_attention_gradient ‘ in host memory. Here after_attention_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; residual_two_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1793: `residual_one_gradient = self._gate_saturating_add_gradient(` This statement continues through source line 1794; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._gate_saturating_add_gradient(after_attention_gradient, cache.input_value, cache.attention.output)‘ to ‘residual_one_gradient ‘ in host memory. Here residual_one_gradient means the signed loss derivative used to update a learned parameter. The important operands are _gate_saturating_add_gradient: the signed loss derivative used to update a learned parameter; after_attention_gradient: the signed loss derivative used to update a learned parameter; cache: the value named ’cache’ in this block. Context: the function _block_backward, which handles block backward.

Line 1794: `after_attention_gradient, cache.input_value, cache.attention.output)` This is continuation line 2 of the 2-line logical statement that begins at source line 1793. Its exact fragment is ‘after_attention_gradient, cache.input_value, cache.attention.output)‘. The important operands are after_attention_gradient: the signed loss derivative used to update a learned parameter; cache: the value named ’cache’ in this block; input_value: the value named ’input value’ in this block. Read together, the complete operation is: This assigns ‘self._gate_saturating_add_gradient(after_attention_gradient, cache.input_value, cache.attention.output)‘ to ‘residual_one_gradient ‘ in host memory. Here residual_one_gradient means the signed loss derivative used to update a learned parameter. The important operands are _gate_saturating_add_gradient: the signed loss derivative used to update a learned parameter; after_attention_gradient: the signed loss derivative used to update a learned parameter; cache: the value named ’cache’ in this block. Context: the function _block_backward, which handles block backward.

Line 1795: `attention_input_gradient, attention_parameters = self._attention_backward(` This statement continues through source line 1796; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._attention_backward(cache.attention, residual_one_gradient)‘ to ‘attention_input_gradient, attention_parameters ‘ in host memory. Here attention_input_gradient means the signed loss derivative used to update

a learned parameter. The important operands are _attention_backward: the value named 'attention backward' in this block; cache: the value named 'cache' in this block; attention: the value named 'attention' in this block. Context: the function _block_backward, which handles block backward.

Line 1796: `cache.attention, residual_one_gradient)` This is continuation line 2 of the 2-line logical statement that begins at source line 1795. Its exact fragment is 'cache.attention, residual_one_gradient)'. The important operands are cache: the value named 'cache' in this block; attention: the value named 'attention' in this block; residual_one_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'self._attention_backward(cache.attention, residual_one_gradient)' to 'attention_input_gradient, attention_parameters ' in host memory. Here attention_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _attention_backward: the value named 'attention backward' in this block; cache: the value named 'cache' in this block; attention: the value named 'attention' in this block. Context: the function _block_backward, which handles block backward.

Line 1797: `input_gradient = add_block_gradients(` This statement continues through source line 1802; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'add_block_gradients(self.driver, residual_one_gradient, attention_input_gradient, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; residual_one_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1798: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1797. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'add_block_gradients(self.driver, residual_one_gradient, attention_input_gradient, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; residual_one_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1799: `residual_one_gradient,` This is continuation line 3 of the 6-line logical statement that begins at source line 1797. Its exact fragment is 'residual_one_gradient,'. The important operands are residual_one_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'add_block_gradients(self.driver, residual_one_gradient, attention_input_gradient, timeout_seconds=self.layer_timeout_second)' to 'input_gradient ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; residual_one_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1800: `attention_input_gradient,` This is continuation line 4 of the 6-line logical statement that begins at source line 1797. Its exact fragment is 'attention_input_gradient,'. The important operands are attention_input_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'add_block_gradients(self.driver, residual_one_gradient, attention_input_gradient, timeout_seconds=self.layer_timeout_second)' to 'input_gradient ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; residual_one_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1801: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1797. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'add_block_gradients(self.driver, residual_one_gradient, attention_input_gradient, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver:

the value named 'driver' in this block; residual_one_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1802: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1797. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'add_block_gradients(self.driver, residual_one_gradient, attention_input_gradient, timeout_seconds=self.layer_timeout_seconds,)' to 'input_gradient ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are add_block_gradients: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; residual_one_gradient: the signed loss derivative used to update a learned parameter. Context: the function _block_backward, which handles block backward.

Line 1803: `return input_gradient, {**attention_parameters, **mlp_parameters}` This returns 'input_gradient, {**attention_parameters, **mlp_parameters}' to the caller of the function _block_backward, which handles block backward, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; attention_parameters: the value named 'attention parameters' in this block; mlp_parameters: the value named 'mlp parameters' in this block.

Line 1805: `def _sum_timestep_gradients(self, gradient: BlockGradient) -> BlockGradient:` This starts function _sum_timestep_gradients. Its indented body performs sum timestep gradients as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1806: `parts = [` This statement continues through source line 1809; the explanation uses the complete expression rather than only the first visual fragment. This assigns '[BlockGradient(gradient.values[timestep], gradient.exponent) for timestep in range(gradient.values.shape[0])]' to 'parts ' in host memory. Here parts means the value named 'parts' in this block. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _sum_timestep_gradients, which handles sum timestep gradients.

Line 1807: `BlockGradient(gradient.values[timestep], gradient.exponent)` This is continuation line 2 of the 4-line logical statement that begins at source line 1806. Its exact fragment is 'BlockGradient(gradient.values[timestep], gradient.exponent)'. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Read together, the complete operation is: This assigns '[BlockGradient(gradient.values[timestep], gradient.exponent) for timestep in range(gradient.values.shape[0])]' to 'parts ' in host memory. Here parts means the value named 'parts' in this block. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _sum_timestep_gradients, which handles sum timestep gradients.

Line 1808: `for timestep in range(gradient.values.shape[0])` This is continuation line 3 of the 4-line logical statement that begins at source line 1806. Its exact fragment is 'for timestep in range(gradient.values.shape[0])'. The important operands are for: the value named 'for' in this block; timestep: one discrete SNN update instant; in: the value named 'in' in this block. Read together, the complete operation is: This assigns '[BlockGradient(gradient.values[timestep], gradient.exponent) for timestep in range(gradient.values.shape[0])]' to 'parts ' in host memory. Here parts means the value named 'parts' in this block. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _sum_timestep_gradients, which handles sum timestep gradients.

Line 1809: `]` This is continuation line 4 of the 4-line logical statement that begins at source line 1806. Its exact fragment is ']'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '[BlockGradient(gradient.values[timestep], gradient.exponent) for timestep in range(gradient.values.shape[0])]' to 'parts ' in host memory. Here parts means the value named 'parts' in this block. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named 'values' in this block. Context: the function _sum_timestep_gradients, which handles sum timestep gradients.

Line 1810: `while len(parts) > 1:` This repeats the following host-code block while ‘len(parts) > 1‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 1811: `reduced: list[BlockGradient] = []` This assigns ‘[]‘ to ‘reduced‘ in host memory. Here reduced means the value named ’reduced’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _sum_timestep_gradients, which handles sum timestep gradients.

Line 1812: `for index in range(0, len(parts) - 1, 2):` This iterates index over ‘range(0, len(parts) - 1, 2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _sum_timestep_gradients, which handles sum timestep gradients.

Line 1813: `reduced.append(add_block_gradients(` This statement continues through source line 1818; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘reduced.append‘ with ‘add_block_gradients(self.driver, parts[index], parts[index + 1], timeout_seconds=self.layer_timeout_seconds,)‘ inside the function _sum_timestep_gradients, which handles sum timestep gradients. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1814: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1813. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This calls ‘reduced.append‘ with ‘add_block_gradients(self.driver, parts[index], parts[index + 1], timeout_seconds=self.layer_timeout_seconds,)‘ inside the function _sum_timestep_gradients, which handles sum timestep gradients. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1815: `parts[index],` This is continuation line 3 of the 6-line logical statement that begins at source line 1813. Its exact fragment is ‘parts[index],‘. The important operands are parts: the value named ’parts’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘reduced.append‘ with ‘add_block_gradients(self.driver, parts[index], parts[index + 1], timeout_seconds=self.layer_timeout_seconds)‘ inside the function _sum_timestep_gradients, which handles sum timestep gradients. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1816: `parts[index + 1],` This is continuation line 4 of the 6-line logical statement that begins at source line 1813. Its exact fragment is ‘parts[index + 1],‘. The important operands are parts: the value named ’parts’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘reduced.append‘ with ‘add_block_gradients(self.driver, parts[index], parts[index + 1], timeout_seconds=self.layer_timeout_seconds,)‘ inside the function _sum_timestep_gradients, which handles sum timestep gradients. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1817: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1813. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This calls ‘reduced.append‘ with ‘add_block_gradients(self.driver, parts[index], parts[index + 1], timeout_seconds=self.layer_timeout_seconds,)‘ inside the function _sum_timestep_gradients, which handles sum timestep gradients. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1818: `))` This is continuation line 6 of the 6-line logical statement that begins at source line 1813. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘reduced.append‘ with ‘add_block_gradients(self.driver, parts[index], parts[index + 1], timeout_seconds=self.layer_timeout_seconds,)‘ inside the function _sum_timestep_gradients, which handles sum timestep gradients. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1819: `if len(parts) & 1:` This executes the following indented host-code branch only when ‘len(parts) & 1‘ is true. The important operands are len: the value named ’len’ in this block; parts: the value named ’parts’ in this block. Context: the function _sum_timestep_gradients, which handles sum timestep gradients.

Line 1820: `reduced.append(parts[-1])` This calls ‘reduced.append‘ with ‘parts[-1]‘ inside the function _sum_timestep_gradien which handles sum timestep gradients. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1821: `parts = reduced` This assigns ‘reduced‘ to ‘parts ‘ in host memory. Here parts means the value named ’parts’ in this block. The important operands are reduced: the value named ’reduced’ in this block. Context: the function _sum_timestep_gradients, which handles sum timestep gradients.

Line 1822: `return parts[0]` This returns ‘parts[0]‘ to the caller of the function _sum_timestep_gradients, which handles sum timestep gradients, ending this invocation. The important operands are parts: the value named ’parts’ in this block.

Line 1824: `def _tokenizer_backward(` This starts function _tokenizer_backward. Its indented body performs tokenizer backward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1825: `self,` Inside the function _tokenizer_backward, which handles tokenizer backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1826: `caches: tuple[TokenizerLayerCache, ...],` Inside the function _tokenizer_backward, which handles tokenizer backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are caches: the value named ’caches’ in this block; tuple: the value named ’tuple’ in this block; TokenizerLayerCache: the value named ’tokenizer layer cache’ in this block.

Line 1827: `output_gradient: BlockGradient,` Inside the function _tokenizer_backward, which handles tokenizer backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 1828: `) -> tuple[BlockGradient, dict[str, ParameterGradient]]:` Inside the function _tokenizer_backward, which handles tokenizer backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are tuple: the value named ’tuple’ in this block; BlockGradient: the signed loss derivative used to update a learned parameter; dict: the value named ’dict’ in this block.

Line 1829: `gradient = output_gradient` This assigns ‘output_gradient‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are output_gradient: the signed loss derivative used to update a learned parameter. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1830: `parameters: dict[str, ParameterGradient] = {}` This assigns ‘{}‘ to ‘parameters‘ in host memory. Here parameters means the value named ’parameters’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1831: `for index in range(4, 0, -1):` This iterates index over ‘range(4, 0, -1)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _tokenizer_backward, which handles tokenizer backward.

Line 1832: `cache = caches[index]` This assigns ‘caches[index]‘ to ‘cache ‘ in host memory. Here cache means the value named ’cache’ in this block. The important operands are caches: the value named ’caches’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1833: `if cache.lif is None:` This executes the following indented host-code branch only when ‘cache.lif is None‘ is true. The important operands are cache: the value named ’cache’ in this block; lif: the value named ’lif’ in this block; is: the value named ’is’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1834: `raise RuntimeError("nonzero tokenizer layer has no LIF trace")` This rejects an invalid state by raising ‘RuntimeError("nonzero tokenizer layer has no LIF trace")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1835: `flat_gradient = BlockGradient(` This statement continues through source line 1838; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘BlockGradient(gradient.values.reshape(-1, *gradient.values.shape[2:]), gradient.exponent,)‘ to ‘flat_gradient ‘ in host memory. Here flat_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1836: `gradient.values.reshape(-1, *gradient.values.shape[2:]),` This is continuation line 2 of the 4-line logical statement that begins at source line 1835. Its exact fragment is ‘gradient.values.reshape(-1, *gradient.values.shape[2:]),‘. The important operands are gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; reshape: the value named ’reshape’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(gradient.values.reshape(-1, *gradient.values.shape[2:]), gradient.exponent,)‘ to ‘flat_gradient ‘ in host memory. Here flat_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1837: `gradient.exponent,` This is continuation line 3 of the 4-line logical statement that begins at source line 1835. Its exact fragment is ‘gradient.exponent,‘. The important operands are gradient: the signed loss derivative used to update a learned parameter; exponent: the value named ’exponent’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(gradient.values.reshape(-1, *gradient.values.shape[2:]), gradient.exponent,)‘ to ‘flat_gradient ‘ in host memory. Here flat_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1838: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1835. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘BlockGradient(gradient.values.reshape(-1, *gradient.values.shape[2:]), gradient.exponent,)‘ to ‘flat_gradient ‘ in host memory. Here flat_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1839: `name = f"patch_embed.block{index}"` This assigns ‘f"patch_embed.block{index}"‘ to ‘name ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1840: `projection_input_gradient, parameter = self._projection_conv2d_backward(` This statement continues through source line 1845; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._projection_conv2d_backward(name, cache.projection_input, flat_gradient, padding=1,)‘ to ‘projection_input_gradient, parameter ‘ in host memory. Here projection_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; name: the value named ’name’ in this block; cache: the value named ’cache’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1841: `name,` This is continuation line 2 of the 6-line logical statement that begins at source line 1840. Its exact fragment is ‘name,‘. The important operands are name: the value named ’name’ in this block. Read together, the complete operation is: This assigns ‘self._projection_conv2d_backward(name, cache.projection_input, flat_gradient, padding=1,)‘ to ‘projection_input_gradient, parameter ‘ in host memory. Here projection_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; name: the value named ’name’ in this block; cache: the value named ’cache’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1842: `cache.projection_input,` This is continuation line 3 of the 6-line logical statement that begins at source line 1840. Its exact fragment is ‘cache.projection_input,‘. The important operands are cache: the value named ’cache’ in this block; projection_input: the value named ’projection input’ in this block. Read together, the complete operation is: This assigns ‘self._projection_conv2d_backward(name, cache.projection_input, flat_gradient, padding=1,)‘ to ‘projection_input_gradient, parameter ‘ in host memory. Here projection_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; name: the value named ’name’ in this block; cache: the value named ’cache’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1843: `flat_gradient,` This is continuation line 4 of the 6-line logical statement that begins at source line 1840. Its exact fragment is ‘flat_gradient,‘. The important operands are flat_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘self._projection_conv2d_backward(name, cache.projection_input, flat_gradient, padding=1,)‘ to ‘projection_input_gradient, parameter ‘ in host memory. Here projection_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; name: the value named ’name’ in this block; cache: the value named ’cache’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1844: `padding=1,` This is continuation line 5 of the 6-line logical statement that begins at source line 1840. Its exact fragment is ‘padding=1,‘. The important operands are padding: the value named ’padding’ in this block. Read together, the complete operation is: This assigns ‘self._projection_conv2d_backward(name, cache.projection_input, flat_gradient, padding=1,)‘ to ‘projection_input_gradient, parameter ‘ in host memory. Here projection_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; name: the value named ’name’ in this block; cache: the value named ’cache’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1845: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1840. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘self._projection_conv2d_backward(name, cache.projection_input, flat_gradient, padding=1,)‘ to ‘projection_input_gradient, parameter ‘ in host memory. Here projection_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; name: the value named ’name’ in this block; cache: the value named ’cache’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1846: `parameters[name] = parameter` This assigns ‘parameter‘ to ‘parameters[name] ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are parameter: the value named ’parameter’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1847: `if cache.pooled:` This executes the following indented host-code branch only when ‘cache.pooled‘ is true. The important operands are cache: the value named ’cache’ in this block; pooled: the value named ’pooled’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1848: `flat_spikes = cache.lif.spikes.reshape(-1, *cache.lif.spikes.shape[2:])` This assigns ‘cache.lif.spikes.re
1, *cache.lif.spikes.shape[2:])‘ to ‘flat_spikes ‘ in host memory. Here flat_spikes means a binary event produced when a neuron crosses its threshold. The important operands are cache: the value named ’cache’ in this block; lif: the value named ’lif’ in this block; spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1849: `spike_gradient, _ = execute_maxpool2d_backward(` This statement continues through source line 1857; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_maxpool2d_backward(self.driver, flat_spikes, projection_input_gradient.values, kernel_size=3, stride=2, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spike_gradient, _ ‘ in host memory. Here spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are execute_maxpool2d_backward: the value named ’execute maxpool2d backward’ in this block; driver: the value named ’driver’ in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1850: `self.driver,` This is continuation line 2 of the 9-line logical statement that begins at source line 1849. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘execute_maxpool2d_backward(self.driver, flat_spikes, projection_input_gradient.values, kernel_size=3, stride=2, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spike_gradient, _ ‘ in host memory. Here spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are execute_maxpool2d_backward: the value named ’execute maxpool2d backward’ in this block; driver: the value named ’driver’ in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1851: `flat_spikes,` This is continuation line 3 of the 9-line logical statement that begins at source line 1849. Its exact fragment is ‘flat_spikes,‘. The important operands are flat_spikes: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns ‘execute_maxpool2d_backward(self.driver, flat_spikes, projection_input_gradient.values, kernel_size=3, stride=2, padding=1, timeout_seconds=self.layer_timeout_seconds
)‘ to ‘spike_gradient, _ ‘ in host memory. Here spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are execute_maxpool2d_backward: the value named ’execute maxpool2d backward’ in this block; driver: the value named ’driver’ in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1852: `projection_input_gradient.values,` This is continuation line 4 of the 9-line logical statement that begins at source line 1849. Its exact fragment is ‘projection_input_gradient.values,‘. The important operands are projection_input_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Read together, the complete operation is: This assigns ‘execute_maxpool2d_backward(self.driver, flat_spikes, projection_input_gradient.values, kernel_size=3, stride=2, padding=1, timeout_seconds=self.layer_timeout_seconds
)‘ to ‘spike_gradient, _ ‘ in host memory. Here spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are execute_maxpool2d_backward: the value named ’execute maxpool2d backward’ in this block; driver: the value named ’driver’ in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1853: `kernel_size=3,` This is continuation line 5 of the 9-line logical statement that begins at source line 1849. Its exact fragment is ‘kernel_size=3,‘. The important operands are kernel_size: the value named ’kernel size’ in this block. Read together, the complete operation is: This assigns ‘execute_maxpool2d_backward(self.driver, flat_spikes, projection_input_gradient.values, kernel_size=3, stride=2, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘spike_gradient, _ ‘ in host memory. Here spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are execute_maxpool2d_backward: the value named ’execute maxpool2d backward’ in this block; driver: the value named ’driver’ in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1854: `stride=2,` This is continuation line 6 of the 9-line logical statement that begins at source line 1849. Its exact fragment is 'stride=2,'. The important operands are stride: the value named 'stride' in this block. Read together, the complete operation is: This assigns 'execute_maxpool2d_backward(self.driver, flat_spikes, projection_input_gradient.values, kernel_size=3, stride=2, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'spike_gradient, _ ' in host memory. Here spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; driver: the value named 'driver' in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1855: `padding=1,` This is continuation line 7 of the 9-line logical statement that begins at source line 1849. Its exact fragment is 'padding=1,'. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'execute_maxpool2d_backward(self.driver, flat_spikes, projection_input_gradient.values, kernel_size=3, stride=2, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'spike_gradient, _ ' in host memory. Here spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; driver: the value named 'driver' in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1856: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 8 of the 9-line logical statement that begins at source line 1849. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_maxpool2d_backward(self.driver, flat_spikes, projection_input_gradient.values, kernel_size=3, stride=2, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'spike_gradient, _ ' in host memory. Here spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; driver: the value named 'driver' in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1857: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 1849. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_maxpool2d_backward(self.driver, flat_spikes, projection_input_gradient.values, kernel_size=3, stride=2, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'spike_gradient, _ ' in host memory. Here spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block; driver: the value named 'driver' in this block; flat_spikes: a binary event produced when a neuron crosses its threshold. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1858: `projection_input_gradient = BlockGradient(` This statement continues through source line 1859; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'BlockGradient(spike_gradient, projection_input_gradient.exponent)' to 'projection_input_gradient ' in host memory. Here projection_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; spike_gradient: a binary event produced when a neuron crosses its threshold; projection_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1859: `spike_gradient, projection_input_gradient.exponent)` This is continuation line 2 of the 2-line logical statement that begins at source line 1858. Its exact fragment is 'spike_gradient, projection_input_gradient.exponent)'. The important operands are spike_gradient: a binary event produced when a neuron crosses its threshold; projection_input_gradient: the signed loss derivative used to update a learned parameter; exponent: the value named 'exponent' in this block. Read together, the complete operation is: This assigns 'BlockGradient(spike_gradient, projection_input_gradient.exponent)' to 'projection_input_gradient ' in host memory. Here projection_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; spike_gradient: a binary event produced when a neuron crosses its threshold; projection_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1860: `lif_spike_gradient = BlockGradient(` This statement continues through source line 1863; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘BlockGradient(projection_input_gradient.values.reshape(cache.lif.spikes.shape), projection_input_gradient.exponent,)‘ to ‘lif_spike_gradient ‘ in host memory. Here lif_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; projection_input_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1861: `projection_input_gradient.values.reshape(cache.lif.spikes.shape),` This is continuation line 2 of the 4-line logical statement that begins at source line 1860. Its exact fragment is ‘projection_input_gradient.values.reshape(cache.l The important operands are projection_input_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; reshape: the value named ’reshape’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(projection_input_gradient.values.reshape(cache.lif.spikes.shape), projection_input_gradient.exponent,)‘ to ‘lif_spike_gradient ‘ in host memory. Here lif_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; projection_input_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1862: `projection_input_gradient.exponent,` This is continuation line 3 of the 4-line logical statement that begins at source line 1860. Its exact fragment is ‘projection_input_gradient.exponent,‘. The important operands are projection_input_gradient: the signed loss derivative used to update a learned parameter; exponent: the value named ’exponent’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(projection_input_gradient.values.reshape projection_input_gradient.exponent,)‘ to ‘lif_spike_gradient ‘ in host memory. Here lif_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; projection_input_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1863: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1860. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘BlockGradient(projection_input_gradient.values.reshape(cache.lif.spikes.shape), projection_input_gradient.exponent,)‘ to ‘lif_spike_gradient ‘ in host memory. Here lif_spike_gradient means a binary event produced when a neuron crosses its threshold. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; projection_input_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1864: `gradient = self._lif_backward(cache.lif, lif_spike_gradient)` This assigns ‘self._lif_backward(cache.lif, lif_spike_gradient)‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are _lif_backward: the value named ’lif backward’ in this block; cache: the value named ’cache’ in this block; lif: the value named ’lif’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1866: `first_output_gradient = self._sum_timestep_gradients(gradient)` This assigns ‘self._sum_timestep_gradie to ‘first_output_gradient ‘ in host memory. Here first_output_gradient means the signed loss derivative used to update a learned parameter. The important operands are _sum_timestep_gradients: the signed loss derivative used to update a learned parameter; gradient: the signed loss derivative used to update a learned parameter. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1867: `first_cache = caches[0]` This assigns ‘caches[0]‘ to ‘first_cache ‘ in host memory. Here first_cache means the value named ’first cache’ in this block. The important operands are caches: the value named ’caches’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1868: `image_gradient, first_parameter = self._projection_conv2d_backward(` This statement continues through source line 1873; the explanation uses the complete expression rather than only the first visual fragment. This as-

signs ‘self._projection_conv2d_backward("patch_embed.block0", first_cache.projection_input, first_output_gradient, padding=1,)‘ to ‘image_gradient, first_parameter ‘ in host memory. Here image_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; patch_embed: the value named ’patch embed’ in this block; block0: the value named ’block0’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1869: `"patch_embed.block0",` This is continuation line 2 of the 6-line logical statement that begins at source line 1868. Its exact fragment is ‘"patch_embed.block0",‘. The important operands are patch_embed: the value named ’patch embed’ in this block; block0: the value named ’block0’ in this block. Read together, the complete operation is: This assigns ‘self._projection_conv2d_backward("patch_embed.block0", first_cache.projection_input, first_output_gradient, padding=1,)‘ to ‘image_gradient, first_parameter ‘ in host memory. Here image_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; patch_embed: the value named ’patch embed’ in this block; block0: the value named ’block0’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1870: `first_cache.projection_input,` This is continuation line 3 of the 6-line logical statement that begins at source line 1868. Its exact fragment is ‘first_cache.projection_input,‘. The important operands are first_cache: the value named ’first cache’ in this block; projection_input: the value named ’projection input’ in this block. Read together, the complete operation is: This assigns ‘self._projection_conv2d_backward("patch_embed.block0", first_cache.projection_input, first_output_gradient, padding=1,)‘ to ‘image_gradient, first_parameter ‘ in host memory. Here image_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; patch_embed: the value named ’patch embed’ in this block; block0: the value named ’block0’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1871: `first_output_gradient,` This is continuation line 4 of the 6-line logical statement that begins at source line 1868. Its exact fragment is ‘first_output_gradient,‘. The important operands are first_output_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘self._projection_conv2d_backward("patch_embed.block0", first_cache.projection_input, first_output_gradient, padding=1,)‘ to ‘image_gradient, first_parameter ‘ in host memory. Here image_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; patch_embed: the value named ’patch embed’ in this block; block0: the value named ’block0’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1872: `padding=1,` This is continuation line 5 of the 6-line logical statement that begins at source line 1868. Its exact fragment is ‘padding=1,‘. The important operands are padding: the value named ’padding’ in this block. Read together, the complete operation is: This assigns ‘self._projection_conv2d_backward("patch_embed.block0", first_cache.projection_input, first_output_gradient, padding=1,)‘ to ‘image_gradient, first_parameter ‘ in host memory. Here image_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; patch_embed: the value named ’patch embed’ in this block; block0: the value named ’block0’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1873: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1868. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘self._projection_conv2d_backward("patch_embed.block0", first_cache.projection_input, first_output_gradient, padding=1,)‘ to ‘image_gradient, first_parameter ‘ in host memory. Here image_gradient means the signed loss derivative used to update a learned parameter. The important operands are _projection_conv2d_backward: the value named ’projection conv2d backward’ in this block; patch_embed: the value named ’patch embed’ in this block; block0: the value named ’block0’ in this block. Context: the function _tokenizer_backward, which handles tokenizer backward.

Line 1874: `parameters["patch_embed.block0"] = first_parameter` Inside the function _tokenizer_backward, which handles tokenizer backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are

parameters: the value named 'parameters' in this block; patch_embed: the value named 'patch embed' in this block; block0: the value named 'block0' in this block.

Line 1875: `return image_gradient, parameters` This returns 'image_gradient, parameters' to the caller of the function _tokenizer_backward, which handles tokenizer backward, ending this invocation. The important operands are image_gradient: the signed loss derivative used to update a learned parameter; parameters: the value named 'parameters' in this block.

Line 1877: `def backward(` This starts function backward. Its indented body performs backward as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1878: `self,` Inside the function backward, which handles backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1879: `cache: SpikingformerTrainingCache,` Inside the function backward, which handles backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are cache: the value named 'cache' in this block; SpikingformerTrainingCache: the value named 'spikingformer training cache' in this block.

Line 1880: `labels,` Inside the function backward, which handles backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are labels: the value named 'labels' in this block.

Line 1881: `) -> TrainingBackwardResult:` Inside the function backward, which handles backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are TrainingBackwardResult: the value named 'training backward result' in this block.

Line 1882: `"""Reverse every exported operator and produce all trainable gradients."""` This is executable documentation attached to the function backward, which handles backward. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1884: `labels_array = np.asarray(labels, dtype=np.int64)` This assigns 'np.asarray(labels, dtype=np.int64)' to 'labels_array ' in host memory. Here labels_array means the value named 'labels array' in this block. The important operands are asarray: the value named 'asarray' in this block; labels: the value named 'labels' in this block; dtype: the value named 'dtype' in this block. Context: the function backward, which handles backward.

Line 1885: `probabilities = execute_softmax_q15(` This statement continues through source line 1890; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_softmax_q15(self.driver, cache.logits_accumulator, difference_shift=self.softmax_difference_shift, timeout_seconds=self.layer_timeout_second)' to 'probabilities ' in host memory. Here probabilities means the value named 'probabilities' in this block. The important operands are execute_softmax_q15: the value named 'execute softmax q15' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1886: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1885. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_softmax_q15(self.driver, cache.logits_accumulator, difference_shift=self.softmax_difference_shift, timeout_seconds=self.layer_timeout_seconds,)' to 'probabilities ' in host memory. Here probabilities means the value named 'probabilities' in this block. The important operands are execute_softmax_q15: the value named 'execute softmax q15' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1887: `cache.logits_accumulator,` This is continuation line 3 of the 6-line logical statement that begins at source line 1885. Its exact fragment is 'cache.logits_accumulator,'. The important operands are cache: the value named 'cache' in this block; logits_accumulator: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This assigns 'execute_softmax_q15(self.driver, cache.logits_accumulator, difference_shift=self.softmax_difference_shift, timeout_seconds=self.layer_timeout_seconds,)' to 'probabilities ' in host memory. Here probabilities means the value named 'probabilities' in this block. The important operands are execute_softmax_q15: the value named 'execute softmax q15' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1888: `difference_shift=self.softmax_difference_shift,` This is continuation line 4 of the 6-line logical statement that begins at source line 1885. Its exact fragment is 'difference_shift=self.softmax_difference_shift,'. The important operands are difference_shift: the value named 'difference shift' in this block; softmax_difference_shift: the value named 'softmax difference shift' in this block. Read together, the complete operation is: This assigns 'execute_softmax_q15(self.driver, cache.logits_accumulator, difference_shift=self.softmax_difference_shift, timeout_seconds=self.lay
)' to 'probabilities ' in host memory. Here probabilities means the value named 'probabilities' in this block. The important operands are execute_softmax_q15: the value named 'execute softmax q15' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1889: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1885. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_softmax_q15(self.driver, cache.logits_accumulator, difference_shift=self.softmax_difference_shift, timeout_seconds=self.lay
)' to 'probabilities ' in host memory. Here probabilities means the value named 'probabilities' in this block. The important operands are execute_softmax_q15: the value named 'execute softmax q15' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1890: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1885. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_softmax_q15(self.driver, cache.logits_accumulator, difference_shift=self.softmax_difference_shift, timeout_seconds=self.layer_timeout_seconds,)' to 'probabilities ' in host memory. Here probabilities means the value named 'probabilities' in this block. The important operands are execute_softmax_q15: the value named 'execute softmax q15' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1891: `head_output_gradient = execute_cross_entropy_gradient_q15(` This statement continues through source line 1896; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_cross_entropy_gradient_q15(self.driver, probabilities, labels_array, timeout_seconds=self.layer_timeout_seconds,)' to 'head_output_gradient ' in host memory. Here head_output_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_cross_entropy_gradient_q15: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; probabilities: the value named 'probabilities' in this block. Context: the function backward, which handles backward.

Line 1892: `self.driver,` This is continuation line 2 of the 6-line logical statement that begins at source line 1891. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_cross_entropy_gradient_q15(self.driver, probabilities, labels_array, timeout_seconds=self.layer_timeout_seconds,)' to 'head_output_gradient ' in host memory. Here head_output_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_cross_entropy_gradient_q15: the signed loss derivative used to update a learned parameter; driver: the value named 'driver' in this block; probabilities: the value named 'probabilities' in this block. Context: the function backward, which handles backward.

Line 1893: `probabilities,` This is continuation line 3 of the 6-line logical statement that begins at source line 1891. Its exact fragment is 'probabilities,'. The important operands are probabilities: the value named 'probabilities' in

this block. Read together, the complete operation is: This assigns ‘execute_cross_entropy_gradient_q15(self.driver, probabilities, labels_array, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_output_gradient ‘ in host memory. Here head_output_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_cross_entropy_gradient_q15: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; probabilities: the value named ’probabilities’ in this block. Context: the function backward, which handles backward.

Line 1894: `labels_array,` This is continuation line 4 of the 6-line logical statement that begins at source line 1891. Its exact fragment is ‘labels_array,‘. The important operands are labels_array: the value named ’labels array’ in this block. Read together, the complete operation is: This assigns ‘execute_cross_entropy_gradient_q15(self.driver, probabilities, labels_array, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_output_gradient ‘ in host memory. Here head_output_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_cross_entropy_gradient_q15: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; probabilities: the value named ’probabilities’ in this block. Context: the function backward, which handles backward.

Line 1895: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1891. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘execute_cross_entropy_gradient_q15(self.driver, probabilities, labels_array, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_output_gradient ‘ in host memory. Here head_output_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_cross_entropy_gradient_q15: the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; probabilities: the value named ’probabilities’ in this block. Context: the function backward, which handles backward.

Line 1896: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1891. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘execute_cross_entropy_gradient_q15(self.driver, probabilities, labels_array, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_output_gradient ‘ in host memory. Here head_output_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_cross_entropy_gradient_ the signed loss derivative used to update a learned parameter; driver: the value named ’driver’ in this block; probabilities: the value named ’probabilities’ in this block. Context: the function backward, which handles backward.

Line 1897: `head = self.state.head` This assigns ‘self.state.head‘ to ‘head ‘ in host memory. Here head means the value named ’head’ in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; head: the value named ’head’ in this block. Context: the function backward, which handles backward.

Line 1898: `head_input_gradient, head_parameter = execute_affine_backward_block(` This statement continues through source line 1905; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_affine_backward_block(self.driver, cache.head_input, head.weight_k_by_n, head.bias_accumulator_units, head_output_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_input_gradient, head_parameter ‘ in host memory. Here head_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_affine_backward_block: the value named ’execute affine backward block’ in this block; driver: the value named ’driver’ in this block; cache: the value named ’cache’ in this block. Context: the function backward, which handles backward.

Line 1899: `self.driver,` This is continuation line 2 of the 8-line logical statement that begins at source line 1898. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘execute_affine_backward_block(self.driver, cache.head_input, head.weight_k_by_n, head.bias_accumulator_units, head_output_gradient, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_input_gradient, head_parameter ‘ in host memory. Here head_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_affine_backward_block: the value named ’execute affine backward block’ in this block; driver: the value named ’driver’ in this block; cache: the value named ’cache’ in this block. Context: the function backward, which handles backward.

Line 1900: `cache.head_input,` This is continuation line 3 of the 8-line logical statement that begins at source line 1898. Its exact fragment is 'cache.head_input,'. The important operands are cache: the value named 'cache' in this block; head_input: the value named 'head input' in this block. Read together, the complete operation is: This assigns 'execute_affine_backward_block(self.driver, cache.head_input, head.weight_k_by_n, head.bias_accumulator_units, head_output_gradient, timeout_seconds=self.layer_timeout_seconds,)' to 'head_input_gradient, head_parameter ' in host memory. Here head_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_affine_backward_block: the value named 'execute affine backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1901: `head.weight_k_by_n,` This is continuation line 4 of the 8-line logical statement that begins at source line 1898. Its exact fragment is 'head.weight_k_by_n,'. The important operands are head: the value named 'head' in this block; weight_k_by_n: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'execute_affine_backward_block(self.driver, cache.head_input, head.weight_k_by_n, head.bias_accumulator_units, head_output_gradient, timeout_seconds=self.layer_timeout_seconds,)' to 'head_input_gradient, head_parameter ' in host memory. Here head_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_affine_backward_block: the value named 'execute affine backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1902: `head.bias_accumulator_units,` This is continuation line 5 of the 8-line logical statement that begins at source line 1898. Its exact fragment is 'head.bias_accumulator_units,'. The important operands are head: the value named 'head' in this block; bias_accumulator_units: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'execute_affine_backward_block(self.driver, cache.head_input, head.weight_k_by_n, head.bias_accumulator_units, head_output_gradient, timeout_seconds=self.layer_timeout_seconds,)' to 'head_input_gradient, head_parameter ' in host memory. Here head_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_affine_backward_block: the value named 'execute affine backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1903: `head_output_gradient,` This is continuation line 6 of the 8-line logical statement that begins at source line 1898. Its exact fragment is 'head_output_gradient,'. The important operands are head_output_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'execute_affine_backward_block(self.driver, cache.head_input, head.weight_k_by_n, head.bias_accumulator_units, head_output_gradient, timeout_seconds=self.layer_timeout_seconds,)' to 'head_input_gradient, head_parameter ' in host memory. Here head_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_affine_backward_block: the value named 'execute affine backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1904: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 7 of the 8-line logical statement that begins at source line 1898. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_affine_backward_block(self.driver, cache.head_input, head.weight_k_by_n, head.bias_accumulator_units, head_output_g timeout_seconds=self.layer_timeout_seconds,)' to 'head_input_gradient, head_parameter ' in host memory. Here head_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_affine_backward_block: the value named 'execute affine backward block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1905: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 1898. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_affine_backward_block(self.driver, cache.head_input, head.weight_k_by_n, head.bias_accumulator_units, head_output_gradient, timeout_seconds=self.layer_timeout_seconds,)' to 'head_input_gradient, head_parameter ' in host memory. Here head_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_affine_backward_block: the value named 'execute affine backward

block' in this block; driver: the value named 'driver' in this block; cache: the value named 'cache' in this block. Context: the function backward, which handles backward.

Line 1906: `clip_mask = (` This statement continues through source line 1908; the explanation uses the complete expression rather than only the first visual fragment. Inside the function backward, which handles backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are clip_mask: the value named 'clip mask' in this block; cache: the value named 'cache' in this block; head_preclip: the value named 'head preclip' in this block.

Line 1907: `(cache.head_preclip >= -128) & (cache.head_preclip <= 127)` This is continuation line 2 of the 3-line logical statement that begins at source line 1906. Its exact fragment is '(cache.head_preclip >= -128) & (cache.head_preclip <= 127)'. The important operands are cache: the value named 'cache' in this block; head_preclip: the value named 'head preclip' in this block. Read together, the complete operation is: Inside the function backward, which handles backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are clip_mask: the value named 'clip mask' in this block; cache: the value named 'cache' in this block; head_preclip: the value named 'head preclip' in this block.

Line 1908: `).astype(np.int64)` This is continuation line 3 of the 3-line logical statement that begins at source line 1906. Its exact fragment is ').astype(np.int64)'. The important operands are astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: Inside the function backward, which handles backward, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are clip_mask: the value named 'clip mask' in this block; cache: the value named 'cache' in this block; head_preclip: the value named 'head preclip' in this block.

Line 1909: `head_input_values = execute_vector_tensor(` This statement continues through source line 1915; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, clip_mask, head_input_gradient.values, timeout_seconds=self.layer_timeout_)' to 'head_input_values ' in host memory. Here head_input_values means the value named 'head input values' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function backward, which handles backward.

Line 1910: `self.driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1909. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, clip_mask, head_input_gradient.values, timeout_seconds=self.layer_timeout_seconds,)' to 'head_input_values ' in host memory. Here head_input_values means the value named 'head input values' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function backward, which handles backward.

Line 1911: `VectorOperation.SELECT_NONZERO,` This is continuation line 3 of the 7-line logical statement that begins at source line 1909. Its exact fragment is 'VectorOperation.SELECT_NONZERO,'. The important operands are VectorOperation: the value named 'vector operation' in this block; SELECT_NONZERO: the value named 'select nonzero' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, clip_mask, head_input_gradient.values, timeout_seconds=self.layer_timeout_seconds,)' to 'head_input_values ' in host memory. Here head_input_values means the value named 'head input values' in this block. The important operands are execute_vector_tensor: the value named 'execute vector tensor' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function backward, which handles backward.

Line 1912: `clip_mask,` This is continuation line 4 of the 7-line logical statement that begins at source line 1909. Its exact fragment is 'clip_mask,'. The important operands are clip_mask: the value named 'clip mask' in this block. Read together, the complete operation is: This assigns 'execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO,

clip_mask, head_input_gradient.values, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_input_values ‘ in host memory. Here head_input_values means the value named ’head input values’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function backward, which handles backward.

Line 1913: `head_input_gradient.values,` This is continuation line 5 of the 7-line logical statement that begins at source line 1909. Its exact fragment is ‘head_input_gradient.values,‘. The important operands are head_input_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, clip_mask, head_input_gradient.values, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_input_values ‘ in host memory. Here head_input_values means the value named ’head input values’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function backward, which handles backward.

Line 1914: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1909. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, clip_mask, head_input_gradient.values, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_input_values ‘ in host memory. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function backward, which handles backward.

Line 1915: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1909. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘execute_vector_tensor(self.driver, VectorOperation.SELECT_NONZERO, clip_mask, head_input_gradient.values, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘head_input_values ‘ in host memory. Here head_input_values means the value named ’head input values’ in this block. The important operands are execute_vector_tensor: the value named ’execute vector tensor’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function backward, which handles backward.

Line 1916: `head_input_gradient = BlockGradient(` This statement continues through source line 1917; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘BlockGradient(head_input_values, head_input_gradient.exponent)‘ to ‘head_input_gradient ‘ in host memory. Here head_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; head_input_values: the value named ’head input values’ in this block; head_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1917: `head_input_values, head_input_gradient.exponent)` This is continuation line 2 of the 2-line logical statement that begins at source line 1916. Its exact fragment is ‘head_input_values, head_input_gradient.exponent)‘. The important operands are head_input_values: the value named ’head input values’ in this block; head_input_gradient: the signed loss derivative used to update a learned parameter; exponent: the value named ’exponent’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(head_input_values, head_input_gradient.exponent)‘ to ‘head_input_gradient ‘ in host memory. Here head_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; head_input_values: the value named ’head input values’ in this block; head_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1918: `divisor = (` This statement continues through source line 1922; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(cache.final_value.shape[0] * cache.final_value.shape[3] * cache.final_value.shape[4])‘ to ‘divisor ‘ in host memory. Here divisor means the value named ’divisor’ in this block.

The important operands are cache: the value named 'cache' in this block; final_value: the value named 'final value' in this block; shape: the value named 'shape' in this block. Context: the function backward, which handles backward.

Line 1919: `cache.final_value.shape[0]` This is continuation line 2 of the 5-line logical statement that begins at source line 1918. Its exact fragment is 'cache.final_value.shape[0]'. The important operands are cache: the value named 'cache' in this block; final_value: the value named 'final value' in this block; shape: the value named 'shape' in this block. Read together, the complete operation is: This assigns '(cache.final_value.shape[0] * cache.final_value.shape[3] * cache.final_value.shape[4])' to 'divisor ' in host memory. Here divisor means the value named 'divisor' in this block. The important operands are cache: the value named 'cache' in this block; final_value: the value named 'final value' in this block; shape: the value named 'shape' in this block. Context: the function backward, which handles backward.

Line 1920: `* cache.final_value.shape[3]` This is continuation line 3 of the 5-line logical statement that begins at source line 1918. Its exact fragment is '* cache.final_value.shape[3]'. The important operands are cache: the value named 'cache' in this block; final_value: the value named 'final value' in this block; shape: the value named 'shape' in this block. Read together, the complete operation is: This assigns '(cache.final_value.shape[0] * cache.final_value.shape[3] * cache.final_value.shape[4])' to 'divisor ' in host memory. Here divisor means the value named 'divisor' in this block. The important operands are cache: the value named 'cache' in this block; final_value: the value named 'final value' in this block; shape: the value named 'shape' in this block. Context: the function backward, which handles backward.

Line 1921: `* cache.final_value.shape[4]` This is continuation line 4 of the 5-line logical statement that begins at source line 1918. Its exact fragment is '* cache.final_value.shape[4]'. The important operands are cache: the value named 'cache' in this block; final_value: the value named 'final value' in this block; shape: the value named 'shape' in this block. Read together, the complete operation is: This assigns '(cache.final_value.shape[0] * cache.final_value.shape[3] * cache.final_value.shape[4])' to 'divisor ' in host memory. Here divisor means the value named 'divisor' in this block. The important operands are cache: the value named 'cache' in this block; final_value: the value named 'final value' in this block; shape: the value named 'shape' in this block. Context: the function backward, which handles backward.

Line 1922: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 1918. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(cache.final_value.shape[0] * cache.final_value.shape[3] * cache.final_value.shape[4])' to 'divisor ' in host memory. Here divisor means the value named 'divisor' in this block. The important operands are cache: the value named 'cache' in this block; final_value: the value named 'final value' in this block; shape: the value named 'shape' in this block. Context: the function backward, which handles backward.

Line 1923: `denominator = int(round(divisor * self.fixed_scale * self.head_activation_scale))` This assigns 'int(round(divisor * self.fixed_scale * self.head_activation_scale))' to 'denominator ' in host memory. Here denominator means the value named 'denominator' in this block. The important operands are round: the value named 'round' in this block; divisor: the value named 'divisor' in this block; fixed_scale: the real-value spacing represented by one quantized integer step. Context: the function backward, which handles backward.

Line 1924: `if denominator <= 0 or denominator & (denominator - 1):` This executes the following indented host-code branch only when 'denominator <= 0 or denominator & (denominator - 1)' is true. The important operands are denominator: the value named 'denominator' in this block; or: the value named 'or' in this block. Context: the function backward, which handles backward.

Line 1925: `raise ValueError("the exported head pooling denominator must be a power of two")` This rejects an invalid state by raising 'ValueError("the exported head pooling denominator must be a power of two")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1926: `pooling_shift = denominator.bit_length() - 1` This assigns 'denominator.bit_length() - 1' to 'pooling_shift ' in host memory. Here pooling_shift means the value named 'pooling shift' in this block. The important operands are denominator: the value named 'denominator' in this block; bit_length: the value named 'bit length' in this block. Context: the function backward, which handles backward.

