Line 346: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_MULTIPLY_Q15, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 347: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 349: `ST_OFFSET_ADD: begin` This is the ST_OFFSET_ADD case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OFFSET_ADD, the machine performs the named control phase..

Line 350: `offset_sum_r <= offset_left_r + offset_right_r;` This makes offset_sum_r, the value named ’offset sum r’ in this block, equal to ‘offset_left_r + offset_right_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are offset_left_r: the value named ’offset left r’ in this block; offset_right_r: the value named ’offset right r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OFFSET_ADD, the machine performs the named control phase..

Line 351: `state <= ST_OFFSET_EXTEND;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OFFSET_EXTEND‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OFFSET_EXTEND: the value named ’st offset extend’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OFFSET_ADD, the machine performs the named control phase..

Line 352: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OFFSET_ADD, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 354: `ST_OFFSET_EXTEND: begin` This is the ST_OFFSET_EXTEND case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OFFSET_EXTEND, the machine performs the named control phase..

Line 355: `wide_result_r <= {{31{offset_sum_r[32]}}, offset_sum_r};` This makes wide_result_r, the value named ’wide result r’ in this block, equal to ‘{{31{offset_sum_r[32]}}, offset_sum_r}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are offset_sum_r: the value named ’offset sum r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OFFSET_EXTEND, the machine performs the named control phase..

Line 356: `state <= ST_PRECOMPUTE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_PRECOMPUTE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PRECOMPUTE: the value named ’st precompute’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OFFSET_EXTEND, the machine performs the named control phase..

Line 357: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OFFSET_EXTEND, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 359: `ST_PRECOMPUTE: begin` This is the ST_PRECOMPUTE case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip..

Line 360: `saturated_value_r <= saturate_s32(wide_result_r);` This makes saturated_value_r, the value named 'saturated value r' in this block, equal to 'saturate_s32(wide_result_r)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturate_s32: the value named 'saturate s32' in this block; wide_result_r: the value named 'wide result r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip..

Line 361: `distance_difference_r <= {lane_a_r[31], lane_a_r}` This statement continues through source line 362; the explanation uses the complete expression rather than only the first visual fragment. This makes distance_difference_r, the value named 'distance difference r' in this block, equal to '{lane_a_r[31], lane_a_r} - {threshold_r[31], threshold_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath; threshold_r: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip..

Line 362: `- {threshold_r[31], threshold_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 361. Its exact fragment is '- {threshold_r[31], threshold_r};'. The important operands are threshold_r: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This makes distance_difference_r, the value named 'distance difference r' in this block, equal to '{lane_a_r[31], lane_a_r} - {threshold_r[31], threshold_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath; threshold_r: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip..

Line 363: `lane_a_negative_r <= lane_a_r < 0;` This makes lane_a_negative_r, one parallel arithmetic element within a vector or tensor datapath, equal to 'lane_a_r < 0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip..

Line 364: `lane_a_ge_threshold_r <= lane_a_r >= threshold_r;` This makes lane_a_ge_threshold_r, the membrane level at which a neuron emits a spike, equal to 'lane_a_r >= threshold_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath; threshold_r: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip..

Line 365: `lane_a_le_negative_threshold_r <= lane_a_r <= negative_threshold_r;` This makes lane_a_le_negative_thr the membrane level at which a neuron emits a spike, equal to 'lane_a_r <= negative_threshold_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath; negative_threshold_r: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip..

Line 366: `lane_a_ge_b_r <= lane_a_r >= lane_b_r;` This makes lane_a_ge_b_r, one parallel arithmetic element within a vector or tensor datapath, equal to 'lane_a_r >= lane_b_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath; lane_b_r: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip..

Line 367: `lane_a_zero_r <= lane_a_r == 0;` This makes lane_a_zero_r, one parallel arithmetic element within a vector or tensor datapath, equal to 'lane_a_r == 0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip..

Line 368: `state <= ST_DISTANCE_ABSOLUTE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_DISTANCE_ABSOLUTE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DISTANCE_ABSOLUTE: the value named ’st distance absolute’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip..

Line 369: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PRECOMPUTE, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 371: `ST_DISTANCE_ABSOLUTE: begin` This is the ST_DISTANCE_ABSOLUTE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_DISTANCE_ABSOLUTE, the machine performs the named control phase..

Line 372: `distance_r <= distance_difference_r[32]` This statement continues through source line 374; the explanation uses the complete expression rather than only the first visual fragment. This makes distance_r, the value named ’distance r’ in this block, equal to ‘distance_difference_r[32] ? (~distance_difference_r[31:0] + 1’b1) : distance_difference_r[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are distance_difference_r: the value named ’distance difference r’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DISTANCE_ABSOLUTE, the machine performs the named control phase..

Line 373: `? (~distance_difference_r[31:0] + 1’b1)` This is continuation line 2 of the 3-line logical statement that begins at source line 372. Its exact fragment is ‘? (~distance_difference_r[31:0] + 1’b1)‘. The important operands are distance_difference_r: the value named ’distance difference r’ in this block; b1: the value named ’b1’ in this block. Read together, the complete operation is: This makes distance_r, the value named ’distance r’ in this block, equal to ‘distance_difference_r[32] ? (~distance_difference_r[31:0] + 1’b1) : distance_difference_r[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are distance_difference_r: the value named ’distance difference r’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DISTANCE_ABSOLUTE, the machine performs the named control phase..

Line 374: `: distance_difference_r[31:0];` This is continuation line 3 of the 3-line logical statement that begins at source line 372. Its exact fragment is ‘: distance_difference_r[31:0];‘. The important operands are distance_difference_r: the value named ’distance difference r’ in this block. Read together, the complete operation is: This makes distance_r, the value named ’distance r’ in this block, equal to ‘distance_difference_r[32] ? (~distance_difference_r[31:0] + 1’b1) : distance_difference_r[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are distance_difference_r: the value named ’distance difference r’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DISTANCE_ABSOLUTE, the machine performs the named control phase..

Line 375: `state <= ST_COMPARE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_COMPARE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMPARE: the value named ’st compare’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DISTANCE_ABSOLUTE, the machine performs the named control phase..

Line 376: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DISTANCE_ABSOLUTE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 378: `ST_COMPARE: begin` This is the ST_COMPARE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMPARE, the machine performs the named control phase..

Line 379: `inside_surrogate_window_r <= distance_r <= surrogate_window_r;` This makes inside_surrogate_window_r, the value named 'inside surrogate window r' in this block, equal to 'distance_r <= surrogate_window_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are distance_r: the value named 'distance r' in this block; surrogate_window_r: the value named 'surrogate window r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPARE, the machine performs the named control phase..

Line 380: `lane_a_below_clamp_r <= lane_a_r < clamp_minimum_r;` This makes lane_a_below_clamp_r, one parallel arithmetic element within a vector or tensor datapath, equal to 'lane_a_r < clamp_minimum_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath; clamp_minimum_r: the value named 'clamp minimum r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPARE, the machine performs the named control phase..

Line 381: `lane_a_above_clamp_r <= lane_a_r > clamp_maximum_r;` This makes lane_a_above_clamp_r, one parallel arithmetic element within a vector or tensor datapath, equal to 'lane_a_r > clamp_maximum_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath; clamp_maximum_r: the value named 'clamp maximum r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPARE, the machine performs the named control phase..

Line 382: `saturated_below_clamp_r <= saturated_value_r < clamp_minimum_r;` This makes saturated_below_clamp_r, the value named 'saturated below clamp r' in this block, equal to 'saturated_value_r < clamp_minimum_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturated_value_r: the value named 'saturated value r' in this block; clamp_minimum_r: the value named 'clamp minimum r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPARE, the machine performs the named control phase..

Line 383: `saturated_above_clamp_r <= saturated_value_r > clamp_maximum_r;` This makes saturated_above_clamp_r, the value named 'saturated above clamp r' in this block, equal to 'saturated_value_r > clamp_maximum_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturated_value_r: the value named 'saturated value r' in this block; clamp_maximum_r: the value named 'clamp maximum r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPARE, the machine performs the named control phase..

Line 384: `state <= ST_RESULT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_RESULT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_RESULT: the value named 'st result' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPARE, the machine performs the named control phase..

Line 385: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPARE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 387: `ST_RESULT: begin` This is the ST_RESULT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_RESULT, the machine performs the named control phase..

Line 388: `logic signed [31:0] lane_result;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_RESULT, the machine performs the named control phase.. Specifically, lane_result is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 389: `lane_result = 32'sd0;` This makes lane_result, one parallel arithmetic element within a vector or tensor datapath, equal to '32'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESULT, the machine performs the named control phase..

Line 391: `unique case (operation_r)` This starts a multiplexer/state decode selected by 'operation_r'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 392: `OP_ADD_SAT: lane_result = saturated_value_r;` This is the OP_ADD_SAT case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = saturated_value_r;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_ADD_SAT, the machine performs the named control phase..

Line 393: `OP_RELU: lane_result = lane_a_negative_r ? 32'sd0 : lane_a_r;` This is the OP_RELU case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = lane_a_negative_r ? 32'sd0 : lane_a_r;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_RELU, the machine performs the named control phase..

Line 394: `OP_REQUANTIZE,` Within the clocked process that updates registers only on a rising clock edge Within state OP_RELU, the machine performs the named control phase., this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are OP_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code.

Line 395: `OP_FLEX_REQUANTIZE: begin` This is the OP_FLEX_REQUANTIZE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 396: `if (saturated_below_clamp_r) begin` This condition selects the following hardware branch only when 'saturated_below_clamp_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are saturated_below_clamp_r: the value named 'saturated below clamp r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 397: `lane_result = clamp_minimum_r;` This makes lane_result, one parallel arithmetic element within a vector or tensor datapath, equal to 'clamp_minimum_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are clamp_minimum_r: the value named 'clamp minimum r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 398: `end else if (saturated_above_clamp_r) begin` This condition selects the following hardware branch only when 'saturated_above_clamp_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are saturated_above_clamp_r: the value named 'saturated above clamp r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 399: `lane_result = clamp_maximum_r;` This makes lane_result, one parallel arithmetic element within a vector or tensor datapath, equal to 'clamp_maximum_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are clamp_maximum_r: the value named 'clamp maximum r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 400: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 401: `lane_result = saturated_value_r;` This makes lane_result, one parallel arithmetic element within a vector or tensor datapath, equal to 'saturated_value_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturated_value_r: the value named 'saturated value r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 402: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 403: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 404: `OP_BINARY_SPIKE: lane_result = lane_a_ge_threshold_r` This statement continues through source line 405; the explanation uses the complete expression rather than only the first visual fragment. This is the OP_BINARY_SPIKE case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = lane_a_ge_threshold_r ? 32'sd1 : 32'sd0;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_BINARY_SPIKE, the machine performs the named control phase..

Line 405: `? 32'sd1 : 32'sd0;` This is continuation line 2 of the 2-line logical statement that begins at source line 404. Its exact fragment is '? 32'sd1 : 32'sd0;'. The important operands are sd1: the value named 'sd1' in this block; sd0: the value named 'sd0' in this block. Read together, the complete operation is: This is the OP_BINARY_SPIKE case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = lane_a_ge_threshold_r ? 32'sd1 : 32'sd0;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_BINARY_SPIKE, the machine performs the named control phase..

Line 406: `OP_TERNARY_SPIKE: begin` This is the OP_TERNARY_SPIKE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state OP_TERNARY_SPIKE, the machine performs the named control phase..

Line 407: `if (lane_a_ge_threshold_r) lane_result = 32'sd1;` This condition selects the following hardware branch only when 'lane_a_ge_threshold_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lane_a_ge_threshold_r: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state OP_TERNARY_SPIKE, the machine performs the named control phase..

Line 408: `else if (lane_a_le_negative_threshold_r) lane_result = -32'sd1;` This condition selects the following hardware branch only when 'lane_a_le_negative_threshold_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lane_a_le_negative_threshold_r: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state OP_TERNARY_SPIKE, the machine performs the named control phase..

Line 409: `else lane_result = 32'sd0;` Within the clocked process that updates registers only on a rising clock edge Within state OP_TERNARY_SPIKE, the machine performs the named control phase., this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are lane_result: one parallel arithmetic element within a vector or tensor datapath; sd0: the value named 'sd0' in this block.

Line 410: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_TERNARY_SPIKE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 411: `OP_SURROGATE_GRADIENT: lane_result =` This statement continues through source line 412; the explanation uses the complete expression rather than only the first visual fragment. This is the OP_SURROGATE_GRADIENT case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = inside_surrogate_windov ? lane_b_r : 32'sd0;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_SURROGATE_GRADIENT, the machine performs the named control phase..

Line 412: `inside_surrogate_window_r ? lane_b_r : 32'sd0;` This is continuation line 2 of the 2-line logical statement that begins at source line 411. Its exact fragment is 'inside_surrogate_window_r ? lane_b_r : 32'sd0;'. The important operands are inside_surrogate_window_r: the value named 'inside surrogate window r' in this block; lane_b_r: one parallel arithmetic element within a vector or tensor datapath; sd0: the value named 'sd0' in this block. Read together, the complete operation is: This is the OP_SURROGATE_GRADIENT case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = inside_surrogate_window_r ? lane_b_r : 32'sd0;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_SURROGATE_GRADIENT, the machine performs the named control phase..

Line 413: `OP_MAXIMUM: lane_result = lane_a_ge_b_r` This statement continues through source line 414; the explanation uses the complete expression rather than only the first visual fragment. This is the OP_MAXIMUM case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = lane_a_ge_b_r ? lane_a_r : lane_b_r;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_MAXIMUM, the machine performs the named control phase..

Line 414: `? lane_a_r : lane_b_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 413. Its exact fragment is '? lane_a_r : lane_b_r;'. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath; lane_b_r: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This is the OP_MAXIMUM case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = lane_a_ge_b_r ? lane_a_r : lane_b_r;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_MAXIMUM, the machine performs the named control phase..

Line 415: `OP_MULTIPLY_Q15: lane_result = saturated_value_r;` This is the OP_MULTIPLY_Q15 case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = saturated_value_r;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_MULTIPLY_Q15, the machine performs the named control phase..

Line 416: `OP_CLAMP: begin` This is the OP_CLAMP case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state OP_CLAMP, the machine performs the named control phase..

Line 417: `if (lane_a_below_clamp_r) lane_result = clamp_minimum_r;` This condition selects the following hardware branch only when 'lane_a_below_clamp_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lane_a_below_clamp_r: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state OP_CLAMP, the machine performs the named control phase..

Line 418: `else if (lane_a_above_clamp_r) lane_result = clamp_maximum_r;` This condition selects the following hardware branch only when 'lane_a_above_clamp_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lane_a_above_clamp_r: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state OP_CLAMP, the machine performs the named control phase..

Line 419: `else lane_result = lane_a_r;` Within the clocked process that updates registers only on a rising clock edge Within state OP_CLAMP, the machine performs the named control phase., this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are lane_result: one parallel arithmetic element within a vector or tensor datapath; lane_a_r: one parallel arithmetic element within a vector or tensor datapath.

Line 420: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_CLAMP, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 421: `OP_SELECT_ZERO: lane_result = lane_a_zero_r` This statement continues through source line 422; the explanation uses the complete expression rather than only the first visual fragment. This is the OP_SELECT_ZERO case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = lane_a_zero_r ? lane_b_r : 32'sd0;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_SELECT_ZERO, the machine performs the named control phase..

Line 422: `? lane_b_r : 32'sd0;` This is continuation line 2 of the 2-line logical statement that begins at source line 421. Its exact fragment is '? lane_b_r : 32'sd0;'. The important operands are lane_b_r: one parallel arithmetic element within a vector or tensor datapath; sd0: the value named 'sd0' in this block. Read together, the complete operation is: This is the OP_SELECT_ZERO case branch, which performs this explicitly named phase. Line 427: `default: lane_result = 32'sd0;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'lane_result = 32'sd0;'; context is the clocked process that updates registers only on a rising clock edge Within state OP_COMPARE_GE, the machine performs the named control phase..

Line 428: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_COMPARE_GE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 429: `// Keep the operation-select mux local to the scalar lane` Design intent: Keep the operation-select mux local to the scalar lane This comment anchors the surrounding logic in the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

Line 430: `// pipeline. The following state moves this registered value` Design intent: pipeline. The following state moves this registered value This comment anchors the surrounding logic in the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

Line 431: `// into the wide retained output vector, avoiding a routed` Design intent: into the wide retained output vector, avoiding a routed This comment anchors the surrounding logic in the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

Line 432: `// comparison-to-distant-result path across the device.` Design intent: comparison-to-distant-result path across the device. This comment anchors the surrounding logic in the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

Line 433: `lane_result_r <= lane_result;` This makes lane_result_r, one parallel arithmetic element within a vector or tensor datapath, equal to ‘lane_result‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_result: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge.

Line 434: `state <= ST_STORE_RESULT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_STORE_RESULT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_STORE_RESULT: the value named ’st store result’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 435: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 437: `ST_STORE_RESULT: begin` This is the ST_STORE_RESULT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 438: `result[lane_index*DATA_BITS +: DATA_BITS] <= lane_result_r;` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase., this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are result: the value named ’result’ in this block; lane_index: an integer selecting one tensor element, lane, bank, or state entry; DATA_BITS: the value named ’data bits’ in this block.

Line 439: `if (lane_index == $clog2(LANES)'(LANES - 1)) begin` This condition selects the following hardware branch only when ‘lane_index == $clog2(LANES)’(LANES - 1)‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lane_index: an integer selecting one tensor element, lane, bank, or state entry; clog2: the value named ’clog2’ in this block; LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 440: `state <= ST_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT: the value named ’st output’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 441: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 442: `lane_index <= lane_index + 1'b1;` This makes lane_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'lane_index + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 443: `state <= ST_LOAD_LANE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LOAD_LANE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_LANE: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 444: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 445: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 447: `ST_OUTPUT: if (output_ready) state <= ST_IDLE;` This is the ST_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'if (output_ready) state <= ST_IDLE;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 448: `default: state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'state <= ST_IDLE;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 449: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 450: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 451: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 453: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 454: `if (LANES != 8) $fatal(1, "neuraedge_vector_alu currently requires LANES=8");` This condition selects the following hardware branch only when 'LANES != 8) $fatal(1, "neuraedge_vector_alu currently requires LANES=8"' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are LANES: one parallel arithmetic element within a vector or tensor datapath; fatal: the value named 'fatal' in this block; neuraedge_vector_alu: the value named 'neuraedge vector alu' in this block. Context: the module's structural declarations.

Line 455: `if (DATA_BITS != 32) $fatal(1, "neuraedge_vector_alu currently requires DATA_BITS=32");` This condition selects the following hardware branch only when 'DATA_BITS != 32) $fatal(1, "neuraedge_vector_alu currently requires DATA_BITS=32"' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are DATA_BITS: the value named 'data bits' in this block; fatal: the value named 'fatal' in this block; neuraedge_vector_alu: the value named 'neuraedge vector alu' in this block. Context: the module's structural declarations.

Line 456: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 457: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 459: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

23 rtl/neuraedge_weight_bank.sv

Role in the complete system: stores one 16-column by 2,048-entry weight tile in banked FPGA memory.

23.1 Beginner architecture map

Dataflow responsibility Each bank stores sixteen weight bytes for every reduction position. Eight banks feed outer mode rows or adjacent reduction groups, allowing the same memory organization to support matrix tiles and narrow dot-product schedules.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_weight_bank into physical nets and primitives. The source declares 6 input-port lines, 1 output-port lines, 1 clocked process(es), and 0 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control This block is primarily a datapath or storage primitive rather than a large state machine. Registers still divide combinational work into cycles and hold valid/data stable during downstream stalls.

Connections to other blocks This source instantiates unique as case. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

23.2 Complete source

```
`timescale 1ns / 1ps
`default_nettype none

module neuraedge_weight_bank #(
    parameter int DEPTH = 256,
    parameter int ADDRESS_BITS = 8
) (
    input  wire clk,

    end

    initial begin
        if (DEPTH != (1 << ADDRESS_BITS)) $fatal(1, "weight bank depth/address mismatch");
    end
endmodule

`default_nettype wire
```

23.3 Line annotations

Line 1: `‘timescale 1ns / 1ps` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `‘default_nettype none` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_weight_bank #(` This opens neuraedge_weight_bank, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that stores one 16-column by 2,048-entry weight tile in banked FPGA memory.

Line 5: `parameter int DEPTH = 256,` This statement continues through source line 15; the explanation uses the complete expression rather than only the first visual fragment. This fixes DEPTH to 256, parameter int ADDRESS_BITS = 8) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [1:0] write_segment, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [127:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 6: `parameter int ADDRESS_BITS = 8` This is continuation line 2 of the 11-line logical statement that begins at source line 5. Its exact fragment is ‘parameter int ADDRESS_BITS = 8‘. The important operands are parameter: the value named 'parameter' in this block; ADDRESS_BITS: the value named 'address bits' in this block. Read together, the complete operation is: This fixes DEPTH to 256, parameter int ADDRESS_BITS = 8) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [1:0] write_segment, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [127:0] read_data) during elaboration. The important operands are input: the value named 'input' in this block; write_enable: a control bit that permits the associated state or storage update. Read together, the complete operation is: This fixes DEPTH to 256, parameter int ADDRESS_BITS = 8) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [1:0] write_segment, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [127:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 10: `input wire [ADDRESS_BITS-1:0] write_address,` This is continuation line 6 of the 11-line logical statement that begins at source line 5. Its exact fragment is ‘input wire [ADDRESS_BITS-1:0] write_address,‘. The important operands are input: the value named 'input' in this block; ADDRESS_BITS: the value named 'address bits' in this block; write_address: the value named 'write address' in this block. Read together, the complete operation is: This fixes DEPTH to 256, parameter int ADDRESS_BITS = 8) (input wire clk, input wire write_enable, input

wire [ADDRESS_BITS-1:0] write_address, input wire [1:0] write_segment, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [127:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 11: `input wire [1:0] write_segment,` This is continuation line 7 of the 11-line logical statement that begins at source line 5. Its exact fragment is 'input wire [1:0] write_segment,'. The important operands are input: the value named 'input' in this block; write_segment: the value named 'write segment' in this block. Read together, the complete operation is: This fixes DEPTH to 256, parameter int ADDRESS_BITS = 8) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [1:0] write_segment, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [127:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 12: `input wire [63:0] write_data,` This is continuation line 8 of the 11-line logical statement that begins at source line 5. Its exact fragment is 'input wire [63:0] write_data,'. The important operands are input: the value named 'input' in this block; write_data: the payload carried with the surrounding valid/ready handshake. Read together, the complete operation is: This fixes DEPTH to 256, parameter int ADDRESS_BITS = 8) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [1:0] write_segment, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [127:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 13: `input wire [ADDRESS_BITS-1:0] read_address,` This is continuation line 9 of the 11-line logical statement that begins at source line 5. Its exact fragment is 'input wire [ADDRESS_BITS-1:0] read_address,'. The important operands are input: the value named 'input' in this block; ADDRESS_BITS: the value named 'address bits' in this block; read_address: the value named 'read address' in this block. Read together, the complete operation is: This fixes DEPTH to 256, parameter int ADDRESS_BITS = 8) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [1:0] write_segment, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [127:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 14: `output logic [127:0] read_data` This is continuation line 10 of the 11-line logical statement that begins at source line 5. Its exact fragment is 'output logic [127:0] read_data'. The important operands are output: the value named 'output' in this block; read_data: the payload carried with the surrounding valid/ready handshake. Read together, the complete operation is: This fixes DEPTH to 256, parameter int ADDRESS_BITS = 8) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [1:0] write_segment, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [127:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 15: `);` This is continuation line 11 of the 11-line logical statement that begins at source line 5. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes DEPTH to 256, parameter int ADDRESS_BITS = 8) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [1:0] write_segment, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [127:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 16: `// Four independent 64-bit memories map directly to BRAM primitives. The` Design intent: Four independent 64-bit memories map directly to BRAM primitives. The This comment anchors the surrounding logic in the block that stores one 16-column by 2,048-entry weight tile in banked FPGA memory.

Line 17: `// segment write enable avoids the 3D partial-write pattern that Vivado` Design intent: segment write enable avoids the 3D partial-write pattern that Vivado This comment anchors the surrounding logic in the block that stores one 16-column by 2,048-entry weight tile in banked FPGA memory.

Line 18: `// otherwise expands into half a million flip-flops.` Design intent: otherwise expands into half a million flip-flops. This comment anchors the surrounding logic in the block that stores one 16-column by 2,048-entry weight tile in banked FPGA memory.

Line 19: `(* ram_style = "block" *) logic [63:0] memory0 [0:DEPTH-1];` Within the module's structural declarations, this exact statement contributes to the block that stores one 16-column by 2,048-entry weight tile in banked FPGA memory. The important operands are ram_style: the value named 'ram style' in this block; block: the value named 'block' in this block; memory0: local FPGA storage addressed by surrounding index logic.

Line 20: `(* ram_style = "block" *) logic [63:0] memory1 [0:DEPTH-1];` Within the module's structural declarations, this exact statement contributes to the block that stores one 16-column by 2,048-entry weight tile in banked FPGA memory. The important operands are ram_style: the value named 'ram style' in this block; block: the value named 'block' in this block; memory1: local FPGA storage addressed by surrounding index logic.

Line 21: `logic [127:0] memory_read_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, memory_read_data_r is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 24: `if (write_enable) begin` This condition selects the following hardware branch only when 'write_enable' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are write_enable: a control bit that permits the associated state or storage update. Context: the clocked process that updates registers only on a rising clock edge.

Line 25: `unique case (write_segment)` This starts a multiplexer/state decode selected by 'write_segment'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 26: `2'd0: memory0[write_address] <= write_data;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that stores one 16-column by 2,048-entry weight tile in banked FPGA memory. The important operands are d0: the value named 'd0' in this block; memory0: local FPGA storage addressed by surrounding index logic; write_address: the value named 'write address' in this block.

Line 27: `2'd1: memory1[write_address] <= write_data;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that stores one 16-column by 2,048-entry weight tile in banked FPGA memory. The important operands are d1: the value named 'd1' in this block; memory1: local FPGA storage addressed by surrounding index logic; write_address: the value named 'write address' in this block.

Line 28: `default: memory1[write_address] <= write_data;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'memory1[write_address] <= write_data;'; context is the clocked process that updates registers only on a rising clock edge.

Line 29: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 30: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 31: `memory_read_data_r[63:0] <= memory0[read_address];` This makes memory_read_data_r[63:0], local FPGA storage addressed by surrounding index logic, equal to 'memory0[read_address]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are memory0: local FPGA storage addressed by surrounding index logic; read_address: the value named 'read address' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 32: `memory_read_data_r[127:64] <= memory1[read_address];` This makes memory_read_data_r[127:64], local FPGA storage addressed by surrounding index logic, equal to ‘memory1[read_address]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are memory1: local FPGA storage addressed by surrounding index logic; read_address: the value named ’read address’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 33: `read_data <= memory_read_data_r;` This makes read_data, the payload carried with the surrounding valid/ready handshake, equal to ‘memory_read_data_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are memory_read_data_r: local FPGA storage addressed by surrounding index logic. Context: the clocked process that updates registers only on a rising clock edge.