Line 1927: `final_gradient = BlockGradient(` This statement continues through source line 1933; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘BlockGradient(np.broadcast_to(head_input_gradient.values[np.newaxis, :, :, np.newaxis, np.newaxis], cache.final_value.shape,).copy(), head_input_gradient.expo - pooling_shift,)‘ to ‘final_gradient ‘ in host memory. Here final_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; broadcast_to: the value named ’broadcast to’ in this block; head_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1928: `np.broadcast_to(` This is continuation line 2 of the 7-line logical statement that begins at source line 1927. Its exact fragment is ‘np.broadcast_to(‘. The important operands are broadcast_to: the value named ’broadcast to’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(np.broadcast_to(head_input_gradient.values[np.newaxis, :, :, np.newaxis, np.newaxis], cache.final_value.shape,).copy(), head_input_gradient.expo - pooling_shift,)‘ to ‘final_gradient ‘ in host memory. Here final_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; broadcast_to: the value named ’broadcast to’ in this block; head_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1929: `head_input_gradient.values[np.newaxis, :, :, np.newaxis, np.newaxis],` This is continuation line 3 of the 7-line logical statement that begins at source line 1927. Its exact fragment is ‘head_input_gradient.values[np.newaxis, :, :, np.newaxis, np.newaxis],‘. The important operands are head_input_gradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; newaxis: the value named ’newaxis’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(np.broadcast_to(head_input_gradient.values[np.newaxis, :, :, np.newaxis, np.newaxis], cache.final_value.shape,).copy(), head_input_gradient.exponent - pooling_shift,)‘ to ‘final_gradient ‘ in host memory. Here final_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; broadcast_to: the value named ’broadcast to’ in this block; head_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1930: `cache.final_value.shape,` This is continuation line 4 of the 7-line logical statement that begins at source line 1927. Its exact fragment is ‘cache.final_value.shape,‘. The important operands are cache: the value named ’cache’ in this block; final_value: the value named ’final value’ in this block; shape: the value named ’shape’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(np.broadcast_to(head_input_gradient.values[np.newaxis, :, :, np.newaxis, np.newaxis], cache.final_value.shape,).copy(), head_input_gradient.exponent - pooling_shift,)‘ to ‘final_gradient ‘ in host memory. Here final_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; broadcast_to: the value named ’broadcast to’ in this block; head_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1931: `).copy(),` This is continuation line 5 of the 7-line logical statement that begins at source line 1927. Its exact fragment is ‘).copy(),‘. The important operands are copy: the value named ’copy’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(np.broadcast_to(head_input_gradient.values[np.newaxis, :, :, np.newaxis, np.newaxis], cache.final_value.shape,).copy(), head_input_gradient.exponent - pooling_shift,)‘ to ‘final_gradient ‘ in host memory. Here final_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; broadcast_to: the value named ’broadcast to’ in this block; head_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1932: `head_input_gradient.exponent - pooling_shift,` This is continuation line 6 of the 7-line logical statement that begins at source line 1927. Its exact fragment is ‘head_input_gradient.exponent - pooling_shift,‘. The important operands are head_input_gradient: the signed loss derivative used to update a learned parameter; exponent: the value named ’exponent’ in this block; pooling_shift: the value named ’pooling shift’ in this block. Read together, the complete operation is: This assigns ‘BlockGradient(np.broadcast_to(head_input_gradient.values[np.newaxis, :, :, np.newaxis, np.newaxis], cache.final_value.shape,).copy(), head_input_gradient.exponent - pooling_shift,)‘ to ‘final_gradient ‘ in host memory. Here final_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; broadcast_to: the value named ’broadcast to’ in this block; head_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1933: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1927. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'BlockGradient(np.broadcast_to(head_input_gradient.values[np.newaxis, :, :, np.newaxis, np.newaxis], cache.final_value.shape,).copy(), head_input_gradient.exponent - pooling_shift,)' to 'final_gradient ' in host memory. Here final_gradient means the signed loss derivative used to update a learned parameter. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; broadcast_to: the value named 'broadcast to' in this block; head_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1935: `parameter_gradients: dict[str, ParameterGradient] = {"head": head_parameter}` This assigns '{"head": head_parameter}' to 'parameter_gradients' in host memory. Here parameter_gradients means the signed loss derivative used to update a learned parameter. The important operands are head: the value named 'head' in this block; head_parameter: the value named 'head parameter' in this block. Context: the function backward, which handles backward.

Line 1936: `gradient = final_gradient` This assigns 'final_gradient' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are final_gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1937: `for block_cache in reversed(cache.blocks):` This iterates block_cache over 'reversed(cache.blocks)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function backward, which handles backward.

Line 1938: `gradient, block_parameters = self._block_backward(block_cache, gradient)` This assigns 'self._block_bac gradient)' to 'gradient, block_parameters ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are _block_backward: the value named 'block backward' in this block; block_cache: the value named 'block cache' in this block; gradient: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1939: `overlap = set(parameter_gradients) & set(block_parameters)` This assigns 'set(parameter_gradients) & set(block_parameters)' to 'overlap ' in host memory. Here overlap means the value named 'overlap' in this block. The important operands are set: the value named 'set' in this block; parameter_gradients: the signed loss derivative used to update a learned parameter; block_parameters: the value named 'block parameters' in this block. Context: the function backward, which handles backward.

Line 1940: `if overlap:` This executes the following indented host-code branch only when 'overlap' is true. The important operands are overlap: the value named 'overlap' in this block. Context: the function backward, which handles backward.

Line 1941: `raise RuntimeError(f"duplicate block parameter gradients: {sorted(overlap)}")` This rejects an invalid state by raising 'RuntimeError(f"duplicate block parameter gradients: {sorted(overlap)}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1942: `parameter_gradients.update(block_parameters)` This calls 'parameter_gradients.update' with 'block_parameter inside the function backward, which handles backward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1943: `image_gradient, tokenizer_parameters = self._tokenizer_backward(` This statement continues through source line 1944; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._tokenizer_backward(cache.tokenizer, gradient)' to 'image_gradient, tokenizer_parameters ' in host memory. Here image_gradient means the signed loss derivative used to update a learned parameter. The important operands are _tokenizer_backward: the value named 'tokenizer backward' in this block; cache: the value named 'cache' in this block; tokenizer: the value named 'tokenizer' in this block. Context: the function backward, which handles backward.

Line 1944: `cache.tokenizer, gradient)` This is continuation line 2 of the 2-line logical statement that begins at source line 1943. Its exact fragment is ‘cache.tokenizer, gradient)‘. The important operands are cache: the value named ’cache’ in this block; tokenizer: the value named ’tokenizer’ in this block; gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns ‘self._tokenizer_backward(cache.tokenizer, gradient)‘ to ‘image_gradient, tokenizer_parameters ‘ in host memory. Here image_gradient means the signed loss derivative used to update a learned parameter. The important operands are _tokenizer_backward: the value named ’tokenizer backward’ in this block; cache: the value named ’cache’ in this block; tokenizer: the value named ’tokenizer’ in this block. Context: the function backward, which handles backward.

Line 1945: `overlap = set(parameter_gradients) & set(tokenizer_parameters)` This assigns ‘set(parameter_gradients) & set(tokenizer_parameters)‘ to ‘overlap ‘ in host memory. Here overlap means the value named ’overlap’ in this block. The important operands are set: the value named ’set’ in this block; parameter_gradients: the signed loss derivative used to update a learned parameter; tokenizer_parameters: the value named ’tokenizer parameters’ in this block. Context: the function backward, which handles backward.

Line 1946: `if overlap:` This executes the following indented host-code branch only when ‘overlap‘ is true. The important operands are overlap: the value named ’overlap’ in this block. Context: the function backward, which handles backward.

Line 1947: `raise RuntimeError(f"duplicate tokenizer parameter gradients: {sorted(overlap)}")` This rejects an invalid state by raising ‘RuntimeError(f"duplicate tokenizer parameter gradients: {sorted(overlap)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1948: `parameter_gradients.update(tokenizer_parameters)` This calls ‘parameter_gradients.update‘ with ‘tokenizer_parameters‘ inside the function backward, which handles backward. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1949: `expected = set(self.state.projection_names) | {"head"}` This assigns ‘set(self.state.projection_names) | {"head"}‘ to ‘expected ‘ in host memory. Here expected means the value named ’expected’ in this block. The important operands are set: the value named ’set’ in this block; state: the finite-state-machine phase retained in flip-flops; projection_names: the value named ’projection names’ in this block. Context: the function backward, which handles backward.

Line 1950: `if set(parameter_gradients) != expected:` This executes the following indented host-code branch only when ‘set(parameter_gradients) != expected‘ is true. The important operands are set: the value named ’set’ in this block; parameter_gradients: the signed loss derivative used to update a learned parameter; expected: the value named ’expected’ in this block. Context: the function backward, which handles backward.

Line 1951: `missing = sorted(expected - set(parameter_gradients))` This assigns ‘sorted(expected - set(parameter_gradie to ‘missing ‘ in host memory. Here missing means the value named ’missing’ in this block. The important operands are sorted: the value named ’sorted’ in this block; expected: the value named ’expected’ in this block; set: the value named ’set’ in this block. Context: the function backward, which handles backward.

Line 1952: `extra = sorted(set(parameter_gradients) - expected)` This assigns ‘sorted(set(parameter_gradients) - expected)‘ to ‘extra ‘ in host memory. Here extra means the value named ’extra’ in this block. The important operands are sorted: the value named ’sorted’ in this block; set: the value named ’set’ in this block; parameter_gradients: the signed loss derivative used to update a learned parameter. Context: the function backward, which handles backward.

Line 1953: `raise RuntimeError(f"reverse graph coverage mismatch: missing={missing}, extra={extra}")` This rejects an invalid state by raising ‘RuntimeError(f"reverse graph coverage mismatch: missing={missing}, extra={extra}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1955: `selected = probabilities[np.arange(probabilities.shape[0]), labels_array]` This assigns ‘probabilities[np.arange(probabilities.shape[0]), labels_array]‘ to ‘selected ‘ in host memory. Here selected means the value named ’selected’ in this block. The important operands are probabilities: the value named ’probabilities’ in this block; arange: the value named ’arange’ in this block; shape: the value named ’shape’ in this block. Context: the function backward, which handles backward.

Line 1956: `loss = float(-np.log(np.maximum(selected, 1) / float(1 << 15)).mean())` This assigns ‘float(-np.log(np.maximum(selected, 1) / float(1 << 15)).mean())‘ to ‘loss ‘ in host memory. Here loss means the value named ’loss’ in this block. The important operands are float: the value named ’float’ in this block; log: the value named ’log’ in this block; maximum: the value named ’maximum’ in this block. Context: the function backward, which handles backward.

Line 1957: `return TrainingBackwardResult(` This statement continues through source line 1963; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘TrainingBackwardResult(loss, probabilities, np.argmax(cache.logits_accumulator, axis=1), parameter_gradients, image_gradient,)‘ to the caller of the function backward, which handles backward, ending this invocation. The important operands are TrainingBackwardResult: the value named ’training backward result’ in this block; loss: the value named ’loss’ in this block; probabilities: the value named ’probabilities’ in this block.

Line 1958: `loss,` This is continuation line 2 of the 7-line logical statement that begins at source line 1957. Its exact fragment is ‘loss,‘. The important operands are loss: the value named ’loss’ in this block. Read together, the complete operation is: This returns ‘TrainingBackwardResult(loss, probabilities, np.argmax(cache.logits_accumulator, axis=1), parameter_gradients, image_gradient,)‘ to the caller of the function backward, which handles backward, ending this invocation. The important operands are TrainingBackwardResult: the value named ’training backward result’ in this block; loss: the value named ’loss’ in this block; probabilities: the value named ’probabilities’ in this block.

Line 1959: `probabilities,` This is continuation line 3 of the 7-line logical statement that begins at source line 1957. Its exact fragment is ‘probabilities,‘. The important operands are probabilities: the value named ’probabilities’ in this block. Read together, the complete operation is: This returns ‘TrainingBackwardResult(loss, probabilities, np.argmax(cache.logits_accumulator, axis=1), parameter_gradients, image_gradient,)‘ to the caller of the function backward, which handles backward, ending this invocation. The important operands are TrainingBackwardResult: the value named ’training backward result’ in this block; loss: the value named ’loss’ in this block; probabilities: the value named ’probabilities’ in this block.

Line 1960: `np.argmax(cache.logits_accumulator, axis=1),` This is continuation line 4 of the 7-line logical statement that begins at source line 1957. Its exact fragment is ‘np.argmax(cache.logits_accumulator, axis=1),‘. The important operands are argmax: the value named ’argmax’ in this block; cache: the value named ’cache’ in this block; logits_accumulator: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This returns ‘TrainingBackwardResult(loss, probabilities, np.argmax(cache.logits_accumulator, axis=1), parameter_gradients, image_gradient,)‘ to the caller of the function backward, which handles backward, ending this invocation. The important operands are TrainingBackwardResult: the value named ’training backward result’ in this block; loss: the value named ’loss’ in this block; probabilities: the value named ’probabilities’ in this block.

Line 1961: `parameter_gradients,` This is continuation line 5 of the 7-line logical statement that begins at source line 1957. Its exact fragment is ‘parameter_gradients,‘. The important operands are parameter_gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This returns ‘TrainingBackwardResult(loss, probabilities, np.argmax(cache.logits_accumulator, axis=1), parameter_gradients, image_gradient,)‘ to the caller of the function backward, which handles backward, ending this invocation. The important operands are TrainingBackwardResult: the value named ’training backward result’ in this block; loss: the value named ’loss’ in this block; probabilities: the value named ’probabilities’ in this block.

Line 1962: `image_gradient,` This is continuation line 6 of the 7-line logical statement that begins at source line 1957. Its exact fragment is ‘image_gradient,‘. The important operands are image_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This returns ‘TrainingBackwardResult(loss, probabilities, np.argmax(cache.logits_accumulator, axis=1), parameter_gradients, image_gradient,)‘ to the caller

of the function backward, which handles backward, ending this invocation. The important operands are TrainingBackwardResult: the value named 'training backward result' in this block; loss: the value named 'loss' in this block; probabilities: the value named 'probabilities' in this block.

Line 1963: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1957. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'TrainingBackwardResult(loss, probabilities, np.argmax(cache.logits_accumulator, axis=1), parameter_gradients, image_gradient,)' to the caller of the function backward, which handles backward, ending this invocation. The important operands are TrainingBackwardResult: the value named 'training backward result' in this block; loss: the value named 'loss' in this block; probabilities: the value named 'probabilities' in this block.

Line 1965: `def train_step(` This starts function train_step. Its indented body performs train step as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 1966: `self,` Inside the function train_step, which handles train step, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1967: `normalized_image,` Inside the function train_step, which handles train step, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are normalized_image: the value named 'normalized image' in this block.

Line 1968: `labels,` Inside the function train_step, which handles train step, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are labels: the value named 'labels' in this block.

Line 1969: `*,` Inside the function train_step, which handles train step, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 1970: `learning_rate: float,` Inside the function train_step, which handles train step, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude; float: the value named 'float' in this block.

Line 1971: `momentum: float = 0.9,` This assigns '0.9,' to 'momentum' in host memory. Here momentum means the value named 'momentum' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function train_step, which handles train step.

Line 1972: `weight_decay: float = 5e-4,` This assigns '5e-4,' to 'weight_decay' in host memory. Here weight_decay means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function train_step, which handles train step.

Line 1973: `gradient_clip_q15: int = 4 << 15,` This assigns '4 << 15,' to 'gradient_clip_q15' in host memory. Here gradient_clip_q15 means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function train_step, which handles train step.

Line 1974: `) -> TrainingStepResult:` Inside the function train_step, which handles train step, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are TrainingStepResult: the value named 'training step result' in this block.

Line 1975: `"""Execute one full forward, reverse, and all-parameter SGDW update."""` This is executable documentation attached to the function train_step, which handles train step. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1977: `cache = self.forward(normalized_image)` This assigns 'self.forward(normalized_image)' to 'cache ' in host memory. Here cache means the value named 'cache' in this block. The important operands are forward: the value named 'forward' in this block; normalized_image: the value named 'normalized image' in this block. Context: the function train_step, which handles train step.

Line 1978: `backward = self.backward(cache, labels)` This assigns 'self.backward(cache, labels)' to 'backward ' in host memory. Here backward means the value named 'backward' in this block. The important operands are backward: the value named 'backward' in this block; cache: the value named 'cache' in this block; labels: the value named 'labels' in this block. Context: the function train_step, which handles train step.

Line 1979: `self.state.apply_gradients(` This statement continues through source line 1987; the explanation uses the complete expression rather than only the first visual fragment. This calls 'self.state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=self.layer_timeout_seconds, ' inside the function train_step, which handles train step. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1980: `self.driver,` This is continuation line 2 of the 9-line logical statement that begins at source line 1979. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This calls 'self.state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=self.layer_timeout_seconds, ' inside the function train_step, which handles train step. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1981: `backward.parameter_gradients,` This is continuation line 3 of the 9-line logical statement that begins at source line 1979. Its exact fragment is 'backward.parameter_gradients,'. The important operands are backward: the value named 'backward' in this block; parameter_gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This calls 'self.state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=self.layer_timeout_seconds, ' inside the function train_step, which handles train step. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1982: `learning_rate=learning_rate,` This is continuation line 4 of the 9-line logical statement that begins at source line 1979. Its exact fragment is 'learning_rate=learning_rate,'. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This calls 'self.state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=self.layer_timeout_sec
' inside the function train_step, which handles train step. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1983: `momentum=momentum,` This is continuation line 5 of the 9-line logical statement that begins at source line 1979. Its exact fragment is 'momentum=momentum,'. The important operands are momentum: the value named 'momentum' in this block. Read together, the complete operation is: This calls 'self.state.apply_gradients' with ' self.driver, backward.parameter_gradients, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=self.layer_timeout_seconds, ' inside the function train_step, which handles train step. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1984: `weight_decay=weight_decay,` This is continuation line 6 of the 9-line logical statement that begins at source line 1979. Its exact fragment is ‘weight_decay=weight_decay,‘. The important operands are weight_decay: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls ‘self.state.apply_gradients‘ with ‘ self.driver, backward.parameter_gradients, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_d gradient_clip_q15=gradient_clip_q15, timeout_seconds=self.layer_timeout_seconds, ‘ inside the function train_step, which handles train step. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1985: `gradient_clip_q15=gradient_clip_q15,` This is continuation line 7 of the 9-line logical statement that begins at source line 1979. Its exact fragment is ‘gradient_clip_q15=gradient_clip_q15,‘. The important operands are gradient_clip_q15: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This calls ‘self.state.apply_gradients‘ with ‘ self.driver, backward.parameter_gradients, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=self.layer_timeo ‘ inside the function train_step, which handles train step. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1986: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 8 of the 9-line logical statement that begins at source line 1979. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This calls ‘self.state.apply_gradients‘ with ‘ self.driver, backward.parameter_gradients, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_d gradient_clip_q15=gradient_clip_q15, timeout_seconds=self.layer_timeout_seconds, ‘ inside the function train_step, which handles train step. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1987: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 1979. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘self.state.apply_gradients‘ with ‘ self.driver, backward.parameter_gradients, learning_rate=learning_rate, momentum=momentum, weight_decay=weight_decay, gradient_clip_q15=gradient_clip_q15, timeout_seconds=self.layer_timeout_seconds, ‘ inside the function train_step, which handles train step. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 1988: `return TrainingStepResult(` This statement continues through source line 1993; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘TrainingStepResult(backward.loss, backward.probabilities_q15, backward.predicted_class, self.state.optimizer_step,)‘ to the caller of the function train_step, which handles train step, ending this invocation. The important operands are TrainingStepResult: the value named ’training step result’ in this block; backward: the value named ’backward’ in this block; loss: the value named ’loss’ in this block.

Line 1989: `backward.loss,` This is continuation line 2 of the 6-line logical statement that begins at source line 1988. Its exact fragment is ‘backward.loss,‘. The important operands are backward: the value named ’backward’ in this block; loss: the value named ’loss’ in this block. Read together, the complete operation is: This returns ‘TrainingStepResult(backward.loss, backward.probabilities_q15, backward.predicted_class, self.state.optimizer_step,)‘ to the caller of the function train_step, which handles train step, ending this invocation. The important operands are TrainingStepResult: the value named ’training step result’ in this block; backward: the value named ’backward’ in this block; loss: the value named ’loss’ in this block.

Line 1990: `backward.probabilities_q15,` This is continuation line 3 of the 6-line logical statement that begins at source line 1988. Its exact fragment is ‘backward.probabilities_q15,‘. The important operands are backward: the value named ’backward’ in this block; probabilities_q15: the value named ’probabilities q15’ in this block. Read together, the complete operation is: This returns ‘TrainingStepResult(backward.loss, backward.probabilities_q15, backward.predicted_class, self.state.optimizer_step,)‘ to the caller of the function train_step, which handles train step, ending this invocation. The important operands are TrainingStepResult: the value named ’training step result’ in this block; backward: the value named ’backward’ in this block; loss: the value named ’loss’ in this block.

Line 1991: `backward.predicted_class,` This is continuation line 4 of the 6-line logical statement that begins at source line 1988. Its exact fragment is ‘backward.predicted_class,‘. The important operands are backward: the value named ’backward’ in this block; predicted_class: the value named ’predicted class’ in this block. Read together, the complete operation is: This returns ‘TrainingStepResult(backward.loss, backward.probabilities_q15, backward.predicted_class, self.state.optimizer_step,)‘ to the caller of the function train_step, which handles train step, ending this invocation. The important operands are TrainingStepResult: the value named ’training step result’ in this block; backward: the value named ’backward’ in this block; loss: the value named ’loss’ in this block.

Line 1992: `self.state.optimizer_step,` This is continuation line 5 of the 6-line logical statement that begins at source line 1988. Its exact fragment is ‘self.state.optimizer_step,‘. The important operands are state: the finite-state-machine phase retained in flip-flops; optimizer_step: the value named ’optimizer step’ in this block. Read together, the complete operation is: This returns ‘TrainingStepResult(backward.loss, backward.probabilities_q15, backward.predicted_class, self.state.optimizer_step,)‘ to the caller of the function train_step, which handles train step, ending this invocation. The important operands are TrainingStepResult: the value named ’training step result’ in this block; backward: the value named ’backward’ in this block; loss: the value named ’loss’ in this block.

Line 1993: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1988. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘TrainingStepResult(backward.loss, backward.probabilities_q15, backward.predicted_class, self.state.optimizer_step,)‘ to the caller of the function train_step, which handles train step, ending this invocation. The important operands are TrainingStepResult: the value named ’training step result’ in this block; backward: the value named ’backward’ in this block; loss: the value named ’loss’ in this block.

45 software/train_spikingformer_pynq.py

Role in the complete system: provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

45.1 Beginner architecture map

Dataflow responsibility The command-line entry point validates the overlay, parameter archive, dataset shards, and ABI before constructing the runtime. It translates pause-file and resume options into explicit checkpoint behavior, reports board telemetry and validation accuracy, and exits nonzero when required physical artifacts or numerical checks fail.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: Cifar10ShardSet. Functions: parse_arguments, atomic_json, file_sha256, augment_cifar10, cosine_learning_rate, evaluate, ___init___, batches. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

45.2 Complete source

45.3 Line annotations

Line 1: `"""Run resumable full-backbone Spikingformer fine-tuning on a PYNQ overlay."""` This is executable documentation attached to the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import argparse` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import hashlib` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `import json` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `import math` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `import os` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `import shutil` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `import time` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `from dataclasses import asdict` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `from datetime import datetime, timezone` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `from pathlib import Path` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `from typing import Iterator` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `import numpy as np` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `from neuraedge_pynq import NeuraEdgeDriver` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `from run_spikingformer_pynq import prepare_input` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `from spikingformer_accelerator import SpikingformerAcceleratorModel` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `from spikingformer_parameters import SpikingformerParameterArchive` This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 23: `from spikingformer_training_runtime import (` This statement continues through source line 26; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `SpikingformerOnDeviceTrainer,` This is continuation line 2 of the 4-line logical statement that begins at source line 23. Its exact fragment is ‘SpikingformerOnDeviceTrainer,‘. The important operands are SpikingformerOnDeviceTrainer: the value named ’spikingformer on device trainer’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 25: `TrainableSpikingformerState,` This is continuation line 3 of the 4-line logical statement that begins at source line 23. Its exact fragment is 'TrainableSpikingformerState,'. The important operands are TrainableSpikingformerState: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 26: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 23. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 29: `def parse_arguments() -> argparse.Namespace:` This starts function parse_arguments. Its indented body performs parse arguments as part of the file that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports; it runs only when called.

Line 30: `parser = argparse.ArgumentParser()` This assigns 'argparse.ArgumentParser()' to 'parser ' in host memory. Here parser means the value named 'parser' in this block. The important operands are argparse: the value named 'argparse' in this block; ArgumentParser: the value named 'argument parser' in this block. Context: the function parse_arguments, which handles parse arguments.

Line 31: `parser.add_argument("-bitfile", type=Path, required=True)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 32: `parser.add_argument("-manifest", type=Path, required=True)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 33: `parser.add_argument("-data-manifest", type=Path, required=True)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 34: `parser.add_argument("-output-dir", type=Path, required=True)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 35: `parser.add_argument("-epochs", type=int, default=400)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 36: `parser.add_argument("-batch-size", type=int, default=1)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 37: `parser.add_argument("-learning-rate", type=float, default=0.25)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 38: `parser.add_argument("-minimum-learning-rate", type=float, default=0.01)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 39: `parser.add_argument("-momentum", type=float, default=0.9)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 40: `parser.add_argument("-weight-decay", type=float, default=5e-4)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 41: `parser.add_argument("-gradient-clip-q15", type=int, default=4 << 15)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 42: `parser.add_argument("-seed", type=int, default=20260713)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 43: `parser.add_argument("-checkpoint-interval", type=int, default=1)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 44: `parser.add_argument("-layer-timeout-seconds", type=float, default=600.0)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 45: `parser.add_argument("-resume", action="store_true")` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 46: `parser.add_argument("-no-download", action="store_true")` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 47: `return parser.parse_args()` This returns ‘parser.parse_args()‘ to the caller of the function parse_arguments, which handles parse arguments, ending this invocation. The important operands are parser: the value named ’parser’ in this block; parse_args: the value named ’parse args’ in this block.

Line 50: `def atomic_json(path: Path, value: dict[str, object]) -> None:` This starts function atomic_json. Its indented body performs atomic json as part of the file that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports; it runs only when called.

Line 51: `path.parent.mkdir(parents=True, exist_ok=True)` This calls ‘path.parent.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the function atomic_json, which handles atomic json. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 52: `temporary = path.with_name(path.name + ".tmp")` This assigns ‘path.with_name(path.name + ".tmp")‘ to ‘temporary ‘ in host memory. Here temporary means the value named ’temporary’ in this block. The important operands are path: the value named ’path’ in this block; with_name: the value named ’with name’ in this block; name: the value named ’name’ in this block. Context: the function atomic_json, which handles atomic json.

Line 53: `temporary.write_text(json.dumps(value, indent=2) + "\n", encoding="ascii")` This calls ‘temporary.write_text‘ with ‘json.dumps(value, indent=2) + "\n", encoding="ascii"‘ inside the function atomic_json, which handles atomic json. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 54: `os.replace(temporary, path)` This calls ‘os.replace‘ with ‘temporary, path‘ inside the function atomic_json, which handles atomic json. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 57: `def file_sha256(path: Path) -> str:` This starts function file_sha256. Its indented body performs file sha256 as part of the file that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports; it runs only when called.

Line 58: `digest = hashlib.sha256()` This assigns ‘hashlib.sha256()‘ to ‘digest ‘ in host memory. Here digest means the value named ’digest’ in this block. The important operands are hashlib: the value named ’hashlib’ in this block; sha256: the value named ’sha256’ in this block. Context: the function file_sha256, which handles file sha256.

Line 59: `with path.open("rb") as stream:` This opens a managed resource scope for ‘path.open("rb") as stream‘ so files, tracing, or temporary state are finalized even if the function file_sha256, which handles file sha256 raises an error.

Line 60: `for chunk in iter(lambda: stream.read(1 << 20), b""):` This iterates chunk over ‘iter(lambda: stream.read(1 << 20), b"")‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function file_sha256, which handles file sha256.

Line 61: `digest.update(chunk)` This calls ‘digest.update‘ with ‘chunk‘ inside the function file_sha256, which handles file sha256. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 62: `return digest.hexdigest()` This returns ‘digest.hexdigest()‘ to the caller of the function file_sha256, which handles file sha256, ending this invocation. The important operands are digest: the value named ’digest’ in this block; hexdigest: the value named ’hexdigest’ in this block.

Line 65: `class Cifar10ShardSet:` This defines class Cifar10ShardSet, which groups data and methods for cifar10 shard set. Instances exist in host memory and organize the flow that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 66: `"""Validated deterministic traversal of one manifest split."""` This is executable documentation attached to the class Cifar10ShardSet, which handles cifar10 shard set. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 68: `def __init__(self, manifest_path: Path, split: str) -> None:` This starts function ___init___. Its indented body performs init as part of the file that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports; it runs only when called.

Line 69: `manifest_path = manifest_path.expanduser().resolve()` This assigns ‘manifest_path.expanduser().resolve()‘ to ‘manifest_path ‘ in host memory. Here manifest_path means the value named ’manifest path’ in this block. The important operands are manifest_path: the value named ’manifest path’ in this block; expanduser: the value named ’expanduser’ in this block; resolve: the value named ’resolve’ in this block. Context: the function ___init___, which handles init.

Line 70: `manifest = json.loads(manifest_path.read_text(encoding="ascii"))` This assigns ‘json.loads(manifest_path.rea to ‘manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are json: the value named ’json’ in this block; loads: the value named ’loads’ in this block; manifest_path: the value named ’manifest path’ in this block. Context: the function ___init___, which handles init.

Line 71: `if manifest.get("format") != "neuraedge-official-cifar10-shards-v1":` This executes the following indented host-code branch only when ‘manifest.get("format") != "neuraedge-official-cifar10-shards-v1"‘ is true. The important operands are manifest: the value named ’manifest’ in this block; get: the value named ’get’ in this block; format: the value named ’format’ in this block. Context: the function ___init___, which handles init.

Line 72: `raise ValueError("unsupported CIFAR-10 shard manifest")` This rejects an invalid state by raising ‘ValueError("unsupported CIFAR-10 shard manifest")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 73: `entries = manifest.get("splits", {}).get(split)` This assigns ‘manifest.get("splits", {}).get(split)‘ to ‘entries ‘ in host memory. Here entries means the value named ’entries’ in this block. The important operands are manifest: the value named ’manifest’ in this block; get: the value named ’get’ in this block; splits: the value named ’splits’ in this block. Context: the function ___init___, which handles init.

Line 74: `if not isinstance(entries, list) or not entries:` This executes the following indented host-code branch only when ‘not isinstance(entries, list) or not entries‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; entries: the value named ’entries’ in this block. Context: the function ___init___, which handles init.

Line 75: `raise ValueError(f"CIFAR-10 manifest has no {split} shards")` This rejects an invalid state by raising ‘ValueError(f"CIFAR-10 manifest has no {split} shards")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 76: `self.entries = tuple(entries)` This assigns ‘tuple(entries)‘ to ‘self.entries ‘ in host memory. Here entries means the value named ’entries’ in this block. The important operands are tuple: the value named ’tuple’ in this block; entries: the value named ’entries’ in this block. Context: the function ___init___, which handles init.

Line 77: `self.root = manifest_path.parent` This assigns ‘manifest_path.parent‘ to ‘self.root ‘ in host memory. Here root means the value named ’root’ in this block. The important operands are manifest_path: the value named ’manifest path’ in this block; parent: the value named ’parent’ in this block. Context: the function ___init___, which handles init.

Line 78: `self.split = split` This assigns ‘split‘ to ‘self.split ‘ in host memory. Here split means the value named ’split’ in this block. The important operands are split: the value named ’split’ in this block. Context: the function ___init___, which handles init.

Line 79: `self.sample_count = sum(int(entry["samples"]) for entry in self.entries)` This assigns ‘sum(int(entry["sam
for entry in self.entries)‘ to ‘self.sample_count ‘ in host memory. Here sample_count means an integer count retained for control or measurable telemetry. The important operands are sum: the value named ’sum’ in this block; entry: the value named ’entry’ in this block; samples: the value named ’samples’ in this block. Context: the function ___init___, which handles init.

Line 80: `for entry in self.entries:` This iterates entry over ‘self.entries‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function ___init___, which handles init.

Line 81: `path = self.root / str(entry["file"])` This assigns ‘self.root / str(entry["file"])‘ to ‘path ‘ in host memory. Here path means the value named ’path’ in this block. The important operands are root: the value named ’root’ in this block; str: the value named ’str’ in this block; entry: the value named ’entry’ in this block. Context: the function ___init___, which handles init.

Line 82: `if not path.is_file() or file_sha256(path) != entry["sha256"]:` This executes the following indented host-code branch only when ‘not path.is_file() or file_sha256(path) != entry["sha256"]‘ is true. The important operands are not: the value named ’not’ in this block; path: the value named ’path’ in this block; is_file: the value named ’is file’ in this block. Context: the function ___init___, which handles init.

Line 83: `raise ValueError(f"CIFAR-10 shard integrity failure: {path}")` This rejects an invalid state by raising ‘ValueError(f"CIFAR-10 shard integrity failure: {path}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 85: `def batches(` This starts function batches. Its indented body performs batches as part of the file that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports; it runs only when called.

Line 86: `self,` Inside the function batches, which handles batches, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The expression is a literal or structural operator and has no hidden software state.

Line 87: `*,` Inside the function batches, which handles batches, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The expression is a literal or structural operator and has no hidden software state.

Line 88: `epoch: int,` Inside the function batches, which handles batches, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are epoch: the value named ’epoch’ in this block.

Line 89: `batch_size: int,` Inside the function batches, which handles batches, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are batch_size: the value named ’batch size’ in this block.

Line 90: `seed: int,` Inside the function batches, which handles batches, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are seed: the value named ’seed’ in this block.

Line 91: `shuffle: bool,` Inside the function batches, which handles batches, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are shuffle: the value named ’shuffle’ in this block; bool: the value named ’bool’ in this block.

Line 92: `start_batch: int = 0,` This assigns ‘0,‘ to ‘start_batch‘ in host memory. Here start_batch means the value named ’start batch’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function batches, which handles batches.

Line 93: `) -> Iterator[tuple[int, np.ndarray, np.ndarray]:` Inside the function batches, which handles batches, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are Iterator: the value named ’iterator’ in this block; tuple: the value named ’tuple’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 94: `rng = np.random.default_rng(seed + epoch * 1_000_003 + (0 if self.split == "train" else 97))` Inside the function batches, which handles batches, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are rng: the value named ’rng’ in this block; random: the value named ’random’ in this block; default_rng: the value named ’default rng’ in this block.

Line 95: `shard_order = np.arange(len(self.entries))` This assigns ‘np.arange(len(self.entries))‘ to ‘shard_order ‘ in host memory. Here shard_order means the value named ’shard order’ in this block. The important operands are arange: the value named ’arange’ in this block; len: the value named ’len’ in this block; entries: the value named ’entries’ in this block. Context: the function batches, which handles batches.

Line 96: `if shuffle:` This executes the following indented host-code branch only when ‘shuffle‘ is true. The important operands are shuffle: the value named ’shuffle’ in this block. Context: the function batches, which handles batches.

Line 97: `rng.shuffle(shard_order)` This calls ‘rng.shuffle‘ with ‘shard_order‘ inside the function batches, which handles batches. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 98: `global_batch = 0` This assigns ‘0‘ to ‘global_batch ‘ in host memory. Here global_batch means the value named ’global batch’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function batches, which handles batches.

Line 99: `for shard_index in shard_order:` This iterates shard_index over ‘shard_order‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function batches, which handles batches.

Line 100: `entry = self.entries[int(shard_index)]` This assigns ‘self.entries[int(shard_index)]‘ to ‘entry ‘ in host memory. Here entry means the value named ’entry’ in this block. The important operands are entries: the value named ’entries’ in this block; shard_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function batches, which handles batches.

Line 101: `with np.load(self.root / str(entry["file"]), allow_pickle=False) as shard:` This opens a managed resource scope for ‘np.load(self.root / str(entry["file"]), allow_pickle=False) as shard‘ so files, tracing, or temporary state are finalized even if the function batches, which handles batches raises an error.

Line 102: `images = np.asarray(shard["images"], dtype=np.uint8)` This assigns ‘np.asarray(shard["images"], dtype=np.uin
to ‘images ‘ in host memory. Here images means the value named ’images’ in this block. The important operands are asarray: the value named ’asarray’ in this block; shard: the value named ’shard’ in this block; images: the value named ’images’ in this block. Context: the function batches, which handles batches.

Line 103: `labels = np.asarray(shard["labels"], dtype=np.int64)` This assigns ‘np.asarray(shard["labels"], dtype=np.int6
to ‘labels ‘ in host memory. Here labels means the value named ’labels’ in this block. The important operands are asarray: the value named ’asarray’ in this block; shard: the value named ’shard’ in this block; labels: the value named ’labels’ in this block. Context: the function batches, which handles batches.

Line 104: `order = np.arange(len(labels))` This assigns ‘np.arange(len(labels))‘ to ‘order ‘ in host memory. Here order means the value named ’order’ in this block. The important operands are arange: the value named ’arange’ in this block; len: the value named ’len’ in this block; labels: the value named ’labels’ in this block. Context: the function batches, which handles batches.

Line 105: `if shuffle:` This executes the following indented host-code branch only when ‘shuffle‘ is true. The important operands are shuffle: the value named ’shuffle’ in this block. Context: the function batches, which handles batches.

Line 106: `rng.shuffle(order)` This calls ‘rng.shuffle‘ with ‘order‘ inside the function batches, which handles batches. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 107: `for start in range(0, len(order), batch_size):` This iterates start over ‘range(0, len(order), batch_size)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function batches, which handles batches.

Line 108: `selected = order[start:start + batch_size]` This assigns ‘order[start:start + batch_size]‘ to ‘selected ‘ in host memory. Here selected means the value named ’selected’ in this block. The important operands are order: the value named ’order’ in this block; start: the value named ’start’ in this block; batch_size: the value named ’batch size’ in this block. Context: the function batches, which handles batches.

Line 109: `if global_batch >= start_batch:` This executes the following indented host-code branch only when ‘global_batch >= start_batch‘ is true. The important operands are global_batch: the value named ’global batch’ in this block; start_batch: the value named ’start batch’ in this block. Context: the function batches, which handles batches.

Line 110: `yield global_batch, images[selected], labels[selected]` Inside the function batches, which handles batches, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are yield: the value named ’yield’ in this block; global_batch: the value named ’global batch’ in this block; images: the value named ’images’ in this block.

Line 111: `global_batch += 1` Inside the function batches, which handles batches, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are global_batch: the value named ’global batch’ in this block.

Line 114: `def augment_cifar10(images: np.ndarray, seed: int) -> np.ndarray:` This starts function augment_cifar10. Its indented body performs augment cifar10 as part of the file that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports; it runs only when called.

Line 115: `"""Deterministic reflect-pad crop and horizontal flip for one batch."""` This is executable documentation attached to the function augment_cifar10, which handles augment cifar10. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 117: `rng = np.random.default_rng(seed)` This assigns ‘np.random.default_rng(seed)‘ to ‘rng ‘ in host memory. Here rng means the value named ’rng’ in this block. The important operands are random: the value named ’random’ in this block; default_rng: the value named ’default rng’ in this block; seed: the value named ’seed’ in this block. Context: the function augment_cifar10, which handles augment cifar10.

Line 118: `output = np.empty_like(images)` This assigns ‘np.empty_like(images)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are empty_like: the value named ’empty like’ in this block; images: the value named ’images’ in this block. Context: the function augment_cifar10, which handles augment cifar10.

Line 119: `for index, image in enumerate(images):` This iterates index, image over ‘enumerate(images)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function augment_cifar10, which handles augment cifar10.

Line 120: `padded = np.pad(image, ((4, 4), (4, 4), (0, 0)), mode="reflect")` This assigns ‘np.pad(image, ((4, 4), (4, 4), (0, 0)), mode="reflect")‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are pad: the value named ’pad’ in this block; image: the value named ’image’ in this block; mode: the value named ’mode’ in this block. Context: the function augment_cifar10, which handles augment cifar10.

Line 121: `y = int(rng.integers(0, 9))` This assigns ‘int(rng.integers(0, 9))‘ to ‘y ‘ in host memory. Here y means the value named ’y’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function augment_cifar10, which handles augment cifar10.

Line 122: `x = int(rng.integers(0, 9))` This assigns ‘int(rng.integers(0, 9))‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function augment_cifar10, which handles augment cifar10.

Line 123: `crop = padded[y:y + 32, x:x + 32]` This assigns ‘padded[y:y + 32, x:x + 32]‘ to ‘crop ‘ in host memory. Here crop means the value named ’crop’ in this block. The important operands are padded: the value named ’padded’ in this block; y: the value named ’y’ in this block; x: the value named ’x’ in this block. Context: the function augment_cifar10, which handles augment cifar10.

Line 124: `output[index] = crop[:, ::-1] if rng.random() < 0.5 else crop` This assigns ‘crop[:, ::-1] if rng.random() < 0.5 else crop‘ to ‘output[index] ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are crop: the value named ’crop’ in this block; rng: the value named ’rng’ in this block; random: the value named ’random’ in this block. Context: the function augment_cifar10, which handles augment cifar10.

Line 125: `return output` This returns ‘output‘ to the caller of the function augment_cifar10, which handles augment cifar10, ending this invocation. The important operands are output: the value named ’output’ in this block.

Line 128: `def cosine_learning_rate(` This starts function cosine_learning_rate. Its indented body performs cosine learning rate as part of the file that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports; it runs only when called.

Line 129: `epoch: int,` Inside the function cosine_learning_rate, which handles cosine learning rate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are epoch: the value named ’epoch’ in this block.

Line 130: `epochs: int,` Inside the function cosine_learning_rate, which handles cosine learning rate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are epochs: the value named ’epochs’ in this block.

Line 131: `maximum: float,` Inside the function cosine_learning_rate, which handles cosine learning rate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are maximum: the value named ’maximum’ in this block; float: the value named ’float’ in this block.

Line 132: `minimum: float,` Inside the function cosine_learning_rate, which handles cosine learning rate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are minimum: the value named ’minimum’ in this block; float: the value named ’float’ in this block.

Line 133: `) -> float:` Inside the function cosine_learning_rate, which handles cosine learning rate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are float: the value named ’float’ in this block.

Line 134: `if epochs == 1:` This executes the following indented host-code branch only when ‘epochs == 1‘ is true. The important operands are epochs: the value named ’epochs’ in this block. Context: the function cosine_learning_rate, which handles cosine learning rate.

Line 135: `return minimum` This returns ‘minimum‘ to the caller of the function cosine_learning_rate, which handles cosine learning rate, ending this invocation. The important operands are minimum: the value named ’minimum’ in this block.

Line 136: `phase = epoch / float(epochs - 1)` This assigns ‘epoch / float(epochs - 1)‘ to ‘phase ‘ in host memory. Here phase means the value named ’phase’ in this block. The important operands are epoch: the value named ’epoch’ in this block; float: the value named ’float’ in this block; epochs: the value named ’epochs’ in this block. Context: the function cosine_learning_rate, which handles cosine learning rate.

Line 137: `return minimum + 0.5 * (maximum - minimum) * (1.0 + math.cos(math.pi * phase))` This returns ‘minimum + 0.5 * (maximum - minimum) * (1.0 + math.cos(math.pi * phase))‘ to the caller of the function cosine_learning_rate, which handles cosine learning rate, ending this invocation. The important operands are minimum: the value named ’minimum’ in this block; maximum: the value named ’maximum’ in this block; math: the value named ’math’ in this block.

Line 140: `def evaluate(` This starts function evaluate. Its indented body performs evaluate as part of the file that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports; it runs only when called.

Line 141: `model: SpikingformerAcceleratorModel,` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are model: the value named ’model’ in this block; SpikingformerAcceleratorModel: the value named ’spikingformer accelerator model’ in this block.

Line 142: `dataset: Cifar10ShardSet,` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are dataset: the value named ’dataset’ in this block; Cifar10ShardSet: the value named ’cifar10 shard set’ in this block.

Line 143: `*,` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The expression is a literal or structural operator and has no hidden software state.

Line 144: `batch_size: int,` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are batch_size: the value named ’batch size’ in this block.

Line 145: `seed: int,` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are seed: the value named ’seed’ in this block.

Line 146: `) -> tuple[float, int, int]:` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are tuple: the value named ’tuple’ in this block; float: the value named ’float’ in this block.

Line 147: `correct = 0` This assigns ‘0‘ to ‘correct ‘ in host memory. Here correct means the value named ’correct’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function evaluate, which handles evaluate.

Line 148: `total = 0` This assigns ‘0‘ to ‘total ‘ in host memory. Here total means the value named ’total’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function evaluate, which handles evaluate.

Line 149: `for _, raw_images, labels in dataset.batches(` This line opens or closes a multi-line Python expression inside the function evaluate, which handles evaluate; the neighboring lines supply its arguments or elements.

Line 150: `epoch=0, batch_size=batch_size, seed=seed, shuffle=False):` This assigns ‘0, batch_size=batch_size, seed=seed, shuffle=False):‘ to ‘epoch‘ in host memory. Here epoch means the value named ’epoch’ in this block. The important operands are batch_size: the value named ’batch size’ in this block; seed: the value named ’seed’ in this block; shuffle: the value named ’shuffle’ in this block. Context: the function evaluate, which handles evaluate.

Line 151: `images = prepare_input(raw_images, "raw-u8")` This assigns ‘prepare_input(raw_images, "raw-u8")‘ to ‘images ‘ in host memory. Here images means the value named ’images’ in this block. The important operands are prepare_input: the value named ’prepare input’ in this block; raw_images: the value named ’raw images’ in this block; raw: the value named ’raw’ in this block. Context: the function evaluate, which handles evaluate.

Line 152: `prediction = model.infer(images).predicted_class` This assigns ‘model.infer(images).predicted_class‘ to ‘prediction ‘ in host memory. Here prediction means the class index with the greatest classifier score. The important operands are model: the value named ’model’ in this block; infer: the value named ’infer’ in this block; images: the value named ’images’ in this block. Context: the function evaluate, which handles evaluate.

Line 153: `correct += int(np.count_nonzero(prediction == labels))` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are correct: the value named ’correct’ in this block; count_nonzero: the value named ’count nonzero’ in this block; prediction: the class index with the greatest classifier score.

Line 154: `total += len(labels)` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are total: the value named ’total’ in this block; len: the value named ’len’ in this block; labels: the value named ’labels’ in this block.

Line 155: `return 100.0 * correct / total, correct, total` This returns ‘100.0 * correct / total, correct, total‘ to the caller of the function evaluate, which handles evaluate, ending this invocation. The important operands are correct: the value named ’correct’ in this block; total: the value named ’total’ in this block.