Line 34: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 36: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 37: `if (DEPTH != (1 << ADDRESS_BITS)) $fatal(1, "weight bank depth/address mismatch");` This condition selects the following hardware branch only when ‘DEPTH != (1 << ADDRESS_BITS)) $fatal(1, "weight bank depth/address mismatch"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are DEPTH: the value named ’depth’ in this block; ADDRESS_BITS: the value named ’address bits’ in this block; fatal: the value named ’fatal’ in this block. Context: the module’s structural declarations.

Line 38: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 39: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 41: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that stores one 16-column by 2,048-entry weight tile in banked FPGA memory.

24 software/benchmark_compiler_memory.py

Role in the complete system: measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

24.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: none. Functions: benchmark, parse_arguments. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

24.2 Complete source

24.3 Line annotations

Line 1: `"""Measure compilation time and Python memory for one real exported projection."""` This is executable documentation attached to the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import argparse` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import json` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `import platform` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `import time` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `import tracemalloc` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `from datetime import datetime, timezone` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `from pathlib import Path` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `import numpy as np` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `from neuraedge_compiler import compile_spike_gemm` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `from spikingformer_parameters import SpikingformerParameterArchive` This imports the named Python API so the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `def benchmark(manifest: Path, projection_name: str, rows: int) -> dict[str, object]:` This starts function benchmark. Its indented body performs benchmark as part of the file that measures time, memory, command count, and byte traffic for the largest real Spikingformer projection; it runs only when called.

Line 20: `if rows <= 0:` This executes the following indented host-code branch only when ‘rows <= 0‘ is true. The important operands are rows: one output-row position processed by the tensor tile. Context: the function benchmark, which handles benchmark.

Line 21: `raise ValueError("rows must be positive")` This rejects an invalid state by raising ‘ValueError("rows must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 22: `archive = SpikingformerParameterArchive(manifest)` This assigns ‘SpikingformerParameterArchive(manifest)‘ to ‘archive ‘ in host memory. Here archive means the value named ’archive’ in this block. The important operands are SpikingformerParameterArchive: the value named ’spikingformer parameter archive’ in this block; manifest: the value named ’manifest’ in this block. Context: the function benchmark, which handles benchmark.

Line 23: `projection = archive.projection(projection_name)` This assigns ‘archive.projection(projection_name)‘ to ‘projection ‘ in host memory. Here projection means the value named ’projection’ in this block. The important operands are archive: the value named ’archive’ in this block; projection: the value named ’projection’ in this block; projection_name: the value named ’projection name’ in this block. Context: the function benchmark, which handles benchmark.

Line 24: `spikes = np.zeros((rows, projection.weight_k_by_n.shape[0]), dtype=np.uint8)` This assigns ‘np.zeros((rows projection.weight_k_by_n.shape[0]), dtype=np.uint8)‘ to ‘spikes ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are zeros: the value named ’zeros’ in this block; rows: one output-row position processed by the tensor tile; projection: the value named ’projection’ in this block. Context: the function benchmark, which handles benchmark.

Line 25: `tracemalloc.start()` This calls ‘tracemalloc.start‘ with “ inside the function benchmark, which handles benchmark. The call advances the host-side job that measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

Line 26: `started = time.perf_counter()` This assigns ‘time.perf_counter()‘ to ‘started ‘ in host memory. Here started means the value named ’started’ in this block. The important operands are time: the value named ’time’ in this block; perf_counter: a hardware telemetry register that accumulates measured events. Context: the function benchmark, which handles benchmark.

Line 27: `program = compile_spike_gemm(spikes, projection.weight_k_by_n)` This assigns ‘compile_spike_gemm(spikes, projection.weight_k_by_n)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold; spikes: a binary event produced when a neuron crosses its threshold; projection: the value named ’projection’ in this block. Context: the function benchmark, which handles benchmark.

Line 28: `elapsed = time.perf_counter() - started` This assigns ‘time.perf_counter() - started‘ to ‘elapsed ‘ in host memory. Here elapsed means the value named ’elapsed’ in this block. The important operands are time: the value named ’time’ in this block; perf_counter: a hardware telemetry register that accumulates measured events; started: the value named ’started’ in this block. Context: the function benchmark, which handles benchmark.

Line 29: `current_bytes, peak_bytes = tracemalloc.get_traced_memory()` This assigns ‘tracemalloc.get_traced_memory()
to ‘current_bytes, peak_bytes ‘ in host memory. Here current_bytes means the value named ’current bytes’ in this block.
The important operands are tracemalloc: the value named ’tracemalloc’ in this block; get_traced_memory: local FPGA
storage addressed by surrounding index logic. Context: the function benchmark, which handles benchmark.

Line 30: `tracemalloc.stop()` This calls ‘tracemalloc.stop‘ with “ inside the function benchmark, which handles
benchmark. The call advances the host-side job that measures time, memory, command count, and byte traffic for the
largest real Spikingformer projection.

Line 31: `output_beats = sum(instruction.output_beats for instruction in program.instructions)` This assigns ‘sum(instruction.output_beats for instruction in program.instructions)‘ to ‘output_beats ‘ in host memory. Here
output_beats means the value named ’output beats’ in this block. The important operands are sum: the value named
’sum’ in this block; instruction: the value named ’instruction’ in this block; output_beats: the value named ’output
beats’ in this block. Context: the function benchmark, which handles benchmark.

Line 32: `descriptor_bytes = 24 * len(program.instructions)` This assigns ‘24 * len(program.instructions)‘ to
‘descriptor_bytes ‘ in host memory. Here descriptor_bytes means a DMA record header plus one command and its
declared payload. The important operands are len: the value named ’len’ in this block; program: the value named
’program’ in this block; instructions: the value named ’instructions’ in this block. Context: the function benchmark,
which handles benchmark.

Line 33: `return {` This statement continues through source line 49; the explanation uses the complete expression
rather than only the first visual fragment. This returns ‘{ "format": "neuraedge-compiler-memory-benchmark-v1", "completed_utc": datetime.now(timezone.utc).isoformat(), "python": platform.python_version(), "numpy": np.__version__,
"manifest": str(manifest.resolve()), "projection": projection_name, "shape": list(program.shape), "instructions": len(program.instruc
"payload_input_bytes": program.estimated_input_bytes, "descriptor_bytes": descriptor_bytes, "dma_input_bytes":
program.estimated_input_bytes + descriptor_bytes, "dma_output_bytes": output_beats * 8, "compile_seconds": elapsed,
"tracemalloc_current_bytes": current_bytes, "tracemalloc_peak_bytes": peak_bytes, }‘ to the caller of the function
benchmark, which handles benchmark, ending this invocation. The important operands are format: the value named
’format’ in this block; neuraedge: the value named ’neuraedge’ in this block; compiler: the value named ’compiler’ in
this block.

Line 34: `"format": "neuraedge-compiler-memory-benchmark-v1",` This is continuation line 2 of the 17-line logical statement that begins at source line 33. Its exact fragment is ‘"format": "neuraedge-compiler-memory-benchmark-v1",‘.
The important operands are format: the value named ’format’ in this block; neuraedge: the value named ’neuraedge’ in
this block; compiler: the value named ’compiler’ in this block. Read together, the complete operation is: This returns
‘{ "format": "neuraedge-compiler-memory-benchmark-v1", "completed_utc": datetime.now(timezone.utc).isoformat(),
"python": platform.python_version(), "numpy": np.__version__, "manifest": str(manifest.resolve()), "projection": projection_name, "shape": list(program.shape), "instructions": len(program.instructions), "payload_input_bytes": program.estimated_input_bytes, "descriptor_bytes": descriptor_bytes, "dma_input_bytes": program.estimated_input_bytes
+ descriptor_bytes, "dma_output_bytes": output_beats * 8, "compile_seconds": elapsed, "tracemalloc_current_bytes":
current_bytes, "tracemalloc_peak_bytes": peak_bytes, }‘ to the caller of the function benchmark, which handles benchmark, ending this invocation. The important operands are format: the value named ’format’ in this block; neuraedge:
the value named ’neuraedge’ in this block; compiler: the value named ’compiler’ in this block.

Line 35: `"completed_utc": datetime.now(timezone.utc).isoformat(),` This is continuation line 3 of the 17-line
logical statement that begins at source line 33. Its exact fragment is ‘"completed_utc": datetime.now(timezone.utc).isoformat(),‘.
The important operands are completed_utc: the value named ’completed utc’ in this block; datetime: the value named
’datetime’ in this block; now: the value named ’now’ in this block. Read together, the complete operation is: This returns
‘{ "format": "neuraedge-compiler-memory-benchmark-v1", "completed_utc": datetime.now(timezone.utc).isoformat(),
"python": platform.python_version(), "numpy": np.__version__, "manifest": str(manifest.resolve()), "projection": projection_name, "shape": list(program.shape), "instructions": len(program.instructions), "payload_input_bytes": program.estimated_input_bytes, "descriptor_bytes": descriptor_bytes, "dma_input_bytes": program.estimated_input_bytes

Line 49: `}` This is continuation line 17 of the 17-line logical statement that begins at source line 33. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns '{ "format": "neuraedge-compiler-memory-benchmark-v1", "completed_utc": datetime.now(timezone.utc).isoformat(), "python": platform.python_version(), "numpy": np.___version___, "manifest": str(manifest.resolve()), "projection": projection_name, "shape": list(program.shape), "instructions": len(program.instructions), "payload_input_bytes": program.estimated_input_bytes, "descriptor_bytes": descriptor_bytes, "dma_input_bytes": program.estimated_input_bytes + descriptor_bytes, "dma_output_bytes": output_beats * 8, "compile_seconds": elapsed, "tracemalloc_current_bytes": current_bytes, "tracemalloc_peak_bytes": peak_bytes, }' to the caller of the function benchmark, which handles benchmark, ending this invocation. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; compiler: the value named 'compiler' in this block.

Line 52: `def parse_arguments() -> argparse.Namespace:` This starts function parse_arguments. Its indented body performs parse arguments as part of the file that measures time, memory, command count, and byte traffic for the largest real Spikingformer projection; it runs only when called.

Line 53: `parser = argparse.ArgumentParser()` This assigns 'argparse.ArgumentParser()' to 'parser ' in host memory. Here parser means the value named 'parser' in this block. The important operands are argparse: the value named 'argparse' in this block; ArgumentParser: the value named 'argument parser' in this block. Context: the function parse_arguments, which handles parse arguments.

Line 54: `parser.add_argument("-manifest", required=True, type=Path)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 55: `parser.add_argument("-projection", default="patch_embed.block3")` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 56: `parser.add_argument("-rows", type=int, default=1024)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 57: `parser.add_argument("-output", type=Path)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 58: `return parser.parse_args()` This returns 'parser.parse_args()' to the caller of the function parse_arguments, which handles parse arguments, ending this invocation. The important operands are parser: the value named 'parser' in this block; parse_args: the value named 'parse args' in this block.

Line 61: `if __name__ == "__main__":` This executes the following indented host-code branch only when '___name___ == "___main___"' is true. The important operands are ___name___: the value named 'name' in this block; ___main___: the value named 'main' in this block. Context: the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

Line 62: `arguments = parse_arguments()` This assigns 'parse_arguments()' to 'arguments ' in host memory. Here arguments means the value named 'arguments' in this block. The important operands are parse_arguments: the value named 'parse arguments' in this block. Context: the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

Line 63: `result = benchmark(arguments.manifest, arguments.projection, arguments.rows)` This assigns 'benchmark(arguments.manifest, arguments.projection, arguments.rows)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are benchmark: the value named 'benchmark' in this block;

arguments: the value named 'arguments' in this block; manifest: the value named 'manifest' in this block. Context: the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

Line 64: `payload = json.dumps(result, indent=2) + "\n"` This assigns ‘json.dumps(result, indent=2) + "\n"‘ to ‘payload ‘ in host memory. Here payload means stream data belonging to the current command. The important operands are json: the value named 'json' in this block; dumps: the value named 'dumps' in this block; result: the value named 'result' in this block. Context: the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

Line 65: `if arguments.output is not None:` This executes the following indented host-code branch only when ‘arguments.output is not None‘ is true. The important operands are arguments: the value named 'arguments' in this block; output: the value named 'output' in this block; is: the value named 'is' in this block. Context: the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

Line 66: `arguments.output.parent.mkdir(parents=True, exist_ok=True)` This calls ‘arguments.output.parent.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection. The call advances the host-side job that measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

Line 67: `arguments.output.write_text(payload, encoding="ascii")` This calls ‘arguments.output.write_text‘ with ‘payload, encoding="ascii"‘ inside the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection. The call advances the host-side job that measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

Line 68: `print(payload, end="")` This calls ‘print‘ with ‘payload, end=""‘ inside the file whose role is to measures time, memory, command count, and byte traffic for the largest real Spikingformer projection. The call advances the host-side job that measures time, memory, command count, and byte traffic for the largest real Spikingformer projection.