Line 158: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 159: `arguments = parse_arguments()` This assigns ‘parse_arguments()‘ to ‘arguments ‘ in host memory. Here arguments means the value named ’arguments’ in this block. The important operands are parse_arguments: the value named ’parse arguments’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 160: `if arguments.epochs <= 0 or arguments.batch_size <= 0:` This executes the following indented host-code branch only when ‘arguments.epochs <= 0 or arguments.batch_size <= 0‘ is true. The important operands are arguments: the value named ’arguments’ in this block; epochs: the value named ’epochs’ in this block; or: the value named ’or’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 161: `raise ValueError("epochs and batch-size must be positive")` This rejects an invalid state by raising ‘ValueError("epochs and batch-size must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 162: `if arguments.checkpoint_interval <= 0:` This executes the following indented host-code branch only when ‘arguments.checkpoint_interval <= 0‘ is true. The important operands are arguments: the value named ’arguments’ in this block; checkpoint_interval: the value named ’checkpoint interval’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 163: `raise ValueError("checkpoint-interval must be positive")` This rejects an invalid state by raising ‘ValueError("checkpoint-interval must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 164: `output_dir = arguments.output_dir.expanduser().resolve()` This assigns ‘arguments.output_dir.expanduser().
to ‘output_dir ‘ in host memory. Here output_dir means the value named ’output dir’ in this block. The important operands are arguments: the value named ’arguments’ in this block; output_dir: the value named ’output dir’ in this block; expanduser: the value named ’expanduser’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 165: `output_dir.mkdir(parents=True, exist_ok=True)` This calls ‘output_dir.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 166: `pause_path = output_dir / "PAUSE"` This assigns ‘output_dir / "PAUSE"‘ to ‘pause_path ‘ in host memory. Here pause_path means the value named ’pause path’ in this block. The important operands are output_dir: the value named ’output dir’ in this block; PAUSE: the value named ’pause’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 167: `status_path = output_dir / "training_status.json"` This assigns ‘output_dir / "training_status.json"‘ to ‘status_path ‘ in host memory. Here status_path means the value named ’status path’ in this block. The important operands are output_dir: the value named ’output dir’ in this block; training_status: the value named ’training status’ in this block; json: the value named ’json’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 168: `latest_path = output_dir / "latest_checkpoint.npz"` This assigns ‘output_dir / "latest_checkpoint.npz"‘ to ‘latest_path ‘ in host memory. Here latest_path means the value named ’latest path’ in this block. The important operands are output_dir: the value named ’output dir’ in this block; latest_checkpoint: the value named ’latest checkpoint’ in this block; npz: the value named ’npz’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 169: `best_path = output_dir / "best_checkpoint.npz"` This assigns ‘output_dir / "best_checkpoint.npz"‘ to ‘best_path ‘ in host memory. Here best_path means the value named ’best path’ in this block. The important operands are output_dir: the value named ’output dir’ in this block; best_checkpoint: the value named ’best checkpoint’ in this block; npz: the value named ’npz’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 170: `history_path = output_dir / "training_history.jsonl"` This assigns ‘output_dir / "training_history.jsonl"‘ to ‘history_path ‘ in host memory. Here history_path means the value named ’history path’ in this block. The important operands are output_dir: the value named ’output dir’ in this block; training_history: the value named ’training history’ in this block; jsonl: the value named ’jsonl’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 172: `archive = SpikingformerParameterArchive(arguments.manifest)` This assigns ‘SpikingformerParameterArchive(arguments.manifest)‘ to ‘archive ‘ in host memory. Here archive means the value named ’archive’ in this block. The important operands are SpikingformerParameterArchive: the value named ’spikingformer parameter archive’ in this block; arguments: the value named ’arguments’ in this block; manifest: the value named ’manifest’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 173: `state = TrainableSpikingformerState(archive)` This assigns ‘TrainableSpikingformerState(archive)‘ to ‘state ‘ in host memory. Here state means the finite-state-machine phase retained in flip-flops. The important operands are TrainableSpikingformerState: the finite-state-machine phase retained in flip-flops; archive: the value named ’archive’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 174: `start_epoch = 0` This assigns ‘0‘ to ‘start_epoch ‘ in host memory. Here start_epoch means the value named ’start epoch’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 175: `start_batch = 0` This assigns ‘0‘ to ‘start_batch ‘ in host memory. Here start_batch means the value named ’start batch’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 176: `best_accuracy = 0.0` This assigns ‘0.0‘ to ‘best_accuracy ‘ in host memory. Here best_accuracy means the value named ’best accuracy’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 177: `if arguments.resume:` This executes the following indented host-code branch only when ‘arguments.resume‘ is true. The important operands are arguments: the value named ’arguments’ in this block; resume: the value named ’resume’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 178: `if not latest_path.is_file():` This executes the following indented host-code branch only when ‘not latest_path.is_file()‘ is true. The important operands are not: the value named ’not’ in this block; latest_path: the value named ’latest path’ in this block; is_file: the value named ’is file’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 179: `raise FileNotFoundError(f"resume checkpoint does not exist: {latest_path}")` This rejects an invalid state by raising ‘FileNotFoundError(f"resume checkpoint does not exist: {latest_path}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 180: `metadata = state.load_checkpoint(latest_path)` This assigns ‘state.load_checkpoint(latest_path)‘ to ‘metadata ‘ in host memory. Here metadata means the value named ’metadata’ in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; load_checkpoint: the value named ’load checkpoint’ in this block; latest_path: the value named ’latest path’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 181: `start_epoch = int(metadata["epoch"])` This assigns ‘int(metadata["epoch"])‘ to ‘start_epoch ‘ in host memory. Here start_epoch means the value named ’start epoch’ in this block. The important operands are metadata: the value named ’metadata’ in this block; epoch: the value named ’epoch’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 182: `start_batch = int(metadata["batch_index"])` This assigns ‘int(metadata["batch_index"])‘ to ‘start_batch ‘ in host memory. Here start_batch means the value named ’start batch’ in this block. The important operands are metadata: the value named ’metadata’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 183: `best_accuracy = float(metadata["best_accuracy_percent"])` This assigns ‘float(metadata["best_accuracy_perc to ‘best_accuracy ‘ in host memory. Here best_accuracy means the value named ’best accuracy’ in this block. The important operands are float: the value named ’float’ in this block; metadata: the value named ’metadata’ in this block; best_accuracy_percent: the value named ’best accuracy percent’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 185: `train_data = Cifar10ShardSet(arguments.data_manifest, "train")` This assigns ‘Cifar10ShardSet(arguments.d "train")‘ to ‘train_data ‘ in host memory. Here train_data means the payload carried with the surrounding valid/ready handshake. The important operands are Cifar10ShardSet: the value named ’cifar10 shard set’ in this block; arguments: the value named ’arguments’ in this block; data_manifest: the value named ’data manifest’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 186: `test_data = Cifar10ShardSet(arguments.data_manifest, "test")` This assigns ‘Cifar10ShardSet(arguments.dat "test")‘ to ‘test_data ‘ in host memory. Here test_data means the payload carried with the surrounding valid/ready handshake. The important operands are Cifar10ShardSet: the value named ’cifar10 shard set’ in this block; arguments: the value named ’arguments’ in this block; data_manifest: the value named ’data manifest’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 187: `driver = NeuraEdgeDriver.from_bitfile(` This statement continues through source line 188; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘NeuraEdgeDriver.from_bitfile(arguments.bitfile, download=not arguments.no_download)‘ to ‘driver ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are NeuraEdgeDriver: the value named ’neura edge driver’ in this block; from_bitfile: the value named ’from bitfile’ in this block; arguments: the value named ’arguments’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 188: `arguments.bitfile, download=not arguments.no_download)` This is continuation line 2 of the 2-line logical statement that begins at source line 187. Its exact fragment is ‘arguments.bitfile, download=not arguments.no_download)‘. The important operands are arguments: the value named ’arguments’ in this block; bitfile: the value named ’bitfile’ in this block; download: the value named ’download’ in this block. Read together, the complete operation is: This assigns ‘NeuraEdgeDriver.from_bitfile(arguments.bitfile, download=not arguments.no_download)‘ to ‘driver ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are NeuraEdgeDriver: the value named ’neura edge driver’ in this block; from_bitfile: the value named ’from bitfile’ in this block; arguments: the value named ’arguments’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 189: `trainer = SpikingformerOnDeviceTrainer(` This statement continues through source line 190; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘SpikingformerOnDeviceTrainer(state, driver, layer_timeout_seconds=arguments.layer_timeout_seconds)‘ to ‘trainer ‘ in host memory. Here trainer means the value named ’trainer’ in this block. The important operands are SpikingformerOnDeviceTrainer: the value named ’spikingformer on device trainer’ in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named ’driver’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 190: `state, driver, layer_timeout_seconds=arguments.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 189. Its exact fragment is ‘state, driver, layer_timeout_seconds=arguments The important operands are state: the finite-state-machine phase retained in flip-flops; driver: the value named ’driver’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘SpikingformerOnDeviceTrainer(state, driver, layer_timeout_seconds=arguments.layer_timeout_seconds)‘ to ‘trainer ‘ in host memory. Here trainer means the value named ’trainer’ in this block. The important operands are SpikingformerOnDeviceTrainer: the value named ’spikingformer on device trainer’ in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named ’driver’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 191: `inference_model = SpikingformerAcceleratorModel(` This statement continues through source line 192; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘SpikingformerAcceleratorModel(state, driver, layer_timeout_seconds=arguments.layer_timeout_seconds)‘ to ‘inference_model ‘ in host memory. Here inference_model means the value named ’inference model’ in this block. The important operands are SpikingformerAcceleratorModel: the value named ’spikingformer accelerator model’ in this block; state: the finite-

state-machine phase retained in flip-flops; driver: the value named 'driver' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 192: `state, driver, layer_timeout_seconds=arguments.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 191. Its exact fragment is 'state, driver, layer_timeout_seconds=arguments The important operands are state: the finite-state-machine phase retained in flip-flops; driver: the value named 'driver' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'SpikingformerAcceleratorModel(state, driver, layer_timeout_seconds=arguments.layer_timeout_seconds) to 'inference_model ' in host memory. Here inference_model means the value named 'inference model' in this block. The important operands are SpikingformerAcceleratorModel: the value named 'spikingformer accelerator model' in this block; state: the finite-state-machine phase retained in flip-flops; driver: the value named 'driver' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 194: `job_started = time.time()` This assigns 'time.time()' to 'job_started ' in host memory. Here job_started means the value named 'job started' in this block. The important operands are time: the value named 'time' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 195: `for epoch in range(start_epoch, arguments.epochs):` This iterates epoch over 'range(start_epoch, arguments.epochs)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 196: `epoch_batch_start = start_batch if epoch == start_epoch else 0` Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are epoch_batch_start: the value named 'epoch batch start' in this block; start_batch: the value named 'start batch' in this block; epoch: the value named 'epoch' in this block.

Line 197: `learning_rate = cosine_learning_rate(` This statement continues through source line 202; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'cosine_learning_rate(epoch, arguments.epochs, arguments.learning_rate, arguments.minimum_learning_rate,)' to 'learning_rate ' in host memory. Here learning_rate means the fixed-point multiplier controlling update magnitude. The important operands are cosine_learning_rate: the fixed-point multiplier controlling update magnitude; epoch: the value named 'epoch' in this block; arguments: the value named 'arguments' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 198: `epoch,` This is continuation line 2 of the 6-line logical statement that begins at source line 197. Its exact fragment is 'epoch,'. The important operands are epoch: the value named 'epoch' in this block. Read together, the complete operation is: This assigns 'cosine_learning_rate(epoch, arguments.epochs, arguments.learning_rate, arguments.minimum_learning_rate,)' to 'learning_rate ' in host memory. Here learning_rate means the fixed-point multiplier controlling update magnitude. The important operands are cosine_learning_rate: the fixed-point multiplier controlling update magnitude; epoch: the value named 'epoch' in this block; arguments: the value named 'arguments' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 199: `arguments.epochs,` This is continuation line 3 of the 6-line logical statement that begins at source line 197. Its exact fragment is 'arguments.epochs,'. The important operands are arguments: the value named 'arguments' in this block; epochs: the value named 'epochs' in this block. Read together, the complete operation is: This assigns 'cosine_learning_rate(epoch, arguments.epochs, arguments.learning_rate, arguments.minimum_learning_rate,)' to 'learning_rate ' in host memory. Here learning_rate means the fixed-point multiplier controlling update magnitude. The important operands are cosine_learning_rate: the fixed-point multiplier controlling update magnitude; epoch: the value named 'epoch' in this block; arguments: the value named 'arguments' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 200: `arguments.learning_rate,` This is continuation line 4 of the 6-line logical statement that begins at source line 197. Its exact fragment is 'arguments.learning_rate,'. The important operands are arguments: the value named 'arguments' in this block; learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns 'cosine_learning_rate(epoch, arguments.epochs, arguments.learning_rate, arguments.minimum_learning_rate,)' to 'learning_rate ' in host memory. Here learning_rate means the fixed-point multiplier controlling update magnitude. The important operands are cosine_learning_rate: the fixed-point multiplier controlling update magnitude; epoch: the value named 'epoch' in this block; arguments: the value named 'arguments' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 201: `arguments.minimum_learning_rate,` This is continuation line 5 of the 6-line logical statement that begins at source line 197. Its exact fragment is 'arguments.minimum_learning_rate,'. The important operands are arguments: the value named 'arguments' in this block; minimum_learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns 'cosine_learning_rate(epoch, arguments.epochs, arguments.learning_rate, arguments.minimum_learning_rate,)' to 'learning_rate ' in host memory. Here learning_rate means the fixed-point multiplier controlling update magnitude. The important operands are cosine_learning_rate: the fixed-point multiplier controlling update magnitude; epoch: the value named 'epoch' in this block; arguments: the value named 'arguments' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 202: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 197. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'cosine_learning_rate(epoch, arguments.epochs, arguments.learning_rate, arguments.minimum_learning_rate,)' to 'learning_rate ' in host memory. Here learning_rate means the fixed-point multiplier controlling update magnitude. The important operands are cosine_learning_rate: the fixed-point multiplier controlling update magnitude; epoch: the value named 'epoch' in this block; arguments: the value named 'arguments' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 203: `epoch_loss = 0.0` This assigns '0.0' to 'epoch_loss ' in host memory. Here epoch_loss means the value named 'epoch loss' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 204: `epoch_correct = 0` This assigns '0' to 'epoch_correct ' in host memory. Here epoch_correct means the value named 'epoch correct' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 205: `epoch_samples = 0` This assigns '0' to 'epoch_samples ' in host memory. Here epoch_samples means the value named 'epoch samples' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 206: `last_batch = epoch_batch_start - 1` This assigns 'epoch_batch_start - 1' to 'last_batch ' in host memory. Here last_batch means the AXI-Stream marker for the final beat of a packet or command payload. The important operands are epoch_batch_start: the value named 'epoch batch start' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 207: `for batch_index, raw_images, labels in train_data.batches(` This line opens or closes a multi-line Python expression inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports; the neighboring lines supply its arguments or elements.

Line 208: `epoch=epoch,` This assigns ‘epoch,‘ to ‘epoch‘ in host memory. Here epoch means the value named ’epoch’ in this block. The important operands are epoch: the value named ’epoch’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 209: `batch_size=arguments.batch_size,` This assigns ‘arguments.batch_size,‘ to ‘batch_size‘ in host memory. Here batch_size means the value named ’batch size’ in this block. The important operands are arguments: the value named ’arguments’ in this block; batch_size: the value named ’batch size’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 210: `seed=arguments.seed,` This assigns ‘arguments.seed,‘ to ‘seed‘ in host memory. Here seed means the value named ’seed’ in this block. The important operands are arguments: the value named ’arguments’ in this block; seed: the value named ’seed’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 211: `shuffle=True,` This assigns ‘True,‘ to ‘shuffle‘ in host memory. Here shuffle means the value named ’shuffle’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 212: `start_batch=epoch_batch_start,` This assigns ‘epoch_batch_start,‘ to ‘start_batch‘ in host memory. Here start_batch means the value named ’start batch’ in this block. The important operands are epoch_batch_start: the value named ’epoch batch start’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 213: `):` Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The expression is a literal or structural operator and has no hidden software state.

Line 214: `if pause_path.exists():` This executes the following indented host-code branch only when ‘pause_path.exists()‘ is true. The important operands are pause_path: the value named ’pause path’ in this block; exists: the value named ’exists’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 215: `state.save_checkpoint(` This statement continues through source line 221; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘state.save_checkpoint‘ with ‘ latest_path, epoch=epoch, batch_index=batch_index, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate, "pause_boundary": True}, ‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 216: `latest_path,` This is continuation line 2 of the 7-line logical statement that begins at source line 215. Its exact fragment is ‘latest_path,‘. The important operands are latest_path: the value named ’latest path’ in this block. Read together, the complete operation is: This calls ‘state.save_checkpoint‘ with ‘ latest_path, epoch=epoch, batch_index=batch_index, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate, "pause_boundary": True}, ‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 217: `epoch=epoch,` This is continuation line 3 of the 7-line logical statement that begins at source line 215. Its exact fragment is ‘epoch=epoch,‘. The important operands are epoch: the value named ’epoch’ in this block. Read together, the complete operation is: This calls ‘state.save_checkpoint‘ with ‘ latest_path, epoch=epoch, batch_index=batch_index, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate, "pause_boundary": True}, ‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs,

and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 218: `batch_index=batch_index,` This is continuation line 4 of the 7-line logical statement that begins at source line 215. Its exact fragment is ‘batch_index=batch_index,‘. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘state.save_checkpoint‘ with ‘ latest_path, epoch=epoch, batch_index=batch_index, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate, "pause_boundary": True}, ‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 219: `best_accuracy_percent=best_accuracy,` This is continuation line 5 of the 7-line logical statement that begins at source line 215. Its exact fragment is ‘best_accuracy_percent=best_accuracy,‘. The important operands are best_accuracy_percent: the value named ’best accuracy percent’ in this block; best_accuracy: the value named ’best accuracy’ in this block. Read together, the complete operation is: This calls ‘state.save_checkpoint‘ with ‘ latest_path, epoch=epoch, batch_index=batch_index, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate, "pause_boundary": True}, ‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 220: `extra={"learning_rate": learning_rate, "pause_boundary": True},` This is continuation line 6 of the 7-line logical statement that begins at source line 215. Its exact fragment is ‘extra={"learning_rate": learning_rate, "pause_boundary": True},‘. The important operands are extra: the value named ’extra’ in this block; learning_rate: the fixed-point multiplier controlling update magnitude; pause_boundary: the value named ’pause boundary’ in this block. Read together, the complete operation is: This calls ‘state.save_checkpoint‘ with ‘ latest_path, epoch=epoch, batch_index=batch_index, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate, "pause_boundary": True}, ‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 221: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 215. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘state.save_checkpoint‘ with ‘ latest_path, epoch=epoch, batch_index=batch_index, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate, "pause_boundary": True}, ‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 222: `atomic_json(status_path, {` This statement continues through source line 229; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘atomic_json‘ with ‘status_path, { "status": "paused", "epoch": epoch, "batch_index": batch_index, "optimizer_step": state.optimizer_step, "latest_checkpoint": str(latest_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 223: `"status": "paused",` This is continuation line 2 of the 8-line logical statement that begins at source line 222. Its exact fragment is ‘"status": "paused",‘. The important operands are status: the value named ’status’ in this block; paused: the value named ’paused’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "paused", "epoch": epoch, "batch_index": batch_index, "optimizer_step": state.optimizer_step, "latest_checkpoint": str(latest_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 224: `"epoch": epoch,` This is continuation line 3 of the 8-line logical statement that begins at source line 222. Its exact fragment is ‘"epoch": epoch,‘. The important operands are epoch: the value named ’epoch’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "paused", "epoch": epoch, "batch_index": batch_index, "optimizer_step": state.optimizer_step, "latest_checkpoint": str(latest_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 225: `"batch_index": batch_index,` This is continuation line 4 of the 8-line logical statement that begins at source line 222. Its exact fragment is ‘"batch_index": batch_index,‘. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "paused", "epoch": epoch, "batch_index": batch_index, "optimizer_step": state.optimizer_step, "latest_checkpoint": str(latest_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 226: `"optimizer_step": state.optimizer_step,` This is continuation line 5 of the 8-line logical statement that begins at source line 222. Its exact fragment is ‘"optimizer_step": state.optimizer_step,‘. The important operands are optimizer_step: the value named ’optimizer step’ in this block; state: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "paused", "epoch": epoch, "batch_index": batch_index, "optimizer_step": state.optimizer_step, "latest_checkpoint": str(latest_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 227: `"latest_checkpoint": str(latest_path),` This is continuation line 6 of the 8-line logical statement that begins at source line 222. Its exact fragment is ‘"latest_checkpoint": str(latest_path),‘. The important operands are latest_checkpoint: the value named ’latest checkpoint’ in this block; str: the value named ’str’ in this block; latest_path: the value named ’latest path’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "paused", "epoch": epoch, "batch_index": batch_index, "optimizer_step": state.optimizer_step, "latest_checkpoint": str(latest_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 228: `"updated_utc": datetime.now(timezone.utc).isoformat(),` This is continuation line 7 of the 8-line logical statement that begins at source line 222. Its exact fragment is ‘"updated_utc": datetime.now(timezone.utc).isoformat(),‘. The important operands are updated_utc: the value named ’updated utc’ in this block; datetime: the value named ’datetime’ in this block; now: the value named ’now’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "paused", "epoch": epoch, "batch_index": batch_index, "optimizer_step": state.optimizer_step, "latest_checkpoint": str(latest_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 229: `})` This is continuation line 8 of the 8-line logical statement that begins at source line 222. Its exact fragment is ‘})‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "paused", "epoch": epoch, "batch_index": batch_index, "optimizer_step": state.optimizer_step, "latest_checkpoint": str(latest_path), "updated_utc": datetime.now(timezone.utc).isoform
}‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 230: `raise SystemExit(0)` This rejects an invalid state by raising ‘SystemExit(0)‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 231: `augmented = augment_cifar10(` This statement continues through source line 232; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘augment_cifar10(raw_images, arguments.seed + epoch * 10_000_019 + batch_index)‘ to ‘augmented ‘ in host memory. Here augmented means the value named ’augmented’ in this block. The important operands are augment_cifar10: the value named ’augment cifar10’ in this block; raw_images: the value named ’raw images’ in this block; arguments: the value named ’arguments’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 232: `raw_images, arguments.seed + epoch * 10_000_019 + batch_index)` This is continuation line 2 of the 2-line logical statement that begins at source line 231. Its exact fragment is ‘raw_images, arguments.seed + epoch * 10_000_019 + batch_index)‘. The important operands are raw_images: the value named ’raw images’ in this block; arguments: the value named ’arguments’ in this block; seed: the value named ’seed’ in this block. Read together, the complete operation is: This assigns ‘augment_cifar10(raw_images, arguments.seed + epoch * 10_000_019 + batch_index)‘ to ‘augmented ‘ in host memory. Here augmented means the value named ’augmented’ in this block. The important operands are augment_cifar10: the value named ’augment cifar10’ in this block; raw_images: the value named ’raw images’ in this block; arguments: the value named ’arguments’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 233: `images = prepare_input(augmented, "raw-u8")` This assigns ‘prepare_input(augmented, "raw-u8")‘ to ‘images ‘ in host memory. Here images means the value named ’images’ in this block. The important operands are prepare_input: the value named ’prepare input’ in this block; augmented: the value named ’augmented’ in this block; raw: the value named ’raw’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 234: `batch_started = time.perf_counter()` This assigns ‘time.perf_counter()‘ to ‘batch_started ‘ in host memory. Here batch_started means the value named ’batch started’ in this block. The important operands are time: the value named ’time’ in this block; perf_counter: a hardware telemetry register that accumulates measured events. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 235: `result = trainer.train_step(` This statement continues through source line 242; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘trainer.train_step(images, labels, learning_rate=learning_rate, momentum=arguments.momentum, weight_decay=arguments.weight_decay, gradient_clip_q15=argume
)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are trainer: the value named ’trainer’ in this block; train_step: the value named ’train step’ in this block; images: the value named ’images’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 236: `images,` This is continuation line 2 of the 8-line logical statement that begins at source line 235. Its exact fragment is ‘images,‘. The important operands are images: the value named ’images’ in this block. Read together, the complete operation is: This assigns ‘trainer.train_step(images, labels, learning_rate=learning_rate, momentum=arguments.momentum, weight_decay=arguments.weight_decay, gradient_clip_q15=arguments.gradient_clip_q15,
)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are trainer: the value named ’trainer’ in this block; train_step: the value named ’train step’ in this block; images: the value named ’images’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 237: `labels,` This is continuation line 3 of the 8-line logical statement that begins at source line 235. Its exact fragment is ‘labels,‘. The important operands are labels: the value named ’labels’ in this block. Read together, the complete operation is: This assigns ‘trainer.train_step(images, labels, learning_rate=learning_rate, momentum=arguments.momentum, weight_decay=arguments.weight_decay, gradient_clip_q15=arguments.gradient_clip_q15,
)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are trainer: the value named ’trainer’ in this block; train_step: the value named ’train step’ in this block; images: the value named ’images’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 238: `learning_rate=learning_rate,` This is continuation line 4 of the 8-line logical statement that begins at source line 235. Its exact fragment is 'learning_rate=learning_rate,'. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns 'trainer.train_step(images, labels, learning_rate=learning_rate, momentum=arguments.momentum, weight_decay=arguments.we gradient_clip_q15=arguments.gradient_clip_q15,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are trainer: the value named 'trainer' in this block; train_step: the value named 'train step' in this block; images: the value named 'images' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 239: `momentum=arguments.momentum,` This is continuation line 5 of the 8-line logical statement that begins at source line 235. Its exact fragment is 'momentum=arguments.momentum,'. The important operands are momentum: the value named 'momentum' in this block; arguments: the value named 'arguments' in this block. Read together, the complete operation is: This assigns 'trainer.train_step(images, labels, learning_rate=learning_rate, momentum=arguments.momentum, weight_decay=arguments.weight_decay, gradient_clip_q15=arguments.gradient_clip_q15,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are trainer: the value named 'trainer' in this block; train_step: the value named 'train step' in this block; images: the value named 'images' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 240: `weight_decay=arguments.weight_decay,` This is continuation line 6 of the 8-line logical statement that begins at source line 235. Its exact fragment is 'weight_decay=arguments.weight_decay,'. The important operands are weight_decay: a learned coefficient multiplied by an activation; arguments: the value named 'arguments' in this block. Read together, the complete operation is: This assigns 'trainer.train_step(images, labels, learning_rate=learning_rate, momentum=arguments.momentum, weight_decay=arguments.weight_decay, gradient_clip_q15=arguments.gradient_clip_q15,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are trainer: the value named 'trainer' in this block; train_step: the value named 'train step' in this block; images: the value named 'images' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 241: `gradient_clip_q15=arguments.gradient_clip_q15,` This is continuation line 7 of the 8-line logical statement that begins at source line 235. Its exact fragment is 'gradient_clip_q15=arguments.gradient_clip_q15,'. The important operands are gradient_clip_q15: the signed loss derivative used to update a learned parameter; arguments: the value named 'arguments' in this block. Read together, the complete operation is: This assigns 'trainer.train_step(images, labels, learning_rate=learning_rate, momentum=arguments.momentum, weight_decay=arguments.weight_decay, gradient_clip_q15=arguments.gradient_clip_q15,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are trainer: the value named 'trainer' in this block; train_step: the value named 'train step' in this block; images: the value named 'images' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 242: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 235. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'trainer.train_step(images, labels, learning_rate=learning_rate, momentum=arguments.momentum, weight_decay=arguments.weight_decay, gradient_clip_q15=arguments.gradient_clip_q15,)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are trainer: the value named 'trainer' in this block; train_step: the value named 'train step' in this block; images: the value named 'images' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 243: `batch_seconds = time.perf_counter() - batch_started` This assigns 'time.perf_counter() - batch_started' to 'batch_seconds ' in host memory. Here batch_seconds means the value named 'batch seconds' in this block. The important operands are time: the value named 'time' in this block; perf_counter: a hardware telemetry register that accumulates measured events; batch_started: the value named 'batch started' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 244: `epoch_loss += result.loss * len(labels)` Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the

host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are epoch_loss: the value named 'epoch loss' in this block; result: the value named 'result' in this block; loss: the value named 'loss' in this block.

Line 245: `epoch_correct += int(np.count_nonzero(result.predicted_class == labels))` Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are epoch_correct: the value named 'epoch correct' in this block; count_nonzero: the value named 'count nonzero' in this block; result: the value named 'result' in this block.

Line 246: `epoch_samples += len(labels)` Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are epoch_samples: the value named 'epoch samples' in this block; len: the value named 'len' in this block; labels: the value named 'labels' in this block.

Line 247: `last_batch = batch_index` This assigns 'batch_index' to 'last_batch ' in host memory. Here last_batch means the AXI-Stream marker for the final beat of a packet or command payload. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 248: `if state.optimizer_step % arguments.checkpoint_interval == 0:` This executes the following indented host-code branch only when 'state.optimizer_step % arguments.checkpoint_interval == 0' is true. The important operands are state: the finite-state-machine phase retained in flip-flops; optimizer_step: the value named 'optimizer step' in this block; arguments: the value named 'arguments' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 249: `checkpoint_hash = state.save_checkpoint(` This statement continues through source line 255; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'state.save_checkpoint(latest_path, epoch=epoch, batch_index=batch_index + 1, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate},)' to 'checkpoint_hash ' in host memory. Here checkpoint_hash means the value named 'checkpoint hash' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; latest_path: the value named 'latest path' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 250: `latest_path,` This is continuation line 2 of the 7-line logical statement that begins at source line 249. Its exact fragment is 'latest_path,'. The important operands are latest_path: the value named 'latest path' in this block. Read together, the complete operation is: This assigns 'state.save_checkpoint(latest_path, epoch=epoch, batch_index=batch_index + 1, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate},)' to 'checkpoint_hash ' in host memory. Here checkpoint_hash means the value named 'checkpoint hash' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; latest_path: the value named 'latest path' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 251: `epoch=epoch,` This is continuation line 3 of the 7-line logical statement that begins at source line 249. Its exact fragment is 'epoch=epoch,'. The important operands are epoch: the value named 'epoch' in this block. Read together, the complete operation is: This assigns 'state.save_checkpoint(latest_path, epoch=epoch, batch_index=batch_index + 1, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate},)' to 'checkpoint_hash ' in host memory. Here checkpoint_hash means the value named 'checkpoint hash' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; latest_path: the value named 'latest path' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 252: `batch_index=batch_index + 1,` This is continuation line 4 of the 7-line logical statement that begins at source line 249. Its exact fragment is 'batch_index=batch_index + 1,'. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns 'state.save_checkpoint(latest_path, epoch=epoch, batch_index=batch_index + 1, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate},)' to 'checkpoint_hash ' in host memory. Here checkpoint_hash means the value named 'checkpoint hash' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; latest_path: the value named 'latest path' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 253: `best_accuracy_percent=best_accuracy,` This is continuation line 5 of the 7-line logical statement that begins at source line 249. Its exact fragment is 'best_accuracy_percent=best_accuracy,'. The important operands are best_accuracy_percent: the value named 'best accuracy percent' in this block; best_accuracy: the value named 'best accuracy' in this block. Read together, the complete operation is: This assigns 'state.save_checkpoint(latest_path, epoch=epoch, batch_index=batch_index + 1, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate},)' to 'checkpoint_hash ' in host memory. Here checkpoint_hash means the value named 'checkpoint hash' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; latest_path: the value named 'latest path' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 254: `extra={"learning_rate": learning_rate},` This is continuation line 6 of the 7-line logical statement that begins at source line 249. Its exact fragment is 'extra={"learning_rate": learning_rate},'. The important operands are extra: the value named 'extra' in this block; learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns 'state.save_checkpoint(latest_path, epoch=epoch, batch_index=batch_index + 1, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate},)' to 'checkpoint_hash ' in host memory. Here checkpoint_hash means the value named 'checkpoint hash' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; latest_path: the value named 'latest path' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 255: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 249. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'state.save_checkpoint(latest_path, epoch=epoch, batch_index=batch_index + 1, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate},)' to 'checkpoint_hash ' in host memory. Here checkpoint_hash means the value named 'checkpoint hash' in this block. The important operands are state: the finite-state-machine phase retained in flip-flops; save_checkpoint: the value named 'save checkpoint' in this block; latest_path: the value named 'latest path' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 256: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 257: `checkpoint_hash = None` This assigns 'None' to 'checkpoint_hash ' in host memory. Here checkpoint_hash means the value named 'checkpoint hash' in this block. The important operands are None: the value named 'none' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 258: `event = {` This statement continues through source line 270; the explanation uses the complete expression rather than only the first visual fragment. Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named 'event' in this block; train_batch: the value named 'train batch' in this block; utc: the value named 'utc' in this block.

Line 259: `"event": "train_batch",` This is continuation line 2 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"event": "train_batch",‘. The important operands are event: the value named ’event’ in this block; train_batch: the value named ’train batch’ in this block. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named ’event’ in this block; train_batch: the value named ’train batch’ in this block; utc: the value named ’utc’ in this block.

Line 260: `"utc": datetime.now(timezone.utc).isoformat(),` This is continuation line 3 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"utc": datetime.now(timezone.utc).isoformat(),‘. The important operands are utc: the value named ’utc’ in this block; datetime: the value named ’datetime’ in this block; now: the value named ’now’ in this block. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named ’event’ in this block; train_batch: the value named ’train batch’ in this block; utc: the value named ’utc’ in this block.

Line 261: `"epoch": epoch,` This is continuation line 4 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"epoch": epoch,‘. The important operands are epoch: the value named ’epoch’ in this block. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named ’event’ in this block; train_batch: the value named ’train batch’ in this block; utc: the value named ’utc’ in this block.

Line 262: `"batch_index": batch_index,` This is continuation line 5 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"batch_index": batch_index,‘. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named ’event’ in this block; train_batch: the value named ’train batch’ in this block; utc: the value named ’utc’ in this block.

Line 263: `"optimizer_step": result.optimizer_step,` This is continuation line 6 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"optimizer_step": result.optimizer_step,‘. The important operands are optimizer_step: the value named ’optimizer step’ in this block; result: the value named ’result’ in this block. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named ’event’ in this block; train_batch: the value named ’train batch’ in this block; utc: the value named ’utc’ in this block.

Line 264: `"samples": len(labels),` This is continuation line 7 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"samples": len(labels),‘. The important operands are samples: the value named ’samples’ in this block; len: the value named ’len’ in this block; labels: the value named ’labels’ in this block. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named ’event’ in this block; train_batch: the value named ’train batch’ in this block; utc: the value named ’utc’ in this block.

Line 265: `"loss": result.loss,` This is continuation line 8 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"loss": result.loss,‘. The important operands are loss: the value named ’loss’ in this block; result: the value named ’result’ in this block. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports,

this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named 'event' in this block; train_batch: the value named 'train batch' in this block; utc: the value named 'utc' in this block.

Line 266: `"batch_accuracy_percent": 100.0 * float(np.mean(result.predicted_class == labels)),` This is continuation line 9 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"batch_accuracy_percent": 100.0 * float(np.mean(result.predicted_class == labels)),‘. The important operands are batch_accuracy_percent: the value named 'batch accuracy percent' in this block; float: the value named 'float' in this block; mean: the arithmetic average used by normalization. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named 'event' in this block; train_batch: the value named 'train batch' in this block; utc: the value named 'utc' in this block.

Line 267: `"learning_rate": learning_rate,` This is continuation line 10 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"learning_rate": learning_rate,‘. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named 'event' in this block; train_batch: the value named 'train batch' in this block; utc: the value named 'utc' in this block.

Line 268: `"elapsed_seconds": batch_seconds,` This is continuation line 11 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"elapsed_seconds": batch_seconds,‘. The important operands are elapsed_seconds: the value named 'elapsed seconds' in this block; batch_seconds: the value named 'batch seconds' in this block. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named 'event' in this block; train_batch: the value named 'train batch' in this block; utc: the value named 'utc' in this block.

Line 269: `"checkpoint_sha256": checkpoint_hash,` This is continuation line 12 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘"checkpoint_sha256": checkpoint_hash,‘. The important operands are checkpoint_sha256: the value named 'checkpoint sha256' in this block; checkpoint_hash: the value named 'checkpoint hash' in this block. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named 'event' in this block; train_batch: the value named 'train batch' in this block; utc: the value named 'utc' in this block.

Line 270: `}` This is continuation line 13 of the 13-line logical statement that begins at source line 258. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports, this statement advances the host implementation that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The important operands are event: the value named 'event' in this block; train_batch: the value named 'train batch' in this block; utc: the value named 'utc' in this block.

Line 271: `with history_path.open("a", encoding="ascii") as history:` This opens a managed resource scope for ‘history_path.open("a", encoding="ascii") as history‘ so files, tracing, or temporary state are finalized even if the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports raises an error.

Line 272: `history.write(json.dumps(event, separators=(",", ":")) + "\n")` This calls ‘history.write‘ with ‘json.dumps(event, separators=(",", ":")) + "\n"‘ inside the file whose role is to provides the board-training command

line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 273: `history.flush()` This calls ‘history.flush‘ with “ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 274: `os.fsync(history.fileno())` This calls ‘os.fsync‘ with ‘history.fileno()‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 275: `atomic_json(status_path, {` This statement continues through source line 288; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 276: `"status": "running",` This is continuation line 2 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"status": "running",‘. The important operands are status: the value named ’status’ in this block; running: the value named ’running’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 277: `"epoch": epoch,` This is continuation line 3 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"epoch": epoch,‘. The important operands are epoch: the value named ’epoch’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 278: `"epochs": arguments.epochs,` This is continuation line 4 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"epochs": arguments.epochs,‘. The important operands are epochs: the value named ’epochs’ in this block; arguments: the value named ’arguments’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 279: `"batch_index": batch_index + 1,` This is continuation line 5 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"batch_index": batch_index + 1,‘. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seco batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc). }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 280: `"optimizer_step": state.optimizer_step,` This is continuation line 6 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"optimizer_step": state.optimizer_step,‘. The important operands are optimizer_step: the value named 'optimizer step' in this block; state: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 281: `"running_loss": epoch_loss / epoch_samples,` This is continuation line 7 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"running_loss": epoch_loss / epoch_samples,‘. The important operands are running_loss: the value named 'running loss' in this block; epoch_loss: the value named 'epoch loss' in this block; epoch_samples: the value named 'epoch samples' in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 282: `"running_accuracy_percent": 100.0 * epoch_correct / epoch_samples,` This is continuation line 8 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"running_accuracy_percent": 100.0 * epoch_correct / epoch_samples,‘. The important operands are running_accuracy_percent: the value named 'running accuracy percent' in this block; epoch_correct: the value named 'epoch correct' in this block; epoch_samples: the value named 'epoch samples' in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 283: `"best_accuracy_percent": best_accuracy,` This is continuation line 9 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"best_accuracy_percent": best_accuracy,‘. The important operands are best_accuracy_percent: the value named 'best accuracy percent' in this block; best_accuracy: the value named 'best accuracy' in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume,

pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 284: `"last_batch_seconds": batch_seconds,` This is continuation line 10 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"last_batch_seconds": batch_seconds,‘. The important operands are last_batch_seconds: the AXI-Stream marker for the final beat of a packet or command payload; batch_seconds: the value named ’batch seconds’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 285: `"latest_checkpoint": str(latest_path),` This is continuation line 11 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"latest_checkpoint": str(latest_path),‘. The important operands are latest_checkpoint: the value named ’latest checkpoint’ in this block; str: the value named ’str’ in this block; latest_path: the value named ’latest path’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 286: `"pause_file": str(pause_path),` This is continuation line 12 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"pause_file": str(pause_path),‘. The important operands are pause_file: the value named ’pause file’ in this block; str: the value named ’str’ in this block; pause_path: the value named ’pause path’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 287: `"updated_utc": datetime.now(timezone.utc).isoformat(),` This is continuation line 13 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘"updated_utc": datetime.now(timezone.utc).isoformat(),‘. The important operands are updated_utc: the value named ’updated utc’ in this block; datetime: the value named ’datetime’ in this block; now: the value named ’now’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 288: `})` This is continuation line 14 of the 14-line logical statement that begins at source line 275. Its exact fragment is ‘})‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "running", "epoch": epoch, "epochs": arguments.epochs, "batch_index": batch_index + 1, "optimizer_step": state.optimizer_step, "running_loss": epoch_loss / epoch_samples, "running_accuracy_percent": 100.0 * epoch_correct / epoch_samples, "best_accuracy_percent": best_accuracy, "last_batch_seconds": batch_seconds, "latest_checkpoint": str(latest_path), "pause_file": str(pause_path),

"updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 290: `evaluation_accuracy, evaluation_correct, evaluation_total = evaluate(` This statement continues through source line 295; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘evaluate(inference_model, test_data, batch_size=arguments.batch_size, seed=arguments.seed,)‘ to ‘evaluation_accuracy, evaluation_correct, evaluation_total ‘ in host memory. Here evaluation_accuracy means the value named ’evaluation accuracy’ in this block. The important operands are evaluate: the value named ’evaluate’ in this block; inference_model: the value named ’inference model’ in this block; test_data: the payload carried with the surrounding valid/ready handshake. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 291: `inference_model,` This is continuation line 2 of the 6-line logical statement that begins at source line 290. Its exact fragment is ‘inference_model,‘. The important operands are inference_model: the value named ’inference model’ in this block. Read together, the complete operation is: This assigns ‘evaluate(inference_model, test_data, batch_size=arguments.batch_size, seed=arguments.seed,)‘ to ‘evaluation_accuracy, evaluation_correct, evaluation_total ‘ in host memory. Here evaluation_accuracy means the value named ’evaluation accuracy’ in this block. The important operands are evaluate: the value named ’evaluate’ in this block; inference_model: the value named ’inference model’ in this block; test_data: the payload carried with the surrounding valid/ready handshake. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 292: `test_data,` This is continuation line 3 of the 6-line logical statement that begins at source line 290. Its exact fragment is ‘test_data,‘. The important operands are test_data: the payload carried with the surrounding valid/ready handshake. Read together, the complete operation is: This assigns ‘evaluate(inference_model, test_data, batch_size=arguments.batch_size, seed=arguments.seed,)‘ to ‘evaluation_accuracy, evaluation_correct, evaluation_total ‘ in host memory. Here evaluation_accuracy means the value named ’evaluation accuracy’ in this block. The important operands are evaluate: the value named ’evaluate’ in this block; inference_model: the value named ’inference model’ in this block; test_data: the payload carried with the surrounding valid/ready handshake. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 293: `batch_size=arguments.batch_size,` This is continuation line 4 of the 6-line logical statement that begins at source line 290. Its exact fragment is ‘batch_size=arguments.batch_size,‘. The important operands are batch_size: the value named ’batch size’ in this block; arguments: the value named ’arguments’ in this block. Read together, the complete operation is: This assigns ‘evaluate(inference_model, test_data, batch_size=arguments.batch_size, seed=arguments.seed,)‘ to ‘evaluation_accuracy, evaluation_correct, evaluation_total ‘ in host memory. Here evaluation_accuracy means the value named ’evaluation accuracy’ in this block. The important operands are evaluate: the value named ’evaluate’ in this block; inference_model: the value named ’inference model’ in this block; test_data: the payload carried with the surrounding valid/ready handshake. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 294: `seed=arguments.seed,` This is continuation line 5 of the 6-line logical statement that begins at source line 290. Its exact fragment is ‘seed=arguments.seed,‘. The important operands are seed: the value named ’seed’ in this block; arguments: the value named ’arguments’ in this block. Read together, the complete operation is: This assigns ‘evaluate(inference_model, test_data, batch_size=arguments.batch_size, seed=arguments.seed,)‘ to ‘evaluation_accuracy, evaluation_correct, evaluation_total ‘ in host memory. Here evaluation_accuracy means the value named ’evaluation accuracy’ in this block. The important operands are evaluate: the value named ’evaluate’ in this block; inference_model: the value named ’inference model’ in this block; test_data: the payload carried with the surrounding valid/ready handshake. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 295: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 290. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘evaluate(inference_model, test_data, batch_size=arguments.batch_size, seed=arguments.seed,)‘ to ‘evaluation_accuracy, evaluation_correct, evaluation_total ‘ in host memory. Here evaluation_accuracy means the

value named 'evaluation accuracy' in this block. The important operands are evaluate: the value named 'evaluate' in this block; inference_model: the value named 'inference model' in this block; test_data: the payload carried with the surrounding valid/ready handshake. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 296: `improved = evaluation_accuracy > best_accuracy` This assigns 'evaluation_accuracy > best_accuracy' to 'improved ' in host memory. Here improved means the value named 'improved' in this block. The important operands are evaluation_accuracy: the value named 'evaluation accuracy' in this block; best_accuracy: the value named 'best accuracy' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 297: `if improved:` This executes the following indented host-code branch only when 'improved' is true. The important operands are improved: the value named 'improved' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 298: `best_accuracy = evaluation_accuracy` This assigns 'evaluation_accuracy' to 'best_accuracy ' in host memory. Here best_accuracy means the value named 'best accuracy' in this block. The important operands are evaluation_accuracy: the value named 'evaluation accuracy' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 299: `state.save_checkpoint(` This statement continues through source line 305; the explanation uses the complete expression rather than only the first visual fragment. This calls 'state.save_checkpoint' with ' latest_path, epoch=epoch + 1, batch_index=0, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate}, ' inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 300: `latest_path,` This is continuation line 2 of the 7-line logical statement that begins at source line 299. Its exact fragment is 'latest_path,'. The important operands are latest_path: the value named 'latest path' in this block. Read together, the complete operation is: This calls 'state.save_checkpoint' with ' latest_path, epoch=epoch + 1, batch_index=0, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate}, ' inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 301: `epoch=epoch + 1,` This is continuation line 3 of the 7-line logical statement that begins at source line 299. Its exact fragment is 'epoch=epoch + 1,'. The important operands are epoch: the value named 'epoch' in this block. Read together, the complete operation is: This calls 'state.save_checkpoint' with ' latest_path, epoch=epoch + 1, batch_index=0, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate}, ' inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 302: `batch_index=0,` This is continuation line 4 of the 7-line logical statement that begins at source line 299. Its exact fragment is 'batch_index=0,'. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'state.save_checkpoint' with ' latest_path, epoch=epoch + 1, batch_index=0, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate}, ' inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 303: `best_accuracy_percent=best_accuracy,` This is continuation line 5 of the 7-line logical statement that begins at source line 299. Its exact fragment is 'best_accuracy_percent=best_accuracy,'. The important operands are best_accuracy_percent: the value named 'best accuracy percent' in this block; best_accuracy: the value named 'best accuracy' in this block. Read together, the complete operation is: This calls 'state.save_checkpoint' with ' latest_path,

epoch=epoch + 1, batch_index=0, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate}, ‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 304: `extra={"learning_rate": learning_rate},` This is continuation line 6 of the 7-line logical statement that begins at source line 299. Its exact fragment is ‘extra={"learning_rate": learning_rate},‘. The important operands are extra: the value named ’extra’ in this block; learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This calls ‘state.save_checkpoint‘ with ‘ latest_path, epoch=epoch + 1, batch_index=0, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate}, ‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 305: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 299. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘state.save_checkpoint‘ with ‘ latest_path, epoch=epoch + 1, batch_index=0, best_accuracy_percent=best_accuracy, extra={"learning_rate": learning_rate}, ‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 306: `if improved:` This executes the following indented host-code branch only when ‘improved‘ is true. The important operands are improved: the value named ’improved’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 307: `temporary_best = best_path.with_name(best_path.name + ".tmp")` This assigns ‘best_path.with_name(best_p + ".tmp")‘ to ‘temporary_best ‘ in host memory. Here temporary_best means the value named ’temporary best’ in this block. The important operands are best_path: the value named ’best path’ in this block; with_name: the value named ’with name’ in this block; name: the value named ’name’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 308: `shutil.copyfile(latest_path, temporary_best)` This calls ‘shutil.copyfile‘ with ‘latest_path, temporary_best‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 309: `os.replace(temporary_best, best_path)` This calls ‘os.replace‘ with ‘temporary_best, best_path‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 310: `epoch_event = {` This statement continues through source line 323; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isof "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percent": evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }‘ to ‘epoch_event ‘ in host memory. Here epoch_event means the value named ’epoch event’ in this block. The important operands are event: the value named ’event’ in this block; epoch_complete: the value named ’epoch complete’ in this block; utc: the value named ’utc’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 311: `"event": "epoch_complete",` This is continuation line 2 of the 14-line logical statement that begins at source line 310. Its exact fragment is ‘"event": "epoch_complete",‘. The important operands are event: the value named