25 software/evaluate_spikingformer.py

Role in the complete system: evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

25.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: RunningTensorStats, CalibrationObserver. Functions: evaluate, parse_arguments, from_tensor, update, as_dict, ___init___, ___call___, as_dict. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

25.3 Line annotations

Line 1: `"""Evaluate the trained Spikingformer and capture hardware calibration data."""` This is executable documentation attached to the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import argparse` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import csv` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `import json` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `import time` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `from pathlib import Path` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `import numpy as np` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `import torch` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `from torch.utils.data import DataLoader` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `from torchvision import datasets, transforms` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `from spikingformer_reference import load_checkpoint` This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `from spikingformer_quantization import (` This statement continues through source line 21; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `prepare_hardware_emulation,` This is continuation line 2 of the 4-line logical statement that begins at source line 18. Its exact fragment is ‘prepare_hardware_emulation,‘. The important operands are prepare_hardware_emulation: the value named ’prepare hardware emulation’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `quantize_cifar_input_u8,` This is continuation line 3 of the 4-line logical statement that begins at source line 18. Its exact fragment is ‘quantize_cifar_input_u8,‘. The important operands are quantize_cifar_input_u8: the value named ’quantize cifar input u8’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 18. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `CIFAR10_CLASSES = (` This statement continues through source line 27; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘("airplane", "automobile", "bird", "cat", "deer", "dog", "frog", "horse", "ship", "truck",)‘ to ‘CIFAR10_CLASSES ‘ in host memory. Here CIFAR10_CLASSES means the value named ’cifar10 classes’ in this block. The important operands are airplane: one parallel arithmetic element within a vector or tensor datapath; automobile: the value named ’automobile’ in this block; bird: the value named ’bird’ in this block. Context: the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 25: `"airplane", "automobile", "bird", "cat", "deer",` This is continuation line 2 of the 4-line logical statement that begins at source line 24. Its exact fragment is ‘"airplane", "automobile", "bird", "cat", "deer",‘. The important operands are airplane: one parallel arithmetic element within a vector or tensor datapath; automobile: the value named 'automobile' in this block; bird: the value named 'bird' in this block. Read together, the complete operation is: This assigns ‘("airplane", "automobile", "bird", "cat", "deer", "dog", "frog", "horse", "ship", "truck",)‘ to ‘CIFAR10_CLASSES ‘ in host memory. Here CIFAR10_CLASSES means the value named 'cifar10 classes' in this block. The important operands are airplane: one parallel arithmetic element within a vector or tensor datapath; automobile: the value named 'automobile' in this block; bird: the value named 'bird' in this block. Context: the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 26: `"dog", "frog", "horse", "ship", "truck",` This is continuation line 3 of the 4-line logical statement that begins at source line 24. Its exact fragment is ‘"dog", "frog", "horse", "ship", "truck",‘. The important operands are dog: the value named 'dog' in this block; frog: the value named 'frog' in this block; horse: the value named 'horse' in this block. Read together, the complete operation is: This assigns ‘("airplane", "automobile", "bird", "cat", "deer", "dog", "frog", "horse", "ship", "truck",)‘ to ‘CIFAR10_CLASSES ‘ in host memory. Here CIFAR10_CLASSES means the value named 'cifar10 classes' in this block. The important operands are airplane: one parallel arithmetic element within a vector or tensor datapath; automobile: the value named 'automobile' in this block; bird: the value named 'bird' in this block. Context: the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 27: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 24. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘("airplane", "automobile", "bird", "cat", "deer", "dog", "frog", "horse", "ship", "truck",)‘ to ‘CIFAR10_CLASSES ‘ in host memory. Here CIFAR10_CLASSES means the value named 'cifar10 classes' in this block. The important operands are airplane: one parallel arithmetic element within a vector or tensor datapath; automobile: the value named 'automobile' in this block; bird: the value named 'bird' in this block. Context: the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 28: `CIFAR10_MEAN = (0.4914, 0.4822, 0.4465)` This assigns ‘(0.4914, 0.4822, 0.4465)‘ to ‘CIFAR10_MEAN ‘ in host memory. Here CIFAR10_MEAN means the arithmetic average used by normalization. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 29: `CIFAR10_STD = (0.2470, 0.2435, 0.2616)` This assigns ‘(0.2470, 0.2435, 0.2616)‘ to ‘CIFAR10_STD ‘ in host memory. Here CIFAR10_STD means the value named 'cifar10 std' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 32: `@dataclass` This decorator changes how the following class or function is constructed. ‘@dataclass‘ is applied at import time on the host and is part of the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set; it creates no FPGA circuit by itself.

Line 33: `class RunningTensorStats:` This defines class RunningTensorStats, which groups data and methods for running tensor stats. Instances exist in host memory and organize the flow that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 34: `"""Numerically stable aggregate statistics retained on the source device."""` This is executable documentation attached to the class RunningTensorStats, which handles running tensor stats. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 36: `elements: int` Inside the class RunningTensorStats, which handles running tensor stats, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are elements: the value named 'elements' in this block.

Line 37: `batches: int` Inside the class RunningTensorStats, which handles running tensor stats, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are batches: the value named 'batches' in this block.

Line 38: `minimum: torch.Tensor` Inside the class RunningTensorStats, which handles running tensor stats, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are minimum: the value named 'minimum' in this block; torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 39: `maximum: torch.Tensor` Inside the class RunningTensorStats, which handles running tensor stats, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are maximum: the value named 'maximum' in this block; torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 40: `total: torch.Tensor` Inside the class RunningTensorStats, which handles running tensor stats, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are total: the value named 'total' in this block; torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 41: `total_squares: torch.Tensor` Inside the class RunningTensorStats, which handles running tensor stats, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are total_squares: the value named 'total squares' in this block; torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 42: `nonzero: torch.Tensor` Inside the class RunningTensorStats, which handles running tensor stats, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are nonzero: the value named 'nonzero' in this block; torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 43: `is_spike: bool` Inside the class RunningTensorStats, which handles running tensor stats, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are is_spike: a binary event produced when a neuron crosses its threshold; bool: the value named 'bool' in this block.

Line 45: `@classmethod` This decorator changes how the following class or function is constructed. '@classmethod' is applied at import time on the host and is part of the class RunningTensorStats, which handles running tensor stats; it creates no FPGA circuit by itself.

Line 46: `def from_tensor(cls, value: torch.Tensor, is_spike: bool) -> "RunningTensorStats":` This starts function from_tensor. Its indented body performs from tensor as part of the file that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set; it runs only when called.

Line 47: `detached = value.detach().float()` This assigns 'value.detach().float()' to 'detached ' in host memory. Here detached means the value named 'detached' in this block. The important operands are value: the value named 'value' in this block; detach: the value named 'detach' in this block; float: the value named 'float' in this block. Context: the function from_tensor, which handles from tensor.

Line 48: `return cls(` This statement continues through source line 57; the explanation uses the complete expression rather than only the first visual fragment. This returns 'cls(elements=detached.numel(), batches=1, minimum=detached.amin(), maximum=detached.amax(), total=detached.sum(dtype=torch.float64), total_squares=detached.square(). nonzero=torch.count_nonzero(detached), is_spike=is_spike,)' to the caller of the function from_tensor, which handles from tensor, ending this invocation. The important operands are cls: the value named 'cls' in this block; elements: the value named 'elements' in this block; detached: the value named 'detached' in this block.

Line 49: `elements=detached.numel(),` This is continuation line 2 of the 10-line logical statement that begins at source line 48. Its exact fragment is 'elements=detached.numel(),'. The important operands are elements: the value named 'elements' in this block; detached: the value named 'detached' in this block; numel: the value named 'numel' in this block. Read together, the complete operation is: This returns 'cls(elements=detached.numel(), batches=1, minimum=detached.amin(), maximum=detached.amax(), total=detached.sum(dtype=torch.float64), total_squares=detached.square(). nonzero=torch.count_nonzero(detached), is_spike=is_spike,)' to the caller of the function from_tensor, which handles from tensor, ending this invocation. The important operands are cls: the value named 'cls' in this block; elements: the value named 'elements' in this block; detached: the value named 'detached' in this block.

Line 50: `batches=1,` This is continuation line 3 of the 10-line logical statement that begins at source line 48. Its exact fragment is 'batches=1,'. The important operands are batches: the value named 'batches' in this block. Read together, the complete operation is: This returns 'cls(elements=detached.numel(), batches=1, minimum=detached.amin(), maximum=detached.amax(), total=detached.sum(dtype=torch.float64), total_squares=detached.square().sum(dtype=torch.float64), nonzero=torch.count_nonzero(detached), is_spike=is_spike,)' to the caller of the function from_tensor, which handles from tensor, ending this invocation. The important operands are cls: the value named 'cls' in this block; elements: the value named 'elements' in this block; detached: the value named 'detached' in this block.

Line 51: `minimum=detached.amin(),` This is continuation line 4 of the 10-line logical statement that begins at source line 48. Its exact fragment is 'minimum=detached.amin(),'. The important operands are minimum: the value named 'minimum' in this block; detached: the value named 'detached' in this block; amin: the value named 'amin' in this block. Read together, the complete operation is: This returns 'cls(elements=detached.numel(), batches=1, minimum=detached.amin(), maximum=detached.amax(), total=detached.sum(dtype=torch.float64), total_squares=detached.square(). nonzero=torch.count_nonzero(detached), is_spike=is_spike,)' to the caller of the function from_tensor, which handles from tensor, ending this invocation. The important operands are cls: the value named 'cls' in this block; elements: the value named 'elements' in this block; detached: the value named 'detached' in this block.

Line 52: `maximum=detached.amax(),` This is continuation line 5 of the 10-line logical statement that begins at source line 48. Its exact fragment is 'maximum=detached.amax(),'. The important operands are maximum: the value named 'maximum' in this block; detached: the value named 'detached' in this block; amax: the value named 'amax' in this block. Read together, the complete operation is: This returns 'cls(elements=detached.numel(), batches=1, minimum=detached.amin(), maximum=detached.amax(), total=detached.sum(dtype=torch.float64), total_squares=detached.square(). nonzero=torch.count_nonzero(detached), is_spike=is_spike,)' to the caller of the function from_tensor, which handles from tensor, ending this invocation. The important operands are cls: the value named 'cls' in this block; elements: the value named 'elements' in this block; detached: the value named 'detached' in this block.

Line 53: `total=detached.sum(dtype=torch.float64),` This is continuation line 6 of the 10-line logical statement that begins at source line 48. Its exact fragment is 'total=detached.sum(dtype=torch.float64),'. The important operands are total: the value named 'total' in this block; detached: the value named 'detached' in this block; sum: the value named 'sum' in this block. Read together, the complete operation is: This returns 'cls(elements=detached.numel(), batches=1, minimum=detached.amin(), maximum=detached.amax(), total=detached.sum(dtype=torch.float64), total_squares=detached.squa nonzero=torch.count_nonzero(detached), is_spike=is_spike,)' to the caller of the function from_tensor, which handles from tensor, ending this invocation. The important operands are cls: the value named 'cls' in this block; elements: the value named 'elements' in this block; detached: the value named 'detached' in this block.

Line 54: `total_squares=detached.square().sum(dtype=torch.float64),` This is continuation line 7 of the 10-line logical statement that begins at source line 48. Its exact fragment is 'total_squares=detached.square().sum(dtype=torch.float64),'. The important operands are total_squares: the value named 'total squares' in this block; detached: the value named 'detached' in this block; square: the value named 'square' in this block. Read together, the complete operation is: This returns 'cls(elements=detached.numel(), batches=1, minimum=detached.amin(), maximum=detached.amax(), total=detached.sum(dtype=torch.float64), total_squares=detached.square().sum(dtype=torch.float64), nonzero=torch.count_nonze is_spike=is_spike,)' to the caller of the function from_tensor, which handles from tensor, ending this invocation. The important operands are cls: the value named 'cls' in this block; elements: the value named 'elements' in this block; detached: the value named 'detached' in this block.

Line 55: `nonzero=torch.count_nonzero(detached),` This is continuation line 8 of the 10-line logical statement that begins at source line 48. Its exact fragment is 'nonzero=torch.count_nonzero(detached),'. The important operands

are nonzero: the value named 'nonzero' in this block; torch: the value named 'torch' in this block; count_nonzero: the value named 'count nonzero' in this block. Read together, the complete operation is: This returns 'cls(elements=detached.numel(), batches=1, minimum=detached.amin(), maximum=detached.amax(), total=detached.sum(dtype=torch.f total_squares=detached.square().sum(dtype=torch.float64), nonzero=torch.count_nonzero(detached), is_spike=is_spike,)' to the caller of the function from_tensor, which handles from tensor, ending this invocation. The important operands are cls: the value named 'cls' in this block; elements: the value named 'elements' in this block; detached: the value named 'detached' in this block.

Line 56: `is_spike=is_spike,` This is continuation line 9 of the 10-line logical statement that begins at source line 48. Its exact fragment is 'is_spike=is_spike,'. The important operands are is_spike: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This returns 'cls(elements=detached.numel(), batches=1, minimum=detached.amin(), maximum=detached.amax(), total=detached.sum(dtype=torch.float64), total_squares=detached.squa nonzero=torch.count_nonzero(detached), is_spike=is_spike,)' to the caller of the function from_tensor, which handles from tensor, ending this invocation. The important operands are cls: the value named 'cls' in this block; elements: the value named 'elements' in this block; detached: the value named 'detached' in this block.

Line 57: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 48. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'cls(elements=detached.numel(), batches=1, minimum=detached.amin(), maximum=detached.amax(), total=detached.sum(dtype=torch.float64), total_squares=detached.square().sum(dtype=torch.float64), nonzero=torch.count_nonzero(detached), is_spike=is_spike,)' to the caller of the function from_tensor, which handles from tensor, ending this invocation. The important operands are cls: the value named 'cls' in this block; elements: the value named 'elements' in this block; detached: the value named 'detached' in this block.

Line 59: `def update(self, value: torch.Tensor, is_spike: bool) -> None:` This starts function update. Its indented body performs update as part of the file that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set; it runs only when called.

Line 60: `if self.is_spike != is_spike:` This executes the following indented host-code branch only when 'self.is_spike != is_spike' is true. The important operands are is_spike: a binary event produced when a neuron crosses its threshold. Context: the function update, which handles update.

Line 61: `raise ValueError("a tensor changed between analog and spike semantics")` This rejects an invalid state by raising 'ValueError("a tensor changed between analog and spike semantics")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 62: `detached = value.detach().float()` This assigns 'value.detach().float()' to 'detached ' in host memory. Here detached means the value named 'detached' in this block. The important operands are value: the value named 'value' in this block; detach: the value named 'detach' in this block; float: the value named 'float' in this block. Context: the function update, which handles update.

Line 63: `self.elements += detached.numel()` Inside the function update, which handles update, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are elements: the value named 'elements' in this block; detached: the value named 'detached' in this block; numel: the value named 'numel' in this block.

Line 64: `self.batches += 1` Inside the function update, which handles update, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are batches: the value named 'batches' in this block.

Line 65: `self.minimum = torch.minimum(self.minimum, detached.amin())` This assigns 'torch.minimum(self.minimum, detached.amin())' to 'self.minimum ' in host memory. Here minimum means the value named 'minimum' in this block. The important operands are torch: the value named 'torch' in this block; minimum: the value named 'minimum' in this block; detached: the value named 'detached' in this block. Context: the function update, which handles update.

Line 66: `self.maximum = torch.maximum(self.maximum, detached.amax())` This assigns ‘torch.maximum(self.maximum, detached.amax())‘ to ‘self.maximum ‘ in host memory. Here maximum means the value named ’maximum’ in this block. The important operands are torch: the value named ’torch’ in this block; maximum: the value named ’maximum’ in this block; detached: the value named ’detached’ in this block. Context: the function update, which handles update.

Line 67: `self.total += detached.sum(dtype=torch.float64)` Inside the function update, which handles update, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are total: the value named ’total’ in this block; detached: the value named ’detached’ in this block; sum: the value named ’sum’ in this block.

Line 68: `self.total_squares += detached.square().sum(dtype=torch.float64)` Inside the function update, which handles update, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are total_squares: the value named ’total squares’ in this block; detached: the value named ’detached’ in this block; square: the value named ’square’ in this block.

Line 69: `self.nonzero += torch.count_nonzero(detached)` Inside the function update, which handles update, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are nonzero: the value named ’nonzero’ in this block; torch: the value named ’torch’ in this block; count_nonzero: the value named ’count nonzero’ in this block.

Line 71: `def as_dict(self) -> dict[str, int | float | bool]:` This starts function as_dict. Its indented body performs as dict as part of the file that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set; it runs only when called.

Line 72: `mean = float((self.total / self.elements).cpu())` This assigns ‘float((self.total / self.elements).cpu())‘ to ‘mean ‘ in host memory. Here mean means the arithmetic average used by normalization. The important operands are float: the value named ’float’ in this block; total: the value named ’total’ in this block; elements: the value named ’elements’ in this block. Context: the function as_dict, which handles as dict.

Line 73: `second_moment = float((self.total_squares / self.elements).cpu())` This assigns ‘float((self.total_squares / self.elements).cpu())‘ to ‘second_moment ‘ in host memory. Here second_moment means the value named ’second moment’ in this block. The important operands are float: the value named ’float’ in this block; total_squares: the value named ’total squares’ in this block; elements: the value named ’elements’ in this block. Context: the function as_dict, which handles as dict.

Line 74: `variance = max(0.0, second_moment - mean * mean)` This assigns ‘max(0.0, second_moment - mean * mean)‘ to ‘variance ‘ in host memory. Here variance means the average squared distance from the mean. The important operands are max: the value named ’max’ in this block; second_moment: the value named ’second moment’ in this block; mean: the arithmetic average used by normalization. Context: the function as_dict, which handles as dict.

Line 75: `return {` This statement continues through source line 85; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()), "maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }‘ to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are elements: the value named ’elements’ in this block; batches: the value named ’batches’ in this block; minimum: the value named ’minimum’ in this block.

Line 76: `"elements": self.elements,` This is continuation line 2 of the 11-line logical statement that begins at source line 75. Its exact fragment is ‘"elements": self.elements,‘. The important operands are elements: the value named ’elements’ in this block. Read together, the complete operation is: This returns ‘{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()), "maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }‘ to the caller of the function as_dict, which

handles as dict, ending this invocation. The important operands are elements: the value named 'elements' in this block; batches: the value named 'batches' in this block; minimum: the value named 'minimum' in this block.

Line 77: `"batches": self.batches,` This is continuation line 3 of the 11-line logical statement that begins at source line 75. Its exact fragment is '"batches": self.batches,'. The important operands are batches: the value named 'batches' in this block. Read together, the complete operation is: This returns '{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()), "maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }' to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are elements: the value named 'elements' in this block; batches: the value named 'batches' in this block; minimum: the value named 'minimum' in this block.

Line 78: `"minimum": float(self.minimum.cpu()),` This is continuation line 4 of the 11-line logical statement that begins at source line 75. Its exact fragment is '"minimum": float(self.minimum.cpu()),'. The important operands are minimum: the value named 'minimum' in this block; float: the value named 'float' in this block; cpu: the value named 'cpu' in this block. Read together, the complete operation is: This returns '{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()), "maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }' to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are elements: the value named 'elements' in this block; batches: the value named 'batches' in this block; minimum: the value named 'minimum' in this block.

Line 79: `"maximum": float(self.maximum.cpu()),` This is continuation line 5 of the 11-line logical statement that begins at source line 75. Its exact fragment is '"maximum": float(self.maximum.cpu()),'. The important operands are maximum: the value named 'maximum' in this block; float: the value named 'float' in this block; cpu: the value named 'cpu' in this block. Read together, the complete operation is: This returns '{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()), "maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }' to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are elements: the value named 'elements' in this block; batches: the value named 'batches' in this block; minimum: the value named 'minimum' in this block.

Line 80: `"mean": mean,` This is continuation line 6 of the 11-line logical statement that begins at source line 75. Its exact fragment is '"mean": mean,'. The important operands are mean: the arithmetic average used by normalization. Read together, the complete operation is: This returns '{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()), "maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }' to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are elements: the value named 'elements' in this block; batches: the value named 'batches' in this block; minimum: the value named 'minimum' in this block.

Line 81: `"standard_deviation": variance ** 0.5,` This is continuation line 7 of the 11-line logical statement that begins at source line 75. Its exact fragment is '"standard_deviation": variance ** 0.5,'. The important operands are standard_deviation: the value named 'standard deviation' in this block; variance: the average squared distance from the mean. Read together, the complete operation is: This returns '{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()), "maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }' to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are elements: the value named 'elements' in this block; batches: the value named 'batches' in this block; minimum: the value named 'minimum' in this block.

Line 82: `"nonzero_fraction": float((self.nonzero / self.elements).cpu()),` This is continuation line 8 of the 11-line logical statement that begins at source line 75. Its exact fragment is '"nonzero_fraction": float((self.nonzero / self.elements).cpu()),'. The important operands are nonzero_fraction: the value named 'nonzero fraction' in this block; float: the value named 'float' in this block; nonzero: the value named 'nonzero' in this block. Read together, the complete operation is: This returns '{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()),

"maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }‘ to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are elements: the value named ’elements’ in this block; batches: the value named ’batches’ in this block; minimum: the value named ’minimum’ in this block.

Line 83: `"zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()),` This is continuation line 9 of the 11-line logical statement that begins at source line 75. Its exact fragment is ‘"zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()),‘. The important operands are zero_fraction: the value named ’zero fraction’ in this block; float: the value named ’float’ in this block; nonzero: the value named ’nonzero’ in this block. Read together, the complete operation is: This returns ‘{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()), "maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }‘ to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are elements: the value named ’elements’ in this block; batches: the value named ’batches’ in this block; minimum: the value named ’minimum’ in this block.

Line 84: `"is_spike": self.is_spike,` This is continuation line 10 of the 11-line logical statement that begins at source line 75. Its exact fragment is ‘"is_spike": self.is_spike,‘. The important operands are is_spike: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This returns ‘{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()), "maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }‘ to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are elements: the value named ’elements’ in this block; batches: the value named ’batches’ in this block; minimum: the value named ’minimum’ in this block.

Line 85: `}` This is continuation line 11 of the 11-line logical statement that begins at source line 75. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘{ "elements": self.elements, "batches": self.batches, "minimum": float(self.minimum.cpu()), "maximum": float(self.maximum.cpu()), "mean": mean, "standard_deviation": variance ** 0.5, "nonzero_fraction": float((self.nonzero / self.elements).cpu()), "zero_fraction": 1.0 - float((self.nonzero / self.elements).cpu()), "is_spike": self.is_spike, }‘ to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are elements: the value named ’elements’ in this block; batches: the value named ’batches’ in this block; minimum: the value named ’minimum’ in this block.

Line 88: `class CalibrationObserver:` This defines class CalibrationObserver, which groups data and methods for calibration observer. Instances exist in host memory and organize the flow that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 89: `"""Collect aggregate ranges and sparsity without retaining feature maps."""` This is executable documentation attached to the class CalibrationObserver, which handles calibration observer. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 91: `def __init__(self) -> None:` This starts function ___init___. Its indented body performs init as part of the file that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set; it runs only when called.

Line 92: `self.stats: dict[str, RunningTensorStats] = {}` This assigns ‘{}‘ to ‘self.stats‘ in host memory. Here stats means the value named ’stats’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 94: `def __call__(self, name: str, value: torch.Tensor, is_spike: bool) -> None:` This starts function ___call___. Its indented body performs call as part of the file that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set; it runs only when called.

Line 95: `if name in self.stats:` This executes the following indented host-code branch only when ‘name in self.stats‘ is true. The important operands are name: the value named ’name’ in this block; in: the value named ’in’ in this block; stats: the value named ’stats’ in this block. Context: the function ___call___, which handles call.

Line 96: `self.stats[name].update(value, is_spike)` Inside the function ___call___, which handles call, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are stats: the value named ’stats’ in this block; name: the value named ’name’ in this block; update: the value named ’update’ in this block.

Line 97: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function ___call___, which handles call.

Line 98: `self.stats[name] = RunningTensorStats.from_tensor(value, is_spike)` This assigns ‘RunningTensorStats.from_tensor(value, is_spike)‘ to ‘self.stats[name] ‘ in host memory. Here stats means the value named ’stats’ in this block. The important operands are RunningTensorStats: the value named ’running tensor stats’ in this block; from_tensor: the value named ’from tensor’ in this block; value: the value named ’value’ in this block. Context: the function ___call___, which handles call.

Line 100: `def as_dict(self) -> dict[str, dict[str, int | float | bool]]:` This starts function as_dict. Its indented body performs as dict as part of the file that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set; it runs only when called.

Line 101: `return {name: item.as_dict() for name, item in self.stats.items()}` This returns ‘{name: item.as_dict() for name, item in self.stats.items()}‘ to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are name: the value named ’name’ in this block; item: the value named ’item’ in this block; as_dict: the value named ’as dict’ in this block.

Line 104: `def evaluate(arguments: argparse.Namespace) -> dict[str, object]:` This starts function evaluate. Its indented body performs evaluate as part of the file that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set; it runs only when called.

Line 105: `output_dir = Path(arguments.output_dir).resolve()` This assigns ‘Path(arguments.output_dir).resolve()‘ to ‘output_dir ‘ in host memory. Here output_dir means the value named ’output dir’ in this block. The important operands are Path: the value named ’path’ in this block; arguments: the value named ’arguments’ in this block; output_dir: the value named ’output dir’ in this block. Context: the function evaluate, which handles evaluate.

Line 106: `output_dir.mkdir(parents=True, exist_ok=True)` This calls ‘output_dir.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 107: `device = torch.device(arguments.device)` This assigns ‘torch.device(arguments.device)‘ to ‘device ‘ in host memory. Here device means the value named ’device’ in this block. The important operands are torch: the value named ’torch’ in this block; device: the value named ’device’ in this block; arguments: the value named ’arguments’ in this block. Context: the function evaluate, which handles evaluate.

Line 108: `loaded = load_checkpoint(arguments.checkpoint, device=device)` This assigns ‘load_checkpoint(arguments.checkpoint, device=device)‘ to ‘loaded ‘ in host memory. Here loaded means the value named ’loaded’ in this block. The important operands are load_checkpoint: the value named ’load checkpoint’ in this block; arguments: the value named ’arguments’ in this block; checkpoint: the value named ’checkpoint’ in this block. Context: the function evaluate, which handles evaluate.

Line 109: `model = loaded.model` This assigns ‘loaded.model‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are loaded: the value named ’loaded’ in this block; model: the value named ’model’ in this block. Context: the function evaluate, which handles evaluate.

Line 110: `quantization_report: dict[str, object] | None = None` This assigns ‘None‘ to ‘quantization_report‘ in host memory. Here quantization_report means the value named ’quantization report’ in this block. The important operands are None: the value named ’none’ in this block. Context: the function evaluate, which handles evaluate.

Line 111: `if arguments.hardware_emulation:` This executes the following indented host-code branch only when ‘arguments.hardware_emulation‘ is true. The important operands are arguments: the value named ’arguments’ in this block; hardware_emulation: the value named ’hardware emulation’ in this block. Context: the function evaluate, which handles evaluate.

Line 112: `model, hardware_report = prepare_hardware_emulation(` This statement continues through source line 116; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘prepare_hardware_emulation(model, fractional_bits=arguments.fractional_bits, weight_granularity=arguments.weight_granularity)‘ to ‘model, hardware_report ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are prepare_hardware_emulation: the value named ’prepare hardware emulation’ in this block; model: the value named ’model’ in this block; fractional_bits: the value named ’fractional bits’ in this block. Context: the function evaluate, which handles evaluate.

Line 113: `model,` This is continuation line 2 of the 5-line logical statement that begins at source line 112. Its exact fragment is ‘model,‘. The important operands are model: the value named ’model’ in this block. Read together, the complete operation is: This assigns ‘prepare_hardware_emulation(model, fractional_bits=arguments.fractional_bits, weight_granularity=arguments.weight_granularity,)‘ to ‘model, hardware_report ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are prepare_hardware_emulation: the value named ’prepare hardware emulation’ in this block; model: the value named ’model’ in this block; fractional_bits: the value named ’fractional bits’ in this block. Context: the function evaluate, which handles evaluate.