'event' in this block; epoch_complete: the value named 'epoch complete' in this block. Read together, the complete operation is: This assigns '{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percent": evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }' to 'epoch_event ' in host memory. Here epoch_event means the value named 'epoch event' in this block. The important operands are event: the value named 'event' in this block; epoch_complete: the value named 'epoch complete' in this block; utc: the value named 'utc' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 312: `"utc": datetime.now(timezone.utc).isoformat(),` This is continuation line 3 of the 14-line logical statement that begins at source line 310. Its exact fragment is '"utc": datetime.now(timezone.utc).isoformat(),'. The important operands are utc: the value named 'utc' in this block; datetime: the value named 'datetime' in this block; now: the value named 'now' in this block. Read together, the complete operation is: This assigns '{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percent": evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }' to 'epoch_event ' in host memory. Here epoch_event means the value named 'epoch event' in this block. The important operands are event: the value named 'event' in this block; epoch_complete: the value named 'epoch complete' in this block; utc: the value named 'utc' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 313: `"epoch": epoch,` This is continuation line 4 of the 14-line logical statement that begins at source line 310. Its exact fragment is '"epoch": epoch,'. The important operands are epoch: the value named 'epoch' in this block. Read together, the complete operation is: This assigns '{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samp
1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percent": evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }' to 'epoch_event ' in host memory. Here epoch_event means the value named 'epoch event' in this block. The important operands are event: the value named 'event' in this block; epoch_complete: the value named 'epoch complete' in this block; utc: the value named 'utc' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 314: `"last_batch_index": last_batch,` This is continuation line 5 of the 14-line logical statement that begins at source line 310. Its exact fragment is '"last_batch_index": last_batch,'. The important operands are last_batch_index: the AXI-Stream marker for the final beat of a packet or command payload; last_batch: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This assigns '{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percent": evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }' to 'epoch_event ' in host memory. Here epoch_event means the value named 'epoch event' in this block. The important operands are event: the value named 'event' in this block; epoch_complete: the value named 'epoch complete' in this block; utc: the value named 'utc' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 315: `"train_loss": epoch_loss / max(epoch_samples, 1),` This is continuation line 6 of the 14-line logical statement that begins at source line 310. Its exact fragment is '"train_loss": epoch_loss / max(epoch_samples, 1),'. The important operands are train_loss: the value named 'train loss' in this block; epoch_loss: the value named 'epoch loss' in this block; max: the value named 'max' in this block. Read together, the complete operation is: This assigns '{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percent": evaluation_accuracy, "evaluation_correct": evaluation_correct,

"evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }‘ to ‘epoch_event ‘ in host memory. Here epoch_event means the value named 'epoch event' in this block. The important operands are event: the value named 'event' in this block; epoch_complete: the value named 'epoch complete' in this block; utc: the value named 'utc' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 316: `"train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1),` This is continuation line 7 of the 14-line logical statement that begins at source line 310. Its exact fragment is ‘"train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1),‘. The important operands are train_accuracy_percent: the value named 'train accuracy percent' in this block; epoch_correct: the value named 'epoch correct' in this block; max: the value named 'max' in this block. Read together, the complete operation is: This assigns ‘{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percen evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }‘ to ‘epoch_event ‘ in host memory. Here epoch_event means the value named 'epoch event' in this block. The important operands are event: the value named 'event' in this block; epoch_complete: the value named 'epoch complete' in this block; utc: the value named 'utc' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 317: `"evaluation_accuracy_percent": evaluation_accuracy,` This is continuation line 8 of the 14-line logical statement that begins at source line 310. Its exact fragment is ‘"evaluation_accuracy_percent": evaluation_accuracy,‘. The important operands are evaluation_accuracy_percent: the value named 'evaluation accuracy percent' in this block; evaluation_accuracy: the value named 'evaluation accuracy' in this block. Read together, the complete operation is: This assigns ‘{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percent": evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }‘ to ‘epoch_event ‘ in host memory. Here epoch_event means the value named 'epoch event' in this block. The important operands are event: the value named 'event' in this block; epoch_complete: the value named 'epoch complete' in this block; utc: the value named 'utc' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 318: `"evaluation_correct": evaluation_correct,` This is continuation line 9 of the 14-line logical statement that begins at source line 310. Its exact fragment is ‘"evaluation_correct": evaluation_correct,‘. The important operands are evaluation_correct: the value named 'evaluation correct' in this block. Read together, the complete operation is: This assigns ‘{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percent": evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }‘ to ‘epoch_event ‘ in host memory. Here epoch_event means the value named 'epoch event' in this block. The important operands are event: the value named 'event' in this block; epoch_complete: the value named 'epoch complete' in this block; utc: the value named 'utc' in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 319: `"evaluation_samples": evaluation_total,` This is continuation line 10 of the 14-line logical statement that begins at source line 310. Its exact fragment is ‘"evaluation_samples": evaluation_total,‘. The important operands are evaluation_samples: the value named 'evaluation samples' in this block; evaluation_total: the value named 'evaluation total' in this block. Read together, the complete operation is: This assigns ‘{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percen evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()),

}‘ to ‘epoch_event ‘ in host memory. Here epoch_event means the value named ’epoch event’ in this block. The important operands are event: the value named ’event’ in this block; epoch_complete: the value named ’epoch complete’ in this block; utc: the value named ’utc’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 320: `"best_accuracy_percent": best_accuracy,` This is continuation line 11 of the 14-line logical statement that begins at source line 310. Its exact fragment is ‘"best_accuracy_percent": best_accuracy,‘. The important operands are best_accuracy_percent: the value named ’best accuracy percent’ in this block; best_accuracy: the value named ’best accuracy’ in this block. Read together, the complete operation is: This assigns ‘{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percen evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }‘ to ‘epoch_event ‘ in host memory. Here epoch_event means the value named ’epoch event’ in this block. The important operands are event: the value named ’event’ in this block; epoch_complete: the value named ’epoch complete’ in this block; utc: the value named ’utc’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 321: `"optimizer_step": state.optimizer_step,` This is continuation line 12 of the 14-line logical statement that begins at source line 310. Its exact fragment is ‘"optimizer_step": state.optimizer_step,‘. The important operands are optimizer_step: the value named ’optimizer step’ in this block; state: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns ‘{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percen evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }‘ to ‘epoch_event ‘ in host memory. Here epoch_event means the value named ’epoch event’ in this block. The important operands are event: the value named ’event’ in this block; epoch_complete: the value named ’epoch complete’ in this block; utc: the value named ’utc’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 322: `"performance_counters": asdict(driver.performance_snapshot()),` This is continuation line 13 of the 14-line logical statement that begins at source line 310. Its exact fragment is ‘"performance_counters": asdict(driver.performance_snapshot()),‘. The important operands are performance_counters: a hardware telemetry register that accumulates measured events; asdict: the value named ’asdict’ in this block; driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percen evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }‘ to ‘epoch_event ‘ in host memory. Here epoch_event means the value named ’epoch event’ in this block. The important operands are event: the value named ’event’ in this block; epoch_complete: the value named ’epoch complete’ in this block; utc: the value named ’utc’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 323: `}` This is continuation line 14 of the 14-line logical statement that begins at source line 310. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "event": "epoch_complete", "utc": datetime.now(timezone.utc).isoformat(), "epoch": epoch, "last_batch_index": last_batch, "train_loss": epoch_loss / max(epoch_samples, 1), "train_accuracy_percent": 100.0 * epoch_correct / max(epoch_samples, 1), "evaluation_accuracy_percent": evaluation_accuracy, "evaluation_correct": evaluation_correct, "evaluation_samples": evaluation_total, "best_accuracy_percent": best_accuracy, "optimizer_step": state.optimizer_step, "performance_counters": asdict(driver.performance_snapshot()), }‘ to ‘epoch_event ‘ in host memory. Here epoch_event means the value named ’epoch event’ in this block. The important operands are event: the value named ’event’ in this block; epoch_complete: the value named ’epoch complete’ in this block; utc: the value named ’utc’ in this block. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 324: `with history_path.open("a", encoding="ascii") as history:` This opens a managed resource scope for ‘history_path.open("a", encoding="ascii") as history‘ so files, tracing, or temporary state are finalized even if the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports raises an error.

Line 325: `history.write(json.dumps(epoch_event, separators=(",", ":")) + "\n")` This calls ‘history.write‘ with ‘json.dumps(epoch_event, separators=(",", ":")) + "\n"‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 326: `history.flush()` This calls ‘history.flush‘ with “ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 327: `os.fsync(history.fileno())` This calls ‘os.fsync‘ with ‘history.fileno()‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 328: `start_batch = 0` This assigns ‘0‘ to ‘start_batch ‘ in host memory. Here start_batch means the value named ’start batch’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 330: `atomic_json(status_path, {` This statement continues through source line 339; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘atomic_json‘ with ‘status_path, { "status": "complete", "epochs": arguments.epochs, "optimizer_step": state.optimizer_step, "best_accuracy_percent": best_accuracy, "elapsed_seconds": time.time() - job_started, "latest_checkpoint": str(latest_path), "best_checkpoint": str(best_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 331: `"status": "complete",` This is continuation line 2 of the 10-line logical statement that begins at source line 330. Its exact fragment is ‘"status": "complete",‘. The important operands are status: the value named ’status’ in this block; complete: the value named ’complete’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "complete", "epochs": arguments.epochs, "optimizer_step": state.optimizer_step, "best_accuracy_percent": best_accuracy, "elapsed_seconds": time.time() - job_started, "latest_checkpoint": str(latest_path), "best_checkpoint": str(best_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 332: `"epochs": arguments.epochs,` This is continuation line 3 of the 10-line logical statement that begins at source line 330. Its exact fragment is ‘"epochs": arguments.epochs,‘. The important operands are epochs: the value named ’epochs’ in this block; arguments: the value named ’arguments’ in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "complete", "epochs": arguments.epochs, "optimizer_step": state.optimizer_step, "best_accuracy_percent": best_accuracy, "elapsed_seconds": time.time() - job_started, "latest_checkpoint": str(latest_path), "best_checkpoint": str(best_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 333: `"optimizer_step": state.optimizer_step,` This is continuation line 4 of the 10-line logical statement that begins at source line 330. Its exact fragment is ‘"optimizer_step": state.optimizer_step,‘. The important operands

are optimizer_step: the value named 'optimizer step' in this block; state: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "complete", "epochs": arguments.epochs, "optimizer_step": state.optimizer_step, "best_accuracy_percent": best_accuracy, "elapsed_seconds": time.time() - job_started, "latest_checkpoint": str(latest_path), "best_checkpoint": str(best_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 334: `"best_accuracy_percent": best_accuracy,` This is continuation line 5 of the 10-line logical statement that begins at source line 330. Its exact fragment is ‘"best_accuracy_percent": best_accuracy,‘. The important operands are best_accuracy_percent: the value named 'best accuracy percent' in this block; best_accuracy: the value named 'best accuracy' in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "complete", "epochs": arguments.epochs, "optimizer_step": state.optimizer_step, "best_accuracy_percent": best_accuracy, "elapsed_seconds": time.time() - job_started, "latest_checkpoint": str(latest_path), "best_checkpoint": str(best_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 335: `"elapsed_seconds": time.time() - job_started,` This is continuation line 6 of the 10-line logical statement that begins at source line 330. Its exact fragment is ‘"elapsed_seconds": time.time() - job_started,‘. The important operands are elapsed_seconds: the value named 'elapsed seconds' in this block; time: the value named 'time' in this block; job_started: the value named 'job started' in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "complete", "epochs": arguments.epochs, "optimizer_step": state.optimizer_step, "best_accuracy_percent": best_accuracy, "elapsed_seconds": time.time() - job_started, "latest_checkpoint": str(latest_path), "best_checkpoint": str(best_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 336: `"latest_checkpoint": str(latest_path),` This is continuation line 7 of the 10-line logical statement that begins at source line 330. Its exact fragment is ‘"latest_checkpoint": str(latest_path),‘. The important operands are latest_checkpoint: the value named 'latest checkpoint' in this block; str: the value named 'str' in this block; latest_path: the value named 'latest path' in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "complete", "epochs": arguments.epochs, "optimizer_step": state.optimizer_step, "best_accuracy_percent": best_accuracy, "elapsed_seconds": time.time() - job_started, "latest_checkpoint": str(latest_path), "best_checkpoint": str(best_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 337: `"best_checkpoint": str(best_path),` This is continuation line 8 of the 10-line logical statement that begins at source line 330. Its exact fragment is ‘"best_checkpoint": str(best_path),‘. The important operands are best_checkpoint: the value named 'best checkpoint' in this block; str: the value named 'str' in this block; best_path: the value named 'best path' in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "complete", "epochs": arguments.epochs, "optimizer_step": state.optimizer_step, "best_accuracy_percent": best_accuracy, "elapsed_seconds": time.time() - job_started, "latest_checkpoint": str(latest_path), "best_checkpoint": str(best_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 338: `"updated_utc": datetime.now(timezone.utc).isoformat(),` This is continuation line 9 of the 10-line logical statement that begins at source line 330. Its exact fragment is ‘"updated_utc": datetime.now(timezone.utc).isoformat(),‘. The important operands are updated_utc: the value named 'updated utc' in this block; datetime: the value named 'datetime' in this block; now: the value named 'now' in this block. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "complete", "epochs": arguments.epochs, "optimizer_step": state.optimizer_step,

"best_accuracy_percent": best_accuracy, "elapsed_seconds": time.time() - job_started, "latest_checkpoint": str(latest_path), "best_checkpoint": str(best_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

Line 339: `})` This is continuation line 10 of the 10-line logical statement that begins at source line 330. Its exact fragment is ‘})‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘atomic_json‘ with ‘status_path, { "status": "complete", "epochs": arguments.epochs, "optimizer_step": state.optimizer_step, "best_accuracy_percent": best_accuracy, "elapsed_seconds": time.time() - job_started, "latest_checkpoint": str(latest_path), "best_checkpoint": str(best_path), "updated_utc": datetime.now(timezone.utc).isoformat(), }‘ inside the file whose role is to provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports. The call advances the host-side job that provides the board-training command line, validates artifacts, and coordinates resume, pause, epochs, and reports.

46 tb/tb_neuraedge_activation_lut8.sv

Role in the complete system: drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation.

46.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation.

Simulation-only status tb_neuraedge_activation_lut8 is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

46.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module tb_neuraedge_activation_lut8;` This opens tb_neuraedge_activation_lut8;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation.

Line 5: `logic clk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 6: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 7: `logic clear_table = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clear_table is the value named 'clear table' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 8: `logic load_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `logic load_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic [7:0] load_address = 8'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_address is the value named 'load address' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic signed [15:0] load_value = 16'sd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_value is the value named 'load value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic input_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic [63:0] input_indices = 64'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_indices is the value named 'input indices' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic output_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [127:0] output_values;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_values is the value named 'output values' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, config_error is the value named 'config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic [8:0] loaded_entries;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, loaded_entries is the value named 'loaded entries' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 21: `int checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 23: `neuraedge_activation_lut8 dut (` This instantiates module neuraedge_activation_lut8 as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 24: `.clk(clk), .rst_n(rst_n), .clear_table(clear_table),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n), .clear_table(clear_table'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 25: `.load_valid(load_valid), .load_ready(load_ready),` This connects the child instance's named port 'load_valid' to parent expression 'load_valid), .load_ready(load_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 26: `.load_address(load_address), .load_value(load_value),` This connects the child instance's named port 'load_address' to parent expression 'load_address), .load_value(load_value'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'load address), .load value(load value' in this block.

Line 27: `.input_valid(input_valid), .input_ready(input_ready),` This connects the child instance's named port 'input_valid' to parent expression 'input_valid), .input_ready(input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 28: `.input_indices(input_indices), .output_valid(output_valid),` This connects the child instance's named port 'input_indices' to parent expression 'input_indices), .output_valid(output_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 29: `.output_ready(output_ready), .output_values(output_values),` This connects the child instance's named port 'output_ready' to parent expression 'output_ready), .output_values(output_values'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 30: `.config_error(config_error), .loaded_entries(loaded_entries)` This connects the child instance's named port 'config_error' to parent expression 'config_error), .loaded_entries(loaded_entries'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'config error), .loaded entries(loaded entries' in this block.

Line 31: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 33: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 35: `function automatic logic signed [15:0] table_function(input int address);` Within the combinational helper table function, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; table_function: the value named 'table function' in this block.

Line 36: `int centered;` Within the combinational helper table function, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are centered: the value named 'centered' in this block.

Line 37: `int value;` Within the combinational helper table function, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are value: the value named 'value' in this block.

Line 38: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper table function; it has no arithmetic value of its own.

Line 39: `centered = address - 128;` This makes centered, the value named 'centered' in this block, equal to 'address - 128'. It is driven by combinational or procedural logic in the current evaluation. The important operands are address: the value named 'address' in this block. Context: the combinational helper table function.

Line 40: `value = centered < 0 ? -(centered * centered) : centered * centered;` This makes value, the value named 'value' in this block, equal to 'centered < 0 ? -(centered * centered) : centered * centered'. It is driven by combinational or procedural logic in the current evaluation. The important operands are centered: the value named 'centered' in this block. Context: the combinational helper table function.

Line 41: `table_function = 16'(value);` This makes table_function, the value named 'table function' in this block, equal to '16'(value)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper table function.

Line 42: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper table function; it has no arithmetic value of its own.

Line 43: `endfunction` Within the combinational helper table function, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are endfunction: the value named 'endfunction' in this block.

Line 45: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 46: `int seed;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are seed: the value named 'seed' in this block.

Line 47: `seed = 32'h1a7a2026;` This makes seed, the value named 'seed' in this block, equal to '32'h1a7a2026'. It is driven by combinational or procedural logic in the current evaluation. The important operands are h1a7a2026: the value named 'h1a7a2026' in this block. Context: the module's structural declarations.

Line 48: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 49: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 51: `for (int address = 0; address < 256; address++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 52: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 53: `if (!load_ready) begin` This condition selects the following hardware branch only when '!load_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_ready: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 54: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 55: `$display("ERROR LUT load ready address=%0d", address);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 56: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 57: `load_address = 8'(address);` This makes load_address, the value named 'load address' in this block, equal to '8'(address)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are address: the value named 'address' in this block. Context: the module's structural declarations.

Line 58: `load_value = table_function(address);` This makes load_value, the value named 'load value' in this block, equal to 'table_function(address)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are table_function: the value named 'table function' in this block; address: the value named 'address' in this block. Context: the module's structural declarations.

Line 59: `load_valid = 1'b1;` This makes load_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 60: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 61: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 62: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 63: `load_valid = 1'b0;` This makes load_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 64: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 65: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 66: `if (loaded_entries != 256) begin` This condition selects the following hardware branch only when 'loaded_entries != 256' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are loaded_entries: the value named 'loaded entries' in this block. Context: the module's structural declarations.

Line 67: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 68: `$display("ERROR LUT loaded entries=%0d", loaded_entries);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 69: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 71: `// Rewriting an existing address must update its value without changing` Design intent: Rewriting an existing address must update its value without changing This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation.

Line 72: `// the unique-entry count. The count commits one cycle after acceptance.` Design intent: the unique-entry count. The count commits one cycle after acceptance. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation.

Line 73: `load_address = 8'd42;` This makes load_address, the value named 'load address' in this block, equal to '8'd42'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d42: the value named 'd42' in this block. Context: the module's structural declarations.

Line 74: `load_value = table_function(42);` This makes load_value, the value named 'load value' in this block, equal to 'table_function(42)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are table_function: the value named 'table function' in this block. Context: the module's structural declarations.

Line 75: `load_valid = 1'b1;` This makes load_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 76: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 77: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 78: `load_valid = 1'b0;` This makes load_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 79: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 80: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 81: `if (loaded_entries != 256) begin` This condition selects the following hardware branch only when 'loaded_entries != 256' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are loaded_entries: the value named 'loaded entries' in this block. Context: the module's structural declarations.

Line 82: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 83: `$display("ERROR LUT duplicate changed entries=%0d", loaded_entries);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 84: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 86: `for (int test_index = 0; test_index < 100; test_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 87: `while (!input_ready) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are while: the value named 'while' in this block; input_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 88: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 89: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 90: `input_indices[lane*8 +: 8] = $urandom(seed);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are input_indices: the value named 'input indices' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; urandom: the value named 'urandom' in this block.

Line 91: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 92: `input_valid = 1'b1;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 93: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 94: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 95: `input_valid = 1'b0;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 96: `repeat (test_index % 4) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; test_index: an integer selecting one tensor element, lane, bank, or state entry; negedge: the value named 'negedge' in this block.

Line 97: `while (!output_valid) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are while: the value named 'while' in this block; output_valid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 98: `if (config_error) begin` This condition selects the following hardware branch only when 'config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are config_error: the value named 'config error' in this block. Context: the module's structural declarations.

Line 99: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 100: `$display("ERROR LUT output validity test=%0d", test_index);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 101: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 102: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 103: `if ($signed(output_values[lane*16 +: 16])` This condition selects the following hardware branch only when '$signed(output_values[lane*16 +: 16]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_values: the value named 'output values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the module's structural declarations.

Line 104: `!== table_function(input_indices[lane*8 +: 8])) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are table_function: the value named 'table function' in this block; input_indices: the value named 'input indices' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 105: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 106: `$display("ERROR LUT test=%0d lane=%0d address=%0d got=%0d expected=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 107: `test_index, lane, input_indices[lane*8 +: 8],` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are test_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath; input_indices: the value named 'input indices' in this block.

Line 108: `$signed(output_values[lane*16 +: 16]),` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are output_values: the value named 'output values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 109: `table_function(input_indices[lane*8 +: 8]));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are table_function: the value named 'table function' in this block; input_indices: the value named 'input indices' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 110: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 111: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 112: `checked++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 113: `output_ready = 1'b1;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 114: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 115: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 116: `output_ready = 1'b0;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 117: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 119: `// Clearing the table makes missing entries explicit rather than stale.` Design intent: Clearing the table makes missing entries explicit rather than stale. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation.

Line 120: `clear_table = 1'b1;` This makes clear_table, the value named 'clear table' in this block, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 121: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 122: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 123: `clear_table = 1'b0;` This makes clear_table, the value named 'clear table' in this block, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 124: `input_indices = 64'h0706050403020100;` This makes input_indices, the value named 'input indices' in this block, equal to '64'h0706050403020100'. It is driven by combinational or procedural logic in the current evaluation. The important operands are h0706050403020100: the value named 'h0706050403020100' in this block. Context: the module's structural declarations.

Line 125: `input_valid = 1'b1;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 126: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 127: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 128: `input_valid = 1'b0;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 129: `while (!output_valid) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are while: the value named 'while' in this block; output_valid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 130: `if (!config_error || output_values != 0 || loaded_entries != 0) begin` This condition selects the following hardware branch only when '!config_error || output_values != 0 || loaded_entries != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are config_error: the value named 'config error' in this block; output_values: the value named 'output values' in this block; loaded_entries: the value named 'loaded entries' in this block. Context: the module's structural declarations.

Line 131: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 132: `$display("ERROR LUT clear/missing-entry behavior");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 133: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 135: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 136: `$display("tb_neuraedge_activation_lut8 FAILED errors=%0d checked=%0d", errors, checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 137: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 138: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 139: `$display("tb_neuraedge_activation_lut8 PASSED checked=%0d", checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 140: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 141: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 142: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 144: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 145: `#100_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 146: `$fatal(1, "tb_neuraedge_activation_lut8 watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 147: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 148: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 150: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge activation lut8 RTL block in simulation.

47 tb/tb_neuraedge_alpha_xnor.sv

Role in the complete system: drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation.

47.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation.

Simulation-only status tb_neuraedge_alpha_xnor is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 4 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

47.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module tb_neuraedge_alpha_xnor;` This opens tb_neuraedge_alpha_xnor;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation.

Line 5: `logic clk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 6: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 7: `logic input_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 8: `logic input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `logic [255:0] query_spikes = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, query_spikes is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic [255:0] key_spikes = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, key_spikes is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic [8:0] active_bits = 9'd1;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_bits is the value named 'active bits' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic [8:0] alpha_q8 = 9'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_q8 is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic output_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic [17:0] score_q8;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, score_q8 is the value named 'score q8' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic [8:0] spike_matches;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, spike_matches is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [8:0] zero_matches;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_matches is the value named 'zero matches' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, config_error is the value named 'config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 21: `int checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 22: `logic held_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic [17:0] held_score;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_score is the value named 'held score' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic [8:0] held_spikes;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_spikes is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic [8:0] held_zeros;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_zeros is the value named 'held zeros' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `neuraedge_alpha_xnor dut (` This instantiates module neuraedge_alpha_xnor as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 28: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 29: `.rst_n(rst_n),` This connects the child instance's named port 'rst_n' to parent expression 'rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 30: `.input_valid(input_valid),` This connects the child instance's named port 'input_valid' to parent expression 'input_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 31: `.input_ready(input_ready),` This connects the child instance's named port 'input_ready' to parent expression 'input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 32: `.query_spikes(query_spikes),` This connects the child instance's named port 'query_spikes' to parent expression 'query_spikes'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 33: `.key_spikes(key_spikes),` This connects the child instance's named port 'key_spikes' to parent expression 'key_spikes'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 34: `.active_bits(active_bits),` This connects the child instance's named port 'active_bits' to parent expression 'active_bits'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'active bits' in this block.

Line 35: `.alpha_q8(alpha_q8),` This connects the child instance's named port 'alpha_q8' to parent expression 'alpha_q8'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 36: `.output_valid(output_valid),` This connects the child instance's named port 'output_valid' to parent expression 'output_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 37: `.output_ready(output_ready),` This connects the child instance's named port 'output_ready' to parent expression 'output_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 38: `.score_q8(score_q8),` This connects the child instance's named port 'score_q8' to parent expression 'score_q8'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'score q8' in this block.

Line 39: `.spike_matches(spike_matches),` This connects the child instance's named port 'spike_matches' to parent expression 'spike_matches'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 40: `.zero_matches(zero_matches),` This connects the child instance's named port 'zero_matches' to parent expression 'zero_matches'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'zero matches' in this block.

Line 41: `.config_error(config_error)` This connects the child instance's named port 'config_error' to parent expression 'config_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'config error' in this block.

Line 42: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 44: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 46: `task automatic run_case(` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; run_case: the value named 'run case' in this block.

Line 47: `input logic [255:0] query_value,` This declares query_value as a input port with width [255:0]. It carries the value named 'query value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 48: `input logic [255:0] key_value,` This declares key_value as a input port with width [255:0]. It carries the value named 'key value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 49: `input int bit_count,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 50: `input int alpha_value,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 51: `input int stall_cycles` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 52: `);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 53: `int expected_spikes;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are expected_spikes: a binary event produced when a neuron crosses its threshold.

Line 54: `int expected_zeros;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are expected_zeros: the value named 'expected zeros' in this block.

Line 55: `int expected_score;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are expected_score: the value named 'expected score' in this block.

Line 56: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 57: `expected_spikes = 0;` This makes expected_spikes, a binary event produced when a neuron crosses its threshold, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run case.

Line 58: `expected_zeros = 0;` This makes expected_zeros, the value named 'expected zeros' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run case.

Line 59: `for (int bit_index = 0; bit_index < bit_count; bit_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 60: `if (query_value[bit_index] && key_value[bit_index]) expected_spikes++;` This condition selects the following hardware branch only when 'query_value[bit_index] && key_value[bit_index]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are query_value: the value named 'query value' in this block; bit_index: an integer selecting one tensor element, lane, bank, or state entry; key_value: the value named 'key value' in this block. Context: the simulation task run case.

Line 61: `if (!query_value[bit_index] && !key_value[bit_index]) expected_zeros++;` This condition selects the following hardware branch only when '!query_value[bit_index] && !key_value[bit_index]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are query_value: the value named 'query value' in this block; bit_index: an integer selecting one tensor element, lane, bank, or state entry; key_value: the value named 'key value' in this block. Context: the simulation task run case.

Line 62: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 63: `expected_score = expected_spikes * 256 + expected_zeros * alpha_value;` This makes expected_score, the value named 'expected score' in this block, equal to 'expected_spikes * 256 + expected_zeros * alpha_value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are expected_spikes: a binary event produced when a neuron crosses its threshold; expected_zeros: the value named 'expected zeros' in this block; alpha_value: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the simulation task run case.

Line 65: `while (!input_ready) @(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are while: the value named 'while' in this block; input_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 66: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 67: `query_spikes = query_value;` This makes query_spikes, a binary event produced when a neuron crosses its threshold, equal to 'query_value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are query_value: the value named 'query value' in this block. Context: the simulation task run case.

Line 68: `key_spikes = key_value;` This makes key_spikes, a binary event produced when a neuron crosses its threshold, equal to 'key_value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are key_value: the value named 'key value' in this block. Context: the simulation task run case.

Line 69: `active_bits = 9'(bit_count);` This makes active_bits, the value named 'active bits' in this block, equal to '9'(bit_count)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are bit_count: an integer count retained for control or measurable telemetry. Context: the simulation task run case.

Line 70: `alpha_q8 = 9'(alpha_value);` This makes alpha_q8, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to '9'(alpha_value)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are alpha_value: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the simulation task run case.

Line 71: `input_valid = 1'b1;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task run case.

Line 72: `@(posedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 73: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 74: `input_valid = 1'b0;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run case.

Line 76: `while (!output_valid) @(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are while: the value named 'while' in this block; output_valid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 77: `repeat (stall_cycles) @(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; stall_cycles: the value named 'stall cycles' in this block; negedge: the value named 'negedge' in this block.

Line 78: `output_ready = 1'b1;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task run case.

Line 79: `@(posedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 80: `if (config_error || spike_matches !== expected_spikes` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are config_error: the value named 'config error' in this block; spike_matches: a binary event produced when a neuron crosses its threshold; expected_spikes: a binary event produced when a neuron crosses its threshold.

Line 81: `|| zero_matches !== expected_zeros || score_q8 !== expected_score) begin` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are zero_matches: the value named 'zero matches' in this block; expected_zeros: the value named 'expected zeros' in this block; score_q8: the value named 'score q8' in this block.

Line 82: `errors++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 83: `$display("ERROR alpha-XNOR bits=%0d alpha=%0d got=(%0d,%0d,%0d) expected=(%0d,%0d,%0d)",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 84: `bit_count, alpha_value, spike_matches, zero_matches, score_q8,` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are bit_count: an integer count retained for control or measurable telemetry; alpha_value: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; spike_matches: a binary event produced when a neuron crosses its threshold.

Line 85: `expected_spikes, expected_zeros, expected_score);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are expected_spikes: a binary event produced when a neuron crosses its threshold; expected_zeros: the value named 'expected zeros' in this block; expected_score: the value named 'expected score' in this block.

Line 86: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 87: `checked++;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 88: `@(negedge clk);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 89: `output_ready = 1'b0;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run case.

Line 90: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 91: `endtask` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 93: `always @(posedge clk) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are always: the value named 'always' in this block; posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 94: `if (held_valid && (!output_valid || score_q8 !== held_score` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are held_valid: the producer's statement that its current payload is meaningful; output_valid: the producer's statement that its current payload is meaningful; score_q8: the value named 'score q8' in this block.

Line 95: `|| spike_matches !== held_spikes || zero_matches !== held_zeros)) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are spike_matches: a binary event produced when a neuron crosses its threshold; held_spikes: a binary event produced when a neuron crosses its threshold; zero_matches: the value named 'zero matches' in this block.

Line 96: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 97: `$display("ERROR alpha-XNOR output changed under backpressure");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 98: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 99: `held_valid <= output_valid && !output_ready;` This makes held_valid, the producer's statement that its current payload is meaningful, equal to 'output_valid && !output_ready'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_valid: the producer's statement that its current payload is meaningful; output_ready: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 100: `held_score <= score_q8;` This makes held_score, the value named 'held score' in this block, equal to 'score_q8'. It updates after the active clock edge together with other nonblocking assignments. The important operands are score_q8: the value named 'score q8' in this block. Context: the module's structural declarations.

Line 101: `held_spikes <= spike_matches;` This makes held_spikes, a binary event produced when a neuron crosses its threshold, equal to 'spike_matches'. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_matches: a binary event produced when a neuron crosses its threshold. Context: the module's structural declarations.

Line 102: `held_zeros <= zero_matches;` This makes held_zeros, the value named 'held zeros' in this block, equal to 'zero_matches'. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_matches: the value named 'zero matches' in this block. Context: the module's structural declarations.

Line 103: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 105: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 106: `int seed;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are seed: the value named 'seed' in this block.

Line 107: `logic [255:0] query_random;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, query_random is the value named 'query random' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 108: `logic [255:0] key_random;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, key_random is the value named 'key random' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 109: `int boundary_bits [0:7];` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are boundary_bits: the value named 'boundary bits' in this block.

Line 110: `int boundary_alpha [0:4];` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are boundary_alpha: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 111: `seed = 32'h51a7c0de;` This makes seed, the value named 'seed' in this block, equal to '32'h51a7c0de'. It is driven by combinational or procedural logic in the current evaluation. The important operands are h51a7c0de: the value named 'h51a7c0de' in this block. Context: the module's structural declarations.

Line 112: `boundary_bits = '{1, 31, 32, 33, 127, 128, 255, 256};` This makes boundary_bits, the value named 'boundary bits' in this block, equal to ''{1, 31, 32, 33, 127, 128, 255, 256}'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 113: `boundary_alpha = '{0, 1, 127, 255, 256};` This makes boundary_alpha, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to ''{0, 1, 127, 255, 256}'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 115: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 116: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 118: `for (int boundary = 0; boundary < 8; boundary++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 119: `query_random = '0;` This makes query_random, the value named 'query random' in this block, equal to ''0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 120: `key_random = '0;` This makes key_random, the value named 'key random' in this block, equal to ''0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 121: `for (int word_index = 0; word_index < 8; word_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 122: `query_random[word_index*32 +:  32] = $urandom(seed);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are query_random: the value named 'query random' in this block; word_index: an integer selecting one tensor element, lane, bank, or state entry; urandom: the value named 'urandom' in this block.

Line 123: `key_random[word_index*32 +: 32] = $urandom(seed);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are key_random: the value named 'key random' in this block; word_index: an integer selecting one tensor element, lane, bank, or state entry; urandom: the value named 'urandom' in this block.

Line 124: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 125: `for (int alpha_index = 0; alpha_index < 5; alpha_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 126: `run_case(query_random, key_random, boundary_bits[boundary],` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are run_case: the value named 'run case' in this block; query_random: the value named 'query random' in this block; key_random: the value named 'key random' in this block.

Line 127: `boundary_alpha[alpha_index], (boundary + alpha_index) % 4);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are boundary_alpha: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; alpha_index: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; boundary: the value named 'boundary' in this block.

Line 128: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 129: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 131: `for (int random_case = 0; random_case < 100; random_case++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 132: `for (int word_index = 0; word_index < 8; word_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 133: `query_random[word_index*32 +: 32] = $urandom(seed);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are query_random: the value named 'query random' in this block; word_index: an integer selecting one tensor element, lane, bank, or state entry; urandom: the value named 'urandom' in this block.

Line 134: `key_random[word_index*32 +: 32] = $urandom(seed);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are key_random: the value named 'key random' in this block; word_index: an integer selecting one tensor element, lane, bank, or state entry; urandom: the value named 'urandom' in this block.

Line 135: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 136: `run_case(query_random, key_random, 1 + ($urandom(seed) % 256),` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are run_case: the value named 'run case' in this block; query_random: the value named 'query random' in this block; key_random: the value named 'key random' in this block.

Line 137: `$urandom(seed) % 257, random_case % 3);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are urandom: the value named 'urandom' in this block; seed: the value named 'seed' in this block; random_case: the value named 'random case' in this block.

Line 138: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 140: `// An illegal active length must produce a flagged, deterministic result.` Design intent: An illegal active length must produce a flagged, deterministic result. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation.

Line 141: `while (!input_ready) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are while: the value named 'while' in this block; input_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 142: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 143: `active_bits = 9'd0;` This makes active_bits, the value named 'active bits' in this block, equal to '9'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 144: `alpha_q8 = 9'd0;` This makes alpha_q8, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to '9'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 145: `input_valid = 1'b1;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 146: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 147: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 148: `input_valid = 1'b0;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 149: `while (!output_valid) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are while: the value named 'while' in this block; output_valid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 150: `if (!config_error || score_q8 != 0) begin` This condition selects the following hardware branch only when '!config_error || score_q8 != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are config_error: the value named 'config error' in this block; score_q8: the value named 'score q8' in this block. Context: the module's structural declarations.

Line 151: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 152: `$display("ERROR alpha-XNOR illegal configuration was not rejected");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 153: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 154: `output_ready = 1'b1;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 155: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 156: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 157: `output_ready = 1'b0;` This makes output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 159: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 160: `$display("tb_neuraedge_alpha_xnor FAILED errors=%0d checked=%0d", errors, checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 161: `$fatal(1);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 162: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 163: `$display("tb_neuraedge_alpha_xnor PASSED checked=%0d", checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 164: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 165: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 166: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 168: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 169: `#100_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 170: `$fatal(1, "tb_neuraedge_alpha_xnor watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 171: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 172: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 174: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge alpha xnor RTL block in simulation.

48 tb/tb_neuraedge_buffered_tensor_core.sv

Role in the complete system: drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation.

48.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation.

Simulation-only status tb_neuraedge_buffered_tensor_core is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 4 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

48.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 3: `` `include "tb/fixtures/tensor_tile_params.svh" `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation.

Line 5: `module tb_neuraedge_buffered_tensor_core;` This opens tb_neuraedge_buffered_tensor_core;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation.

Line 6: `import neuraedge_command_pkg::*;` This imports shared package names into the current module so opcodes and mode constants have exactly one definition. The import changes compile-time name visibility; it does not create registers or consume a clock cycle.

**Line 8: `localparam int CASES = `NEURAEDGE_TENSOR_CASES;`** This fixes CASES to `NEURAEDGE_TENSOR_CASES during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CASES denotes the value named 'cases' in this block.

**Line 9: `localparam int ISSUES = `NEURAEDGE_TENSOR_ISSUES;`** This fixes ISSUES to `NEURAEDGE_TENSOR_ISSUES during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ISSUES denotes the value named 'issues' in this block.

**Line 10: `localparam int RESULTS = `NEURAEDGE_TENSOR_RESULTS;`** This fixes RESULTS to `NEURAEDGE_TENSOR_RES during elaboration. Vivado uses that constant to shape or simplify the generated circuit; RESULTS denotes the value named 'results' in this block.

**Line 11: `localparam int COLUMN_LANES = `NEURAEDGE_COLUMN_LANES;`** This fixes COLUMN_LANES to `NEURAEDGE_COLUMN_LANES during elaboration. Vivado uses that constant to shape or simplify the generated circuit; COLUMN_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 13: `logic clk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic command_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic command_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [127:0] command_data = 128'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_data is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic command_done;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_done is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic status_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_error is the value named 'status error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic status_busy;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_busy is the value named 'status busy' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic s_axis_tvalid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic s_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic [63:0] s_axis_tdata = 64'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tdata is the value named 's axis tdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic s_axis_tlast = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tlast is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic m_axis_tvalid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 26: `logic m_axis_tready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic [63:0] m_axis_tdata;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tdata is the value named 'm axis tdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 28: `logic m_axis_tlast;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tlast is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `logic [11:0] status_loaded_activations;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_loaded_activations is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `logic [11:0] status_loaded_weights;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_loaded_weights is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 31: `logic [11:0] status_active_issues;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_active_issues is the value named 'status active issues' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 32: `logic [31:0] status_input_beats;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_input_beats is the value named 'status input beats' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `logic [31:0] status_output_beats;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_output_beats is the value named 'status output beats' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `logic [31:0] status_compute_cycles;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_compute_cycles is the value named 'status compute cycles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 35: `logic [31:0] status_skipped_issues;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_skipped_issues is the value named 'status skipped issues' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 36: `logic [63:0] status_dense_macs;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_dense_macs is a count of ordinary activation-times-weight operations actually issued. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 37: `logic [63:0] status_spike_adds;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_spike_adds is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 39: `logic [63:0] case_mem [0:CASES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, case_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 40: `logic [63:0] activation_mem [0:ISSUES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_mem is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 41: `logic [COLUMN_LANES*8*8-1:0] weight_mem [0:ISSUES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_mem is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 42: `logic signed [63:0] expected_mem [0:RESULTS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, expected_mem is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 44: `int issue_pointer = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are issue_pointer: the value named 'issue pointer' in this block.

Line 45: `int expected_pointer = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are expected_pointer: the value named 'expected pointer' in this block.

Line 46: `int checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 47: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 48: `int cycle = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are cycle: the value named 'cycle' in this block.

Line 49: `logic held_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 50: `logic [63:0] held_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 51: `logic held_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 53: `neuraedge_buffered_tensor_core dut (` This instantiates module neuraedge_buffered_tensor_core as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 54: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 55: `.rst_n(rst_n),` This connects the child instance's named port 'rst_n' to parent expression 'rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 56: `.command_valid(command_valid),` This connects the child instance's named port 'command_valid' to parent expression 'command_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 57: `.command_ready(command_ready),` This connects the child instance's named port 'command_ready' to parent expression 'command_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 58: `.command_data(command_data[41:0]),` This connects the child instance's named port 'command_data' to parent expression 'command_data[41:0]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 59: `.command_done(command_done),` This connects the child instance's named port 'command_done' to parent expression 'command_done'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 60: `.status_error(status_error),` This connects the child instance's named port 'status_error' to parent expression 'status_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status error' in this block.

Line 61: `.status_busy(status_busy),` This connects the child instance's named port 'status_busy' to parent expression 'status_busy'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status busy' in this block.

Line 62: `.s_axis_tvalid(s_axis_tvalid),` This connects the child instance's named port 's_axis_tvalid' to parent expression 's_axis_tvalid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 63: `.s_axis_tready(s_axis_tready),` This connects the child instance's named port 's_axis_tready' to parent expression 's_axis_tready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 64: `.s_axis_tdata(s_axis_tdata),` This connects the child instance's named port 's_axis_tdata' to parent expression 's_axis_tdata'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 's axis tdata' in this block.

Line 65: `.s_axis_tlast(s_axis_tlast),` This connects the child instance's named port 's_axis_tlast' to parent expression 's_axis_tlast'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 66: `.m_axis_tvalid(m_axis_tvalid),` This connects the child instance's named port 'm_axis_tvalid' to parent expression 'm_axis_tvalid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 67: `.m_axis_tready(m_axis_tready),` This connects the child instance's named port 'm_axis_tready' to parent expression 'm_axis_tready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 68: `.m_axis_tdata(m_axis_tdata),` This connects the child instance's named port 'm_axis_tdata' to parent expression 'm_axis_tdata'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'm axis tdata' in this block.

Line 69: `.m_axis_tlast(m_axis_tlast),` This connects the child instance's named port 'm_axis_tlast' to parent expression 'm_axis_tlast'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 70: `.status_loaded_activations(status_loaded_activations),` This connects the child instance's named port ‘status_loaded_activations‘ to parent expression ‘status_loaded_activations‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 71: `.status_loaded_weights(status_loaded_weights),` This connects the child instance's named port ‘status_loaded_weights‘ to parent expression ‘status_loaded_weights‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 72: `.status_active_issues(status_active_issues),` This connects the child instance's named port ‘status_active_issues‘ to parent expression ‘status_active_issues‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status active issues' in this block.

Line 73: `.status_input_beats(status_input_beats),` This connects the child instance's named port ‘status_input_beats‘ to parent expression ‘status_input_beats‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status input beats' in this block.

Line 74: `.status_output_beats(status_output_beats),` This connects the child instance's named port ‘status_output_beats‘ to parent expression ‘status_output_beats‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status output beats' in this block.

Line 75: `.status_compute_cycles(status_compute_cycles),` This connects the child instance's named port ‘status_compute_cycles‘ to parent expression ‘status_compute_cycles‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status compute cycles' in this block.

Line 76: `.status_skipped_issues(status_skipped_issues),` This connects the child instance's named port ‘status_skipped_issues‘ to parent expression ‘status_skipped_issues‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status skipped issues' in this block.

Line 77: `.status_dense_macs(status_dense_macs),` This connects the child instance's named port ‘status_dense_macs‘ to parent expression ‘status_dense_macs‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a count of ordinary activation-times-weight operations actually issued.

Line 78: `.status_spike_adds(status_spike_adds)` This connects the child instance's named port ‘status_spike_adds‘ to parent expression ‘status_spike_adds‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 79: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 81: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 83: `function automatic logic [127:0] make_command(` Within the combinational helper make command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; make_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 84: `input logic [3:0] opcode,` This declares opcode as a input port with width [3:0]. It carries the value named 'opcode' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 85: `input int rows,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 86: `input int columns,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 87: `input int issue_count,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 88: `input int activation_zp,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 89: `input int weight_zp` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 90: `);` Within the combinational helper make command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 91: `logic [127:0] value;` This declares hardware signal storage or wiring in the combinational helper make command. Specifically, value is the value named 'value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 92: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper make command; it has no arithmetic value of its own.