Line 114: `fractional_bits=arguments.fractional_bits,` This is continuation line 3 of the 5-line logical statement that begins at source line 112. Its exact fragment is ‘fractional_bits=arguments.fractional_bits,‘. The important operands are fractional_bits: the value named ’fractional bits’ in this block; arguments: the value named ’arguments’ in this block. Read together, the complete operation is: This assigns ‘prepare_hardware_emulation(model, fractional_bits=arguments.fractional_bits, weight_granularity=arguments.weight_granularity,)‘ to ‘model, hardware_report ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are prepare_hardware_emulation: the value named ’prepare hardware emulation’ in this block; model: the value named ’model’ in this block; fractional_bits: the value named ’fractional bits’ in this block. Context: the function evaluate, which handles evaluate.

Line 115: `weight_granularity=arguments.weight_granularity,` This is continuation line 4 of the 5-line logical statement that begins at source line 112. Its exact fragment is ‘weight_granularity=arguments.weight_granularity,‘. The important operands are weight_granularity: a learned coefficient multiplied by an activation; arguments: the value named ’arguments’ in this block. Read together, the complete operation is: This assigns ‘prepare_hardware_emulation(model, fractional_bits=arguments.fractional_bits, weight_granularity=arguments.weight_granularity,)‘ to ‘model, hardware_report ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are prepare_hardware_emulation: the value named ’prepare hardware emulation’ in this block; model: the value named ’model’ in this block; fractional_bits: the value named ’fractional bits’ in this block. Context: the function evaluate, which handles evaluate.

Line 116: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 112. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘prepare_hardware_emulation(model, fractional_bits=arguments.fractional_bits, weight_granularity=arguments.weight_granularity,)‘ to ‘model, hardware_report ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are prepare_hardware_emulation: the value named ’prepare hardware emulation’ in this block; model: the value named ’model’ in this block; fractional_bits: the value named ’fractional bits’ in this block. Context: the function evaluate, which handles evaluate.

Line 117: `model = model.to(device)` This assigns ‘model.to(device)‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are model: the value named ’model’ in this block; to:

the value named 'to' in this block; device: the value named 'device' in this block. Context: the function evaluate, which handles evaluate.

Line 118: `quantization_report = hardware_report.as_dict()` This assigns 'hardware_report.as_dict()' to 'quantization_report ' in host memory. Here quantization_report means the value named 'quantization report' in this block. The important operands are hardware_report: the value named 'hardware report' in this block; as_dict: the value named 'as dict' in this block. Context: the function evaluate, which handles evaluate.

Line 119: `transform = transforms.Compose([` This statement continues through source line 122; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'transforms.Compose([transforms.ToTensor(), transforms.Normalize(CIFAR10_MEAN, CIFAR10_STD),])' to 'transform ' in host memory. Here transform means the value named 'transform' in this block. The important operands are transforms: the value named 'transforms' in this block; Compose: the value named 'compose' in this block; ToTensor: the value named 'to tensor' in this block. Context: the function evaluate, which handles evaluate.

Line 120: `transforms.ToTensor(),` This is continuation line 2 of the 4-line logical statement that begins at source line 119. Its exact fragment is 'transforms.ToTensor(),'. The important operands are transforms: the value named 'transforms' in this block; ToTensor: the value named 'to tensor' in this block. Read together, the complete operation is: This assigns 'transforms.Compose([transforms.ToTensor(), transforms.Normalize(CIFAR10_MEAN, CIFAR10_STD),])' to 'transform ' in host memory. Here transform means the value named 'transform' in this block. The important operands are transforms: the value named 'transforms' in this block; Compose: the value named 'compose' in this block; ToTensor: the value named 'to tensor' in this block. Context: the function evaluate, which handles evaluate.

Line 121: `transforms.Normalize(CIFAR10_MEAN, CIFAR10_STD),` This is continuation line 3 of the 4-line logical statement that begins at source line 119. Its exact fragment is 'transforms.Normalize(CIFAR10_MEAN, CIFAR10_STD),'. The important operands are transforms: the value named 'transforms' in this block; Normalize: the value named 'normalize' in this block; CIFAR10_MEAN: the arithmetic average used by normalization. Read together, the complete operation is: This assigns 'transforms.Compose([transforms.ToTensor(), transforms.Normalize(CIFAR10_MEAN, CIFAR10_STD),])' to 'transform ' in host memory. Here transform means the value named 'transform' in this block. The important operands are transforms: the value named 'transforms' in this block; Compose: the value named 'compose' in this block; ToTensor: the value named 'to tensor' in this block. Context: the function evaluate, which handles evaluate.

Line 122: `])` This is continuation line 4 of the 4-line logical statement that begins at source line 119. Its exact fragment is '])'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'transforms.Compose([transforms.ToTensor(), transforms.Normalize(CIFAR10_MEAN, CIFAR10_STD),])' to 'transform ' in host memory. Here transform means the value named 'transform' in this block. The important operands are transforms: the value named 'transforms' in this block; Compose: the value named 'compose' in this block; ToTensor: the value named 'to tensor' in this block. Context: the function evaluate, which handles evaluate.

Line 123: `dataset = datasets.CIFAR10(` This statement continues through source line 128; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'datasets.CIFAR10(root=str(Path(arguments.data_root train=False, transform=transform, download=arguments.download,)' to 'dataset ' in host memory. Here dataset means the value named 'dataset' in this block. The important operands are datasets: the value named 'datasets' in this block; CIFAR10: the value named 'cifar10' in this block; root: the value named 'root' in this block. Context: the function evaluate, which handles evaluate.

Line 124: `root=str(Path(arguments.data_root).resolve()),` This is continuation line 2 of the 6-line logical statement that begins at source line 123. Its exact fragment is 'root=str(Path(arguments.data_root).resolve()),'. The important operands are root: the value named 'root' in this block; str: the value named 'str' in this block; Path: the value named 'path' in this block. Read together, the complete operation is: This assigns 'datasets.CIFAR10(root=str(Path(arguments.data_root).resolve()), train=False, transform=transform, download=arguments.download,)' to 'dataset ' in host memory. Here dataset means the value named 'dataset' in this block. The important operands are datasets: the value named 'datasets' in this block; CIFAR10: the value named 'cifar10' in this block; root: the value named 'root' in this block. Context: the function evaluate, which handles evaluate.

Line 125: `train=False,` This is continuation line 3 of the 6-line logical statement that begins at source line 123. Its exact fragment is 'train=False,'. The important operands are train: the value named 'train' in this block. Read together, the complete operation is: This assigns 'datasets.CIFAR10(root=str(Path(arguments.data_root).resolve()), train=False, transform=transform, download=arguments.download,)' to 'dataset ' in host memory. Here dataset means the value named 'dataset' in this block. The important operands are datasets: the value named 'datasets' in this block; CIFAR10: the value named 'cifar10' in this block; root: the value named 'root' in this block. Context: the function evaluate, which handles evaluate.

Line 126: `transform=transform,` This is continuation line 4 of the 6-line logical statement that begins at source line 123. Its exact fragment is 'transform=transform,'. The important operands are transform: the value named 'transform' in this block. Read together, the complete operation is: This assigns 'datasets.CIFAR10(root=str(Path(arguments.data_root).resolve(train=False, transform=transform, download=arguments.download,)' to 'dataset ' in host memory. Here dataset means the value named 'dataset' in this block. The important operands are datasets: the value named 'datasets' in this block; CIFAR10: the value named 'cifar10' in this block; root: the value named 'root' in this block. Context: the function evaluate, which handles evaluate.

Line 127: `download=arguments.download,` This is continuation line 5 of the 6-line logical statement that begins at source line 123. Its exact fragment is 'download=arguments.download,'. The important operands are download: the value named 'download' in this block; arguments: the value named 'arguments' in this block. Read together, the complete operation is: This assigns 'datasets.CIFAR10(root=str(Path(arguments.data_root).resolve()), train=False, transform=transform, download=arguments.download,)' to 'dataset ' in host memory. Here dataset means the value named 'dataset' in this block. The important operands are datasets: the value named 'datasets' in this block; CIFAR10: the value named 'cifar10' in this block; root: the value named 'root' in this block. Context: the function evaluate, which handles evaluate.

Line 128: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 123. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'datasets.CIFAR10(root=str(Path(arguments.data_root).resolve()), train=False, transform=transform, download=arguments.download,)' to 'dataset ' in host memory. Here dataset means the value named 'dataset' in this block. The important operands are datasets: the value named 'datasets' in this block; CIFAR10: the value named 'cifar10' in this block; root: the value named 'root' in this block. Context: the function evaluate, which handles evaluate.

Line 129: `generator = torch.Generator().manual_seed(arguments.seed)` This assigns 'torch.Generator().manual_seed(arg to 'generator ' in host memory. Here generator means the value named 'generator' in this block. The important operands are torch: the value named 'torch' in this block; Generator: the value named 'generator' in this block; manual_seed: the value named 'manual seed' in this block. Context: the function evaluate, which handles evaluate.

Line 130: `loader = DataLoader(` This statement continues through source line 138; the explanation uses the complete expression rather than only the first visual fragment. Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are loader: the value named 'loader' in this block; DataLoader: the value named 'data loader' in this block; dataset: the value named 'dataset' in this block.

Line 131: `dataset,` This is continuation line 2 of the 9-line logical statement that begins at source line 130. Its exact fragment is 'dataset,'. The important operands are dataset: the value named 'dataset' in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are loader: the value named 'loader' in this block; DataLoader: the value named 'data loader' in this block; dataset: the value named 'dataset' in this block.

Line 132: `batch_size=arguments.batch_size,` This is continuation line 3 of the 9-line logical statement that begins at source line 130. Its exact fragment is 'batch_size=arguments.batch_size,'. The important operands are batch_size: the value named 'batch size' in this block; arguments: the value named 'arguments' in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important

operands are loader: the value named 'loader' in this block; DataLoader: the value named 'data loader' in this block; dataset: the value named 'dataset' in this block.

Line 133: `shuffle=False,` This is continuation line 4 of the 9-line logical statement that begins at source line 130. Its exact fragment is 'shuffle=False,'. The important operands are shuffle: the value named 'shuffle' in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are loader: the value named 'loader' in this block; DataLoader: the value named 'data loader' in this block; dataset: the value named 'dataset' in this block.

Line 134: `num_workers=arguments.workers,` This is continuation line 5 of the 9-line logical statement that begins at source line 130. Its exact fragment is 'num_workers=arguments.workers,'. The important operands are num_workers: the value named 'num workers' in this block; arguments: the value named 'arguments' in this block; workers: the value named 'workers' in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are loader: the value named 'loader' in this block; DataLoader: the value named 'data loader' in this block; dataset: the value named 'dataset' in this block.

Line 135: `pin_memory=device.type == "cuda",` This is continuation line 6 of the 9-line logical statement that begins at source line 130. Its exact fragment is 'pin_memory=device.type == "cuda",'. The important operands are pin_memory: local FPGA storage addressed by surrounding index logic; device: the value named 'device' in this block; type: the value named 'type' in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are loader: the value named 'loader' in this block; DataLoader: the value named 'data loader' in this block; dataset: the value named 'dataset' in this block.

Line 136: `persistent_workers=arguments.workers > 0,` This is continuation line 7 of the 9-line logical statement that begins at source line 130. Its exact fragment is 'persistent_workers=arguments.workers > 0,'. The important operands are persistent_workers: the value named 'persistent workers' in this block; arguments: the value named 'arguments' in this block; workers: the value named 'workers' in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are loader: the value named 'loader' in this block; DataLoader: the value named 'data loader' in this block; dataset: the value named 'dataset' in this block.

Line 137: `generator=generator,` This is continuation line 8 of the 9-line logical statement that begins at source line 130. Its exact fragment is 'generator=generator,'. The important operands are generator: the value named 'generator' in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are loader: the value named 'loader' in this block; DataLoader: the value named 'data loader' in this block; dataset: the value named 'dataset' in this block.

Line 138: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 130. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are loader: the value named 'loader' in this block; DataLoader: the value named 'data loader' in this block; dataset: the value named 'dataset' in this block.

Line 139: `observer = CalibrationObserver() if arguments.collect_stats else None` This assigns 'CalibrationObserver() if arguments.collect_stats else None' to 'observer ' in host memory. Here observer means the value named 'observer' in this block. The important operands are CalibrationObserver: the value named 'calibration observer' in this block; arguments: the value named 'arguments' in this block; collect_stats: the value named 'collect stats' in this block. Context: the function evaluate, which handles evaluate.

Line 140: `confusion = np.zeros((10, 10), dtype=np.int64)` This assigns ‘np.zeros((10, 10), dtype=np.int64)‘ to ‘confusion ‘ in host memory. Here confusion means the value named ’confusion’ in this block. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function evaluate, which handles evaluate.

Line 141: `all_logits: list[np.ndarray] = []` This assigns ‘[]‘ to ‘all_logits‘ in host memory. Here all_logits means the ten unnormalized classifier scores used for argmax. The expression is a literal or structural operator and has no hidden software state. Context: the function evaluate, which handles evaluate.

Line 142: `all_labels: list[np.ndarray] = []` This assigns ‘[]‘ to ‘all_labels‘ in host memory. Here all_labels means the value named ’all labels’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function evaluate, which handles evaluate.

Line 143: `correct = 0` This assigns ‘0‘ to ‘correct ‘ in host memory. Here correct means the value named ’correct’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function evaluate, which handles evaluate.

Line 144: `samples = 0` This assigns ‘0‘ to ‘samples ‘ in host memory. Here samples means the value named ’samples’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function evaluate, which handles evaluate.

Line 145: `started = time.perf_counter()` This assigns ‘time.perf_counter()‘ to ‘started ‘ in host memory. Here started means the value named ’started’ in this block. The important operands are time: the value named ’time’ in this block; perf_counter: a hardware telemetry register that accumulates measured events. Context: the function evaluate, which handles evaluate.

Line 147: `with torch.inference_mode():` This opens a managed resource scope for ‘torch.inference_mode()‘ so files, tracing, or temporary state are finalized even if the function evaluate, which handles evaluate raises an error.

Line 148: `for batch_index, (image, label) in enumerate(loader):` This iterates batch_index, (image, label) over ‘enumerate(loader)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function evaluate, which handles evaluate.

Line 149: `image = image.to(device, non_blocking=True)` This assigns ‘image.to(device, non_blocking=True)‘ to ‘image ‘ in host memory. Here image means the value named ’image’ in this block. The important operands are image: the value named ’image’ in this block; to: the value named ’to’ in this block; device: the value named ’device’ in this block. Context: the function evaluate, which handles evaluate.

Line 150: `label = label.to(device, non_blocking=True)` This assigns ‘label.to(device, non_blocking=True)‘ to ‘label ‘ in host memory. Here label means the value named ’label’ in this block. The important operands are label: the value named ’label’ in this block; to: the value named ’to’ in this block; device: the value named ’device’ in this block. Context: the function evaluate, which handles evaluate.

Line 151: `if arguments.hardware_emulation:` This executes the following indented host-code branch only when ‘arguments.hardware_emulation‘ is true. The important operands are arguments: the value named ’arguments’ in this block; hardware_emulation: the value named ’hardware emulation’ in this block. Context: the function evaluate, which handles evaluate.

Line 152: `image, _, _ = quantize_cifar_input_u8(image)` This assigns ‘quantize_cifar_input_u8(image)‘ to ‘image, _, _ ‘ in host memory. Here image means the value named ’image’ in this block. The important operands are quantize_cifar_input_u8: the value named ’quantize cifar input u8’ in this block; image: the value named ’image’ in this block. Context: the function evaluate, which handles evaluate.

Line 153: `logits = model(image, observer=observer)` This assigns ‘model(image, observer=observer)‘ to ‘logits ‘ in host memory. Here logits means the ten unnormalized classifier scores used for argmax. The important operands are model: the value named ’model’ in this block; image: the value named ’image’ in this block; observer: the value named ’observer’ in this block. Context: the function evaluate, which handles evaluate.

Line 154: `prediction = logits.argmax(dim=1)` This assigns ‘logits.argmax(dim=1)‘ to ‘prediction ‘ in host memory. Here prediction means the class index with the greatest classifier score. The important operands are logits: the ten unnormalized classifier scores used for argmax; argmax: the value named ’argmax’ in this block; dim: the value named ’dim’ in this block. Context: the function evaluate, which handles evaluate.

Line 155: `labels_cpu = label.cpu().numpy()` This assigns ‘label.cpu().numpy()‘ to ‘labels_cpu ‘ in host memory. Here labels_cpu means the value named ’labels cpu’ in this block. The important operands are label: the value named ’label’ in this block; cpu: the value named ’cpu’ in this block; numpy: the value named ’numpy’ in this block. Context: the function evaluate, which handles evaluate.

Line 156: `predictions_cpu = prediction.cpu().numpy()` This assigns ‘prediction.cpu().numpy()‘ to ‘predictions_cpu ‘ in host memory. Here predictions_cpu means the class index with the greatest classifier score. The important operands are prediction: the class index with the greatest classifier score; cpu: the value named ’cpu’ in this block; numpy: the value named ’numpy’ in this block. Context: the function evaluate, which handles evaluate.

Line 157: `np.add.at(confusion, (labels_cpu, predictions_cpu), 1)` This calls ‘np.add.at‘ with ‘confusion, (labels_cpu, predictions_cpu), 1‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 158: `all_logits.append(logits.float().cpu().numpy())` This calls ‘all_logits.append‘ with ‘logits.float().cpu().numpy inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 159: `all_labels.append(labels_cpu)` This calls ‘all_labels.append‘ with ‘labels_cpu‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 160: `correct += int((prediction == label).sum().item())` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are correct: the value named ’correct’ in this block; prediction: the class index with the greatest classifier score; label: the value named ’label’ in this block.

Line 161: `samples += label.numel()` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are samples: the value named ’samples’ in this block; label: the value named ’label’ in this block; numel: the value named ’numel’ in this block.

Line 162: `if arguments.log_interval and (batch_index + 1) % arguments.log_interval == 0:` This executes the following indented host-code branch only when ‘arguments.log_interval and (batch_index + 1) % arguments.log_interval == 0‘ is true. The important operands are arguments: the value named ’arguments’ in this block; log_interval: the value named ’log interval’ in this block; and: the value named ’and’ in this block. Context: the function evaluate, which handles evaluate.

Line 163: `print(` This statement continues through source line 167; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘print‘ with ‘ f"batch={batch_index + 1}/{len(loader)} " f"samples={samples} accuracy={100.0 * correct / samples:.4f}%", flush=True, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 164: `f"batch={batch_index + 1}/{len(loader)} "` This is continuation line 2 of the 5-line logical statement that begins at source line 163. Its exact fragment is ‘f"batch={batch_index + 1}/{len(loader)} "‘. The important operands are f: the value named ’f’ in this block; batch: the value named ’batch’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘print‘ with ‘ f"batch={batch_index + 1}/{len(loader)} " f"samples={samples} accuracy={100.0 * correct / samples:.4f}%", flush=True, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 165: `f"samples={samples} accuracy={100.0 * correct / samples:.4f}%",` This is continuation line 3 of the 5-line logical statement that begins at source line 163. Its exact fragment is ‘f"samples={samples} accuracy={100.0 * correct / samples:.4f}%",‘. The important operands are f: the value named ’f’ in this block; samples: the value named ’samples’ in this block; accuracy: the value named ’accuracy’ in this block. Read together, the complete operation is: This calls ‘print‘ with ‘ f"batch={batch_index + 1}/{len(loader)} " f"samples={samples} accuracy={100.0 * correct / samples:.4f}%", flush=True, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 166: `flush=True,` This is continuation line 4 of the 5-line logical statement that begins at source line 163. Its exact fragment is ‘flush=True,‘. The important operands are flush: the value named ’flush’ in this block. Read together, the complete operation is: This calls ‘print‘ with ‘ f"batch={batch_index + 1}/{len(loader)} " f"samples={samples} accuracy={100.0 * correct / samples:.4f}%", flush=True, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 167: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 163. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘print‘ with ‘ f"batch={batch_index + 1}/{len(loader)} " f"samples={samples} accuracy={100.0 * correct / samples:.4f}%", flush=True, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 169: `elapsed = time.perf_counter() - started` This assigns ‘time.perf_counter() - started‘ to ‘elapsed ‘ in host memory. Here elapsed means the value named ’elapsed’ in this block. The important operands are time: the value named ’time’ in this block; perf_counter: a hardware telemetry register that accumulates measured events; started: the value named ’started’ in this block. Context: the function evaluate, which handles evaluate.

Line 170: `logits_array = np.concatenate(all_logits, axis=0)` This assigns ‘np.concatenate(all_logits, axis=0)‘ to ‘logits_array ‘ in host memory. Here logits_array means the ten unnormalized classifier scores used for argmax. The important operands are concatenate: the value named ’concatenate’ in this block; all_logits: the ten unnormalized classifier scores used for argmax; axis: the value named ’axis’ in this block. Context: the function evaluate, which handles evaluate.

Line 171: `labels_array = np.concatenate(all_labels, axis=0)` This assigns ‘np.concatenate(all_labels, axis=0)‘ to ‘labels_array ‘ in host memory. Here labels_array means the value named ’labels array’ in this block. The important operands are concatenate: the value named ’concatenate’ in this block; all_labels: the value named ’all labels’ in this block; axis: the value named ’axis’ in this block. Context: the function evaluate, which handles evaluate.

Line 172: `predictions_array = logits_array.argmax(axis=1)` This assigns ‘logits_array.argmax(axis=1)‘ to ‘predictions_array ‘ in host memory. Here predictions_array means the class index with the greatest classifier score. The important operands are logits_array: the ten unnormalized classifier scores used for argmax; argmax: the value named ’argmax’ in this block; axis: the value named ’axis’ in this block. Context: the function evaluate, which handles evaluate.

Line 173: `class_totals = confusion.sum(axis=1)` This assigns ‘confusion.sum(axis=1)‘ to ‘class_totals ‘ in host memory. Here class_totals means the value named ’class totals’ in this block. The important operands are confusion: the value named ’confusion’ in this block; sum: the value named ’sum’ in this block; axis: the value named ’axis’ in this block. Context: the function evaluate, which handles evaluate.

Line 174: `class_correct = np.diag(confusion)` This assigns ‘np.diag(confusion)‘ to ‘class_correct ‘ in host memory. Here class_correct means the value named ’class correct’ in this block. The important operands are diag: the value named ’diag’ in this block; confusion: the value named ’confusion’ in this block. Context: the function evaluate, which handles evaluate.

Line 175: `class_accuracy = np.divide(` This statement continues through source line 180; the explanation uses the complete expression rather than only the first visual fragment. Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are class_accuracy: the value named ’class accuracy’ in this block; divide: the value named ’divide’ in this block; class_correct: the value named ’class correct’ in this block.

Line 176: `class_correct,` This is continuation line 2 of the 6-line logical statement that begins at source line 175. Its exact fragment is ‘class_correct,‘. The important operands are class_correct: the value named ’class correct’ in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are class_accuracy: the value named ’class accuracy’ in this block; divide: the value named ’divide’ in this block; class_correct: the value named ’class correct’ in this block.

Line 177: `class_totals,` This is continuation line 3 of the 6-line logical statement that begins at source line 175. Its exact fragment is ‘class_totals,‘. The important operands are class_totals: the value named ’class totals’ in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are class_accuracy: the value named ’class accuracy’ in this block; divide: the value named ’divide’ in this block; class_correct: the value named ’class correct’ in this block.

Line 178: `out=np.zeros(10, dtype=np.float64),` This is continuation line 4 of the 6-line logical statement that begins at source line 175. Its exact fragment is ‘out=np.zeros(10, dtype=np.float64),‘. The important operands are out: the value named ’out’ in this block; zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are class_accuracy: the value named ’class accuracy’ in this block; divide: the value named ’divide’ in this block; class_correct: the value named ’class correct’ in this block.

Line 179: `where=class_totals != 0,` This is continuation line 5 of the 6-line logical statement that begins at source line 175. Its exact fragment is ‘where=class_totals != 0,‘. The important operands are where: the value named ’where’ in this block; class_totals: the value named ’class totals’ in this block. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are class_accuracy: the value named ’class accuracy’ in this block; divide: the value named ’divide’ in this block; class_correct: the value named ’class correct’ in this block.

Line 180: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 175. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are class_accuracy: the value named ’class accuracy’ in this block; divide: the value named ’divide’ in this block; class_correct: the value named ’class correct’ in this block.

Line 181: `accuracy = 100.0 * correct / samples` This assigns ‘100.0 * correct / samples‘ to ‘accuracy ‘ in host memory. Here accuracy means the value named ’accuracy’ in this block. The important operands are correct: the value named ’correct’ in this block; samples: the value named ’samples’ in this block. Context: the function evaluate, which handles evaluate.

Line 183: `np.savez_compressed(` This statement continues through source line 189; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘np.savez_compressed‘ with ‘ output_dir / "spikingformer_predictions.npz", logits=logits_array, labels=labels_array, predictions=predictions_array, confusion_matrix=confusion,

‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 184: `output_dir / "spikingformer_predictions.npz",` This is continuation line 2 of the 7-line logical statement that begins at source line 183. Its exact fragment is ‘output_dir / "spikingformer_predictions.npz",‘. The important operands are output_dir: the value named ’output dir’ in this block; spikingformer_predictions: the class index with the greatest classifier score; npz: the value named ’npz’ in this block. Read together, the complete operation is: This calls ‘np.savez_compressed‘ with ‘ output_dir / "spikingformer_predictions.npz", logits=logits_array, labels=labels_array, predictions=predictions_array, confusion_matrix=confusion, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 185: `logits=logits_array,` This is continuation line 3 of the 7-line logical statement that begins at source line 183. Its exact fragment is ‘logits=logits_array,‘. The important operands are logits: the ten unnormalized classifier scores used for argmax; logits_array: the ten unnormalized classifier scores used for argmax. Read together, the complete operation is: This calls ‘np.savez_compressed‘ with ‘ output_dir / "spikingformer_predictions.npz", logits=logits_array, labels=labels_array, predictions=predictions_array, confusion_matrix=confusion, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 186: `labels=labels_array,` This is continuation line 4 of the 7-line logical statement that begins at source line 183. Its exact fragment is ‘labels=labels_array,‘. The important operands are labels: the value named ’labels’ in this block; labels_array: the value named ’labels array’ in this block. Read together, the complete operation is: This calls ‘np.savez_compressed‘ with ‘ output_dir / "spikingformer_predictions.npz", logits=logits_array, labels=labels_array, predictions=predictions_array, confusion_matrix=confusion, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 187: `predictions=predictions_array,` This is continuation line 5 of the 7-line logical statement that begins at source line 183. Its exact fragment is ‘predictions=predictions_array,‘. The important operands are predictions: the class index with the greatest classifier score; predictions_array: the class index with the greatest classifier score. Read together, the complete operation is: This calls ‘np.savez_compressed‘ with ‘ output_dir / "spikingformer_predictions.npz", logits=logits_array, labels=labels_array, predictions=predictions_array, confusion_matrix=confusion, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 188: `confusion_matrix=confusion,` This is continuation line 6 of the 7-line logical statement that begins at source line 183. Its exact fragment is ‘confusion_matrix=confusion,‘. The important operands are confusion_matrix: the value named ’confusion matrix’ in this block; confusion: the value named ’confusion’ in this block. Read together, the complete operation is: This calls ‘np.savez_compressed‘ with ‘ output_dir / "spikingformer_predictions.npz", logits=logits_array, labels=labels_array, predictions=predictions_array, confusion_matrix=confusion, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 189: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 183. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘np.savez_compressed‘ with ‘ output_dir / "spikingformer_predictions.npz", logits=logits_array, labels=labels_array, predictions=predictions_array, confusion_matrix=confusion, ‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 190: `with (output_dir / "spikingformer_predictions.csv").open(` This opens a managed resource scope for ‘(output_dir / "spikingformer_predictions.csv").open‘ so files, tracing, or temporary state are finalized even if the function evaluate, which handles evaluate raises an error.