Line 93: `value = 128'd0;` This makes value, the value named 'value' in this block, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the combinational helper make command.

Line 94: `value[3:0] = opcode;` This makes value[3:0], the value named 'value' in this block, equal to 'opcode'. It is driven by combinational or procedural logic in the current evaluation. The important operands are opcode: the value named 'opcode' in this block. Context: the combinational helper make command.

Line 95: `value[7:4] = 4'(rows);` This makes value[7:4], the value named 'value' in this block, equal to '4'(rows)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are rows: one output-row position processed by the tensor tile. Context: the combinational helper make command.

Line 96: `value[13:8] = 6'(columns);` This makes value[13:8], the value named 'value' in this block, equal to '6'(columns)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are columns: one output-feature position processed in parallel. Context: the combinational helper make command.

Line 97: `value[25:14] = 12'(issue_count);` This makes value[25:14], the value named 'value' in this block, equal to '12'(issue_count)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_count: an integer count retained for control or measurable telemetry. Context: the combinational helper make command.

Line 98: `value[33:26] = 8'(activation_zp);` This makes value[33:26], the value named 'value' in this block, equal to '8'(activation_zp)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are activation_zp: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the combinational helper make command.

Line 99: `value[41:34] = 8'(weight_zp);` This makes value[41:34], the value named 'value' in this block, equal to '8'(weight_zp)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are weight_zp: a learned coefficient multiplied by an activation. Context: the combinational helper make command.

Line 100: `make_command = value;` This makes make_command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper make command.

Line 101: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper make command; it has no arithmetic value of its own.

Line 102: `endfunction` Within the combinational helper make command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are endfunction: the value named 'endfunction' in this block.

Line 104: `function automatic logic activation_is_zero(` Within the combinational helper activation is zero, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; activation_is_zero: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 105: `input logic [63:0] values,` This declares values as a input port with width [63:0]. It carries the value named 'values' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 106: `input logic [7:0] zero_point` This declares zero_point as a input port with width [7:0]. It carries the integer code representing real numeric zero in affine quantization across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 107: `);` Within the combinational helper activation is zero, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 108: `logic is_zero;` This declares hardware signal storage or wiring in the combinational helper activation is zero. Specifically, is_zero is the value named 'is zero' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 109: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper activation is zero; it has no arithmetic value of its own.

Line 110: `is_zero = 1'b1;` This makes is_zero, the value named 'is zero' in this block, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the combinational helper activation is zero.

Line 111: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational helper activation is zero.

Line 112: `is_zero = is_zero && values[lane*8 +:  8] == zero_point;` This makes is_zero, the value named 'is zero' in this block, equal to 'is_zero && values[lane*8 +: 8] == zero_point'. It is driven by combinational or procedural logic in the current evaluation. The important operands are is_zero: the value named 'is zero' in this block; values: the value named 'values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational helper activation is zero.

Line 113: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper activation is zero; it has no arithmetic value of its own.

Line 114: `activation_is_zero = is_zero;` This makes activation_is_zero, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'is_zero'. It is driven by combinational or procedural logic in the current evaluation. The important operands are is_zero: the value named 'is zero' in this block. Context: the combinational helper activation is zero.

Line 115: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper activation is zero; it has no arithmetic value of its own.

Line 116: `endfunction` Within the combinational helper activation is zero, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are endfunction: the value named 'endfunction' in this block.

Line 118: `task automatic submit_command(input logic [127:0] value);` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 119: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task submit command; it has no arithmetic value of its own.

Line 120: `while (!command_ready) @(negedge clk);` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are while: the value named 'while' in this block; command_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 121: `@(negedge clk);` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 122: `command_data = value;` This makes command_data, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the simulation task submit command.

Line 123: `command_valid = 1'b1;` This makes command_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task submit command.

Line 124: `@(posedge clk);` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 125: `@(negedge clk);` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 126: `command_valid = 1'b0;` This makes command_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task submit command.

Line 127: `command_data = 128'd0;` This makes command_data, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task submit command.

Line 128: `end` This structural keyword opens or closes the branch/process scope described as the simulation task submit command; it has no arithmetic value of its own.

Line 129: `endtask` Within the simulation task submit command, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 131: `task automatic stream_activation_case(` Within the simulation task stream activation case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; stream_activation_case: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 132: `input int first_issue,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 133: `input int issue_count` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 134: `);` Within the simulation task stream activation case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 135: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task stream activation case; it has no arithmetic value of its own.

Line 136: `for (int issue = 0; issue < issue_count; issue++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task stream activation case.

Line 137: `@(negedge clk);` Within the simulation task stream activation case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 138: `s_axis_tvalid = 1'b1;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task stream activation case.

Line 139: `s_axis_tdata = activation_mem[first_issue + issue];` This makes s_axis_tdata, the value named 's axis tdata' in this block, equal to 'activation_mem[first_issue + issue]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are activation_mem: an input feature value consumed by a neuron or multiply-accumulate operation; first_issue: the value named 'first issue' in this block; issue: the value named 'issue' in this block. Context: the simulation task stream activation case.

Line 140: `s_axis_tlast = (issue == issue_count - 1);` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘(issue == issue_count - 1)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue: the value named ’issue’ in this block; issue_count: an integer count retained for control or measurable telemetry. Context: the simulation task stream activation case.

Line 141: `while (!s_axis_tready) @(negedge clk);` Within the simulation task stream activation case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are while: the value named ’while’ in this block; s_axis_tready: the consumer’s statement that it can accept a payload this cycle; negedge: the value named ’negedge’ in this block.

Line 142: `@(posedge clk);` Within the simulation task stream activation case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together.

Line 143: `end` This structural keyword opens or closes the branch/process scope described as the simulation task stream activation case; it has no arithmetic value of its own.

Line 144: `@(negedge clk);` Within the simulation task stream activation case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 145: `s_axis_tvalid = 1’b0;` This makes s_axis_tvalid, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task stream activation case.

Line 146: `s_axis_tlast = 1’b0;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task stream activation case.

Line 147: `s_axis_tdata = 64’d0;` This makes s_axis_tdata, the value named ’s axis tdata’ in this block, equal to ‘64’d0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named ’d0’ in this block. Context: the simulation task stream activation case.

Line 148: `end` This structural keyword opens or closes the branch/process scope described as the simulation task stream activation case; it has no arithmetic value of its own.

Line 149: `endtask` Within the simulation task stream activation case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are endtask: the value named ’endtask’ in this block.

Line 151: `task automatic stream_weight_case(` Within the simulation task stream weight case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are task: the value named ’task’ in this block; automatic: the value named ’automatic’ in this block; stream_weight_case: a learned coefficient multiplied by an activation.

Line 152: `input int first_issue,` This declares int as a input port with width one bit. It carries the value named ’int’ in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 153: `input int issue_count,` This declares int as a input port with width one bit. It carries the value named ’int’ in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 154: `input logic dot8` This declares dot8 as a input port with width one bit. It carries the value named ’dot8’ in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 155: `);` Within the simulation task stream weight case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 156: `int beats_per_issue;` Within the simulation task stream weight case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are beats_per_issue: the value named 'beats per issue' in this block.

Line 157: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task stream weight case; it has no arithmetic value of its own.

Line 158: `beats_per_issue = dot8 ? COLUMN_LANES : COLUMN_LANES / 8;` This makes beats_per_issue, the value named 'beats per issue' in this block, equal to 'dot8 ? COLUMN_LANES : COLUMN_LANES / 8'. It is driven by combinational or procedural logic in the current evaluation. The important operands are dot8: the value named 'dot8' in this block; COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task stream weight case.

Line 159: `for (int issue = 0; issue < issue_count; issue++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task stream weight case.

Line 160: `for (int beat = 0; beat < beats_per_issue; beat++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task stream weight case.

Line 161: `@(negedge clk);` Within the simulation task stream weight case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 162: `s_axis_tvalid = 1'b1;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task stream weight case.

Line 163: `s_axis_tdata = weight_mem[first_issue + issue][beat*64 +: 64];` This makes s_axis_tdata, the value named 's axis tdata' in this block, equal to 'weight_mem[first_issue + issue][beat*64 +: 64]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are weight_mem: a learned coefficient multiplied by an activation; first_issue: the value named 'first issue' in this block; issue: the value named 'issue' in this block. Context: the simulation task stream weight case.

Line 164: `s_axis_tlast = issue == issue_count - 1 && beat == beats_per_issue - 1;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'issue == issue_count - 1 && beat == beats_per_issue - 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue: the value named 'issue' in this block; issue_count: an integer count retained for control or measurable telemetry; beat: the value named 'beat' in this block. Context: the simulation task stream weight case.

Line 165: `while (!s_axis_tready) @(negedge clk);` Within the simulation task stream weight case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are while: the value named 'while' in this block; s_axis_tready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 166: `@(posedge clk);` Within the simulation task stream weight case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 167: `end` This structural keyword opens or closes the branch/process scope described as the simulation task stream weight case; it has no arithmetic value of its own.

Line 168: `end` This structural keyword opens or closes the branch/process scope described as the simulation task stream weight case; it has no arithmetic value of its own.

Line 169: `@(negedge clk);` Within the simulation task stream weight case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 170: `s_axis_tvalid = 1'b0;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task stream weight case.

Line 171: `s_axis_tlast = 1'b0;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task stream weight case.

Line 172: `s_axis_tdata = 64'd0;` This makes s_axis_tdata, the value named 's axis tdata' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task stream weight case.

Line 173: `end` This structural keyword opens or closes the branch/process scope described as the simulation task stream weight case; it has no arithmetic value of its own.

Line 174: `endtask` Within the simulation task stream weight case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 176: `task automatic consume_results(` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; consume_results: the value named 'consume results' in this block.

Line 177: `input int case_index,` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 178: `input int result_count` This declares int as a input port with width one bit. It carries the value named 'int' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 179: `);` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 180: `int received;` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are received: the value named 'received' in this block.

Line 181: `int output_cycle;` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are output_cycle: the value named 'output cycle' in this block.

Line 182: `logic signed [63:0] result_extended;` This declares hardware signal storage or wiring in the simulation task consume results. Specifically, result_extended is the value named 'result extended' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 183: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task consume results; it has no arithmetic value of its own.

Line 184: `received = 0;` This makes received, the value named 'received' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task consume results.

Line 185: `output_cycle = 0;` This makes output_cycle, the value named 'output cycle' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task consume results.

Line 186: `while (received < result_count && output_cycle < 20000) begin` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are while: the value named 'while' in this block; received: the value named 'received' in this block; result_count: an integer count retained for control or measurable telemetry.

Line 187: `@(negedge clk);` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 188: `m_axis_tready = ((output_cycle + case_index) % 7 != 2);` This makes m_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '((output_cycle + case_index) % 7 != 2)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_cycle: the value named 'output cycle' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task consume results.

Line 189: `@(posedge clk);` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 190: `if (m_axis_tvalid && m_axis_tready) begin` This condition selects the following hardware branch only when 'm_axis_tvalid && m_axis_tready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are m_axis_tvalid: the producer's statement that its current payload is meaningful; m_axis_tready: the consumer's statement that it can accept a payload this cycle. Context: the simulation task consume results.

Line 191: `result_extended = {{16{m_axis_tdata[47]}}, m_axis_tdata[47:0]};` This makes result_extended, the value named 'result extended' in this block, equal to '{{16{m_axis_tdata[47]}}, m_axis_tdata[47:0]}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are m_axis_tdata: the value named 'm axis tdata' in this block. Context: the simulation task consume results.

Line 192: `if (result_extended !== expected_mem[expected_pointer]) begin` This condition selects the following hardware branch only when 'result_extended !== expected_mem[expected_pointer]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_extended: the value named 'result extended' in this block; expected_mem: local FPGA storage addressed by surrounding index logic; expected_pointer: the value named 'expected pointer' in this block. Context: the simulation task consume results.

Line 193: `errors++;` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 194: `if (errors <= 30) begin` This statement continues through source line 197; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when ‘errors <= 30) begin $display("ERROR buffered case=%0d row=%0d col=%0d got=%0d expected=%0d", case_index, m_axis_tdata[51:48], m_axis_tdata[57:52], result_extended, expected_mem[expected_pointer]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task consume results.

Line 195: `$display("ERROR buffered case=%0d row=%0d col=%0d got=%0d expected=%0d",` This is continuation line 2 of the 4-line logical statement that begins at source line 194. Its exact fragment is ‘$display("ERROR buffered case=%0d row=%0d col=%0d got=%0d expected=%0d",‘. The important operands are display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block; buffered: local storage that decouples producer and consumer timing. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 30) begin $display("ERROR buffered case=%0d row=%0d col=%0d got=%0d expected=%0d", case_index, m_axis_tdata[51:48], m_axis_tdata[57:52], result_extended, expected_mem[expected_pointer]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task consume results.

Line 196: `case_index, m_axis_tdata[51:48], m_axis_tdata[57:52],` This is continuation line 3 of the 4-line logical statement that begins at source line 194. Its exact fragment is ‘case_index, m_axis_tdata[51:48], m_axis_tdata[57:52],‘. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; m_axis_tdata: the value named ’m axis tdata’ in this block. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 30) begin $display("ERROR buffered case=%0d row=%0d col=%0d got=%0d expected=%0d", case_index, m_axis_tdata[51:48], m_axis_tdata[57:52], result_extended, expected_mem[expected_pointer]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task consume results.

Line 197: `result_extended, expected_mem[expected_pointer]);` This is continuation line 4 of the 4-line logical statement that begins at source line 194. Its exact fragment is ‘result_extended, expected_mem[expected_pointer]);‘. The important operands are result_extended: the value named ’result extended’ in this block; expected_mem: local FPGA storage addressed by surrounding index logic; expected_pointer: the value named ’expected pointer’ in this block. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 30) begin $display("ERROR buffered case=%0d row=%0d col=%0d got=%0d expected=%0d", case_index, m_axis_tdata[51:48], m_axis_tdata[57:52], result_extended, expected_mem[expected_pointer]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task consume results.

Line 198: `end` This structural keyword opens or closes the branch/process scope described as the simulation task consume results; it has no arithmetic value of its own.

Line 199: `end` This structural keyword opens or closes the branch/process scope described as the simulation task consume results; it has no arithmetic value of its own.

Line 200: `if (m_axis_tlast !== (received == result_count - 1)) begin` This condition selects the following hardware branch only when ‘m_axis_tlast !== (received == result_count - 1)‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; received: the value named ’received’ in this block; result_count: an integer count retained for control or measurable telemetry. Context: the simulation task consume results.

Line 201: `errors++;` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 202: `$display("ERROR buffered last mismatch case=%0d result=%0d", case_index, received);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 203: `end` This structural keyword opens or closes the branch/process scope described as the simulation task consume results; it has no arithmetic value of its own.

Line 204: `expected_pointer++;` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are expected_pointer: the value named 'expected pointer' in this block.

Line 205: `received++;` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are received: the value named 'received' in this block.

Line 206: `checked++;` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 207: `end` This structural keyword opens or closes the branch/process scope described as the simulation task consume results; it has no arithmetic value of its own.

Line 208: `output_cycle++;` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are output_cycle: the value named 'output cycle' in this block.

Line 209: `end` This structural keyword opens or closes the branch/process scope described as the simulation task consume results; it has no arithmetic value of its own.

Line 210: `@(negedge clk);` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 211: `m_axis_tready = 1'b0;` This makes m_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task consume results.

Line 212: `if (received != result_count) begin` This condition selects the following hardware branch only when 'received != result_count' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received: the value named 'received' in this block; result_count: an integer count retained for control or measurable telemetry. Context: the simulation task consume results.

Line 213: `errors++;` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 214: `$display("ERROR buffered output timeout case=%0d got=%0d expected=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 215: `case_index, received, result_count);` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; received: the value named 'received' in this block; result_count: an integer count retained for control or measurable telemetry.

Line 216: `end` This structural keyword opens or closes the branch/process scope described as the simulation task consume results; it has no arithmetic value of its own.

Line 217: `end` This structural keyword opens or closes the branch/process scope described as the simulation task consume results; it has no arithmetic value of its own.

Line 218: `endtask` Within the simulation task consume results, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 220: `task automatic run_fixture_case(input int case_index);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; run_fixture_case: the value named 'run fixture case' in this block.

Line 221: `logic [63:0] descriptor;` This declares hardware signal storage or wiring in the simulation task run fixture case. Specifically, descriptor is a DMA record header plus one command and its declared payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 222: `logic [3:0] load_weight_opcode;` This declares hardware signal storage or wiring in the simulation task run fixture case. Specifically, load_weight_opcode is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 223: `logic [3:0] compute_opcode;` This declares hardware signal storage or wiring in the simulation task run fixture case. Specifically, compute_opcode is the value named 'compute opcode' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 224: `int mode;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are mode: the value named 'mode' in this block.

Line 225: `int rows;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are rows: one output-row position processed by the tensor tile.

Line 226: `int columns;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are columns: one output-feature position processed in parallel.

Line 227: `int issue_count;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are issue_count: an integer count retained for control or measurable telemetry.

Line 228: `int activation_zp;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are activation_zp: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 229: `int weight_zp;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are weight_zp: a learned coefficient multiplied by an activation.

Line 230: `int active_count_expected;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are active_count_expected: the value named 'active count expected' in this block.

Line 231: `longint unsigned dense_macs_expected;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are longint: the value named 'longint' in this block; dense_macs_expected: a count of ordinary activation-times-weight operations actually issued.

Line 232: `longint unsigned spike_adds_expected;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are longint: the value named 'longint' in this block; spike_adds_expected: a binary event produced when a neuron crosses its threshold.

Line 233: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 234: `descriptor = case_mem[case_index];` This makes descriptor, a DMA record header plus one command and its declared payload, equal to ‘case_mem[case_index]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are case_mem: local FPGA storage addressed by surrounding index logic; case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run fixture case.

Line 235: `mode = descriptor[1:0];` This makes mode, the value named 'mode' in this block, equal to ‘descriptor[1:0]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are descriptor: a DMA record header plus one command and its declared payload. Context: the simulation task run fixture case.

Line 236: `rows = descriptor[7:4];` This makes rows, one output-row position processed by the tensor tile, equal to ‘descriptor[7:4]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are descriptor: a DMA record header plus one command and its declared payload. Context: the simulation task run fixture case.

Line 237: `columns = descriptor[13:8];` This makes columns, one output-feature position processed in parallel, equal to ‘descriptor[13:8]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are descriptor: a DMA record header plus one command and its declared payload. Context: the simulation task run fixture case.

Line 238: `issue_count = descriptor[25:14];` This makes issue_count, an integer count retained for control or measurable telemetry, equal to ‘descriptor[25:14]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are descriptor: a DMA record header plus one command and its declared payload. Context: the simulation task run fixture case.

Line 239: `activation_zp = descriptor[33:26];` This makes activation_zp, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘descriptor[33:26]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are descriptor: a DMA record header plus one command and its declared payload. Context: the simulation task run fixture case.

Line 240: `weight_zp = descriptor[41:34];` This makes weight_zp, a learned coefficient multiplied by an activation, equal to ‘descriptor[41:34]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are descriptor: a DMA record header plus one command and its declared payload. Context: the simulation task run fixture case.

Line 242: `load_weight_opcode = mode == MODE_DENSE_DOT8` This statement continues through source line 243; the explanation uses the complete expression rather than only the first visual fragment. This makes load_weight_opcode, a learned coefficient multiplied by an activation, equal to ‘mode == MODE_DENSE_DOT8 ? CMD_LOAD_WEIGHTS_DOT8 : CMD_LOAD_WEIGHTS_OUTER‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are mode: the value named 'mode' in this block; MODE_DENSE_DOT8: the value named 'mode

dense dot8' in this block; CMD_LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation. Context: the simulation task run fixture case.

Line 243: `? CMD_LOAD_WEIGHTS_DOT8 : CMD_LOAD_WEIGHTS_OUTER;` This is continuation line 2 of the 2-line logical statement that begins at source line 242. Its exact fragment is '? CMD_LOAD_WEIGHTS_DOT8 : CMD_LOAD_WEIGHTS_O The important operands are CMD_LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation; CMD_LOAD_WE a learned coefficient multiplied by an activation. Read together, the complete operation is: This makes load_weight_opcode, a learned coefficient multiplied by an activation, equal to 'mode == MODE_DENSE_DOT8 ? CMD_LOAD_WEIGHTS_DOT8 : CMD_LOAD_WEIGHTS_OUTER'. It is driven by combinational or procedural logic in the current evaluation. The important operands are mode: the value named 'mode' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; CMD_LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation. Context: the simulation task run fixture case.

Line 244: `unique case (mode)` This starts a multiplexer/state decode selected by 'mode'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 245: `MODE_DENSE_OUTER: compute_opcode = CMD_COMPUTE_DENSE_OUTER;` This is the MODE_DENSE_OUTER case branch, which performs this explicitly named phase. The same-cycle action begins with 'compute_opcode = CMD_COMPUTE_DENSE_OUTER;'; context is the simulation task run fixture case Within state MODE_DENSE_OUTER, the machine performs the named control phase..

Line 246: `MODE_DENSE_DOT8: compute_opcode = CMD_COMPUTE_DENSE_DOT8;` This is the MODE_DENSE_DOT8 case branch, which performs this explicitly named phase. The same-cycle action begins with 'compute_opcode = CMD_COMPUTE_DENSE_DOT8;'; context is the simulation task run fixture case Within state MODE_DENSE_DOT8, the machine performs the named control phase..

Line 247: `MODE_BINARY_WEIGHTED: compute_opcode = CMD_COMPUTE_BINARY;` This is the MODE_BINARY_WEIGHTED case branch, which performs this explicitly named phase. The same-cycle action begins with 'compute_opcode = CMD_COMPUTE_BINARY;'; context is the simulation task run fixture case Within state MODE_BINARY_WEIGHTED, the machine performs the named control phase..

Line 248: `default: compute_opcode = CMD_COMPUTE_TERNARY;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'compute_opcode = CMD_COMPUTE_TERNARY;'; context is the simulation task run fixture case Within state MODE_BINARY_WEIGHTED, the machine performs the named control phase..

Line 249: `endcase` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case Within state MODE_BINARY_WEIGHTED, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 251: `submit_command(make_command(CMD_CLEAR_STATUS, 0, 0, 0, 0, 0));` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; make_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; CMD_CLEAR_STATUS: the value named 'cmd clear status' in this block.

Line 252: `submit_command(make_command(CMD_LOAD_ACTIVATIONS, 0, 0,` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; make_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; CMD_LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 253: `issue_count, activation_zp, 0));` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are issue_count: an integer count retained for control or measurable telemetry; activation_zp: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 254: `stream_activation_case(issue_pointer, issue_count);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are stream_activation_case: an input feature value consumed by a neuron or multiply-accumulate operation; issue_pointer: the value named 'issue pointer' in this block; issue_count: an integer count retained for control or measurable telemetry.

Line 255: `// Compaction is a registered BRAM write pipeline. Status becomes` Design intent: Compaction is a registered BRAM write pipeline. Status becomes This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation.

Line 256: `// architecturally visible when the load command commits.` Design intent: architecturally visible when the load command commits. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation.

Line 257: `wait (command_done);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are wait: the value named 'wait' in this block; command_done: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 258: `@(negedge clk);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 260: `active_count_expected = 0;` This makes active_count_expected, the value named 'active count expected' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run fixture case.

Line 261: `dense_macs_expected = 0;` This makes dense_macs_expected, a count of ordinary activation-times-weight operations actually issued, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run fixture case.

Line 262: `spike_adds_expected = 0;` This makes spike_adds_expected, a binary event produced when a neuron crosses its threshold, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run fixture case.

Line 263: `for (int issue = 0; issue < issue_count; issue++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run fixture case.

Line 264: `if (!activation_is_zero(activation_mem[issue_pointer + issue], activation_zp)) begin` This condition selects the following hardware branch only when '!activation_is_zero(activation_mem[issue_pointer + issue], activation_zp)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are activation_is_zero: an input feature value consumed by a neuron or multiply-accumulate operation; activation_mem: an input feature value consumed by a neuron or multiply-accumulate operation; issue_pointer: the value named 'issue pointer' in this block. Context: the simulation task run fixture case.

Line 265: `active_count_expected++;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are active_count_expected: the value named 'active count expected' in this block.

Line 266: `if (mode == MODE_DENSE_OUTER) begin` This condition selects the following hardware branch only when 'mode == MODE_DENSE_OUTER' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are mode: the value named 'mode' in this block; MODE_DENSE_OUTER: the value named 'mode dense outer' in this block. Context: the simulation task run fixture case.

Line 267: `dense_macs_expected += rows * columns;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are dense_macs_expected: a count of ordinary activation-times-weight operations actually issued; rows: one output-row position processed by the tensor tile; columns: one output-feature position processed in parallel.

Line 268: `end else if (mode == MODE_DENSE_DOT8) begin` This condition selects the following hardware branch only when 'mode == MODE_DENSE_DOT8' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are mode: the value named 'mode' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Context: the simulation task run fixture case.

Line 269: `dense_macs_expected += 8 * columns;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are dense_macs_expected: a count of ordinary activation-times-weight operations actually issued; columns: one output-feature position processed in parallel.

Line 270: `end else begin` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 271: `int active_spikes;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are active_spikes: a binary event produced when a neuron crosses its threshold.

Line 272: `active_spikes = 0;` This makes active_spikes, a binary event produced when a neuron crosses its threshold, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run fixture case.

Line 273: `for (int row = 0; row < 8; row++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run fixture case.

Line 274: `if (row < rows` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are row: one output-row position processed by the tensor tile; rows: one output-row position processed by the tensor tile.

Line 275: `&& activation_mem[issue_pointer + issue][row*8 +: 8] != 0) begin` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are activation_mem: an input feature value consumed by a neuron or multiply-accumulate operation; issue_pointer: the value named 'issue pointer' in this block; issue: the value named 'issue' in this block.

Line 276: `active_spikes++;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are active_spikes: a binary event produced when a neuron crosses its threshold.

Line 277: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 278: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 279: `spike_adds_expected += active_spikes * columns;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are spike_adds_expected: a binary event produced when a neuron crosses its threshold; active_spikes: a binary event produced when a neuron crosses its threshold; columns: one output-feature position processed in parallel.

Line 280: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 281: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 282: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 283: `if (status_loaded_activations != issue_count` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are status_loaded_activations: an input feature value consumed by a neuron or multiply-accumulate operation; issue_count: an integer count retained for control or measurable telemetry.

Line 284: `|| status_active_issues != active_count_expected) begin` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are status_active_issues: the value named 'status active issues' in this block; active_count_expected: the value named 'active count expected' in this block.

Line 285: `errors++;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 286: `$display("ERROR compaction case=%0d loaded=%0d/%0d active=%0d/%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 287: `case_index, status_loaded_activations, issue_count,` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; status_loaded_activations: an input feature value consumed by a neuron or multiply-accumulate operation; issue_count: an integer count retained for control or measurable telemetry.

Line 288: `status_active_issues, active_count_expected);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are status_active_issues: the value named 'status active issues' in this block; active_count_expected: the value named 'active count expected' in this block.

Line 289: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 291: `submit_command(make_command(load_weight_opcode, 0, 0,` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; make_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; load_weight_opcode: a learned coefficient multiplied by an activation.

Line 292: `issue_count, 0, 0));` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are issue_count: an integer count retained for control or measurable telemetry.

Line 293: `stream_weight_case(issue_pointer, issue_count, mode == MODE_DENSE_DOT8);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are stream_weight_case: a learned coefficient multiplied by an activation; issue_pointer: the value named 'issue pointer' in this block; issue_count: an integer count retained for control or measurable telemetry.

Line 294: `if (status_loaded_weights != issue_count) begin` This condition selects the following hardware branch only when 'status_loaded_weights != issue_count' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are status_loaded_weights: a learned coefficient multiplied by an activation; issue_count: an integer count retained for control or measurable telemetry. Context: the simulation task run fixture case.

Line 295: `errors++;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 296: `$display("ERROR weight count case=%0d loaded=%0d expected=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 297: `case_index, status_loaded_weights, issue_count);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; status_loaded_weights: a learned coefficient multiplied by an activation; issue_count: an integer count retained for control or measurable telemetry.

Line 298: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 300: `submit_command(make_command(compute_opcode, rows, columns,` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are submit_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; make_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; compute_opcode: the value named 'compute opcode' in this block.

Line 301: `issue_count, activation_zp, weight_zp));` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are issue_count: an integer count retained for control or measurable telemetry; activation_zp: an input feature value consumed by a neuron or multiply-accumulate operation; weight_zp: a learned coefficient multiplied by an activation.

Line 302: `consume_results(case_index, rows * columns);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are consume_results: the value named 'consume results' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry; rows: one output-row position processed by the tensor tile.

Line 304: `// Completion is a registered architectural event. It follows the` Design intent: Completion is a registered architectural event. It follows the This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation.

Line 305: `// final output transfer so status_error is stable in the same cycle.` Design intent: final output transfer so status_error is stable in the same cycle. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation.

Line 306: `wait (command_done);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are wait: the value named 'wait' in this block; command_done: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 307: `@(negedge clk);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 309: `if (!command_done || status_busy || status_error` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are command_done: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; status_busy: the value named 'status busy' in this block; status_error: the value named 'status error' in this block.

Line 310: `|| status_skipped_issues != issue_count - active_count_expected` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are status_skipped_issues: the value named 'status skipped issues' in this block; issue_count: an integer count retained for control or measurable telemetry; active_count_expected: the value named 'active count expected' in this block.

Line 311: `|| status_dense_macs != dense_macs_expected` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are status_dense_macs: a count of ordinary activation-times-weight operations actually issued; dense_macs_expected: a count of ordinary activation-times-weight operations actually issued.

Line 312: `|| status_spike_adds != spike_adds_expected) begin` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are status_spike_adds: a binary event produced when a neuron crosses its threshold; spike_adds_expected: a binary event produced when a neuron crosses its threshold.

Line 313: `errors++;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 314: `$display("ERROR completion case=%0d done=%0d busy=%0d error=%0d skipped=%0d/%0d dense=%0d/%0d spike=%0d/%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 315: `case_index, command_done, status_busy, status_error,` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; command_done: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; status_busy: the value named 'status busy' in this block.

Line 316: `status_skipped_issues, issue_count - active_count_expected,` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are status_skipped_issues: the value named 'status skipped issues' in this block; issue_count: an integer count retained for control or measurable telemetry; active_count_expected: the value named 'active count expected' in this block.

Line 317: `status_dense_macs, dense_macs_expected,` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are status_dense_macs: a count of ordinary activation-times-weight operations actually issued; dense_macs_expected: a count of ordinary activation-times-weight operations actually issued.

Line 318: `status_spike_adds, spike_adds_expected);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are status_spike_adds: a binary event produced when a neuron crosses its threshold; spike_adds_expected: a binary event produced when a neuron crosses its threshold.

Line 319: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 320: `$display("buffered_case=%0d mode=%0d results=%0d active=%0d/%0d input_beats=%0d compute_cycles=%0d"` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 321: `case_index, mode, rows * columns, active_count_expected,` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry; mode: the value named 'mode' in this block; rows: one output-row position processed by the tensor tile.

Line 322: `issue_count, status_input_beats, status_compute_cycles);` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are issue_count: an integer count retained for control or measurable telemetry; status_input_beats: the value named 'status input beats' in this block; status_compute_cycles: the value named 'status compute cycles' in this block.

Line 323: `issue_pointer += issue_count;` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are issue_pointer: the value named 'issue pointer' in this block; issue_count: an integer count retained for control or measurable telemetry.

Line 324: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run fixture case; it has no arithmetic value of its own.

Line 325: `endtask` Within the simulation task run fixture case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 327: `task automatic check_counter_add(` Within the simulation task check counter add, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; check_counter_add: a hardware telemetry register that accumulates measured events.

Line 328: `input logic [63:0] value,` This declares value as a input port with width [63:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 329: `input logic [18:0] increment` This declares increment as a input port with width [18:0]. It carries the value named 'increment' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 330: `);` Within the simulation task check counter add, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 331: `logic [63:0] actual;` This declares hardware signal storage or wiring in the simulation task check counter add. Specifically, actual is the value named 'actual' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 332: `logic [63:0] expected;` This declares hardware signal storage or wiring in the simulation task check counter add. Specifically, expected is the value named 'expected' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 333: `logic [24:0] low_sum;` This declares hardware signal storage or wiring in the simulation task check counter add. Specifically, low_sum is the value named 'low sum' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 334: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task check counter add; it has no arithmetic value of its own.

Line 335: `low_sum = dut.add_u19_to_u24(value[23:0], increment);` This makes low_sum, the value named 'low sum' in this block, equal to 'dut.add_u19_to_u24(value[23:0], increment)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are dut: the value named 'dut' in this block; add_u19_to_u24: the value named 'add u19 to u24' in this block; value: the value named 'value' in this block. Context: the simulation task check counter add.

Line 336: `actual = {` This statement continues through source line 339; the explanation uses the complete expression rather than only the first visual fragment. This makes actual, the value named 'actual' in this block, equal to '{ value[63:24] + {{39{1'b0}}, low_sum[24]}, low_sum[23:0] }'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block; b0: the value named 'b0' in this block; low_sum: the value named 'low sum' in this block. Context: the simulation task check counter add.

Line 337: `value[63:24] + {{39{1'b0}}, low_sum[24]},` This is continuation line 2 of the 4-line logical statement that begins at source line 336. Its exact fragment is 'value[63:24] + {{39{1'b0}}, low_sum[24]},'. The important operands are value: the value named 'value' in this block; b0: the value named 'b0' in this block; low_sum: the value named 'low sum' in this block. Read together, the complete operation is: This makes actual, the value named 'actual' in this block, equal to '{ value[63:24] + {{39{1'b0}}, low_sum[24]}, low_sum[23:0] }'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block; b0: the value named 'b0' in this block; low_sum: the value named 'low sum' in this block. Context: the simulation task check counter add.

Line 338: `low_sum[23:0]` This is continuation line 3 of the 4-line logical statement that begins at source line 336. Its exact fragment is 'low_sum[23:0]'. The important operands are low_sum: the value named 'low sum' in this block. Read together, the complete operation is: This makes actual, the value named 'actual' in this block, equal to '{ value[63:24] + {{39{1'b0}}, low_sum[24]}, low_sum[23:0] }'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block; b0: the value named 'b0' in this block; low_sum: the value named 'low sum' in this block. Context: the simulation task check counter add.

Line 339: `};` This is continuation line 4 of the 4-line logical statement that begins at source line 336. Its exact fragment is '};'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This makes actual, the value named 'actual' in this block, equal to '{ value[63:24] + {{39{1'b0}},

low_sum[24]}, low_sum[23:0] }‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named ’value’ in this block; b0: the value named ’b0’ in this block; low_sum: the value named ’low sum’ in this block. Context: the simulation task check counter add.

Line 340: `expected = value + {{45{1'b0}}, increment};` This makes expected, the value named ’expected’ in this block, equal to ‘value + {{45{1’b0}}, increment}‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named ’value’ in this block; b0: the value named ’b0’ in this block; increment: the value named ’increment’ in this block. Context: the simulation task check counter add.

Line 341: `if (actual !== expected) begin` This condition selects the following hardware branch only when ‘actual !== expected‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are actual: the value named ’actual’ in this block; expected: the value named ’expected’ in this block. Context: the simulation task check counter add.

Line 342: `errors++;` Within the simulation task check counter add, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 343: `$display("ERROR counter add value=%h increment=%h actual=%h expected=%h",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 344: `value, increment, actual, expected);` Within the simulation task check counter add, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are value: the value named ’value’ in this block; increment: the value named ’increment’ in this block; actual: the value named ’actual’ in this block.

Line 345: `end` This structural keyword opens or closes the branch/process scope described as the simulation task check counter add; it has no arithmetic value of its own.

Line 346: `end` This structural keyword opens or closes the branch/process scope described as the simulation task check counter add; it has no arithmetic value of its own.

Line 347: `endtask` Within the simulation task check counter add, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are endtask: the value named ’endtask’ in this block.

Line 349: `task automatic verify_counter_adder;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are task: the value named ’task’ in this block; automatic: the value named ’automatic’ in this block; verify_counter_adder: a hardware telemetry register that accumulates measured events.

Line 350: `logic [63:0] random_value;` This declares hardware signal storage or wiring in the simulation task task. Specifically, random_value is the value named ’random value’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 351: `logic [18:0] random_increment;` This declares hardware signal storage or wiring in the simulation task task. Specifically, random_increment is the value named ’random increment’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 352: `int unsigned random_state;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are random_state: the finite-state-machine phase retained in flip-flops.

Line 353: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 354: `check_counter_add(64'd0, 19'd0);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are check_counter_add: a hardware telemetry register that accumulates measured events; d0: the value named 'd0' in this block.

Line 355: `check_counter_add(64'd0, 19'h7ffff);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are check_counter_add: a hardware telemetry register that accumulates measured events; d0: the value named 'd0' in this block; h7ffff: the value named 'h7ffff' in this block.

Line 356: `check_counter_add(64'h0000000000ffffff, 19'd1);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are check_counter_add: a hardware telemetry register that accumulates measured events; h0000000000ffffff: the value named 'h0000000000ffffff' in this block; d1: the value named 'd1' in this block.

Line 357: `check_counter_add(64'h00000000ffffffff, 19'd1);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are check_counter_add: a hardware telemetry register that accumulates measured events; h00000000ffffffff: the value named 'h00000000ffffffff' in this block; d1: the value named 'd1' in this block.

Line 358: `check_counter_add(64'h0000fffffffffffff, 19'd1);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are check_counter_add: a hardware telemetry register that accumulates measured events; h0000fffffffffff: the value named 'h0000fffffffffff' in this block; d1: the value named 'd1' in this block.

Line 359: `check_counter_add(64'h00fffffffffffff, 19'd1);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are check_counter_add: a hardware telemetry register that accumulates measured events; h00fffffffffffff: the value named 'h00fffffffffffff' in this block; d1: the value named 'd1' in this block.

Line 360: `check_counter_add(64'hffffffffffffffff, 19'h7ffff);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are check_counter_add: a hardware telemetry register that accumulates measured events; hffffffffffffff: the value named 'hffffffffffffff' in this block; h7ffff: the value named 'h7ffff' in this block.

Line 361: `check_counter_add(64'h55fffffffffffeaa, 19'h10155);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are check_counter_add: a hardware telemetry register that accumulates measured events; h55fffffffffeaa: the value named 'h55fffffffffeaa' in this block; h10155: the value named 'h10155' in this block.

Line 363: `random_state = 32'h4e455552;` This makes random_state, the finite-state-machine phase retained in flip-flops, equal to '32'h4e455552'. It is driven by combinational or procedural logic in the current evaluation. The important operands are h4e455552: the value named 'h4e455552' in this block. Context: the simulation task task.

Line 364: `for (int vector_index = 0; vector_index < 1024;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 365: `vector_index++) begin` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are vector_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 366: `random_state = random_state * 32'd1664525 + 32'd1013904223;` This makes random_state, the finite-state-machine phase retained in flip-flops, equal to 'random_state * 32'd1664525 + 32'd1013904223'. It is driven by combinational or procedural logic in the current evaluation. The important operands are random_state: the finite-state-machine phase retained in flip-flops; d1664525: the value named 'd1664525' in this block; d1013904223: the value named 'd1013904223' in this block. Context: the simulation task task.

Line 367: `random_value[31:0] = random_state;` This makes random_value[31:0], the value named 'random value' in this block, equal to 'random_state'. It is driven by combinational or procedural logic in the current evaluation. The important operands are random_state: the finite-state-machine phase retained in flip-flops. Context: the simulation task task.

Line 368: `random_state = random_state * 32'd1664525 + 32'd1013904223;` This makes random_state, the finite-state-machine phase retained in flip-flops, equal to 'random_state * 32'd1664525 + 32'd1013904223'. It is driven by combinational or procedural logic in the current evaluation. The important operands are random_state: the finite-state-machine phase retained in flip-flops; d1664525: the value named 'd1664525' in this block; d1013904223: the value named 'd1013904223' in this block. Context: the simulation task task.

Line 369: `random_value[63:32] = random_state;` This makes random_value[63:32], the value named 'random value' in this block, equal to 'random_state'. It is driven by combinational or procedural logic in the current evaluation. The important operands are random_state: the finite-state-machine phase retained in flip-flops. Context: the simulation task task.

Line 370: `random_state = random_state * 32'd1664525 + 32'd1013904223;` This makes random_state, the finite-state-machine phase retained in flip-flops, equal to 'random_state * 32'd1664525 + 32'd1013904223'. It is driven by combinational or procedural logic in the current evaluation. The important operands are random_state: the finite-state-machine phase retained in flip-flops; d1664525: the value named 'd1664525' in this block; d1013904223: the value named 'd1013904223' in this block. Context: the simulation task task.

Line 371: `random_increment = random_state[18:0];` This makes random_increment, the value named 'random increment' in this block, equal to 'random_state[18:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are random_state: the finite-state-machine phase retained in flip-flops. Context: the simulation task task.

Line 372: `check_counter_add(random_value, random_increment);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are check_counter_add: a hardware telemetry register that accumulates measured events; random_value: the value named 'random value' in this block; random_increment: the value named 'random increment' in this block.

Line 373: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 374: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 375: `endtask` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 377: `always @(posedge clk) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are always: the value named 'always' in this block; posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 378: `cycle <= cycle + 1;` This makes cycle, the value named 'cycle' in this block, equal to 'cycle + 1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are cycle: the value named 'cycle' in this block. Context: the module's structural declarations.

Line 379: `if (held_valid && (!m_axis_tvalid || m_axis_tdata !== held_data` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are held_valid: the producer's statement that its current payload is meaningful; m_axis_tvalid: the producer's statement that its current payload is meaningful; m_axis_tdata: the value named 'm axis tdata' in this block.

Line 380: `|| m_axis_tlast !== held_last)) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; held_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 381: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 382: `$display("ERROR buffered output changed while backpressured");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 383: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 384: `held_valid <= m_axis_tvalid && !m_axis_tready;` This makes held_valid, the producer's statement that its current payload is meaningful, equal to 'm_axis_tvalid && !m_axis_tready'. It updates after the active clock edge together with other nonblocking assignments. The important operands are m_axis_tvalid: the producer's statement that its current payload is meaningful; m_axis_tready: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 385: `held_data <= m_axis_tdata;` This makes held_data, the payload carried with the surrounding valid/ready handshake, equal to 'm_axis_tdata'. It updates after the active clock edge together with other nonblocking assignments. The important operands are m_axis_tdata: the value named 'm axis tdata' in this block. Context: the module's structural declarations.

Line 386: `held_last <= m_axis_tlast;` This makes held_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'm_axis_tlast'. It updates after the active clock edge together with other nonblocking assignments. The important operands are m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the module's structural declarations.

Line 387: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 389: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 390: `$readmemh("tb/fixtures/tensor_cases.mem", case_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 391: `$readmemh("tb/fixtures/tensor_activations.mem", activation_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 392: `$readmemh("tb/fixtures/tensor_weights.mem", weight_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 393: `$readmemh("tb/fixtures/tensor_expected.mem", expected_mem);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are readmemh: the value named 'readmemh' in this block; tb: the value named 'tb' in this block; fixtures: the value named 'fixtures' in this block.

Line 395: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 396: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 397: `repeat (2) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 399: `verify_counter_adder();` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are verify_counter_adder: a hardware telemetry register that accumulates measured events.

Line 401: `for (int case_index = 0; case_index < CASES; case_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 402: `run_fixture_case(case_index);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are run_fixture_case: the value named 'run fixture case' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 403: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 405: `if (issue_pointer != ISSUES || expected_pointer != RESULTS || checked != RESULTS) begin` This condition selects the following hardware branch only when 'issue_pointer != ISSUES || expected_pointer != RESULTS || checked != RESULTS' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are issue_pointer: the value named 'issue pointer' in this block; ISSUES: the value named 'issues' in this block; expected_pointer: the value named 'expected pointer' in this block. Context: the module's structural declarations.

Line 406: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 407: `$display("ERROR buffered accounting issue=%0d/%0d expected=%0d/%0d checked=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 408: `issue_pointer, ISSUES, expected_pointer, RESULTS, checked);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are issue_pointer: the value named 'issue pointer' in this block; ISSUES: the value named 'issues' in this block; expected_pointer: the value named 'expected pointer' in this block.

Line 409: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 411: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 412: `$display("tb_neuraedge_buffered_tensor_core FAILED errors=%0d checked=%0d", errors, checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 413: `$fatal(1);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 414: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 415: `$display("tb_neuraedge_buffered_tensor_core PASSED cases=%0d checked=%0d", CASES, checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 416: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 417: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 418: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 420: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 421: `#200_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 422: `$display("ERROR buffered core watchdog state=%0d busy=%0d cmd_ready=%0d s_ready=%0d m_valid=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 423: `dut.state, status_busy, command_ready, s_axis_tready, m_axis_tvalid);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation. The important operands are dut: the value named 'dut' in this block; state: the finite-state-machine phase retained in flip-flops; status_busy: the value named 'status busy' in this block.

Line 424: `$fatal(1);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 425: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 426: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 428: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge buffered tensor core RTL block in simulation.

49 tb/tb_neuraedge_descriptor_sequencer.sv

Role in the complete system: drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

49.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

Simulation-only status tb_neuraedge_descriptor_sequencer is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

```

49.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `‘default_nettype none` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module tb_neuraedge_descriptor_sequencer;` This opens tb_neuraedge_descriptor_sequencer;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

Line 5: `logic clk = 1’b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 6: `logic rst_n = 1’b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 7: `logic program_start = 1’b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_start is the value named 'program start' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 8: `logic clear_status = 1’b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clear_status is the value named 'clear status' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `logic [31:0] program_output_beats = 32’d0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_output_beats is the value named 'program output beats' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic program_active;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_active is the value named 'program active' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic program_done;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_done is the value named 'program done' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic program_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_error is the value named 'program error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic [31:0] program_records;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_records is the number of descriptor records accepted since program start. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic s_axis_tvalid = 1’b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic s_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic [63:0] s_axis_tdata = 64’d0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tdata is the value named 's axis tdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic s_axis_tlast = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tlast is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic m_axis_tvalid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic m_axis_tready = 1'b1;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic [63:0] m_axis_tdata;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tdata is the value named 'm axis tdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic m_axis_tlast;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tlast is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic core_command_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_command_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic core_command_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_command_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic [127:0] core_command_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_command_data is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic core_command_done = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_command_done is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 26: `logic core_status_error = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_status_error is the value named 'core status error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic core_s_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 28: `logic core_s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `logic [63:0] core_s_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `logic core_s_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 31: `logic core_m_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 32: `logic core_m_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `logic [63:0] core_m_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `logic core_m_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 36: `typedef enum logic [1:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 37: `CORE_IDLE = 2'd0,` This assigns a fixed binary encoding to state CORE_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 38: `CORE_INPUT = 2'd1,` This assigns a fixed binary encoding to state CORE_INPUT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 39: `CORE_OUTPUT = 2'd2,` This assigns a fixed binary encoding to state CORE_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 40: `CORE_DONE = 2'd3` This statement continues through source line 41; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state CORE_DONE, which raises completion for one cycle and returns control to idle. The encoding is visible in waveforms even though the source uses the readable name.

Line 41: `} core_state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 40. Its exact fragment is '} core_state_t;'. The important operands are core_state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state CORE_DONE, which raises completion for one cycle and returns control to idle. The encoding is visible in waveforms even though the source uses the readable name.

Line 42: `core_state_t core_state = CORE_IDLE;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are core_state_t: the finite-state-machine phase retained in flip-flops; core_state: the finite-state-machine phase retained in flip-flops; CORE_IDLE: the value named 'core idle' in this block.

Line 43: `logic core_output_index = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 44: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 45: `int output_count = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are output_count: an integer count retained for control or measurable telemetry.

Line 46: `int program_output_index = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are program_output_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 47: `int expected_program_outputs = 2;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are expected_program_outputs: the value named 'expected program outputs' in this block.

Line 48: `int input_count = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are input_count: an integer count retained for control or measurable telemetry.

Line 50: `neuraedge_descriptor_sequencer dut (` This instantiates module neuraedge_descriptor_sequencer as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 51: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 52: `.program_start(program_start),` This connects the child instance's named port 'program_start' to parent expression 'program_start'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'program start' in this block.

Line 53: `.clear_status(clear_status),` This connects the child instance's named port 'clear_status' to parent expression 'clear_status'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'clear status' in this block.

Line 54: `.program_output_beats(program_output_beats),` This connects the child instance's named port 'program_output_beats' to parent expression 'program_output_beats'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'program output beats' in this block.

Line 55: `.program_active(program_active), .program_done(program_done),` This connects the child instance's named port 'program_active' to parent expression 'program_active), .program_done(program_done'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'program active), .program done(program done' in this block.

Line 56: `.program_error(program_error), .program_records(program_records),` This connects the child instance's named port 'program_error' to parent expression 'program_error), .program_records(program_records'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the number of descriptor records accepted since program start.

Line 57: `.s_axis_tvalid(s_axis_tvalid), .s_axis_tready(s_axis_tready),` This connects the child instance's named port 's_axis_tvalid' to parent expression 's_axis_tvalid), .s_axis_tready(s_axis_tready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 58: `.s_axis_tdata(s_axis_tdata), .s_axis_tlast(s_axis_tlast),` This connects the child instance's named port ‘s_axis_tdata‘ to parent expression ‘s_axis_tdata), .s_axis_tlast(s_axis_tlast‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 59: `.m_axis_tvalid(m_axis_tvalid), .m_axis_tready(m_axis_tready),` This connects the child instance's named port ‘m_axis_tvalid‘ to parent expression ‘m_axis_tvalid), .m_axis_tready(m_axis_tready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 60: `.m_axis_tdata(m_axis_tdata), .m_axis_tlast(m_axis_tlast),` This connects the child instance's named port ‘m_axis_tdata‘ to parent expression ‘m_axis_tdata), .m_axis_tlast(m_axis_tlast‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 61: `.core_command_valid(core_command_valid),` This connects the child instance's named port ‘core_command_valid‘ to parent expression ‘core_command_valid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 62: `.core_command_ready(core_command_ready),` This connects the child instance's named port ‘core_command_ready‘ to parent expression ‘core_command_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 63: `.core_command_data(core_command_data),` This connects the child instance's named port ‘core_command_data‘ to parent expression ‘core_command_data‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 64: `.core_command_done(core_command_done),` This connects the child instance's named port ‘core_command_done‘ to parent expression ‘core_command_done‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 65: `.core_status_error(core_status_error),` This connects the child instance's named port ‘core_status_error‘ to parent expression ‘core_status_error‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core status error' in this block.

Line 66: `.core_s_valid(core_s_valid), .core_s_ready(core_s_ready),` This connects the child instance's named port ‘core_s_valid‘ to parent expression ‘core_s_valid), .core_s_ready(core_s_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 67: `.core_s_data(core_s_data), .core_s_last(core_s_last),` This connects the child instance's named port ‘core_s_data‘ to parent expression ‘core_s_data), .core_s_last(core_s_last‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 68: `.core_m_valid(core_m_valid), .core_m_ready(core_m_ready),` This connects the child instance's named port ‘core_m_valid‘ to parent expression ‘core_m_valid), .core_m_ready(core_m_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 69: `.core_m_data(core_m_data), .core_m_last(core_m_last)` This connects the child instance's named port ‘core_m_data‘ to parent expression ‘core_m_data), .core_m_last(core_m_last‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 70: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 72: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 74: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 75: `core_command_ready = core_state == CORE_IDLE;` This makes core_command_ready, the consumer's statement that it can accept a payload this cycle, equal to 'core_state == CORE_IDLE'. It is driven by combinational or procedural logic in the current evaluation. The important operands are core_state: the finite-state-machine phase retained in flip-flops; CORE_IDLE: the value named 'core idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 76: `core_s_ready = core_state == CORE_INPUT;` This makes core_s_ready, the consumer's statement that it can accept a payload this cycle, equal to 'core_state == CORE_INPUT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are core_state: the finite-state-machine phase retained in flip-flops; CORE_INPUT: the value named 'core input' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 77: `core_m_valid = core_state == CORE_OUTPUT;` This makes core_m_valid, the producer's statement that its current payload is meaningful, equal to 'core_state == CORE_OUTPUT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are core_state: the finite-state-machine phase retained in flip-flops; CORE_OUTPUT: the value named 'core output' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 78: `core_m_data = core_output_index ? 64'h2222 : 64'h1111;` This makes core_m_data, the payload carried with the surrounding valid/ready handshake, equal to 'core_output_index ? 64'h2222 : 64'h1111'. It is driven by combinational or procedural logic in the current evaluation. The important operands are core_output_index: an integer selecting one tensor element, lane, bank, or state entry; h2222: the value named 'h2222' in this block; h1111: the value named 'h1111' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 79: `core_m_last = core_output_index;` This makes core_m_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'core_output_index'. It is driven by combinational or procedural logic in the current evaluation. The important operands are core_output_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 80: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 82: `always @(posedge clk) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are always: the value named 'always' in this block; posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 83: `core_command_done <= 1'b0;` This makes core_command_done, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 84: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the module's structural declarations.

Line 85: `core_state <= CORE_IDLE;` This makes core_state, the finite-state-machine phase retained in flip-flops, equal to 'CORE_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are CORE_IDLE: the value named 'core idle' in this block. Context: the module's structural declarations.

Line 86: `core_output_index <= 1'b0;` This makes core_output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 87: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 88: `unique case (core_state)` This starts a multiplexer/state decode selected by 'core_state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 89: `CORE_IDLE: if (core_command_valid && core_command_ready) begin` This is the CORE_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with 'if (core_command_valid && core_command_ready) begin'; context is the module's structural declarations Within state CORE_IDLE, the machine waits for a new operation and does not consume payload data..

Line 90: `unique case (core_command_data[3:0])` This starts a multiplexer/state decode selected by 'core_command_data[3:0 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 91: `4'h1: core_state <= CORE_INPUT;` Within the module's structural declarations Within state CORE_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are h1: the value named 'h1' in this block; core_state: the finite-state-machine phase retained in flip-flops; CORE_INPUT: the value named 'core input' in this block.

Line 92: `4'h4: begin` Within the module's structural declarations Within state CORE_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are h4: the value named 'h4' in this block.

Line 93: `core_output_index <= 1'b0;` This makes core_output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations Within state CORE_IDLE, the machine waits for a new operation and does not consume payload data..

Line 94: `core_state <= CORE_OUTPUT;` This makes core_state, the finite-state-machine phase retained in flip-flops, equal to 'CORE_OUTPUT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are CORE_OUTPUT: the value named 'core output' in this block. Context: the module's structural declarations Within state CORE_IDLE, the machine waits for a new operation and does not consume payload data..

Line 95: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations Within state CORE_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 96: `default: core_state <= CORE_DONE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘core_state <= CORE_DONE;‘; context is the module’s structural declarations Within state CORE_IDLE, the machine waits for a new operation and does not consume payload data..

Line 97: `endcase` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations Within state CORE_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 98: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 99: `CORE_INPUT: if (core_s_valid && core_s_ready) begin` This is the CORE_INPUT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘if (core_s_valid && core_s_ready) begin‘; context is the module’s structural declarations Within state CORE_INPUT, the machine performs the named control phase..

Line 100: `input_count <= input_count + 1;` This makes input_count, an integer count retained for control or measurable telemetry, equal to ‘input_count + 1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_count: an integer count retained for control or measurable telemetry. Context: the module’s structural declarations Within state CORE_INPUT, the machine performs the named control phase..

Line 101: `if ((input_count == 0 && core_s_last)` This condition selects the following hardware branch only when ‘(input_count == 0 && core_s_last‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_count: an integer count retained for control or measurable telemetry; core_s_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the module’s structural declarations Within state CORE_INPUT, the machine performs the named control phase..

Line 102: `|| (input_count == 1 && !core_s_last)) begin` Within the module’s structural declarations Within state CORE_INPUT, the machine performs the named control phase., this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are input_count: an integer count retained for control or measurable telemetry; core_s_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 103: `errors <= errors + 1;` This makes errors, the value named ’errors’ in this block, equal to ‘errors + 1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are errors: the value named ’errors’ in this block. Context: the module’s structural declarations Within state CORE_INPUT, the machine performs the named control phase..

Line 104: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations Within state CORE_INPUT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 105: `if (core_s_last) core_state <= CORE_DONE;` This condition selects the following hardware branch only when ‘core_s_last‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are core_s_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the module’s structural declarations Within state CORE_INPUT, the machine performs the named control phase..

Line 106: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations Within state CORE_INPUT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 107: `CORE_OUTPUT: if (core_m_valid && core_m_ready) begin` This is the CORE_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘if (core_m_valid && core_m_ready) begin‘; context is the module’s structural declarations Within state CORE_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 108: `if (core_output_index) core_state <= CORE_DONE;` This condition selects the following hardware branch only when ‘core_output_index‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are core_output_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module’s structural declarations Within state CORE_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 109: `else core_output_index <= 1'b1;` Within the module’s structural declarations Within state CORE_OUTPUT, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are core_output_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named ’b1’ in this block.

Line 110: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations Within state CORE_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 111: `CORE_DONE: begin` This is the CORE_DONE case branch, which raises completion for one cycle and returns control to idle. The same-cycle action begins with ‘begin‘; context is the module’s structural declarations Within state CORE_DONE, the machine raises completion for one cycle and returns control to idle..

Line 112: `core_command_done <= 1'b1;` This makes core_command_done, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the module’s structural declarations Within state CORE_DONE, the machine raises completion for one cycle and returns control to idle..

Line 113: `core_state <= CORE_IDLE;` This makes core_state, the finite-state-machine phase retained in flip-flops, equal to ‘CORE_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are CORE_IDLE: the value named ’core idle’ in this block. Context: the module’s structural declarations Within state CORE_DONE, the machine raises completion for one cycle and returns control to idle..

Line 114: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations Within state CORE_DONE, the machine raises completion for one cycle and returns control to idle.; it has no arithmetic value of its own.

Line 115: `default: core_state <= CORE_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘core_state <= CORE_IDLE;‘; context is the module’s structural declarations Within state CORE_DONE, the machine raises completion for one cycle and returns control to idle..

Line 116: `endcase` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations Within state CORE_DONE, the machine raises completion for one cycle and returns control to idle.; it has no arithmetic value of its own.

Line 117: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 118: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 120: `always @(posedge clk) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are always: the value named 'always' in this block; posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 121: `if (m_axis_tvalid && m_axis_tready) begin` This condition selects the following hardware branch only when 'm_axis_tvalid && m_axis_tready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are m_axis_tvalid: the producer's statement that its current payload is meaningful; m_axis_tready: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 122: `if (m_axis_tdata !== (program_output_index == 0 ? 64'h1111 : 64'h2222)` This condition selects the following hardware branch only when 'm_axis_tdata !== (program_output_index == 0 ? 64'h1111 : 64'h2222' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are m_axis_tdata: the value named 'm axis tdata' in this block; program_output_index: an integer selecting one tensor element, lane, bank, or state entry; h1111: the value named 'h1111' in this block. Context: the module's structural declarations.

Line 123: `|| m_axis_tlast !== (program_output_index` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; program_output_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 124: `== expected_program_outputs - 1)) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are expected_program_outputs: the value named 'expected program outputs' in this block.

Line 125: `errors <= errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 126: `$display("ERROR output=%0d data=%h last=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 127: `program_output_index, m_axis_tdata, m_axis_tlast);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are program_output_index: an integer selecting one tensor element, lane, bank, or state entry; m_axis_tdata: the value named 'm axis tdata' in this block; m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload.

Line 128: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 129: `output_count <= output_count + 1;` This makes output_count, an integer count retained for control or measurable telemetry, equal to 'output_count + 1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_count: an integer count retained for control or measurable telemetry. Context: the module's structural declarations.

Line 130: `program_output_index <= program_output_index + 1;` This makes program_output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'program_output_index + 1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are program_output_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 131: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 132: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 134: `task automatic send_word(input logic [63:0] data, input logic last);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; send_word: the value named 'send word' in this block.

Line 135: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task send word; it has no arithmetic value of its own.

Line 136: `while (!s_axis_tready) @(negedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are while: the value named 'while' in this block; s_axis_tready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 137: `s_axis_tdata = data;` This makes s_axis_tdata, the value named 's axis tdata' in this block, equal to 'data'. It is driven by combinational or procedural logic in the current evaluation. The important operands are data: the value named 'data' in this block. Context: the simulation task send word.

Line 138: `s_axis_tlast = last;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'last'. It is driven by combinational or procedural logic in the current evaluation. The important operands are last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the simulation task send word.

Line 139: `s_axis_tvalid = 1'b1;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task send word.

Line 140: `@(posedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 141: `@(negedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 142: `s_axis_tvalid = 1'b0;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send word.

Line 143: `s_axis_tlast = 1'b0;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send word.

Line 144: `end` This structural keyword opens or closes the branch/process scope described as the simulation task send word; it has no arithmetic value of its own.

Line 145: `endtask` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 147: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 148: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 149: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 150: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 151: `program_output_beats = 2;` This makes program_output_beats, the value named 'program output beats' in this block, equal to '2'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 152: `program_start = 1'b1;` This makes program_start, the value named 'program start' in this block, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 153: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 154: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 155: `program_start = 1'b0;` This makes program_start, the value named 'program start' in this block, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 157: `// Load command: two payload beats, no output, not the final record.` Design intent: Load command: two payload beats, no output, not the final record. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

Line 158: `send_word({1'b0, 31'd0, 32'd2}, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; b0: the value named 'b0' in this block; d0: the value named 'd0' in this block.

Line 159: `send_word(64'h1, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h1: the value named 'h1' in this block; b0: the value named 'b0' in this block.

Line 160: `send_word(64'd0, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; d0: the value named 'd0' in this block; b0: the value named 'b0' in this block.

Line 161: `send_word(64'habc, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; habc: the value named 'habc' in this block; b0: the value named 'b0' in this block.

Line 162: `send_word(64'hdef, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; hdef: the value named 'hdef' in this block; b0: the value named 'b0' in this block.

Line 164: `// Compute command: no input and two outputs. It is deliberately not` Design intent: Compute command: no input and two outputs. It is deliberately not This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

Line 165: `// the final input record; global output count must still generate TLAST.` Design intent: the final input record; global output count must still generate TLAST. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

Line 166: `send_word({1'b0, 31'd2, 32'd0}, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; b0: the value named 'b0' in this block; d2: the value named 'd2' in this block.

Line 167: `send_word(64'h4, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h4: the value named 'h4' in this block; b0: the value named 'b0' in this block.

Line 168: `send_word(64'd0, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; d0: the value named 'd0' in this block; b0: the value named 'b0' in this block.

Line 170: `// A trailing no-output command proves output TLAST does not depend on` Design intent: A trailing no-output command proves output TLAST does not depend on This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

Line 171: `// which descriptor carries the final input marker.` Design intent: which descriptor carries the final input marker. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

Line 172: `send_word({1'b1, 31'd0, 32'd0}, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; b1: the value named 'b1' in this block; d0: the value named 'd0' in this block.

Line 173: `send_word(64'hf, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; hf: the value named 'hf' in this block; b0: the value named 'b0' in this block.

Line 174: `send_word(64'd0, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; d0: the value named 'd0' in this block; b1: the value named 'b1' in this block.

Line 176: `wait (program_done);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are wait: the value named 'wait' in this block; program_done: the value named 'program done' in this block.

Line 177: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 178: `if (program_error || program_active || program_records != 3` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are program_error: the value named 'program error' in this block; program_active: the value named 'program active' in this block; program_records: the number of descriptor records accepted since program start.

Line 179: `|| input_count != 2 || output_count != 2) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are input_count: an integer count retained for control or measurable telemetry; output_count: an integer count retained for control or measurable telemetry.

Line 180: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 181: `$display("ERROR final active=%0d error=%0d records=%0d input=%0d output=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 182: `program_active, program_error, program_records,` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are program_active: the value named 'program active' in this block; program_error: the value named 'program error' in this block; program_records: the number of descriptor records accepted since program start.

Line 183: `input_count, output_count);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are input_count: an integer count retained for control or measurable telemetry; output_count: an integer count retained for control or measurable telemetry.

Line 184: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 186: `// Declare one output for a core command that produces two. The first` Design intent: Declare one output for a core command that produces two. The first This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

Line 187: `// beat is legal and gets TLAST; the second must be discarded while the` Design intent: beat is legal and gets TLAST; the second must be discarded while the This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

Line 188: `// descriptor sequencer reports an overrun instead of deadlocking.` Design intent: descriptor sequencer reports an overrun instead of deadlocking. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

Line 189: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 190: `program_output_index = 0;` This makes program_output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 191: `expected_program_outputs = 1;` This makes expected_program_outputs, the value named 'expected program outputs' in this block, equal to '1'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 192: `program_output_beats = 1;` This makes program_output_beats, the value named 'program output beats' in this block, equal to '1'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 193: `program_start = 1'b1;` This makes program_start, the value named 'program start' in this block, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 194: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 195: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 196: `program_start = 1'b0;` This makes program_start, the value named 'program start' in this block, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 197: `send_word({1'b1, 31'd1, 32'd0}, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; b1: the value named 'b1' in this block; d1: the value named 'd1' in this block.

Line 198: `send_word(64'h4, 1'b0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; h4: the value named 'h4' in this block; b0: the value named 'b0' in this block.

Line 199: `send_word(64'd0, 1'b1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; d0: the value named 'd0' in this block; b1: the value named 'b1' in this block.

Line 200: `wait (program_done);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are wait: the value named 'wait' in this block; program_done: the value named 'program done' in this block.

Line 201: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 202: `if (!program_error || program_active || program_records != 1` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are program_error: the value named 'program error' in this block; program_active: the value named 'program active' in this block; program_records: the number of descriptor records accepted since program start.

Line 203: `|| output_count != 3) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are output_count: an integer count retained for control or measurable telemetry.

Line 204: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 205: `$display("ERROR overrun active=%0d error=%0d records=%0d output=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 206: `program_active, program_error, program_records, output_count);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The important operands are program_active: the value named 'program active' in this block; program_error: the value named 'program error' in this block; program_records: the number of descriptor records accepted since program start.

Line 207: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 208: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 209: `$display("tb_neuraedge_descriptor_sequencer FAILED errors=%0d", errors);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 210: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 211: `$display("tb_neuraedge_descriptor_sequencer PASSED records=%0d", program_records);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 212: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 213: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 214: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 216: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 217: `#200_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 218: `$fatal(1, "descriptor sequencer watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 219: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 220: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 222: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge descriptor sequencer RTL block in simulation.

50 tb/tb_neuraedge_integer_primitives.sv

Role in the complete system: drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation.

50.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation.

Simulation-only status tb_neuraedge_integer_primitives is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

50.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module tb_neuraedge_integer_primitives;` This opens tb_neuraedge_integer_primitives;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation.

Line 5: `logic clk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 6: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 8: `logic div_input_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, div_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `logic div_input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, div_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic [63:0] div_numerator = 64'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, div_numerator is the value named 'div numerator' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic [31:0] div_denominator = 32'd1;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, div_denominator is the value named 'div denominator' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic div_output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, div_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic div_output_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, div_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic [63:0] div_quotient;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, div_quotient is the value named 'div quotient' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic [31:0] div_remainder;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, div_remainder is the value named 'div remainder' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic divide_by_zero;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divide_by_zero is the value named 'divide by zero' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic sqrt_input_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic sqrt_input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic [63:0] sqrt_radicand = 64'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_radicand is the value named 'sqrt radicand' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic sqrt_output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic sqrt_output_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic [31:0] sqrt_root;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_root is the value named 'sqrt root' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic [32:0] sqrt_remainder;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_remainder is the value named 'sqrt remainder' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 26: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 27: `int div_checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are div_checked: the value named 'div checked' in this block.

Line 28: `int sqrt_checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are sqrt_checked: the value named 'sqrt checked' in this block.

Line 30: `neuraedge_udivider u_divider (` This instantiates module neuraedge_udivider as u_divider. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 31: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 32: `.input_valid(div_input_valid), .input_ready(div_input_ready),` This connects the child instance's named port 'input_valid' to parent expression 'div_input_valid), .input_ready(div_input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 33: `.numerator(div_numerator), .denominator(div_denominator),` This connects the child instance's named port 'numerator' to parent expression 'div_numerator), .denominator(div_denominator'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'div numerator), .denominator(div denominator' in this block.

Line 34: `.output_valid(div_output_valid), .output_ready(div_output_ready),` This connects the child instance's named port 'output_valid' to parent expression 'div_output_valid), .output_ready(div_output_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 35: `.quotient(div_quotient), .remainder(div_remainder),` This connects the child instance's named port 'quotient' to parent expression 'div_quotient), .remainder(div_remainder'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'div quotient), .remainder(div remainder' in this block.

Line 36: `.divide_by_zero(divide_by_zero)` This connects the child instance's named port 'divide_by_zero' to parent expression 'divide_by_zero'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'divide by zero' in this block.

Line 37: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 39: `neuraedge_isqrt64 u_sqrt (` This instantiates module neuraedge_isqrt64 as u_sqrt. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 40: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 41: `.input_valid(sqrt_input_valid), .input_ready(sqrt_input_ready),` This connects the child instance's named port 'input_valid' to parent expression 'sqrt_input_valid), .input_ready(sqrt_input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 42: `.radicand(sqrt_radicand), .output_valid(sqrt_output_valid),` This connects the child instance's named port ‘radicand‘ to parent expression ‘sqrt_radicand), .output_valid(sqrt_output_valid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 43: `.output_ready(sqrt_output_ready), .root(sqrt_root),` This connects the child instance's named port ‘output_ready‘ to parent expression ‘sqrt_output_ready), .root(sqrt_root‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 44: `.remainder(sqrt_remainder)` This connects the child instance's named port ‘remainder‘ to parent expression ‘sqrt_remainder‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'sqrt remainder' in this block.

Line 45: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 47: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 49: `task automatic check_division(input logic [63:0] n, input logic [31:0] d);` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; check_division: the value named 'check division' in this block.

Line 50: `logic [63:0] expected_q;` This declares hardware signal storage or wiring in the simulation task check division. Specifically, expected_q is the value named 'expected q' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 51: `logic [31:0] expected_r;` This declares hardware signal storage or wiring in the simulation task check division. Specifically, expected_r is the value named 'expected r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 52: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task check division; it has no arithmetic value of its own.

Line 53: `expected_q = d == 0 ? 64'hffffffffffffffff : n / d;` This makes expected_q, the value named 'expected q' in this block, equal to ‘d == 0 ? 64'hffffffffffffffff : n / d‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d: the value named 'd' in this block; hffffffffffffff: the value named 'hffffffffffffff' in this block; n: the value named 'n' in this block. Context: the simulation task check division.

Line 54: `expected_r = d == 0 ? n[31:0] : n % d;` This makes expected_r, the value named 'expected r' in this block, equal to ‘d == 0 ? n[31:0] : n % d‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d: the value named 'd' in this block; n: the value named 'n' in this block. Context: the simulation task check division.

Line 55: `while (!div_input_ready) @(negedge clk);` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are while: the value named 'while' in this block; div_input_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 56: `@(negedge clk);` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 57: `div_numerator = n;` This makes div_numerator, the value named 'div numerator' in this block, equal to 'n'. It is driven by combinational or procedural logic in the current evaluation. The important operands are n: the value named 'n' in this block. Context: the simulation task check division.

Line 58: `div_denominator = d;` This makes div_denominator, the value named 'div denominator' in this block, equal to 'd'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d: the value named 'd' in this block. Context: the simulation task check division.

Line 59: `div_input_valid = 1'b1;` This makes div_input_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task check division.

Line 60: `@(posedge clk);` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 61: `@(negedge clk);` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 62: `div_input_valid = 1'b0;` This makes div_input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task check division.

Line 63: `while (!div_output_valid) @(negedge clk);` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are while: the value named 'while' in this block; div_output_valid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 64: `repeat (div_checked % 3) @(negedge clk);` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; div_checked: the value named 'div checked' in this block; negedge: the value named 'negedge' in this block.

Line 65: `if (div_quotient !== expected_q || div_remainder !== expected_r` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are div_quotient: the value named 'div quotient' in this block; expected_q: the value named 'expected q' in this block; div_remainder: the value named 'div remainder' in this block.

Line 66: `|| divide_by_zero !== (d == 0)) begin` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are divide_by_zero: the value named 'divide by zero' in this block; d: the value named 'd' in this block.

Line 67: `errors++;` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 68: `$display("ERROR divider n=%0d d=%0d got=%0d r=%0d expected=%0d r=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 69: `n, d, div_quotient, div_remainder, expected_q, expected_r);` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are n: the value named 'n' in this block; d: the value named 'd' in this block; div_quotient: the value named 'div quotient' in this block.

Line 70: `end` This structural keyword opens or closes the branch/process scope described as the simulation task check division; it has no arithmetic value of its own.

Line 71: `div_output_ready = 1'b1;` This makes div_output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task check division.

Line 72: `@(posedge clk);` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 73: `@(negedge clk);` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 74: `div_output_ready = 1'b0;` This makes div_output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task check division.

Line 75: `div_checked++;` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are div_checked: the value named 'div checked' in this block.

Line 76: `end` This structural keyword opens or closes the branch/process scope described as the simulation task check division; it has no arithmetic value of its own.

Line 77: `endtask` Within the simulation task check division, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 79: `task automatic check_sqrt(input logic [63:0] value);` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; check_sqrt: the value named 'check sqrt' in this block.

Line 80: `logic [63:0] expected_root;` This declares hardware signal storage or wiring in the simulation task check sqrt. Specifically, expected_root is the value named 'expected root' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 81: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task check sqrt; it has no arithmetic value of its own.

Line 82: `expected_root = 0;` This makes expected_root, the value named 'expected root' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task check sqrt.

Line 83: `// The testbench oracle uses binary search, independent of the` Design intent: The testbench oracle uses binary search, independent of the This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation.

Line 84: `// restoring square-root datapath in the DUT.` Design intent: restoring square-root datapath in the DUT. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation.

Line 85: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task check sqrt; it has no arithmetic value of its own.

Line 86: `logic [63:0] low;` This declares hardware signal storage or wiring in the simulation task check sqrt. Specifically, low is the value named 'low' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 87: `logic [63:0] high;` This declares hardware signal storage or wiring in the simulation task check sqrt. Specifically, high is the value named 'high' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 88: `low = 0;` This makes low, the value named 'low' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task check sqrt.

Line 89: `high = 64'h0000000100000000;` This makes high, the value named 'high' in this block, equal to '64'h0000000100000000'
It is driven by combinational or procedural logic in the current evaluation. The important operands are h0000000100000000:
the value named 'h0000000100000000' in this block. Context: the simulation task check sqrt.

Line 90: `while (low + 1 < high) begin` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are while: the value named 'while' in this block; low: the value named 'low' in this block; high: the value named 'high' in this block.

Line 91: `logic [63:0] middle;` This declares hardware signal storage or wiring in the simulation task check sqrt. Specifically, middle is the value named 'middle' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 92: `middle = (low + high) >> 1;` This makes middle, the value named 'middle' in this block, equal to '(low + high) >> 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are low: the value named 'low' in this block; high: the value named 'high' in this block. Context: the simulation task check sqrt.

Line 93: `if (middle <= value / middle) low = middle;` This condition selects the following hardware branch only when 'middle <= value / middle' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are middle: the value named 'middle' in this block; value: the value named 'value' in this block. Context: the simulation task check sqrt.

Line 94: `else high = middle;` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are high: the value named 'high' in this block; middle: the value named 'middle' in this block.

Line 95: `end` This structural keyword opens or closes the branch/process scope described as the simulation task check sqrt; it has no arithmetic value of its own.

Line 96: `expected_root = low;` This makes expected_root, the value named 'expected root' in this block, equal to 'low'. It is driven by combinational or procedural logic in the current evaluation. The important operands are low: the value named 'low' in this block. Context: the simulation task check sqrt.

Line 97: `end` This structural keyword opens or closes the branch/process scope described as the simulation task check sqrt; it has no arithmetic value of its own.

Line 98: `while (!sqrt_input_ready) @(negedge clk);` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are while: the value named 'while' in this block; sqrt_input_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 99: `@(negedge clk);` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 100: `sqrt_radicand = value;` This makes sqrt_radicand, the value named 'sqrt radicand' in this block, equal to 'value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the simulation task check sqrt.

Line 101: `sqrt_input_valid = 1'b1;` This makes sqrt_input_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task check sqrt.

Line 102: `@(posedge clk);` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 103: `@(negedge clk);` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 104: `sqrt_input_valid = 1'b0;` This makes sqrt_input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task check sqrt.

Line 105: `while (!sqrt_output_valid) @(negedge clk);` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are while: the value named 'while' in this block; sqrt_output_valid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 106: `repeat (sqrt_checked % 4) @(negedge clk);` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; sqrt_checked: the value named 'sqrt checked' in this block; negedge: the value named 'negedge' in this block.

Line 107: `if (sqrt_root !== expected_root[31:0]` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are sqrt_root: the value named 'sqrt root' in this block; expected_root: the value named 'expected root' in this block.

Line 108: `|| sqrt_remainder !== value - expected_root * expected_root) begin` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are sqrt_remainder: the value named 'sqrt remainder' in this block; value: the value named 'value' in this block; expected_root: the value named 'expected root' in this block.

Line 109: `errors++;` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 110: `$display("ERROR sqrt value=%0d got=%0d rem=%0d expected=%0d rem=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 111: `value, sqrt_root, sqrt_remainder, expected_root,` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are value: the value named 'value' in this block; sqrt_root: the value named 'sqrt root' in this block; sqrt_remainder: the value named 'sqrt remainder' in this block.

Line 112: `value - expected_root * expected_root);` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are value: the value named 'value' in this block; expected_root: the value named 'expected root' in this block.

Line 113: `end` This structural keyword opens or closes the branch/process scope described as the simulation task check sqrt; it has no arithmetic value of its own.

Line 114: `sqrt_output_ready = 1'b1;` This makes sqrt_output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task check sqrt.

Line 115: `@(posedge clk);` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 116: `@(negedge clk);` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 117: `sqrt_output_ready = 1'b0;` This makes sqrt_output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task check sqrt.

Line 118: `sqrt_checked++;` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are sqrt_checked: the value named 'sqrt checked' in this block.

Line 119: `end` This structural keyword opens or closes the branch/process scope described as the simulation task check sqrt; it has no arithmetic value of its own.

Line 120: `endtask` Within the simulation task check sqrt, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 122: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 123: `int seed;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are seed: the value named 'seed' in this block.

Line 124: `logic [63:0] random_value;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, random_value is the value named 'random value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 125: `seed = 32'hd171de42;` This makes seed, the value named 'seed' in this block, equal to '32'hd171de42'. It is driven by combinational or procedural logic in the current evaluation. The important operands are hd171de42: the value named 'hd171de42' in this block. Context: the module's structural declarations.

Line 126: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 127: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 129: `check_division(0, 1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_division: the value named 'check division' in this block.

Line 130: `check_division(1, 1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_division: the value named 'check division' in this block.

Line 131: `check_division(64'hffffffffffffffff, 32'hffffffff);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_division: the value named 'check division' in this block; hffffffffffffffff: the value named 'hffffffffffffffff' in this block; hffffffff: the value named 'hffffffff' in this block.

Line 132: `check_division(64'd123456789012345, 32'd97);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_division: the value named 'check division' in this block; d123456789012345: the value named 'd123456789012345' in this block; d97: the value named 'd97' in this block.

Line 133: `check_division(1234, 0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_division: the value named 'check division' in this block.

Line 134: `for (int test_index = 0; test_index < 100; test_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 135: `random_value = {$urandom(seed), $urandom(seed)};` This makes random_value, the value named 'random value' in this block, equal to '{$urandom(seed), $urandom(seed)}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are urandom: the value named 'urandom' in this block; seed: the value named 'seed' in this block. Context: the module's structural declarations.

Line 136: `check_division(random_value, 1 + ($urandom(seed) % 32'hfffffffe));` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_division: the value named 'check division' in this block; random_value: the value named 'random value' in this block; urandom: the value named 'urandom' in this block.

Line 137: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 139: `check_sqrt(0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_sqrt: the value named 'check sqrt' in this block.

Line 140: `check_sqrt(1);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_sqrt: the value named 'check sqrt' in this block.

Line 141: `check_sqrt(2);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_sqrt: the value named 'check sqrt' in this block.

Line 142: `check_sqrt(3);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_sqrt: the value named 'check sqrt' in this block.

Line 143: `check_sqrt(4);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_sqrt: the value named 'check sqrt' in this block.

Line 144: `check_sqrt(64'hffffffffffffffff);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_sqrt: the value named 'check sqrt' in this block; hffffffffffffffff: the value named 'hffffffffffffffff' in this block.

Line 145: `for (int test_index = 0; test_index < 100; test_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 146: `random_value = {$urandom(seed), $urandom(seed)};` This makes random_value, the value named 'random value' in this block, equal to '{$urandom(seed), $urandom(seed)}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are urandom: the value named 'urandom' in this block; seed: the value named 'seed' in this block. Context: the module's structural declarations.

Line 147: `check_sqrt(random_value);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are check_sqrt: the value named 'check sqrt' in this block; random_value: the value named 'random value' in this block.

Line 148: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 150: `if (errors != 0) begin` This condition selects the following hardware branch only when 'errors != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 151: `$display("tb_neuraedge_integer_primitives FAILED errors=%0d", errors);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 152: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 153: `end else begin` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 154: `$display("tb_neuraedge_integer_primitives PASSED divisions=%0d square_roots=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 155: `div_checked, sqrt_checked);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The important operands are div_checked: the value named 'div checked' in this block; sqrt_checked: the value named 'sqrt checked' in this block.

Line 156: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 157: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 158: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 160: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 161: `#500_000;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 162: `$fatal(1, "tb_neuraedge_integer_primitives watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 163: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 164: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 166: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge integer primitives RTL block in simulation.

51 tb/tb_neuraedge_lif_bank.sv

Role in the complete system: drives, backpressures, and checks the neuraedge lif bank RTL block in simulation.

51.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge lif bank RTL block in simulation.

Simulation-only status tb_neuraedge_lif_bank is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

```

51.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module tb_neuraedge_lif_bank;` This opens tb_neuraedge_lif_bank;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation.

Line 5: `localparam int LANES = 32;` This fixes LANES to 32 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 6: `localparam int MEMBRANE_BITS = 24;` This fixes MEMBRANE_BITS to 24 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MEMBRANE_BITS denotes the persistent LIF neuron state carrying charge between timesteps.

Line 7: `localparam int CURRENT_BITS = 16;` This fixes CURRENT_BITS to 16 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CURRENT_BITS denotes the value named 'current bits' in this block.

Line 8: `localparam int MAXIMUM_MEMBRANE = (1 << 23) - 1;` This fixes MAXIMUM_MEMBRANE to (1 << 23) - 1 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAXIMUM_MEMBRANE denotes the persistent LIF neuron state carrying charge between timesteps.

Line 9: `localparam int MINIMUM_MEMBRANE = -(1 << 23);` This fixes MINIMUM_MEMBRANE to -(1 << 23) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MINIMUM_MEMBRANE denotes the persistent LIF neuron state carrying charge between timesteps.

Line 11: `logic clk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic clear_state = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clear_state is the finite-state-machine phase retained in flip-flops. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic clear_counters = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clear_counters is a hardware telemetry register that accumulates measured events. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic input_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [LANES*CURRENT_BITS-1:0] current_vector = '0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, current_vector is the value named 'current vector' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic [4:0] leak_shift = 5'd2;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, leak_shift is the retained fraction of prior membrane state. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic signed [MEMBRANE_BITS-1:0] threshold = 24'sd100;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, threshold is the membrane level at which a neuron emits a spike. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic signed [MEMBRANE_BITS-1:0] reset_value = 24'sd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, reset_value is the value named 'reset value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic output_ready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic [LANES-1:0] spikes;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, spikes is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic [LANES*MEMBRANE_BITS-1:0] membrane_vector;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, membrane_vector is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pre_reset_membrane_vector is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 26: `logic [31:0] timestep_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, timestep_count is one discrete SNN update instant. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic [63:0] total_spike_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, total_spike_count is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `integer reference_membrane [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, reference_membrane is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `int reference_timesteps = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are reference_timesteps: one discrete SNN update instant.

Line 31: `int reference_spikes = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are reference_spikes: a binary event produced when a neuron crosses its threshold.

Line 32: `int errors = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 33: `int checked = 0;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 35: `neuraedge_lif_bank dut (` This instantiates module neuraedge_lif_bank as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 36: `.clk(clk),` This connects the child instance's named port ‘clk‘ to parent expression ‘clk‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 37: `.rst_n(rst_n),` This connects the child instance's named port ‘rst_n‘ to parent expression ‘rst_n‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 38: `.clear_state(clear_state),` This connects the child instance's named port ‘clear_state‘ to parent expression ‘clear_state‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the finite-state-machine phase retained in flip-flops.

Line 39: `.clear_counters(clear_counters),` This connects the child instance's named port ‘clear_counters‘ to parent expression ‘clear_counters‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a hardware telemetry register that accumulates measured events.

Line 40: `.input_valid(input_valid),` This connects the child instance's named port ‘input_valid‘ to parent expression ‘input_valid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 41: `.input_ready(input_ready),` This connects the child instance's named port ‘input_ready‘ to parent expression ‘input_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 42: `.current_vector(current_vector),` This connects the child instance's named port ‘current_vector‘ to parent expression ‘current_vector‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'current vector' in this block.

Line 43: `.leak_shift(leak_shift),` This connects the child instance's named port ‘leak_shift‘ to parent expression ‘leak_shift‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the retained fraction of prior membrane state.

Line 44: `.threshold(threshold),` This connects the child instance's named port ‘threshold‘ to parent expression ‘threshold‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the membrane level at which a neuron emits a spike.

Line 45: `.reset_value(reset_value),` This connects the child instance's named port ‘reset_value‘ to parent expression ‘reset_value‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'reset value' in this block.

Line 46: `.output_valid(output_valid),` This connects the child instance's named port ‘output_valid‘ to parent expression ‘output_valid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 47: `.output_ready(output_ready),` This connects the child instance's named port ‘output_ready‘ to parent expression ‘output_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 48: `.spikes(spikes),` This connects the child instance's named port ‘spikes‘ to parent expression ‘spikes‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 49: `.membrane_vector(membrane_vector),` This connects the child instance's named port 'membrane_vector' to parent expression 'membrane_vector'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the persistent LIF neuron state carrying charge between timesteps.

Line 50: `.pre_reset_membrane_vector(pre_reset_membrane_vector),` This connects the child instance's named port 'pre_reset_membrane_vector' to parent expression 'pre_reset_membrane_vector'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the persistent LIF neuron state carrying charge between timesteps.

Line 51: `.timestep_count(timestep_count),` This connects the child instance's named port 'timestep_count' to parent expression 'timestep_count'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one discrete SNN update instant.

Line 52: `.total_spike_count(total_spike_count)` This connects the child instance's named port 'total_spike_count' to parent expression 'total_spike_count'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 53: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 55: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 57: `function automatic int saturate_reference(input longint signed value);` Within the combinational helper saturate reference, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; saturate_reference: the value named 'saturate reference' in this block.

Line 58: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate reference; it has no arithmetic value of its own.

Line 59: `if (value > MAXIMUM_MEMBRANE) saturate_reference = MAXIMUM_MEMBRANE;` This condition selects the following hardware branch only when 'value > MAXIMUM_MEMBRANE' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; MAXIMUM_MEMBRANE: the persistent LIF neuron state carrying charge between timesteps. Context: the combinational helper saturate reference.

Line 60: `else if (value < MINIMUM_MEMBRANE) saturate_reference = MINIMUM_MEMBRANE;` This condition selects the following hardware branch only when 'value < MINIMUM_MEMBRANE' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; MINIMUM_MEMBRANE: the persistent LIF neuron state carrying charge between timesteps. Context: the combinational helper saturate reference.

Line 61: `else saturate_reference = int'(value);` Within the combinational helper saturate reference, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are saturate_reference: the value named 'saturate reference' in this block; value: the value named 'value' in this block.

Line 62: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate reference; it has no arithmetic value of its own.

Line 63: `endfunction` Within the combinational helper saturate reference, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are endfunction: the value named 'endfunction' in this block.

Line 65: `task automatic clear_reference_and_dut(input int reset_level);` Within the simulation task clear reference and dut, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; clear_reference_and_dut: the value named 'clear reference and dut' in this block.

Line 66: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task clear reference and dut; it has no arithmetic value of its own.

Line 67: `reset_value = 24'(reset_level);` This makes reset_value, the value named 'reset value' in this block, equal to '24'(reset_level)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are reset_level: the value named 'reset level' in this block. Context: the simulation task clear reference and dut.

Line 68: `@(negedge clk);` Within the simulation task clear reference and dut, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 69: `clear_state = 1'b1;` This makes clear_state, the finite-state-machine phase retained in flip-flops, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task clear reference and dut.

Line 70: `@(posedge clk);` Within the simulation task clear reference and dut, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 71: `for (int lane = 0; lane < LANES; lane++) reference_membrane[lane] = reset_level;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task clear reference and dut.

Line 72: `reference_timesteps = 0;` This makes reference_timesteps, one discrete SNN update instant, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task clear reference and dut.

Line 73: `@(negedge clk);` Within the simulation task clear reference and dut, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 74: `clear_state = 1'b0;` This makes clear_state, the finite-state-machine phase retained in flip-flops, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task clear reference and dut.

Line 75: `end` This structural keyword opens or closes the branch/process scope described as the simulation task clear reference and dut; it has no arithmetic value of its own.

Line 76: `endtask` Within the simulation task clear reference and dut, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 78: `task automatic run_step(input int stall_cycles);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; run_step: the value named 'run step' in this block.

Line 79: `logic [LANES-1:0] expected_spikes;` This declares hardware signal storage or wiring in the simulation task run step. Specifically, expected_spikes is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 80: `integer expected_membrane [0:LANES-1];` This declares hardware signal storage or wiring in the simulation task run step. Specifically, expected_membrane is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 81: `integer expected_pre_reset_membrane [0:LANES-1];` This declares hardware signal storage or wiring in the simulation task run step. Specifically, expected_pre_reset_membrane is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 82: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 83: `expected_spikes = '0;` This makes expected_spikes, a binary event produced when a neuron crosses its threshold, equal to ''0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task run step.

Line 84: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run step.

Line 85: `int current_value;` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are current_value: the value named 'current value' in this block.

Line 86: `longint signed integrated;` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are longint: the value named 'longint' in this block; integrated: the value named 'integrated' in this block.

Line 87: `current_value = $signed(current_vector[lane*CURRENT_BITS +: CURRENT_BITS]);` This makes current_value, the value named 'current value' in this block, equal to '$signed(current_vector[lane*CURRENT_BITS +: CURRENT_BITS])'. It is driven by combinational or procedural logic in the current evaluation. The important operands are current_vector: the value named 'current vector' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; CURRENT_BITS: the value named 'current bits' in this block. Context: the simulation task run step.

Line 88: `integrated = reference_membrane[lane]` This statement continues through source line 89; the explanation uses the complete expression rather than only the first visual fragment. This makes integrated, the value named 'integrated' in this block, equal to 'reference_membrane[lane] - (reference_membrane[lane] >>> leak_shift) + current_value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are reference_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath; leak_shift: the retained fraction of prior membrane state. Context: the simulation task run step.

Line 89: `- (reference_membrane[lane] >>> leak_shift) + current_value;` This is continuation line 2 of the 2-line logical statement that begins at source line 88. Its exact fragment is '- (reference_membrane[lane] >>> leak_shift) + current_value;'. The important operands are reference_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath; leak_shift: the retained fraction of prior membrane state. Read together, the complete operation is: This makes integrated, the value named 'integrated' in this block, equal to 'reference_membrane[lane] - (reference_membrane[lane] >>> leak_shift) + current_value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are reference_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath; leak_shift: the retained fraction of prior membrane state. Context: the simulation task run step.

Line 90: `expected_membrane[lane] = saturate_reference(integrated);` This makes expected_membrane[lane], the persistent LIF neuron state carrying charge between timesteps, equal to 'saturate_reference(integrated)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturate_reference: the value named 'saturate reference' in this block; integrated: the value named 'integrated' in this block. Context: the simulation task run step.

Line 91: `expected_pre_reset_membrane[lane] = expected_membrane[lane];` This makes expected_pre_reset_membrane[la the persistent LIF neuron state carrying charge between timesteps, equal to 'expected_membrane[lane]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are expected_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task run step.

Line 92: `if (expected_membrane[lane] >= $signed(threshold)) begin` This condition selects the following hardware branch only when 'expected_membrane[lane] >= $signed(threshold)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are expected_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath; threshold: the membrane level at which a neuron emits a spike. Context: the simulation task run step.

Line 93: `expected_spikes[lane] = 1'b1;` This makes expected_spikes[lane], a binary event produced when a neuron crosses its threshold, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task run step.

Line 94: `expected_membrane[lane] = $signed(reset_value);` This makes expected_membrane[lane], the persistent LIF neuron state carrying charge between timesteps, equal to '$signed(reset_value)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are reset_value: the value named 'reset value' in this block. Context: the simulation task run step.

Line 95: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 96: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 98: `while (!input_ready) @(negedge clk);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are while: the value named 'while' in this block; input_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 99: `@(negedge clk);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 100: `input_valid = 1'b1;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task run step.

Line 101: `@(posedge clk);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 102: `@(negedge clk);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 103: `input_valid = 1'b0;` This makes input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task run step.

Line 104: `while (!output_valid) @(negedge clk);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are while: the value named 'while' in this block; output_valid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 105: `repeat (stall_cycles) begin` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; stall_cycles: the value named 'stall cycles' in this block.

Line 106: `if (input_ready) begin` This condition selects the following hardware branch only when 'input_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_ready: the consumer's statement that it can accept a payload this cycle. Context: the simulation task run step.

Line 107: `errors++;` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 108: `$display("ERROR LIF accepted a new step while output was stalled");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 109: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 110: `@(negedge clk);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 111: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 113: `if (!output_valid || spikes !== expected_spikes) begin` This condition selects the following hardware branch only when '!output_valid || spikes !== expected_spikes' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_valid: the producer's statement that its current payload is meaningful; spikes: a binary event produced when a neuron crosses its threshold; expected_spikes: a binary event produced when a neuron crosses its threshold. Context: the simulation task run step.

Line 114: `errors++;` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 115: `$display("ERROR LIF spike mismatch step=%0d got=%h expected=%h",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 116: `reference_timesteps, spikes, expected_spikes);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are reference_timesteps: one discrete SNN update instant; spikes: a binary event produced when a neuron crosses its threshold; expected_spikes: a binary event produced when a neuron crosses its threshold.

Line 117: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 118: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run step.

Line 119: `logic signed [MEMBRANE_BITS-1:0] got_membrane;` This declares hardware signal storage or wiring in the simulation task run step. Specifically, got_membrane is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 120: `logic signed [MEMBRANE_BITS-1:0] got_pre_reset_membrane;` This declares hardware signal storage or wiring in the simulation task run step. Specifically, got_pre_reset_membrane is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 121: `got_membrane = membrane_vector[lane*MEMBRANE_BITS +: MEMBRANE_BITS];` This makes got_membrane, the persistent LIF neuron state carrying charge between timesteps, equal to 'membrane_vector[lane*MEMBRANE_BITS +: MEMBRANE_BITS]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are membrane_vector: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Context: the simulation task run step.

Line 122: `got_pre_reset_membrane = pre_reset_membrane_vector[` This statement continues through source line 123; the explanation uses the complete expression rather than only the first visual fragment. This makes got_pre_reset_membrane, the persistent LIF neuron state carrying charge between timesteps, equal to 'pre_reset_membrane_vector[lane*MEMBRANE_BIT +: MEMBRANE_BITS]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are pre_reset_membrane_vector: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Context: the simulation task run step.

Line 123: `lane*MEMBRANE_BITS +: MEMBRANE_BITS];` This is continuation line 2 of the 2-line logical statement that begins at source line 122. Its exact fragment is 'lane*MEMBRANE_BITS +: MEMBRANE_BITS];'. The important operands are lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This makes got_pre_reset_membrane, the persistent LIF neuron state carrying charge between timesteps, equal to 'pre_reset_membrane_vecto lane*MEMBRANE_BITS +: MEMBRANE_BITS]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are pre_reset_membrane_vector: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Context: the simulation task run step.

Line 124: `if ($signed(got_membrane) !== expected_membrane[lane]) begin` This condition selects the following hardware branch only when ‘$signed(got_membrane) !== expected_membrane[lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are got_membrane: the persistent LIF neuron state carrying charge between timesteps; expected_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task run step.

Line 125: `errors++;` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 126: `if (errors <= 20) begin` This statement continues through source line 128; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR LIF membrane step=%0d lane=%0d got=%0d expected=%0d", reference_timesteps, lane, $signed(got_membrane), expected_membrane[lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task run step.

Line 127: `$display("ERROR LIF membrane step=%0d lane=%0d got=%0d expected=%0d",` This is continuation line 2 of the 3-line logical statement that begins at source line 126. Its exact fragment is ‘$display("ERROR LIF membrane step=%0d lane=%0d got=%0d expected=%0d",‘. The important operands are display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block; LIF: the value named ’lif’ in this block. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR LIF membrane step=%0d lane=%0d got=%0d expected=%0d", reference_timesteps, lane, $signed(got_membrane), expected_membrane[lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task run step.

Line 128: `reference_timesteps, lane, $signed(got_membrane), expected_membrane[lane]);` This is continuation line 3 of the 3-line logical statement that begins at source line 126. Its exact fragment is ‘reference_timesteps, lane, $signed(got_membrane), expected_membrane[lane]);‘. The important operands are reference_timesteps: one discrete SNN update instant; lane: one parallel arithmetic element within a vector or tensor datapath; got_membrane: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR LIF membrane step=%0d lane=%0d got=%0d expected=%0d", reference_timesteps, lane, $signed(got_membrane), expected_membrane[lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block; display: the value named ’display’ in this block; ERROR: the value named ’error’ in this block. Context: the simulation task run step.

Line 129: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 130: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 131: `if ($signed(got_pre_reset_membrane)` This condition selects the following hardware branch only when ‘$signed(got_pre_reset_membrane‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are got_pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the simulation task run step.

Line 132: `!== expected_pre_reset_membrane[lane]) begin` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are expected_pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 133: `errors++;` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 134: `if (errors <= 20) begin` This statement continues through source line 138; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR LIF pre-reset membrane step=%0d lane=%0d got=%0d expected=%0d", reference_timesteps, lane, $signed(got_pre_reset_membrane), expected_pre_reset_membrane[lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run step.

Line 135: `$display("ERROR LIF pre-reset membrane step=%0d lane=%0d got=%0d expected=%0d",` This is continuation line 2 of the 5-line logical statement that begins at source line 134. Its exact fragment is ‘$display("ERROR LIF pre-reset membrane step=%0d lane=%0d got=%0d expected=%0d",‘. The important operands are display: the value named 'display' in this block; ERROR: the value named 'error' in this block; LIF: the value named 'lif' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR LIF pre-reset membrane step=%0d lane=%0d got=%0d expected=%0d", reference_timesteps, lane, $signed(got_pre_reset_membrane), expected_pre_reset_membrane[lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run step.

Line 136: `reference_timesteps, lane,` This is continuation line 3 of the 5-line logical statement that begins at source line 134. Its exact fragment is ‘reference_timesteps, lane,‘. The important operands are reference_timesteps: one discrete SNN update instant; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR LIF pre-reset membrane step=%0d lane=%0d got=%0d expected=%0d", reference_timesteps, lane, $signed(got_pre_reset_membrane), expected_pre_reset_membrane[lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run step.

Line 137: `$signed(got_pre_reset_membrane),` This is continuation line 4 of the 5-line logical statement that begins at source line 134. Its exact fragment is ‘$signed(got_pre_reset_membrane),‘. The important operands are got_pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR LIF pre-reset membrane step=%0d lane=%0d got=%0d expected=%0d", reference_timesteps, lane, $signed(got_pre_reset_membra expected_pre_reset_membrane[lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run step.

Line 138: `expected_pre_reset_membrane[lane]);` This is continuation line 5 of the 5-line logical statement that begins at source line 134. Its exact fragment is ‘expected_pre_reset_membrane[lane]);‘. The important operands are expected_pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This condition selects the following hardware branch only when ‘errors <= 20) begin $display("ERROR LIF pre-reset membrane step=%0d lane=%0d got=%0d expected=%0d", reference_timesteps, lane, $signed(got_pre_reset_membrane), expected_pre_reset_membrane[lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run step.

Line 139: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 140: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 141: `reference_membrane[lane] = expected_membrane[lane];` This makes reference_membrane[lane], the persistent LIF neuron state carrying charge between timesteps, equal to ‘expected_membrane[lane]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are expected_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task run step.

Line 142: `reference_spikes += expected_spikes[lane];` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are reference_spikes: a binary event produced when a neuron crosses its threshold; expected_spikes: a binary event produced when a neuron crosses its threshold; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 143: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 144: `reference_timesteps++;` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are reference_timesteps: one discrete SNN update instant.

Line 146: `output_ready = 1'b1;` This makes output_ready, the consumer’s statement that it can accept a payload this cycle, equal to ‘1’b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named ’b1’ in this block. Context: the simulation task run step.

Line 147: `@(posedge clk);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together.

Line 148: `@(negedge clk);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 149: `output_ready = 1'b0;` This makes output_ready, the consumer’s statement that it can accept a payload this cycle, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task run step.

Line 150: `if (timestep_count != reference_timesteps || total_spike_count != reference_spikes) begin` This condition selects the following hardware branch only when ‘timestep_count != reference_timesteps || total_spike_count != reference_spikes‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are timestep_count: one discrete SNN update instant; reference_timesteps: one discrete SNN update instant; total_spike_count: a binary event produced when a neuron crosses its threshold. Context: the simulation task run step.

Line 151: `errors++;` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are errors: the value named ’errors’ in this block.

Line 152: `$display("ERROR LIF counters got=(%0d,%0d) expected=(%0d,%0d)",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 153: `timestep_count, total_spike_count, reference_timesteps, reference_spikes);` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are timestep_count: one discrete SNN update instant; total_spike_count: a binary event produced when a neuron crosses its threshold; reference_timesteps: one discrete SNN update instant.

Line 154: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 155: `checked++;` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are checked: the value named 'checked' in this block.

Line 156: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run step; it has no arithmetic value of its own.

Line 157: `endtask` Within the simulation task run step, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 159: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 160: `int seed;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are seed: the value named 'seed' in this block.

Line 161: `seed = 32'h1f1f2026;` This makes seed, the value named 'seed' in this block, equal to '32'h1f1f2026'. It is driven by combinational or procedural logic in the current evaluation. The important operands are h1f1f2026: the value named 'h1f1f2026' in this block. Context: the module's structural declarations.

Line 162: `for (int lane = 0; lane < LANES; lane++) reference_membrane[lane] = 0;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 164: `repeat (5) @(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 165: `rst_n = 1'b1;` This makes rst_n, the active-low synchronous reset, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 166: `clear_reference_and_dut(0);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are clear_reference_and_dut: the value named 'clear reference and dut' in this block.

Line 168: `for (int step = 0; step < 100; step++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 169: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 170: `current_vector[lane*CURRENT_BITS +: CURRENT_BITS] =` This statement continues through source line 171; the explanation uses the complete expression rather than only the first visual fragment. Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are current_vector: the value named 'current vector' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; CURRENT_BITS: the value named 'current bits' in this block.

Line 171: `16'($signed(($urandom(seed) % 241) - 120));` This is continuation line 2 of the 2-line logical statement that begins at source line 170. Its exact fragment is '16'($signed(($urandom(seed) % 241) - 120));'. The important operands are urandom: the value named 'urandom' in this block; seed: the value named 'seed' in this block. Read together, the complete operation is: Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are current_vector: the value named 'current vector' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; CURRENT_BITS: the value named 'current bits' in this block.

Line 172: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 173: `leak_shift = 5'(1 + step % 5);` This makes leak_shift, the retained fraction of prior membrane state, equal to '5'(1 + step % 5)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are step: the value named 'step' in this block. Context: the module's structural declarations.

Line 174: `threshold = 24'sd100;` This makes threshold, the membrane level at which a neuron emits a spike, equal to '24'sd100'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd100: the value named 'sd100' in this block. Context: the module's structural declarations.

Line 175: `run_step(step % 4);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are run_step: the value named 'run step' in this block; step: the value named 'step' in this block.

Line 176: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 178: `// Explicit positive saturation boundary.` Design intent: Explicit positive saturation boundary. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation.

Line 179: `clear_reference_and_dut(MAXIMUM_MEMBRANE - 4);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are clear_reference_and_dut: the value named 'clear reference and dut' in this block; MAXIMUM_MEMBRANE: the persistent LIF neuron state carrying charge between timesteps.

Line 180: `leak_shift = 5'd31;` This makes leak_shift, the retained fraction of prior membrane state, equal to '5'd31'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d31: the value named 'd31' in this block. Context: the module's structural declarations.

Line 181: `threshold = 24'sd8388607;` This makes threshold, the membrane level at which a neuron emits a spike, equal to '24'sd8388607'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd8388607: the value named 'sd8388607' in this block. Context: the module's structural declarations.

Line 182: `current_vector = '0;` This makes current_vector, the value named 'current vector' in this block, equal to ''0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 183: `current_vector[CURRENT_BITS-1:0] = 16'sd32767;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are current_vector: the value named 'current vector' in this block; CURRENT_BITS: the value named 'current bits' in this block; sd32767: the value named 'sd32767' in this block.

Line 184: `run_step(2);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are run_step: the value named 'run step' in this block.

Line 186: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 187: `clear_counters = 1'b1;` This makes clear_counters, a hardware telemetry register that accumulates measured events, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 188: `@(posedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 189: `@(negedge clk);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 190: `clear_counters = 1'b0;` This makes clear_counters, a hardware telemetry register that accumulates measured events, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the module's structural declarations.

Line 191: `reference_spikes = 0;` This makes reference_spikes, a binary event produced when a neuron crosses its threshold, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the module's structural declarations.

Line 192: `if (total_spike_count != 0) begin` This condition selects the following hardware branch only when 'total_spike_count != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are total_spike_count: a binary event produced when a neuron crosses its threshold. Context: the module's structural declarations.

Line 193: `errors++;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are errors: the value named 'errors' in this block.

Line 194: `$display("ERROR LIF spike counter did not clear independently");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 195: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 197: `if (errors != 0) begin` This condition selects the following hardware branch only when ‘errors != 0‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named ’errors’ in this block. Context: the module’s structural declarations.

Line 198: `$display("tb_neuraedge_lif_bank FAILED errors=%0d checked=%0d", errors, checked);` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 199: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 200: `end else begin` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 201: `$display("tb_neuraedge_lif_bank PASSED checked=%0d timesteps=%0d spikes=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 202: `checked, reference_timesteps, reference_spikes);` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The important operands are checked: the value named ’checked’ in this block; reference_timesteps: one discrete SNN update instant; reference_spikes: a binary event produced when a neuron crosses its threshold.

Line 203: `$finish;` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 204: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 205: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 207: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 208: `#200_000;` Within the module’s structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 209: `$fatal(1, "tb_neuraedge_lif_bank watchdog timeout");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 210: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 211: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 213: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that drives, backpressures, and checks the neuraedge lif bank RTL block in simulation.

52 tb/tb_neuraedge_linear_backward8.sv

Role in the complete system: drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

52.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

Simulation-only status tb_neuraedge_linear_backward8 is not synthesized into the FPGA. It generates clocks, reset, commands, stalls, and expected values around the design under test, then terminates with an explicit result marker.

Evidence produced The file contains approximately 3 explicit assertions, failure diagnostics, or pass/fail markers. Its VCD/WDB trace is useful evidence only when the final pass marker is present; a simulator exit code by itself is insufficient.

52.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module tb_neuraedge_linear_backward8;` This opens tb_neuraedge_linear_backward8;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

Line 5: `localparam int LANES = 8;` This fixes LANES to 8 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 6: `localparam int RANDOM_CASES = 48;` This fixes RANDOM_CASES to 48 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; RANDOM_CASES denotes the value named 'random cases' in this block.

Line 8: `logic clk = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clk is the clock that makes all registers advance together. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 9: `logic rst_n = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rst_n is the active-low synchronous reset. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 10: `logic clear_counters = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clear_counters is a hardware telemetry register that accumulates measured events. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 11: `logic start_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, start_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 12: `logic start_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, start_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 13: `logic [3:0] active_rows = 4'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_rows is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `logic [3:0] active_inputs = 4'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_inputs is the value named 'active inputs' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `logic [3:0] active_outputs = 4'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_outputs is the value named 'active outputs' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `logic [4:0] input_gradient_shift = 5'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_gradient_shift is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 17: `logic [4:0] weight_gradient_shift = 5'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_gradient_shift is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `logic [1:0] gradient_mode = 2'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gradient_mode is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 19: `logic accumulate_result = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulate_result is the value named 'accumulate result' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic suppress_output = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, suppress_output is the value named 'suppress output' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic reserved_nonzero = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, reserved_nonzero is the value named 'reserved nonzero' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `logic s_axis_tvalid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic s_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `logic [63:0] s_axis_tdata = 64'd0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tdata is the value named 's axis tdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 25: `logic s_axis_tlast = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, s_axis_tlast is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 26: `logic m_axis_tvalid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tvalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic m_axis_tready = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 28: `logic [63:0] m_axis_tdata;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tdata is the value named 'm axis tdata' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `logic m_axis_tlast;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, m_axis_tlast is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 30: `logic busy;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, busy is the value named 'busy' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 31: `logic done;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, done is the value named 'done' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 32: `logic config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, config_error is the value named 'config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `logic [31:0] completed_tiles;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, completed_tiles is the value named 'completed tiles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `logic [31:0] active_cycles;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_cycles is the value named 'active cycles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 36: `integer activation [0:LANES-1][0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 37: `integer weight [0:LANES-1][0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 38: `integer output_gradient [0:LANES-1][0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_gradient is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 39: `logic signed [31:0] expected_input_gradient [0:LANES-1][0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, expected_input_gradient is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 40: `logic signed [23:0] expected_weight_gradient [0:LANES-1][0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, expected_weight_gradient is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 42: `integer errors = 0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, errors is the value named 'errors' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 43: `integer checked_tiles = 0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, checked_tiles is the value named 'checked tiles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 44: `integer seed;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, seed is the value named 'seed' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 45: `logic held_valid = 1'b0;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 46: `logic [63:0] held_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 47: `logic held_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, held_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 49: `neuraedge_linear_backward8 dut (` This instantiates module neuraedge_linear_backward8 as dut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 50: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 51: `.rst_n(rst_n),` This connects the child instance's named port 'rst_n' to parent expression 'rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 52: `.clear_counters(clear_counters),` This connects the child instance's named port 'clear_counters' to parent expression 'clear_counters'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a hardware telemetry register that accumulates measured events.

Line 53: `.start_valid(start_valid),` This connects the child instance's named port 'start_valid' to parent expression 'start_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 54: `.start_ready(start_ready),` This connects the child instance's named port 'start_ready' to parent expression 'start_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 55: `.active_rows(active_rows),` This connects the child instance's named port 'active_rows' to parent expression 'active_rows'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one output-row position processed by the tensor tile.

Line 56: `.active_inputs(active_inputs),` This connects the child instance's named port 'active_inputs' to parent expression 'active_inputs'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'active inputs' in this block.

Line 57: `.active_outputs(active_outputs),` This connects the child instance's named port 'active_outputs' to parent expression 'active_outputs'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'active outputs' in this block.

Line 58: `.input_gradient_shift(input_gradient_shift),` This connects the child instance's named port 'input_gradient_shift' to parent expression 'input_gradient_shift'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the signed loss derivative used to update a learned parameter.

Line 59: `.weight_gradient_shift(weight_gradient_shift),` This connects the child instance's named port 'weight_gradient_ to parent expression 'weight_gradient_shift'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 60: `.gradient_mode(gradient_mode),` This connects the child instance's named port 'gradient_mode' to parent expression 'gradient_mode'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the signed loss derivative used to update a learned parameter.

Line 61: `.accumulate_result(accumulate_result),` This connects the child instance's named port 'accumulate_result' to parent expression 'accumulate_result'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'accumulate result' in this block.

Line 62: `.suppress_output(suppress_output),` This connects the child instance's named port 'suppress_output' to parent expression 'suppress_output'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'suppress output' in this block.

Line 63: `.reserved_nonzero(reserved_nonzero),` This connects the child instance's named port 'reserved_nonzero' to parent expression 'reserved_nonzero'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'reserved nonzero' in this block.

Line 64: `.s_axis_tvalid(s_axis_tvalid),` This connects the child instance's named port 's_axis_tvalid' to parent expression 's_axis_tvalid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 65: `.s_axis_tready(s_axis_tready),` This connects the child instance's named port 's_axis_tready' to parent expression 's_axis_tready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 66: `.s_axis_tdata(s_axis_tdata),` This connects the child instance's named port 's_axis_tdata' to parent expression 's_axis_tdata'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 's axis tdata' in this block.

Line 67: `.s_axis_tlast(s_axis_tlast),` This connects the child instance's named port 's_axis_tlast' to parent expression 's_axis_tlast'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 68: `.m_axis_tvalid(m_axis_tvalid),` This connects the child instance's named port 'm_axis_tvalid' to parent expression 'm_axis_tvalid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 69: `.m_axis_tready(m_axis_tready),` This connects the child instance's named port 'm_axis_tready' to parent expression 'm_axis_tready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 70: `.m_axis_tdata(m_axis_tdata),` This connects the child instance's named port 'm_axis_tdata' to parent expression 'm_axis_tdata'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'm axis tdata' in this block.

Line 71: `.m_axis_tlast(m_axis_tlast),` This connects the child instance's named port 'm_axis_tlast' to parent expression 'm_axis_tlast'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 72: `.busy(busy),` This connects the child instance's named port 'busy' to parent expression 'busy'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'busy' in this block.

Line 73: `.done(done),` This connects the child instance's named port 'done' to parent expression 'done'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'done' in this block.

Line 74: `.config_error(config_error),` This connects the child instance's named port 'config_error' to parent expression 'config_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'config error' in this block.

Line 75: `.completed_tiles(completed_tiles),` This connects the child instance's named port 'completed_tiles' to parent expression 'completed_tiles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'completed tiles' in this block.

Line 76: `.active_cycles(active_cycles)` This connects the child instance's named port 'active_cycles' to parent expression 'active_cycles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'active cycles' in this block.

Line 77: `);` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 79: `always #2.5 clk = ~clk;` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are always: the value named 'always' in this block; clk: the clock that makes all registers advance together.

Line 81: `always @(posedge clk) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are always: the value named 'always' in this block; posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 82: `if (held_valid && (!m_axis_tvalid || m_axis_tdata !== held_data` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are held_valid: the producer's statement that its current payload is meaningful; m_axis_tvalid: the producer's statement that its current payload is meaningful; m_axis_tdata: the value named 'm axis tdata' in this block.

Line 83: `|| m_axis_tlast !== held_last)) begin` Within the module's structural declarations, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; held_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 84: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the module's structural declarations.

Line 85: `$display("ERROR backward output changed while stalled");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 86: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 87: `held_valid <= m_axis_tvalid && !m_axis_tready;` This makes held_valid, the producer's statement that its current payload is meaningful, equal to 'm_axis_tvalid && !m_axis_tready'. It updates after the active clock edge together with other nonblocking assignments. The important operands are m_axis_tvalid: the producer's statement that its current payload is meaningful; m_axis_tready: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 88: `held_data <= m_axis_tdata;` This makes held_data, the payload carried with the surrounding valid/ready handshake, equal to 'm_axis_tdata'. It updates after the active clock edge together with other nonblocking assignments. The important operands are m_axis_tdata: the value named 'm axis tdata' in this block. Context: the module's structural declarations.

Line 89: `held_last <= m_axis_tlast;` This makes held_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'm_axis_tlast'. It updates after the active clock edge together with other nonblocking assignments. The important operands are m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the module's structural declarations.

Line 90: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 92: `function automatic signed [63:0] round_shift_ref(` Within the combinational helper round shift ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; round_shift_ref: the value named 'round shift ref' in this block.

Line 93: `input signed [63:0] value,` This declares value as a input port with width [63:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 94: `input integer shift` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 95: `);` Within the combinational helper round shift ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 96: `reg signed [63:0] magnitude;` This declares hardware signal storage or wiring in the combinational helper round shift ref. Specifically, magnitude is the value named 'magnitude' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 97: `reg signed [63:0] rounded;` This declares hardware signal storage or wiring in the combinational helper round shift ref. Specifically, rounded is the value named 'rounded' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 98: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper round shift ref; it has no arithmetic value of its own.

Line 99: `if (shift == 0) begin` This condition selects the following hardware branch only when 'shift == 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are shift: the value named 'shift' in this block. Context: the combinational helper round shift ref.

Line 100: `round_shift_ref = value;` This makes round_shift_ref, the value named 'round shift ref' in this block, equal to 'value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper round shift ref.

Line 101: `end else begin` This structural keyword opens or closes the branch/process scope described as the combinational helper round shift ref; it has no arithmetic value of its own.

Line 102: `magnitude = value < 0 ? -value : value;` This makes magnitude, the value named 'magnitude' in this block, equal to 'value < 0 ? -value : value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper round shift ref.

Line 103: `rounded = (magnitude + (64'sd1 << (shift - 1))) >>> shift;` This makes rounded, the value named 'rounded' in this block, equal to '(magnitude + (64'sd1 << (shift - 1))) >>> shift'. It is driven by combinational or procedural logic in the current evaluation. The important operands are magnitude: the value named 'magnitude' in this block; sd1: the value named 'sd1' in this block; shift: the value named 'shift' in this block. Context: the combinational helper round shift ref.

Line 104: `round_shift_ref = value < 0 ? -rounded : rounded;` This makes round_shift_ref, the value named 'round shift ref' in this block, equal to 'value < 0 ? -rounded : rounded'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block; rounded: the value named 'rounded' in this block. Context: the combinational helper round shift ref.

Line 105: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper round shift ref; it has no arithmetic value of its own.

Line 106: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper round shift ref; it has no arithmetic value of its own.

Line 107: `endfunction` Within the combinational helper round shift ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endfunction: the value named 'endfunction' in this block.

Line 109: `function automatic signed [31:0] saturate_s32_ref(` Within the combinational helper saturate s32 ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; saturate_s32_ref: the value named 'saturate s32 ref' in this block.

Line 110: `input signed [63:0] value` This declares value as a input port with width [63:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 111: `);` Within the combinational helper saturate s32 ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 112: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s32 ref; it has no arithmetic value of its own.

Line 113: `if (value > 64'sd2147483647) saturate_s32_ref = 32'sh7fffffff;` This condition selects the following hardware branch only when 'value > 64'sd2147483647' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; sd2147483647: the value named 'sd2147483647' in this block. Context: the combinational helper saturate s32 ref.

Line 114: `else if (value < -64'sd2147483648) saturate_s32_ref = 32'sh80000000;` This condition selects the following hardware branch only when 'value < -64'sd2147483648' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; sd2147483648: the value named 'sd2147483648' in this block. Context: the combinational helper saturate s32 ref.

Line 115: `else saturate_s32_ref = value[31:0];` Within the combinational helper saturate s32 ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are saturate_s32_ref: the value named 'saturate s32 ref' in this block; value: the value named 'value' in this block.

Line 116: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s32 ref; it has no arithmetic value of its own.

Line 117: `endfunction` Within the combinational helper saturate s32 ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endfunction: the value named 'endfunction' in this block.

Line 119: `function automatic signed [23:0] saturate_s24_ref(` Within the combinational helper saturate s24 ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; saturate_s24_ref: the value named 'saturate s24 ref' in this block.

Line 120: `input signed [63:0] value` This declares value as a input port with width [63:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 121: `);` Within the combinational helper saturate s24 ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 122: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s24 ref; it has no arithmetic value of its own.

Line 123: `if (value > 64'sd8388607) saturate_s24_ref = 24'sh7fffff;` This condition selects the following hardware branch only when 'value > 64'sd8388607' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; sd8388607: the value named 'sd8388607' in this block. Context: the combinational helper saturate s24 ref.

Line 124: `else if (value < -64'sd8388608) saturate_s24_ref = 24'sh800000;` This condition selects the following hardware branch only when 'value < -64'sd8388608' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; sd8388608: the value named 'sd8388608' in this block. Context: the combinational helper saturate s24 ref.

Line 125: `else saturate_s24_ref = value[23:0];` Within the combinational helper saturate s24 ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are saturate_s24_ref: the value named 'saturate s24 ref' in this block; value: the value named 'value' in this block.

Line 126: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s24 ref; it has no arithmetic value of its own.

Line 127: `endfunction` Within the combinational helper saturate s24 ref, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endfunction: the value named 'endfunction' in this block.

Line 129: `task automatic send_word(input logic [63:0] value, input logic last_value);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; send_word: the value named 'send word' in this block.

Line 130: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task send word; it has no arithmetic value of its own.

Line 131: `while (!s_axis_tready) @(negedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named 'while' in this block; s_axis_tready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 132: `s_axis_tdata = value;` This makes s_axis_tdata, the value named 's axis tdata' in this block, equal to 'value'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the simulation task send word.

Line 133: `s_axis_tlast = last_value;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘last_value‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are last_value: the AXI-Stream marker for the final beat of a packet or command payload. Context: the simulation task send word.

Line 134: `s_axis_tvalid = 1'b1;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to ‘1'b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task send word.

Line 135: `@(posedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 136: `@(negedge clk);` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 137: `s_axis_tvalid = 1'b0;` This makes s_axis_tvalid, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send word.

Line 138: `s_axis_tlast = 1'b0;` This makes s_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1'b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task send word.

Line 139: `s_axis_tdata = 64'd0;` This makes s_axis_tdata, the value named 's axis tdata' in this block, equal to ‘64'd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task send word.

Line 140: `end` This structural keyword opens or closes the branch/process scope described as the simulation task send word; it has no arithmetic value of its own.

Line 141: `endtask` Within the simulation task send word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 143: `task automatic receive_word(` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; receive_word: the value named 'receive word' in this block.

Line 144: `output logic [63:0] value,` This declares value as a output port with width [63:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 145: `output logic last_value,` This declares last_value as a output port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 146: `input integer stall_cycles` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 147: `);` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 148: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task receive word; it has no arithmetic value of its own.

Line 149: `while (!m_axis_tvalid) @(negedge clk);` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named 'while' in this block; m_axis_tvalid: the producer's statement that its current payload is meaningful; negedge: the value named 'negedge' in this block.

Line 150: `repeat (stall_cycles) @(negedge clk);` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are repeat: the value named 'repeat' in this block; stall_cycles: the value named 'stall cycles' in this block; negedge: the value named 'negedge' in this block.

Line 151: `value = m_axis_tdata;` This makes value, the value named 'value' in this block, equal to 'm_axis_tdata'. It is driven by combinational or procedural logic in the current evaluation. The important operands are m_axis_tdata: the value named 'm axis tdata' in this block. Context: the simulation task receive word.

Line 152: `last_value = m_axis_tlast;` This makes last_value, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'm_axis_tlast'. It is driven by combinational or procedural logic in the current evaluation. The important operands are m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the simulation task receive word.

Line 153: `m_axis_tready = 1'b1;` This makes m_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the simulation task receive word.

Line 154: `@(posedge clk);` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 155: `@(negedge clk);` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 156: `m_axis_tready = 1'b0;` This makes m_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the simulation task receive word.

Line 157: `end` This structural keyword opens or closes the branch/process scope described as the simulation task receive word; it has no arithmetic value of its own.

Line 158: `endtask` Within the simulation task receive word, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 160: `task automatic start_tile(` Within the simulation task start tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; start_tile: the value named 'start tile' in this block.

Line 161: `input integer rows,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 162: `input integer inputs,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 163: `input integer outputs,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 164: `input integer dx_shift,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 165: `input integer dw_shift,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 166: `input logic bad_reserved` This declares bad_reserved as a input port with width one bit. It carries the value named 'bad reserved' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 167: `);` Within the simulation task start tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 168: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task start tile; it has no arithmetic value of its own.

Line 169: `while (!start_ready) @(negedge clk);` Within the simulation task start tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named 'while' in this block; start_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 170: `active_rows = rows;` This makes active_rows, one output-row position processed by the tensor tile, equal to ‘rows‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are rows: one output-row position processed by the tensor tile. Context: the simulation task start tile.

Line 171: `active_inputs = inputs;` This makes active_inputs, the value named 'active inputs' in this block, equal to ‘inputs‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are inputs: the value named 'inputs' in this block. Context: the simulation task start tile.

Line 172: `active_outputs = outputs;` This makes active_outputs, the value named 'active outputs' in this block, equal to ‘outputs‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are outputs: the value named 'outputs' in this block. Context: the simulation task start tile.

Line 173: `input_gradient_shift = dx_shift;` This makes input_gradient_shift, the signed loss derivative used to update a learned parameter, equal to ‘dx_shift‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are dx_shift: the value named 'dx shift' in this block. Context: the simulation task start tile.

Line 174: `weight_gradient_shift = dw_shift;` This makes weight_gradient_shift, a learned coefficient multiplied by an activation, equal to ‘dw_shift‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are dw_shift: the value named ’dw shift’ in this block. Context: the simulation task start tile.

Line 175: `gradient_mode = 2'd0;` This makes gradient_mode, the signed loss derivative used to update a learned parameter, equal to ‘2’d0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named ’d0’ in this block. Context: the simulation task start tile.

Line 176: `accumulate_result = 1'b0;` This makes accumulate_result, the value named ’accumulate result’ in this block, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task start tile.

Line 177: `suppress_output = 1'b0;` This makes suppress_output, the value named ’suppress output’ in this block, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task start tile.

Line 178: `reserved_nonzero = bad_reserved;` This makes reserved_nonzero, the value named ’reserved nonzero’ in this block, equal to ‘bad_reserved‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are bad_reserved: the value named ’bad reserved’ in this block. Context: the simulation task start tile.

Line 179: `start_valid = 1'b1;` This makes start_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named ’b1’ in this block. Context: the simulation task start tile.

Line 180: `@(posedge clk);` Within the simulation task start tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together.

Line 181: `@(negedge clk);` Within the simulation task start tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 182: `start_valid = 1'b0;` This makes start_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task start tile.

Line 183: `reserved_nonzero = 1'b0;` This makes reserved_nonzero, the value named ’reserved nonzero’ in this block, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task start tile.

Line 184: `end` This structural keyword opens or closes the branch/process scope described as the simulation task start tile; it has no arithmetic value of its own.

Line 185: `endtask` Within the simulation task start tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endtask: the value named ’endtask’ in this block.

Line 187: `task automatic start_partial_tile(` Within the simulation task start partial tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are task: the value named ’task’ in this block; automatic: the value named ’automatic’ in this block; start_partial_tile: the value named ’start partial tile’ in this block.

Line 188: `input integer rows,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 189: `input integer inputs,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 190: `input integer outputs,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 191: `input integer dx_shift,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 192: `input integer dw_shift,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 193: `input logic [1:0] mode_value,` This declares mode_value as a input port with width [1:0]. It carries the value named 'mode value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 194: `input logic accumulate_value,` This declares accumulate_value as a input port with width one bit. It carries the value named 'accumulate value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 195: `input logic suppress_value` This declares suppress_value as a input port with width one bit. It carries the value named 'suppress value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 196: `);` Within the simulation task start partial tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 197: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task start partial tile; it has no arithmetic value of its own.

Line 198: `while (!start_ready) @(negedge clk);` Within the simulation task start partial tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named 'while' in this block; start_ready: the consumer's statement that it can accept a payload this cycle; negedge: the value named 'negedge' in this block.

Line 199: `active_rows = rows;` This makes active_rows, one output-row position processed by the tensor tile, equal to ‘rows‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are rows: one output-row position processed by the tensor tile. Context: the simulation task start partial tile.

Line 200: `active_inputs = inputs;` This makes active_inputs, the value named 'active inputs' in this block, equal to ‘inputs‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are inputs: the value named 'inputs' in this block. Context: the simulation task start partial tile.

Line 201: `active_outputs = outputs;` This makes active_outputs, the value named 'active outputs' in this block, equal to ‘outputs‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are outputs: the value named 'outputs' in this block. Context: the simulation task start partial tile.

Line 202: `input_gradient_shift = dx_shift;` This makes input_gradient_shift, the signed loss derivative used to update a learned parameter, equal to ‘dx_shift‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are dx_shift: the value named ’dx shift’ in this block. Context: the simulation task start partial tile.

Line 203: `weight_gradient_shift = dw_shift;` This makes weight_gradient_shift, a learned coefficient multiplied by an activation, equal to ‘dw_shift‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are dw_shift: the value named ’dw shift’ in this block. Context: the simulation task start partial tile.

Line 204: `gradient_mode = mode_value;` This makes gradient_mode, the signed loss derivative used to update a learned parameter, equal to ‘mode_value‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are mode_value: the value named ’mode value’ in this block. Context: the simulation task start partial tile.

Line 205: `accumulate_result = accumulate_value;` This makes accumulate_result, the value named ’accumulate result’ in this block, equal to ‘accumulate_value‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are accumulate_value: the value named ’accumulate value’ in this block. Context: the simulation task start partial tile.

Line 206: `suppress_output = suppress_value;` This makes suppress_output, the value named ’suppress output’ in this block, equal to ‘suppress_value‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are suppress_value: the value named ’suppress value’ in this block. Context: the simulation task start partial tile.

Line 207: `reserved_nonzero = 1'b0;` This makes reserved_nonzero, the value named ’reserved nonzero’ in this block, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task start partial tile.

Line 208: `start_valid = 1'b1;` This makes start_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named ’b1’ in this block. Context: the simulation task start partial tile.

Line 209: `@(posedge clk);` Within the simulation task start partial tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together.

Line 210: `@(negedge clk);` Within the simulation task start partial tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 211: `start_valid = 1'b0;` This makes start_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block. Context: the simulation task start partial tile.

Line 212: `end` This structural keyword opens or closes the branch/process scope described as the simulation task start partial tile; it has no arithmetic value of its own.

Line 213: `endtask` Within the simulation task start partial tile, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endtask: the value named ’endtask’ in this block.

Line 215: `task automatic wait_suppressed_done;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; wait_suppressed_done: the value named 'wait suppressed done' in this block.

Line 216: `integer timeout;` This declares hardware signal storage or wiring in the simulation task task. Specifically, timeout is the value named 'timeout' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 217: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 218: `timeout = 0;` This makes timeout, the value named 'timeout' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task task.

Line 219: `while (!done && timeout < 10000) begin` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named 'while' in this block; done: the value named 'done' in this block; timeout: the value named 'timeout' in this block.

Line 220: `@(negedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 221: `if (m_axis_tvalid) begin` This condition selects the following hardware branch only when 'm_axis_tvalid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are m_axis_tvalid: the producer's statement that its current payload is meaningful. Context: the simulation task task.

Line 222: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the simulation task task.

Line 223: `$display("ERROR suppressed backward command emitted output");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 224: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 225: `timeout = timeout + 1;` This makes timeout, the value named 'timeout' in this block, equal to 'timeout + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are timeout: the value named 'timeout' in this block. Context: the simulation task task.

Line 226: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 227: `if (!done) begin` This condition selects the following hardware branch only when '!done' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are done: the value named 'done' in this block. Context: the simulation task task.

Line 228: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the simulation task task.

Line 229: `$display("ERROR suppressed backward command timed out");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 230: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 231: `if (config_error) begin` This condition selects the following hardware branch only when ‘config_error‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are config_error: the value named 'config error' in this block. Context: the simulation task task.

Line 232: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to ‘errors + 1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the simulation task task.

Line 233: `$display("ERROR suppressed backward command reported configuration failure");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 234: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 235: `checked_tiles = checked_tiles + 1;` This makes checked_tiles, the value named 'checked tiles' in this block, equal to ‘checked_tiles + 1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are checked_tiles: the value named 'checked tiles' in this block. Context: the simulation task task.

Line 236: `@(posedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 237: `@(negedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 238: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 239: `endtask` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 241: `task automatic run_exact_accumulation_modes;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; run_exact_accumulation_modes: the value named 'run exact accumulation modes' in this block.

Line 242: `integer row;` This declares hardware signal storage or wiring in the simulation task task. Specifically, row is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 243: `integer input_index;` This declares hardware signal storage or wiring in the simulation task task. Specifically, input_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 244: `integer output_index;` This declares hardware signal storage or wiring in the simulation task task. Specifically, output_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 245: `integer chunk;` This declares hardware signal storage or wiring in the simulation task task. Specifically, chunk is the value named 'chunk' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 246: `integer chunk_size;` This declares hardware signal storage or wiring in the simulation task task. Specifically, chunk_size is the value named 'chunk size' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 247: `integer global_index;` This declares hardware signal storage or wiring in the simulation task task. Specifically, global_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 248: `integer half;` This declares hardware signal storage or wiring in the simulation task task. Specifically, half is the value named 'half' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 249: `integer lane;` This declares hardware signal storage or wiring in the simulation task task. Specifically, lane is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 250: `integer beat_index;` This declares hardware signal storage or wiring in the simulation task task. Specifically, beat_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 251: `integer word_index;` This declares hardware signal storage or wiring in the simulation task task. Specifically, word_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 252: `integer timeout;` This declares hardware signal storage or wiring in the simulation task task. Specifically, timeout is the value named 'timeout' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 253: `reg signed [63:0] accumulator;` This declares hardware signal storage or wiring in the simulation task task. Specifically, accumulator is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 254: `logic [63:0] stream_word;` This declares hardware signal storage or wiring in the simulation task task. Specifically, stream_word is the value named 'stream word' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 255: `logic [63:0] received_word;` This declares hardware signal storage or wiring in the simulation task task. Specifically, received_word is the value named 'received word' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 256: `logic received_last;` This declares hardware signal storage or wiring in the simulation task task. Specifically, received_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 257: `logic [191:0] packed_weight_row;` This declares hardware signal storage or wiring in the simulation task task. Specifically, packed_weight_row is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 258: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 259: `// dX is a reduction over output features. Two commands cover` Design intent: dX is a reduction over output features. Two commands cover This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

Line 260: `// thirteen features while one 47-bit accumulator preserves the` Design intent: thirteen features while one 47-bit accumulator preserves the This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

Line 261: `// exact sum until the final round-by-16 operation.` Design intent: exact sum until the final round-by-16 operation. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

Line 262: `for (row = 0; row < LANES; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 263: `for (input_index = 0; input_index < LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 264: `input_index = input_index + 1) begin` This statement continues through source line 265; the explanation uses the complete expression rather than only the first visual fragment. This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘input_index + 1) begin expected_input_gradient[row][input_index] = 32’sd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; expected_input_gradient: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile. Context: the simulation task task.

Line 265: `expected_input_gradient[row][input_index] = 32’sd0;` This is continuation line 2 of the 2-line logical statement that begins at source line 264. Its exact fragment is ‘expected_input_gradient[row][input_index] = 32’sd0;‘. The important operands are expected_input_gradient: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile; input_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘input_index + 1) begin expected_input_gradient[row][input_index] = 32’sd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; expected_input_gradient: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile. Context: the simulation task task.

Line 266: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 267: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 268: `for (row = 0; row < 5; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 269: `for (input_index = 0; input_index < 6;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 270: `input_index = input_index + 1) begin` This statement continues through source line 271; the explanation uses the complete expression rather than only the first visual fragment. This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘input_index + 1) begin accumulator = 64’sd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; accumulator: a widened running sum that prevents intermediate overflow; sd0: the value named ’sd0’ in this block. Context: the simulation task task.

Line 271: `accumulator = 64’sd0;` This is continuation line 2 of the 2-line logical statement that begins at source line 270. Its exact fragment is ‘accumulator = 64’sd0;‘. The important operands are accumulator: a widened running sum that prevents intermediate overflow; sd0: the value named ’sd0’ in this block. Read together, the complete operation is: This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘input_index + 1) begin accumulator = 64’sd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; accumulator: a widened running sum that prevents intermediate overflow; sd0: the value named ’sd0’ in this block. Context: the simulation task task.

Line 272: `for (output_index = 0; output_index < 13;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 273: `output_index = output_index + 1) begin` This statement continues through source line 276; the explanation uses the complete expression rather than only the first visual fragment. This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index + 1) begin accumulator = accumulator + ((((row*71 + output_index*43 + 11) % 1801) - 900) * (((input_index*97 + output_index*53 + 17) % 2001) - 1000))‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_index: an integer selecting one tensor element, lane, bank, or state entry; accumulator: a widened running sum that prevents intermediate overflow; row: one output-row position processed by the tensor tile. Context: the simulation task task.

Line 274: `accumulator = accumulator` This is continuation line 2 of the 4-line logical statement that begins at source line 273. Its exact fragment is ‘accumulator = accumulator‘. The important operands are accumulator: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index + 1) begin accumulator = accumulator + ((((row*71 + output_index*43 + 11) % 1801) - 900) * (((input_index*97 + output_index*53 + 17) % 2001) - 1000))‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_index: an integer selecting one tensor element, lane, bank, or state entry; accumulator: a widened running sum that prevents intermediate overflow; row: one output-row position processed by the tensor tile. Context: the simulation task task.

Line 275: `+ ((((row*71 + output_index*43 + 11) % 1801) - 900)` This is continuation line 3 of the 4-line logical statement that begins at source line 273. Its exact fragment is ‘+ ((((row*71 + output_index*43 + 11) % 1801) - 900)‘. The important operands are row: one output-row position processed by the tensor tile; output_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index + 1) begin accumulator = accumulator + ((((row*71 + output_index*43 + 11) % 1801) - 900) * (((input_index*97 + output_index*53 + 17) % 2001) - 1000))‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_index: an integer selecting one tensor element, lane, bank, or state entry; accumulator: a widened running sum that prevents intermediate overflow; row: one output-row position processed by the tensor tile. Context: the simulation task task.

Line 276: `* (((input_index*97 + output_index*53 + 17) % 2001) - 1000));` This is continuation line 4 of the 4-line logical statement that begins at source line 273. Its exact fragment is ‘* (((input_index*97 + output_index*53 + 17) % 2001) - 1000));‘. The important operands are input_index: an integer selecting one tensor element, lane, bank,

or state entry; output_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index + 1) begin accumulator = accumulator + ((((row*71 + output_index*43 + 11) % 1801) - 900) * (((input_index*97 + output_index*53 + 17) % 2001) - 1000))‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_index: an integer selecting one tensor element, lane, bank, or state entry; accumulator: a widened running sum that prevents intermediate overflow; row: one output-row position processed by the tensor tile. Context: the simulation task task.

Line 277: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 278: `expected_input_gradient[row][input_index] = saturate_s32_ref(` This statement continues through source line 279; the explanation uses the complete expression rather than only the first visual fragment. This makes expected_input_gradient[row][input_index], the signed loss derivative used to update a learned parameter, equal to ‘saturate_s32_ref(round_shift_ref(accumulator, 4))‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturate_s32_ref: the value named ’saturate s32 ref’ in this block; round_shift_ref: the value named ’round shift ref’ in this block; accumulator: a widened running sum that prevents intermediate overflow. Context: the simulation task task.

Line 279: `round_shift_ref(accumulator, 4));` This is continuation line 2 of the 2-line logical statement that begins at source line 278. Its exact fragment is ‘round_shift_ref(accumulator, 4));‘. The important operands are round_shift_ref: the value named ’round shift ref’ in this block; accumulator: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This makes expected_input_gradient[row][input_index], the signed loss derivative used to update a learned parameter, equal to ‘saturate_s32_ref(round_shift_ref(accumulator, 4))‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturate_s32_ref: the value named ’saturate s32 ref’ in this block; round_shift_ref: the value named ’round shift ref’ in this block; accumulator: a widened running sum that prevents intermediate overflow. Context: the simulation task task.

Line 280: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 281: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 282: `for (chunk = 0; chunk < 2; chunk = chunk + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 283: `chunk_size = chunk == 0 ?  8 :  5;` This makes chunk_size, the value named ’chunk size’ in this block, equal to ‘chunk == 0 ? 8 : 5‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are chunk: the value named ’chunk’ in this block. Context: the simulation task task.

Line 284: `start_partial_tile(5, 6, chunk_size, 4, 0, 2'd1,` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are start_partial_tile: the value named ’start partial tile’ in this block; chunk_size: the value named ’chunk size’ in this block; d1: the value named ’d1’ in this block.

Line 285: `chunk != 0, chunk == 0);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are chunk: the value named ’chunk’ in this block.

Line 286: `for (input_index = 0; input_index < 6;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 287: `input_index = input_index + 1) begin` This statement continues through source line 288; the explanation uses the complete expression rather than only the first visual fragment. This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'input_index + 1) begin for (half = 0; half < 2; half = half + 1) begin'. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named 'for' in this block; half: the value named 'half' in this block. Context: the simulation task task.

Line 288: `for (half = 0; half < 2; half = half + 1) begin` This is continuation line 2 of the 2-line logical statement that begins at source line 287. Its exact fragment is 'for (half = 0; half < 2; half = half + 1) begin'. The important operands are for: the value named 'for' in this block; half: the value named 'half' in this block. Read together, the complete operation is: This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'input_index + 1) begin for (half = 0; half < 2; half = half + 1) begin'. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named 'for' in this block; half: the value named 'half' in this block. Context: the simulation task task.

Line 289: `stream_word = 64'd0;` This makes stream_word, the value named 'stream word' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task task.

Line 290: `for (lane = 0; lane < 4; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 291: `output_index = half * 4 + lane;` This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'half * 4 + lane'. It is driven by combinational or procedural logic in the current evaluation. The important operands are half: the value named 'half' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task task.

Line 292: `if (output_index < chunk_size) begin` This condition selects the following hardware branch only when 'output_index < chunk_size' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_index: an integer selecting one tensor element, lane, bank, or state entry; chunk_size: the value named 'chunk size' in this block. Context: the simulation task task.

Line 293: `global_index = chunk * 8 + output_index;` This makes global_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'chunk * 8 + output_index'. It is driven by combinational or procedural logic in the current evaluation. The important operands are chunk: the value named 'chunk' in this block; output_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 294: `stream_word[lane*16 +:  16] =` This statement continues through source line 295; the explanation uses the complete expression rather than only the first visual fragment. Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named 'stream word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; input_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 295: `((input_index*97 + global_index*53 + 17) % 2001) - 1000;` This is continuation line 2 of the 2-line logical statement that begins at source line 294. Its exact fragment is '((input_index*97 + global_index*53 + 17) % 2001) - 1000;'. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; global_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named 'stream word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; input_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 296: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 297: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 298: `send_word(stream_word, 1'b0);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; stream_word: the value named 'stream word' in this block; b0: the value named 'b0' in this block.

Line 299: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 300: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 301: `for (row = 0; row < 5; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 302: `for (half = 0; half < 2; half = half + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 303: `stream_word = 64'd0;` This makes stream_word, the value named 'stream word' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task task.

Line 304: `for (lane = 0; lane < 4; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 305: `output_index = half * 4 + lane;` This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'half * 4 + lane'. It is driven by combinational or procedural logic in the current evaluation. The important operands are half: the value named 'half' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task task.

Line 306: `if (output_index < chunk_size) begin` This condition selects the following hardware branch only when 'output_index < chunk_size' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_index: an integer selecting one tensor element, lane, bank, or state entry; chunk_size: the value named 'chunk size' in this block. Context: the simulation task task.

Line 307: `global_index = chunk * 8 + output_index;` This makes global_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'chunk * 8 + output_index'. It is driven by combinational or procedural logic in the current evaluation. The important operands are chunk: the value named 'chunk' in this block; output_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 308: `stream_word[lane*16 +:  16] =` This statement continues through source line 309; the explanation uses the complete expression rather than only the first visual fragment. Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named 'stream word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; row: one output-row position processed by the tensor tile.

Line 309: `((row*71 + global_index*43 + 11) % 1801) - 900;` This is continuation line 2 of the 2-line logical statement that begins at source line 308. Its exact fragment is ‘((row*71 + global_index*43 + 11) % 1801) - 900;‘. The important operands are row: one output-row position processed by the tensor tile; global_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named ’stream word’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; row: one output-row position processed by the tensor tile.

Line 310: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 311: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 312: `send_word(stream_word, row == 4 && half == 1);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are send_word: the value named ’send word’ in this block; stream_word: the value named ’stream word’ in this block; row: one output-row position processed by the tensor tile.

Line 313: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 314: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 315: `if (chunk == 0) begin` This condition selects the following hardware branch only when ‘chunk == 0‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are chunk: the value named ’chunk’ in this block. Context: the simulation task task.

Line 316: `wait_suppressed_done();` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are wait_suppressed_done: the value named ’wait suppressed done’ in this block.

Line 317: `end else begin` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 318: `for (beat_index = 0; beat_index < 20;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 319: `beat_index = beat_index + 1) begin` This statement continues through source line 320; the explanation uses the complete expression rather than only the first visual fragment. This makes beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘beat_index + 1) begin receive_word(received_word, received_last, beat_index % 3)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry; receive_word: the value named ’receive word’ in this block; received_word: the value named ’received word’ in this block. Context: the simulation task task.

Line 320: `receive_word(received_word, received_last, beat_index % 3);` This is continuation line 2 of the 2-line logical statement that begins at source line 319. Its exact fragment is ‘receive_word(received_word, received_last, beat_index % 3);‘. The important operands are receive_word: the value named ’receive word’ in this block; received_word: the value named ’received word’ in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This makes beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘beat_index + 1) begin receive_word(received_word, received_last,

beat_index % 3)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry; receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block. Context: the simulation task task.

Line 321: `row = beat_index / 4;` This makes row, one output-row position processed by the tensor tile, equal to ‘beat_index / 4‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 322: `word_index = beat_index % 4;` This makes word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘beat_index % 4‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 323: `for (lane = 0; lane < 2; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 324: `input_index = word_index * 2 + lane;` This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘word_index * 2 + lane‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are word_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task task.

Line 325: `if ($signed(received_word[lane*32 +: 32])` This condition selects the following hardware branch only when ‘$signed(received_word[lane*32 +: 32]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_word: the value named 'received word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task task.

Line 326: `!== expected_input_gradient[row][input_index]) begin` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are expected_input_gradient: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile; input_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 327: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to ‘errors + 1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the simulation task task.

Line 328: `$display("ERROR accumulated dX row=%0d lane=%0d got=%0d expected=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 329: `row, input_index,` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are row: one output-row position processed by the tensor tile; input_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 330: `$signed(received_word[lane*32 +: 32]),` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are received_word: the value named 'received word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 331: `expected_input_gradient[row][input_index]);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are expected_input_gradient: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile; input_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 332: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 333: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 334: `if (received_last != (beat_index == 19)) errors = errors + 1;` This condition selects the following hardware branch only when ‘received_last != (beat_index == 19)‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 335: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 336: `timeout = 0;` This makes timeout, the value named ’timeout’ in this block, equal to ‘0‘. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task task.

Line 337: `while (!done && timeout < 20) begin` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named ’while’ in this block; done: the value named ’done’ in this block; timeout: the value named ’timeout’ in this block.

Line 338: `@(negedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named ’negedge’ in this block; clk: the clock that makes all registers advance together.

Line 339: `timeout = timeout + 1;` This makes timeout, the value named ’timeout’ in this block, equal to ‘timeout + 1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are timeout: the value named ’timeout’ in this block. Context: the simulation task task.

Line 340: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 341: `if (!done || config_error) errors = errors + 1;` This condition selects the following hardware branch only when ‘!done || config_error‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are done: the value named ’done’ in this block; config_error: the value named ’config error’ in this block. Context: the simulation task task.

Line 342: `checked_tiles = checked_tiles + 1;` This makes checked_tiles, the value named ’checked tiles’ in this block, equal to ‘checked_tiles + 1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are checked_tiles: the value named ’checked tiles’ in this block. Context: the simulation task task.

Line 343: `@(posedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named ’posedge’ in this block; clk: the clock that makes all registers advance together.

Line 344: `@(negedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 345: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 346: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 348: `// dW is a reduction over rows. Thirteen rows are split 8+5; the` Design intent: dW is a reduction over rows. Thirteen rows are split 8+5; the This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

Line 349: `// dW-only mode consequently omits every weight input beat.` Design intent: dW-only mode consequently omits every weight input beat. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

Line 350: `for (input_index = 0; input_index < LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 351: `input_index = input_index + 1) begin` This statement continues through source line 352; the explanation uses the complete expression rather than only the first visual fragment. This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘input_index + 1) begin for (output_index = 0; output_index < LANES‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named 'for' in this block; output_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 352: `for (output_index = 0; output_index < LANES;` This is continuation line 2 of the 2-line logical statement that begins at source line 351. Its exact fragment is ‘for (output_index = 0; output_index < LANES;‘. The important operands are for: the value named 'for' in this block; output_index: an integer selecting one tensor element, lane, bank, or state entry; LANES: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘input_index + 1) begin for (output_index = 0; output_index < LANES‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named 'for' in this block; output_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 353: `output_index = output_index + 1) begin` This statement continues through source line 354; the explanation uses the complete expression rather than only the first visual fragment. This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index + 1) begin expected_weight_gradient[input_index][output = 24’sd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_index: an integer selecting one tensor element, lane, bank, or state entry; expected_weight_gradient: a learned coefficient multiplied by an activation; input_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 354: `expected_weight_gradient[input_index][output_index] = 24’sd0;` This is continuation line 2 of the 2-line logical statement that begins at source line 353. Its exact fragment is ‘expected_weight_gradient[input_index][output_index] = 24’sd0;‘. The important operands are expected_weight_gradient: a learned coefficient multiplied by an activation; input_index: an integer selecting one tensor element, lane, bank, or state entry; output_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index + 1) begin expected_weight_gradient[input_index][output_index] = 24’sd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_index: an integer selecting one tensor element, lane, bank,

or state entry; expected_weight_gradient: a learned coefficient multiplied by an activation; input_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 355: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 356: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 357: `for (input_index = 0; input_index < 6;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 358: `input_index = input_index + 1) begin` This statement continues through source line 359; the explanation uses the complete expression rather than only the first visual fragment. This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘input_index + 1) begin for (output_index = 0; output_index < 7‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named ’for’ in this block; output_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 359: `for (output_index = 0; output_index < 7;` This is continuation line 2 of the 2-line logical statement that begins at source line 358. Its exact fragment is ‘for (output_index = 0; output_index < 7;‘. The important operands are for: the value named ’for’ in this block; output_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘input_index + 1) begin for (output_index = 0; output_index < 7‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named ’for’ in this block; output_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 360: `output_index = output_index + 1) begin` This statement continues through source line 361; the explanation uses the complete expression rather than only the first visual fragment. This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index + 1) begin accumulator = 64’sd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_index: an integer selecting one tensor element, lane, bank, or state entry; accumulator: a widened running sum that prevents intermediate overflow; sd0: the value named ’sd0’ in this block. Context: the simulation task task.

Line 361: `accumulator = 64'sd0;` This is continuation line 2 of the 2-line logical statement that begins at source line 360. Its exact fragment is ‘accumulator = 64’sd0;‘. The important operands are accumulator: a widened running sum that prevents intermediate overflow; sd0: the value named ’sd0’ in this block. Read together, the complete operation is: This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index + 1) begin accumulator = 64’sd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_index: an integer selecting one tensor element, lane, bank, or state entry; accumulator: a widened running sum that prevents intermediate overflow; sd0: the value named ’sd0’ in this block. Context: the simulation task task.

Line 362: `for (row = 0; row < 13; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 363: `accumulator = accumulator` This statement continues through source line 365; the explanation uses the complete expression rather than only the first visual fragment. This makes accumulator, a widened running sum that prevents intermediate overflow, equal to ‘accumulator + ((((row*29 + input_index*13 + 7) % 255) - 127) * (((row*71 + output_index*43 + 11) % 1801) - 900))‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are accumulator: a widened running sum that prevents intermediate overflow; row: one output-row

position processed by the tensor tile; input_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 364: `+ ((((row*29 + input_index*13 + 7) % 255) - 127)` This is continuation line 2 of the 3-line logical statement that begins at source line 363. Its exact fragment is '+ ((((row*29 + input_index*13 + 7) % 255) - 127)'. The important operands are row: one output-row position processed by the tensor tile; input_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes accumulator, a widened running sum that prevents intermediate overflow, equal to 'accumulator + ((((row*29 + input_index*13 + 7) % 255) - 127) * (((row*71 + output_index*43 + 11) % 1801) - 900))'. It is driven by combinational or procedural logic in the current evaluation. The important operands are accumulator: a widened running sum that prevents intermediate overflow; row: one output-row position processed by the tensor tile; input_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 365: `* (((row*71 + output_index*43 + 11) % 1801) - 900));` This is continuation line 3 of the 3-line logical statement that begins at source line 363. Its exact fragment is '* (((row*71 + output_index*43 + 11) % 1801) - 900));'. The important operands are row: one output-row position processed by the tensor tile; output_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes accumulator, a widened running sum that prevents intermediate overflow, equal to 'accumulator + ((((row*29 + input_index*13 + 7) % 255) - 127) * (((row*71 + output_index*43 + 11) % 1801) - 900))'. It is driven by combinational or procedural logic in the current evaluation. The important operands are accumulator: a widened running sum that prevents intermediate overflow; row: one output-row position processed by the tensor tile; input_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 366: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 367: `expected_weight_gradient[input_index][output_index]` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are expected_weight_gradient: a learned coefficient multiplied by an activation; input_index: an integer selecting one tensor element, lane, bank, or state entry; output_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 368: `= saturate_s24_ref(round_shift_ref(accumulator, 3));` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are saturate_s24_ref: the value named 'saturate s24 ref' in this block; round_shift_ref: the value named 'round shift ref' in this block; accumulator: a widened running sum that prevents intermediate overflow.

Line 369: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 370: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 371: `for (chunk = 0; chunk < 2; chunk = chunk + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 372: `chunk_size = chunk == 0 ?  8 :  5;` This makes chunk_size, the value named 'chunk size' in this block, equal to 'chunk == 0 ? 8 : 5'. It is driven by combinational or procedural logic in the current evaluation. The important operands are chunk: the value named 'chunk' in this block. Context: the simulation task task.

Line 373: `start_partial_tile(chunk_size, 6, 7, 0, 3, 2'd2,` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are start_partial_tile: the value named 'start partial tile' in this block; chunk_size: the value named 'chunk size' in this block; d2: the value named 'd2' in this block.

Line 374: `chunk != 0, chunk == 0);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are chunk: the value named 'chunk' in this block.

Line 375: `for (row = 0; row < chunk_size; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 376: `global_index = chunk * 8 + row;` This makes global_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'chunk * 8 + row'. It is driven by combinational or procedural logic in the current evaluation. The important operands are chunk: the value named 'chunk' in this block; row: one output-row position processed by the tensor tile. Context: the simulation task task.

Line 377: `for (half = 0; half < 2; half = half + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 378: `stream_word = 64'd0;` This makes stream_word, the value named 'stream word' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task task.

Line 379: `for (lane = 0; lane < 4; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 380: `input_index = half * 4 + lane;` This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'half * 4 + lane'. It is driven by combinational or procedural logic in the current evaluation. The important operands are half: the value named 'half' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task task.

Line 381: `if (input_index < 6) begin` This condition selects the following hardware branch only when 'input_index < 6' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 382: `stream_word[lane*16 +: 16] =` This statement continues through source line 383; the explanation uses the complete expression rather than only the first visual fragment. Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named 'stream word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; global_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 383: `((global_index*29 + input_index*13 + 7) % 255) - 127;` This is continuation line 2 of the 2-line logical statement that begins at source line 382. Its exact fragment is '((global_index*29 + input_index*13 + 7) % 255) - 127;'. The important operands are global_index: an integer selecting one tensor element, lane, bank, or state entry; input_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named 'stream word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; global_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 384: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 385: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 386: `send_word(stream_word, 1'b0);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; stream_word: the value named 'stream word' in this block; b0: the value named 'b0' in this block.

Line 387: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 388: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 389: `for (row = 0; row < chunk_size; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 390: `global_index = chunk * 8 + row;` This makes global_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'chunk * 8 + row'. It is driven by combinational or procedural logic in the current evaluation. The important operands are chunk: the value named 'chunk' in this block; row: one output-row position processed by the tensor tile. Context: the simulation task task.

Line 391: `for (half = 0; half < 2; half = half + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 392: `stream_word = 64'd0;` This makes stream_word, the value named 'stream word' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task task.

Line 393: `for (lane = 0; lane < 4; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 394: `output_index = half * 4 + lane;` This makes output_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'half * 4 + lane'. It is driven by combinational or procedural logic in the current evaluation. The important operands are half: the value named 'half' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task task.

Line 395: `if (output_index < 7) begin` This condition selects the following hardware branch only when 'output_index < 7' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 396: `stream_word[lane*16 +: 16] =` This statement continues through source line 397; the explanation uses the complete expression rather than only the first visual fragment. Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named 'stream word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; global_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 397: `((global_index*71 + output_index*43 + 11) % 1801) - 900;` This is continuation line 2 of the 2-line logical statement that begins at source line 396. Its exact fragment is '((global_index*71 + output_index*43 + 11) % 1801) - 900;'. The important operands are global_index: an integer selecting one tensor element, lane, bank, or state entry; output_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named 'stream word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; global_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 398: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 399: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 400: `send_word(stream_word,` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; stream_word: the value named 'stream word' in this block.

Line 401: `row == chunk_size - 1 && half == 1);` This makes row, one output-row position processed by the tensor tile, equal to '= chunk_size - 1 && half == 1)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are chunk_size: the value named 'chunk size' in this block; half: the value named 'half' in this block. Context: the simulation task task.

Line 402: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 403: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 404: `if (chunk == 0) begin` This condition selects the following hardware branch only when 'chunk == 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are chunk: the value named 'chunk' in this block. Context: the simulation task task.

Line 405: `wait_suppressed_done();` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are wait_suppressed_done: the value named 'wait suppressed done' in this block.

Line 406: `end else begin` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 407: `packed_weight_row = 192'd0;` This makes packed_weight_row, a learned coefficient multiplied by an activation, equal to '192'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task task.

Line 408: `for (beat_index = 0; beat_index < 18;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 409: `beat_index = beat_index + 1) begin` This statement continues through source line 410; the explanation uses the complete expression rather than only the first visual fragment. This makes beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'beat_index + 1) begin receive_word(received_word, received_last, beat_index % 4)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry; receive_word: the value named

'receive word' in this block; received_word: the value named 'received word' in this block. Context: the simulation task task.

Line 410: `receive_word(received_word, received_last, beat_index % 4);` This is continuation line 2 of the 2-line logical statement that begins at source line 409. Its exact fragment is 'receive_word(received_word, received_last, beat_index % 4);'. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This makes beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'beat_index + 1) begin receive_word(received_word, received_last, beat_index % 4)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry; receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block. Context: the simulation task task.

Line 411: `input_index = beat_index / 3;` This makes input_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'beat_index / 3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 412: `word_index = beat_index % 3;` This makes word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'beat_index % 3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 413: `packed_weight_row[word_index*64 +: 64] = received_word;` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are packed_weight_row: a learned coefficient multiplied by an activation; word_index: an integer selecting one tensor element, lane, bank, or state entry; received_word: the value named 'received word' in this block.

Line 414: `if (word_index == 2) begin` This condition selects the following hardware branch only when 'word_index == 2' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 415: `for (lane = 0; lane < LANES; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task task.

Line 416: `if ($signed(packed_weight_row[lane*24 +: 24])` This condition selects the following hardware branch only when '$signed(packed_weight_row[lane*24 +: 24]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are packed_weight_row: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task task.

Line 417: `!== expected_weight_gradient[input_index][lane]) begin` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are expected_weight_gradient: a learned coefficient multiplied by an activation; input_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 418: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the simulation task task.

Line 419: `$display("ERROR accumulated dW row=%0d lane=%0d got=%0d expected=%0d",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 420: `input_index, lane,` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are input_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 421: `$signed(packed_weight_row[lane*24 +: 24]),` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are packed_weight_row: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 422: `expected_weight_gradient[input_index][lane]);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are expected_weight_gradient: a learned coefficient multiplied by an activation; input_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 423: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 424: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 425: `packed_weight_row = 192'd0;` This makes packed_weight_row, a learned coefficient multiplied by an activation, equal to '192'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task task.

Line 426: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 427: `if (received_last != (beat_index == 17)) errors = errors + 1;` This condition selects the following hardware branch only when 'received_last != (beat_index == 17)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task task.

Line 428: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 429: `timeout = 0;` This makes timeout, the value named 'timeout' in this block, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task task.

Line 430: `while (!done && timeout < 20) begin` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named 'while' in this block; done: the value named 'done' in this block; timeout: the value named 'timeout' in this block.

Line 431: `@(negedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 432: `timeout = timeout + 1;` This makes timeout, the value named 'timeout' in this block, equal to 'timeout + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are timeout: the value named 'timeout' in this block. Context: the simulation task task.

Line 433: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 434: `if (!done || config_error) errors = errors + 1;` This condition selects the following hardware branch only when '!done || config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are done: the value named 'done' in this block; config_error: the value named 'config error' in this block. Context: the simulation task task.

Line 435: `checked_tiles = checked_tiles + 1;` This makes checked_tiles, the value named 'checked tiles' in this block, equal to 'checked_tiles + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are checked_tiles: the value named 'checked tiles' in this block. Context: the simulation task task.

Line 436: `@(posedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 437: `@(negedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 438: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 439: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 441: `// Emitting the final result invalidates the retained shape.` Design intent: Emitting the final result invalidates the retained shape. This comment anchors the surrounding logic in the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation.

Line 442: `start_partial_tile(5, 6, 5, 4, 0, 2'd1, 1'b1, 1'b1);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are start_partial_tile: the value named 'start partial tile' in this block; d1: the value named 'd1' in this block; b1: the value named 'b1' in this block.

Line 443: `while (!done) @(negedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are while: the value named 'while' in this block; done: the value named 'done' in this block; negedge: the value named 'negedge' in this block.

Line 444: `if (!config_error) begin` This condition selects the following hardware branch only when '!config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are config_error: the value named 'config error' in this block. Context: the simulation task task.

Line 445: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the simulation task task.

Line 446: `$display("ERROR stale dX accumulator remained valid after final output");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 447: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 448: `@(posedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are posedge: the value named 'posedge' in this block; clk: the clock that makes all registers advance together.

Line 449: `@(negedge clk);` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are negedge: the value named 'negedge' in this block; clk: the clock that makes all registers advance together.

Line 450: `end` This structural keyword opens or closes the branch/process scope described as the simulation task task; it has no arithmetic value of its own.

Line 451: `endtask` Within the simulation task task, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 453: `task automatic prepare_case(` Within the simulation task prepare case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; prepare_case: the value named 'prepare case' in this block.

Line 454: `input integer rows,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 455: `input integer inputs,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 456: `input integer outputs,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 457: `input integer pattern,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 458: `input integer dx_shift,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 459: `input integer dw_shift` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 460: `);` Within the simulation task prepare case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 461: `integer row;` This declares hardware signal storage or wiring in the simulation task prepare case. Specifically, row is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 462: `integer column;` This declares hardware signal storage or wiring in the simulation task prepare case. Specifically, column is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 463: `integer reduction;` This declares hardware signal storage or wiring in the simulation task prepare case. Specifically, reduction is the value named 'reduction' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 464: `reg signed [63:0] accumulator;` This declares hardware signal storage or wiring in the simulation task prepare case. Specifically, accumulator is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 465: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 466: `for (row = 0; row < LANES; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 467: `for (column = 0; column < LANES; column = column + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 468: `activation[row][column] = 0;` This makes activation[row][column], an input feature value consumed by a neuron or multiply-accumulate operation, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task prepare case.

Line 469: `weight[row][column] = 0;` This makes weight[row][column], a learned coefficient multiplied by an activation, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task prepare case.

Line 470: `output_gradient[row][column] = 0;` This makes output_gradient[row][column], the signed loss derivative used to update a learned parameter, equal to '0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the simulation task prepare case.

Line 471: `expected_input_gradient[row][column] = 32'sd0;` This makes expected_input_gradient[row][column], the signed loss derivative used to update a learned parameter, equal to '32'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the simulation task prepare case.

Line 472: `expected_weight_gradient[row][column] = 24'sd0;` This makes expected_weight_gradient[row][column], a learned coefficient multiplied by an activation, equal to '24'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the simulation task prepare case.

Line 473: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 474: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 476: `for (row = 0; row < rows; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 477: `for (column = 0; column < inputs; column = column + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 478: `if (pattern == 1) activation[row][column] = 127;` This condition selects the following hardware branch only when ‘pattern == 1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pattern: the value named 'pattern' in this block. Context: the simulation task prepare case.

Line 479: `else if (pattern == 2) activation[row][column] = -128;` This condition selects the following hardware branch only when ‘pattern == 2‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pattern: the value named 'pattern' in this block. Context: the simulation task prepare case.

Line 480: `else if (pattern == 3) activation[row][column] = 127;` This condition selects the following hardware branch only when ‘pattern == 3‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pattern: the value named 'pattern' in this block. Context: the simulation task prepare case.

Line 481: `else activation[row][column] = $urandom_range(255, 0) - 128;` Within the simulation task prepare case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are activation: an input feature value consumed by a neuron or multiply-accumulate operation; row: one output-row position processed by the tensor tile; column: one output-feature position processed in parallel.

Line 482: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 483: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 484: `for (row = 0; row < inputs; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 485: `for (column = 0; column < outputs; column = column + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 486: `if (pattern == 1) weight[row][column] = -32768;` This condition selects the following hardware branch only when ‘pattern == 1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pattern: the value named 'pattern' in this block. Context: the simulation task prepare case.

Line 487: `else if (pattern == 2) weight[row][column] = 32767;` This condition selects the following hardware branch only when ‘pattern == 2‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pattern: the value named ’pattern’ in this block. Context: the simulation task prepare case.

Line 488: `else if (pattern == 3) weight[row][column] = 32767;` This condition selects the following hardware branch only when ‘pattern == 3‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pattern: the value named ’pattern’ in this block. Context: the simulation task prepare case.

Line 489: `else weight[row][column] = $urandom_range(65535, 0) - 32768;` Within the simulation task prepare case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are weight: a learned coefficient multiplied by an activation; row: one output-row position processed by the tensor tile; column: one output-feature position processed in parallel.

Line 490: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 491: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 492: `for (row = 0; row < rows; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 493: `for (column = 0; column < outputs; column = column + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 494: `if (pattern == 1) output_gradient[row][column] = -32768;` This condition selects the following hardware branch only when ‘pattern == 1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pattern: the value named ’pattern’ in this block. Context: the simulation task prepare case.

Line 495: `else if (pattern == 2) output_gradient[row][column] = 32767;` This condition selects the following hardware branch only when ‘pattern == 2‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pattern: the value named ’pattern’ in this block. Context: the simulation task prepare case.

Line 496: `else if (pattern == 3) output_gradient[row][column] = -32768;` This condition selects the following hardware branch only when ‘pattern == 3‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pattern: the value named ’pattern’ in this block. Context: the simulation task prepare case.

Line 497: `else output_gradient[row][column] = $urandom_range(65535, 0) - 32768;` Within the simulation task prepare case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile; column: one output-feature position processed in parallel.

Line 498: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 499: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 501: `for (row = 0; row < rows; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 502: `for (column = 0; column < inputs; column = column + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 503: `accumulator = 64'sd0;` This makes accumulator, a widened running sum that prevents intermediate overflow, equal to '64'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the simulation task prepare case.

Line 504: `for (reduction = 0; reduction < outputs; reduction = reduction + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 505: `accumulator = accumulator` This statement continues through source line 506; the explanation uses the complete expression rather than only the first visual fragment. This makes accumulator, a widened running sum that prevents intermediate overflow, equal to 'accumulator + output_gradient[row][reduction] * weight[column][reduction]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are accumulator: a widened running sum that prevents intermediate overflow; output_gradient: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile. Context: the simulation task prepare case.

Line 506: `+ output_gradient[row][reduction] * weight[column][reduction];` This is continuation line 2 of the 2-line logical statement that begins at source line 505. Its exact fragment is '+ output_gradient[row][reduction] * weight[column][reduction];'. The important operands are output_gradient: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile; reduction: the value named 'reduction' in this block. Read together, the complete operation is: This makes accumulator, a widened running sum that prevents intermediate overflow, equal to 'accumulator + output_gradient[row][reduction] * weight[column][reduction]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are accumulator: a widened running sum that prevents intermediate overflow; output_gradient: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile. Context: the simulation task prepare case.

Line 507: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 508: `expected_input_gradient[row][column] = saturate_s32_ref(` This statement continues through source line 509; the explanation uses the complete expression rather than only the first visual fragment. This makes expected_input_gradient[row][column], the signed loss derivative used to update a learned parameter, equal to 'saturate_s32_ref(round_shift_ref(accumulator, dx_shift))'. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturate_s32_ref: the value named 'saturate s32 ref' in this block; round_shift_ref: the value named 'round shift ref' in this block; accumulator: a widened running sum that prevents intermediate overflow. Context: the simulation task prepare case.

Line 509: `round_shift_ref(accumulator, dx_shift));` This is continuation line 2 of the 2-line logical statement that begins at source line 508. Its exact fragment is 'round_shift_ref(accumulator, dx_shift));'. The important operands are round_shift_ref: the value named 'round shift ref' in this block; accumulator: a widened running sum that prevents intermediate overflow; dx_shift: the value named 'dx shift' in this block. Read together, the complete operation is: This makes expected_input_gradient[row][column], the signed loss derivative used to update a learned parameter, equal to 'saturate_s32_ref(round_shift_ref(accumulator, dx_shift))'. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturate_s32_ref: the value named 'saturate s32 ref' in this block;

round_shift_ref: the value named 'round shift ref' in this block; accumulator: a widened running sum that prevents intermediate overflow. Context: the simulation task prepare case.

Line 510: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 511: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 512: `for (row = 0; row < inputs; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 513: `for (column = 0; column < outputs; column = column + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 514: `accumulator = 64'sd0;` This makes accumulator, a widened running sum that prevents intermediate overflow, equal to '64'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the simulation task prepare case.

Line 515: `for (reduction = 0; reduction < rows; reduction = reduction + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task prepare case.

Line 516: `accumulator = accumulator` This statement continues through source line 517; the explanation uses the complete expression rather than only the first visual fragment. This makes accumulator, a widened running sum that prevents intermediate overflow, equal to 'accumulator + activation[reduction][row] * output_gradient[reduction][column]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are accumulator: a widened running sum that prevents intermediate overflow; activation: an input feature value consumed by a neuron or multiply-accumulate operation; reduction: the value named 'reduction' in this block. Context: the simulation task prepare case.

Line 517: `+ activation[reduction][row] * output_gradient[reduction][column];` This is continuation line 2 of the 2-line logical statement that begins at source line 516. Its exact fragment is '+ activation[reduction][row] * output_gradient[reduction][column];'. The important operands are activation: an input feature value consumed by a neuron or multiply-accumulate operation; reduction: the value named 'reduction' in this block; row: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes accumulator, a widened running sum that prevents intermediate overflow, equal to 'accumulator + activation[reduction][row] * output_gradient[reduction][column]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are accumulator: a widened running sum that prevents intermediate overflow; activation: an input feature value consumed by a neuron or multiply-accumulate operation; reduction: the value named 'reduction' in this block. Context: the simulation task prepare case.

Line 518: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 519: `expected_weight_gradient[row][column] = saturate_s24_ref(` This statement continues through source line 520; the explanation uses the complete expression rather than only the first visual fragment. This makes expected_weight_gradient[row][column], a learned coefficient multiplied by an activation, equal to 'saturate_s24_ref(round_shift_ref(accumulator, dw_shift))'. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturate_s24_ref: the value named 'saturate s24 ref' in this block; round_shift_ref: the value named 'round shift ref' in this block; accumulator: a widened running sum that prevents intermediate overflow. Context: the simulation task prepare case.

Line 520: `round_shift_ref(accumulator, dw_shift));` This is continuation line 2 of the 2-line logical statement that begins at source line 519. Its exact fragment is 'round_shift_ref(accumulator, dw_shift));'. The important operands are round_shift_ref: the value named 'round shift ref' in this block; accumulator: a widened running sum that prevents intermediate overflow; dw_shift: the value named 'dw shift' in this block. Read together, the complete operation is: This makes expected_weight_gradient[row][column], a learned coefficient multiplied by an activation, equal to 'saturate_s24_ref(round_shift_ref(accumulator, dw_shift))'. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturate_s24_ref: the value named 'saturate s24 ref' in this block; round_shift_ref: the value named 'round shift ref' in this block; accumulator: a widened running sum that prevents intermediate overflow. Context: the simulation task prepare case.

Line 521: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 522: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 523: `end` This structural keyword opens or closes the branch/process scope described as the simulation task prepare case; it has no arithmetic value of its own.

Line 524: `endtask` Within the simulation task prepare case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are endtask: the value named 'endtask' in this block.

Line 526: `task automatic run_case(` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are task: the value named 'task' in this block; automatic: the value named 'automatic' in this block; run_case: the value named 'run case' in this block.

Line 527: `input integer rows,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 528: `input integer inputs,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 529: `input integer outputs,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 530: `input integer pattern,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 531: `input integer dx_shift,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 532: `input integer dw_shift,` This declares integer as a input port with width one bit. It carries the value named 'integer' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 533: `input logic malformed_tlast` This declares malformed_tlast as a input port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 534: `);` Within the simulation task run case, this exact statement contributes to the block that drives, back-pressures, and checks the neuraedge linear backward8 RTL block in simulation. The expression is a literal or structural operator and has no hidden software state.

Line 535: `integer row;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, row is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 536: `integer lane;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, lane is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 537: `integer half;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, half is the value named 'half' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 538: `integer beat_index;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, beat_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 539: `integer row_index;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, row_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 540: `integer word_index;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, word_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 541: `integer lane_index;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, lane_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 542: `integer total_output_beats;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, total_output_beats is the value named 'total output beats' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 543: `integer timeout;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, timeout is the value named 'timeout' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 544: `logic [63:0] stream_word;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, stream_word is the value named 'stream word' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 545: `logic [63:0] received_word;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, received_word is the value named 'received word' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 546: `logic received_last;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, received_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 547: `logic [191:0] packed_weight_row;` This declares hardware signal storage or wiring in the simulation task run case. Specifically, packed_weight_row is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 548: `begin` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 549: `prepare_case(rows, inputs, outputs, pattern, dx_shift, dw_shift);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are prepare_case: the value named 'prepare case' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block.

Line 550: `start_tile(rows, inputs, outputs, dx_shift, dw_shift, 1'b0);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are start_tile: the value named 'start tile' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block.

Line 552: `for (row = 0; row < rows; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 553: `for (half = 0; half < 2; half = half + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 554: `stream_word = 64'd0;` This makes stream_word, the value named 'stream word' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task run case.

Line 555: `for (lane = 0; lane < 4; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 556: `stream_word[lane*16 +: 16] = activation[row][half*4 + lane];` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named 'stream word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; activation: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 557: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 558: `send_word(stream_word,` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; stream_word: the value named 'stream word' in this block.

Line 559: `malformed_tlast && row == 0 && half == 0);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are malformed_tlast: the AXI-Stream marker for the final beat of a packet or command payload; row: one output-row position processed by the tensor tile; half: the value named 'half' in this block.

Line 560: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 561: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 562: `for (row = 0; row < inputs; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 563: `for (half = 0; half < 2; half = half + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 564: `stream_word = 64'd0;` This makes stream_word, the value named 'stream word' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task run case.

Line 565: `for (lane = 0; lane < 4; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 566: `stream_word[lane*16 +: 16] = weight[row][half*4 + lane];` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named 'stream word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; weight: a learned coefficient multiplied by an activation.

Line 567: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 568: `send_word(stream_word, 1'b0);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; stream_word: the value named 'stream word' in this block; b0: the value named 'b0' in this block.

Line 569: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 570: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 571: `for (row = 0; row < rows; row = row + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 572: `for (half = 0; half < 2; half = half + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 573: `stream_word = 64'd0;` This makes stream_word, the value named 'stream word' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task run case.

Line 574: `for (lane = 0; lane < 4; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 575: `stream_word[lane*16 +:  16] = output_gradient[row][half*4 + lane];` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are stream_word: the value named 'stream word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; output_gradient: the signed loss derivative used to update a learned parameter.

Line 576: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 577: `send_word(stream_word, row == rows - 1 && half == 1);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are send_word: the value named 'send word' in this block; stream_word: the value named 'stream word' in this block; row: one output-row position processed by the tensor tile.

Line 578: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 579: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 581: `total_output_beats = 4 * rows + 3 * inputs;` This makes total_output_beats, the value named 'total output beats' in this block, equal to '4 * rows + 3 * inputs'. It is driven by combinational or procedural logic in the current evaluation. The important operands are rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block. Context: the simulation task run case.

Line 582: `packed_weight_row = 192'd0;` This makes packed_weight_row, a learned coefficient multiplied by an activation, equal to '192'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the simulation task run case.

Line 583: `for (beat_index = 0; beat_index < total_output_beats;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 584: `beat_index = beat_index + 1) begin` This statement continues through source line 585; the explanation uses the complete expression rather than only the first visual fragment. This makes beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'beat_index + 1) begin receive_word(received_word, received_last, beat_index % 4)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry; receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block. Context: the simulation task run case.

Line 585: `receive_word(received_word, received_last, beat_index % 4);` This is continuation line 2 of the 2-line logical statement that begins at source line 584. Its exact fragment is 'receive_word(received_word, received_last, beat_index % 4);'. The important operands are receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block; received_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This makes beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'beat_index + 1) begin receive_word(received_word, received_last, beat_index % 4)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry; receive_word: the value named 'receive word' in this block; received_word: the value named 'received word' in this block. Context: the simulation task run case.

Line 586: `if (received_last != (beat_index == total_output_beats - 1)) begin` This condition selects the following hardware branch only when 'received_last != (beat_index == total_output_beats - 1)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_last: the AXI-Stream marker for the final beat of a packet or command payload; beat_index: an integer selecting one tensor element, lane, bank, or state entry; total_output_beats: the value named 'total output beats' in this block. Context: the simulation task run case.

Line 587: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the simulation task run case.

Line 588: `$display("ERROR backward TLAST case=%0d beat=%0d got=%0b",` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 589: `checked_tiles, beat_index, received_last);` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are checked_tiles: the value named 'checked tiles' in this block; beat_index: an integer selecting one tensor element, lane, bank, or state entry; received_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 590: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 591: `if (beat_index < 4 * rows) begin` This condition selects the following hardware branch only when 'beat_index $<$ 4 * rows' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry; rows: one output-row position processed by the tensor tile. Context: the simulation task run case.

Line 592: `row_index = beat_index / 4;` This makes row_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'beat_index / 4'. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run case.

Line 593: `word_index = beat_index % 4;` This makes word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'beat_index % 4'. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run case.

Line 594: `for (lane = 0; lane < 2; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 595: `lane_index = word_index * 2 + lane;` This makes lane_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'word_index * 2 + lane'. It is driven by combinational or procedural logic in the current evaluation. The important operands are word_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task run case.

Line 596: `if ($signed(received_word[lane*32 +: 32])` This condition selects the following hardware branch only when '$signed(received_word[lane*32 +: 32]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are received_word: the value named 'received word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task run case.

Line 597: `!== expected_input_gradient[row_index][lane_index]) begin` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are expected_input_gradient: the signed loss derivative used to update a learned parameter; row_index: an integer selecting one tensor element, lane, bank, or state entry; lane_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 598: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the simulation task run case.

Line 599: `if (errors <= 30) begin` This statement continues through source line 603; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR dX tile=%0d row=%0d lane=%0d got=%0d expected=%0d", checked_tiles, row_index, lane_index, $signed(received_word[lane*32 +: 32]), expected_input_gradient[row_index][lane_index]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 600: `$display("ERROR dX tile=%0d row=%0d lane=%0d got=%0d expected=%0d",` This is continuation line 2 of the 5-line logical statement that begins at source line 599. Its exact fragment is '$display("ERROR dX tile=%0d row=%0d lane=%0d got=%0d expected=%0d",'. The important operands are display: the value named 'display' in this block; ERROR: the value named 'error' in this block; dX: the value named 'd x' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR dX tile=%0d row=%0d lane=%0d got=%0d expected=%0d", checked_tiles, row_index, lane_index, $signed(received_word[lane*32 +: 32]), expected_input_gradient[row_index][lane_index]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 601: `checked_tiles, row_index, lane_index,` This is continuation line 3 of the 5-line logical statement that begins at source line 599. Its exact fragment is 'checked_tiles, row_index, lane_index,'. The important operands are checked_tiles: the value named 'checked tiles' in this block; row_index: an integer selecting one tensor element, lane, bank, or state entry; lane_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR dX tile=%0d row=%0d lane=%0d got=%0d expected=%0d", checked_tiles, row_index, lane_index, $signed(received_word[lane*32 +: 32]), expected_input_gradient[row_index][lane_index]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 602: `$signed(received_word[lane*32 +: 32]),` This is continuation line 4 of the 5-line logical statement that begins at source line 599. Its exact fragment is '$signed(received_word[lane*32 +: 32]),'. The important operands are received_word: the value named 'received word' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR dX tile=%0d row=%0d lane=%0d got=%0d expected=%0d", checked_tiles, row_index, lane_index, $signed(received_word[lane*32 +: 32]), expected_input_gradient[row_index][lane_index]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 603: `expected_input_gradient[row_index][lane_index]);` This is continuation line 5 of the 5-line logical statement that begins at source line 599. Its exact fragment is 'expected_input_gradient[row_index][lane_index]);'. The important operands are expected_input_gradient: the signed loss derivative used to update a learned parameter; row_index: an integer selecting one tensor element, lane, bank, or state entry; lane_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR dX tile=%0d row=%0d

lane=%0d got=%0d expected=%0d", checked_tiles, row_index, lane_index, $signed(received_word[lane*32 +: 32]), expected_input_gradient[row_index][lane_index]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 604: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 605: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 606: `end` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 607: `end else begin` This structural keyword opens or closes the branch/process scope described as the simulation task run case; it has no arithmetic value of its own.

Line 608: `row_index = (beat_index - 4 * rows) / 3;` This makes row_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘(beat_index - 4 * rows) / 3‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry; rows: one output-row position processed by the tensor tile. Context: the simulation task run case.

Line 609: `word_index = (beat_index - 4 * rows) % 3;` This makes word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘(beat_index - 4 * rows) % 3‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are beat_index: an integer selecting one tensor element, lane, bank, or state entry; rows: one output-row position processed by the tensor tile. Context: the simulation task run case.

Line 610: `packed_weight_row[word_index*64 +: 64] = received_word;` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are packed_weight_row: a learned coefficient multiplied by an activation; word_index: an integer selecting one tensor element, lane, bank, or state entry; received_word: the value named 'received word' in this block.

Line 611: `if (word_index == 2) begin` This condition selects the following hardware branch only when ‘word_index == 2‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the simulation task run case.

Line 612: `for (lane = 0; lane < LANES; lane = lane + 1) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the simulation task run case.

Line 613: `if ($signed(packed_weight_row[lane*24 +: 24])` This condition selects the following hardware branch only when ‘$signed(packed_weight_row[lane*24 +: 24]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are packed_weight_row: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the simulation task run case.

Line 614: `!== expected_weight_gradient[row_index][lane]) begin` Within the simulation task run case, this exact statement contributes to the block that drives, backpressures, and checks the neuraedge linear backward8 RTL block in simulation. The important operands are expected_weight_gradient: a learned coefficient multiplied by an activation; row_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 615: `errors = errors + 1;` This makes errors, the value named 'errors' in this block, equal to 'errors + 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are errors: the value named 'errors' in this block. Context: the simulation task run case.

Line 616: `if (errors <= 30) begin` This statement continues through source line 620; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR dW tile=%0d row=%0d lane=%0d got=%0d expected=%0d", checked_tiles, row_index, lane, $signed(packed_weight_row[lane*24 +: 24]), expected_weight_gradient[row_index][lane]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 617: `$display("ERROR dW tile=%0d row=%0d lane=%0d got=%0d expected=%0d",` This is continuation line 2 of the 5-line logical statement that begins at source line 616. Its exact fragment is '$display("ERROR dW tile=%0d row=%0d lane=%0d got=%0d expected=%0d",'. The important operands are display: the value named 'display' in this block; ERROR: the value named 'error' in this block; dW: the value named 'd w' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR dW tile=%0d row=%0d lane=%0d got=%0d expected=%0d", checked_tiles, row_index, lane, $signed(packed_weight_row[lane*24 +: 24]), expected_weight_gradient[row_index][lane]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.

Line 618: `checked_tiles, row_index, lane,` This is continuation line 3 of the 5-line logical statement that begins at source line 616. Its exact fragment is 'checked_tiles, row_index, lane,'. The important operands are checked_tiles: the value named 'checked tiles' in this block; row_index: an integer selecting one tensor element, lane, bank, or state entry; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This condition selects the following hardware branch only when 'errors <= 30) begin $display("ERROR dW tile=%0d row=%0d lane=%0d got=%0d expected=%0d", checked_tiles, row_index, lane, $signed(packed_weight_row[lane*24 +: 24]), expected_weight_gradient[row_index][lane]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are errors: the value named 'errors' in this block; display: the value named 'display' in this block; ERROR: the value named 'error' in this block. Context: the simulation task run case.