Line 191: `"w", newline="", encoding="ascii") as handle:` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are w: the value named 'w' in this block; newline: the value named 'newline' in this block; encoding: the value named 'encoding' in this block.

Line 192: `writer = csv.writer(handle)` This assigns ‘csv.writer(handle)‘ to ‘writer ‘ in host memory. Here writer means the value named 'writer' in this block. The important operands are csv: the value named 'csv' in this block; writer: the value named 'writer' in this block; handle: the value named 'handle' in this block. Context: the function evaluate, which handles evaluate.

Line 193: `writer.writerow(("sample", "label", "prediction", "correct", *(` This statement continues through source line 194; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘writer.writerow‘ with ‘("sample", "label", "prediction", "correct", *(f"logit_{name}" for name in CIFAR10_CLASSES))‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 194: `f"logit_{name}" for name in CIFAR10_CLASSES)))` This is continuation line 2 of the 2-line logical statement that begins at source line 193. Its exact fragment is ‘f"logit_{name}" for name in CIFAR10_CLASSES)))‘. The important operands are f: the value named 'f' in this block; logit_: the value named 'logit' in this block; name: the value named 'name' in this block. Read together, the complete operation is: This calls ‘writer.writerow‘ with ‘("sample", "label", "prediction", "correct", *(f"logit_{name}" for name in CIFAR10_CLASSES))‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 195: `for index, (label, prediction, logits) in enumerate(zip(` This line opens or closes a multi-line Python expression inside the function evaluate, which handles evaluate; the neighboring lines supply its arguments or elements.

Line 196: `labels_array, predictions_array, logits_array)):` Inside the function evaluate, which handles evaluate, this statement advances the host implementation that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The important operands are labels_array: the value named 'labels array' in this block; predictions_array: the class index with the greatest classifier score; logits_array: the ten unnormalized classifier scores used for argmax.

Line 197: `writer.writerow((` This statement continues through source line 203; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘writer.writerow‘ with ‘(index, int(label), int(prediction), int(label == prediction), *(f"{float(item):.9g}" for item in logits),)‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 198: `index,` This is continuation line 2 of the 7-line logical statement that begins at source line 197. Its exact fragment is ‘index,‘. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘writer.writerow‘ with ‘(index, int(label), int(prediction), int(label == prediction), *(f"{float(item):.9g}" for item in logits),)‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 199: `int(label),` This is continuation line 3 of the 7-line logical statement that begins at source line 197. Its exact fragment is ‘int(label),‘. The important operands are label: the value named 'label' in this block. Read together, the complete operation is: This calls ‘writer.writerow‘ with ‘(index, int(label), int(prediction), int(label == prediction), *(f"{float(item):.9g}" for item in logits),)‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 200: `int(prediction),` This is continuation line 4 of the 7-line logical statement that begins at source line 197. Its exact fragment is ‘int(prediction),‘. The important operands are prediction: the class index with the greatest classifier score. Read together, the complete operation is: This calls ‘writer.writerow‘ with ‘(index, int(label), int(prediction), int(label == prediction), *(f"{float(item):.9g}" for item in logits),)‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 201: `int(label == prediction),` This is continuation line 5 of the 7-line logical statement that begins at source line 197. Its exact fragment is ‘int(label == prediction),‘. The important operands are label: the value named ’label’ in this block; prediction: the class index with the greatest classifier score. Read together, the complete operation is: This calls ‘writer.writerow‘ with ‘(index, int(label), int(prediction), int(label == prediction), *(f"{float(item):.9g}" for item in logits),)‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 202: `*(f"{float(item):.9g}" for item in logits),` This is continuation line 6 of the 7-line logical statement that begins at source line 197. Its exact fragment is ‘*(f"{float(item):.9g}" for item in logits),‘. The important operands are f: the value named ’f’ in this block; float: the value named ’float’ in this block; item: the value named ’item’ in this block. Read together, the complete operation is: This calls ‘writer.writerow‘ with ‘(index, int(label), int(prediction), int(label == prediction), *(f"{float(item):.9g}" for item in logits),)‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 203: `))` This is continuation line 7 of the 7-line logical statement that begins at source line 197. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘writer.writerow‘ with ‘(index, int(label), int(prediction), int(label == prediction), *(f"{float(item):.9g}" for item in logits),)‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 205: `report: dict[str, object] = {` This statement continues through source line 227; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "checkpoint": str(loaded.checkpoint_path), "architecture": loaded.architecture, "checkpoint_epoch": loaded.epoch, "checkpoint_recorded_metric_percent": loaded.metric, "dataset": "CIFAR-10 official test split", "samples": samples, "correct": correct, "top1_accuracy_percent": accuracy, "batch_size": arguments.batch_size, "device": str(device), "elapsed_seconds": elapsed, "images_per_second": samples / elapsed, "normalization_mean": CIFAR10_MEAN, "normalization_std": CIFAR10_STD, "class_accuracy_percent": { name: 100.0 * float(class_accuracy[index]) for index, name in enumerate(CIFAR10_CLASSES) }, "confusion_matrix_rows_true_c confusion.tolist(), "activation_statistics": observer.as_dict() if observer else {}, "hardware_emulation": quantization_report, }‘ to ‘report‘ in host memory. Here report means the value named ’report’ in this block. The important operands are checkpoint: the value named ’checkpoint’ in this block; str: the value named ’str’ in this block; loaded: the value named ’loaded’ in this block. Context: the function evaluate, which handles evaluate.

Line 206: `"checkpoint": str(loaded.checkpoint_path),` This is continuation line 2 of the 23-line logical statement that begins at source line 205. Its exact fragment is ‘"checkpoint": str(loaded.checkpoint_path),‘. The important operands are checkpoint: the value named ’checkpoint’ in this block; str: the value named ’str’ in this block; loaded: the value named ’loaded’ in this block. Read together, the complete operation is: This assigns ‘{ "checkpoint": str(loaded.checkpoint_path), "architecture": loaded.architecture, "checkpoint_epoch": loaded.epoch, "checkpoint_recorded_metric_percent": loaded.metric, "dataset": "CIFAR-10 official test split", "samples": samples, "correct": correct, "top1_accuracy_percent": accuracy, "batch_size": arguments.batch_size, "device": str(device), "elapsed_seconds": elapsed, "images_per_second": samples / elapsed, "normalization_mean": CIFAR10_MEAN, "normalization_std": CIFAR10_STD, "class_accuracy_percent": { name: 100.0 * float(class_accuracy[index]) for index, name in enumerate(CIFAR10_CLASSES) }, "confusion_matrix_rows_true_columns_predicted": confusion.tolist(), "activation_statistics": observer.as_dict() if observer else {}, "hardware_emulation": quantization_report, }‘ to ‘report‘ in host memory. Here report means the value named ’report’ in this block. The important operands are checkpoint: the value named ’checkpoint’ in this block; str: the value named ’str’ in this block; loaded: the value named ’loaded’ in this block. Context: the function evaluate, which handles evaluate.

Line 207: `"architecture": loaded.architecture,` This is continuation line 3 of the 23-line logical statement that begins at source line 205. Its exact fragment is ‘"architecture": loaded.architecture,‘. The important operands are architecture: the value named ’architecture’ in this block; loaded: the value named ’loaded’ in this block. Read together, the complete operation is: This assigns ‘{ "checkpoint": str(loaded.checkpoint_path), "architecture": loaded.architecture, "checkpoint_epoch": loaded.epoch, "checkpoint_recorded_metric_percent": loaded.metric, "dataset": "CIFAR-10 official test split", "samples": samples, "correct": correct, "top1_accuracy_percent": accuracy, "batch_size": arguments.batch_size, "device": str(device), "elapsed_seconds": elapsed, "images_per_second": samples / elapsed, "normalization_mean": CIFAR10_MEAN, "normalization_std": CIFAR10_STD, "class_accuracy_percent": { name: 100.0 * float(class_accuracy[index]) for index, name in enumerate(CIFAR10_CLASSES) }, "confusion_matrix_rows_true_columns_predicted": confusion.tolist(), "activation_statistics": observer.as_dict() if observer else {}, "hardware_emulation": quantization_report, }‘ to ‘report‘ in host memory. Read together, the complete operation is: This calls ‘print‘ with ‘json.dumps({ "samples": samples, "correct": correct, "top1_accuracy_percent": accuracy, "elapsed_seconds": elapsed, "images_per_second": samples / elapsed, "output_dir": str(output_dir), }, indent=2), flush=True‘ inside the function evaluate, which handles evaluate. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 238: `return report` This returns ‘report‘ to the caller of the function evaluate, which handles evaluate, ending this invocation. The important operands are report: the value named ’report’ in this block.

Line 241: `def parse_arguments() -> argparse.Namespace:` This starts function parse_arguments. Its indented body performs parse arguments as part of the file that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set; it runs only when called.

Line 242: `parser = argparse.ArgumentParser()` This assigns ‘argparse.ArgumentParser()‘ to ‘parser ‘ in host memory. Here parser means the value named ’parser’ in this block. The important operands are argparse: the value named ’argparse’ in this block; ArgumentParser: the value named ’argument parser’ in this block. Context: the function parse_arguments, which handles parse arguments.

Line 243: `parser.add_argument("-checkpoint", required=True)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 244: `parser.add_argument("-data-root", required=True)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 245: `parser.add_argument("-output-dir", required=True)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 246: `parser.add_argument("-device", default="cuda")` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 247: `parser.add_argument("-batch-size", type=int, default=32)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 248: `parser.add_argument("-workers", type=int, default=2)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 249: `parser.add_argument("-seed", type=int, default=42)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 250: `parser.add_argument("-log-interval", type=int, default=20)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 251: `parser.add_argument("-collect-stats", action="store_true")` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 252: `parser.add_argument("-hardware-emulation", action="store_true")` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 253: `parser.add_argument("-fractional-bits", type=int, default=10)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 254: `parser.add_argument(` This statement continues through source line 255; the explanation uses the complete expression rather than only the first visual fragment. This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 255: `"-weight-granularity", choices=("tensor", "channel"), default="tensor")` This is continuation line 2 of the 2-line logical statement that begins at source line 254. Its exact fragment is ‘"–weight-granularity", choices=("tensor", "channel"), default="tensor")‘. The important operands are weight: a learned coefficient multiplied by an activation; granularity: the value named 'granularity' in this block; choices: the value named 'choices' in this block. Read together, the complete operation is: This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 256: `parser.add_argument("-download", action="store_true")` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 257: `return parser.parse_args()` This returns ‘parser.parse_args()‘ to the caller of the function parse_arguments, which handles parse arguments, ending this invocation. The important operands are parser: the value named ’parser’ in this block; parse_args: the value named ’parse args’ in this block.

Line 260: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

Line 261: `evaluate(parse_arguments())` This calls ‘evaluate‘ with ‘parse_arguments()‘ inside the file whose role is to evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set. The call advances the host-side job that evaluates the source checkpoint and exported integer arithmetic over the complete CIFAR-10 test set.

26 software/export_cifar10_shards.py

Role in the complete system: writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

26.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: none. Functions: parse_arguments, sha256, write_split. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

26.2 Complete source

26.3 Line annotations

Line 1: `"""Download the official CIFAR-10 split and export board-friendly NPZ shards."""` This is executable documentation attached to the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import argparse` This imports the named Python API so the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import hashlib` This imports the named Python API so the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `import json` This imports the named Python API so the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `import os` This imports the named Python API so the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `from datetime import datetime, timezone` This imports the named Python API so the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `from pathlib import Path` This imports the named Python API so the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `import numpy as np` This imports the named Python API so the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `def parse_arguments() -> argparse.Namespace:` This starts function parse_arguments. Its indented body performs parse arguments as part of the file that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning; it runs only when called.

Line 16: `parser = argparse.ArgumentParser()` This assigns ‘argparse.ArgumentParser()‘ to ‘parser ‘ in host memory. Here parser means the value named ’parser’ in this block. The important operands are argparse: the value named ’argparse’ in this block; ArgumentParser: the value named ’argument parser’ in this block. Context: the function parse_arguments, which handles parse arguments.

Line 17: `parser.add_argument("-dataset-root", type=Path, required=True)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 18: `parser.add_argument("-output-dir", type=Path, required=True)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 19: `parser.add_argument("-shard-size", type=int, default=1000)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 20: `parser.add_argument("-no-download", action="store_true")` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 21: `return parser.parse_args()` This returns ‘parser.parse_args()‘ to the caller of the function parse_arguments, which handles parse arguments, ending this invocation. The important operands are parser: the value named ’parser’ in this block; parse_args: the value named ’parse args’ in this block.

Line 24: `def sha256(path: Path) -> str:` This starts function sha256. Its indented body performs sha256 as part of the file that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning; it runs only when called.

Line 25: `digest = hashlib.sha256()` This assigns ‘hashlib.sha256()‘ to ‘digest ‘ in host memory. Here digest means the value named ’digest’ in this block. The important operands are hashlib: the value named ’hashlib’ in this block; sha256: the value named ’sha256’ in this block. Context: the function sha256, which handles sha256.

Line 26: `with path.open("rb") as stream:` This opens a managed resource scope for ‘path.open("rb") as stream‘ so files, tracing, or temporary state are finalized even if the function sha256, which handles sha256 raises an error.

Line 27: `for chunk in iter(lambda: stream.read(1 << 20), b""):` This iterates chunk over ‘iter(lambda: stream.read(1 << 20), b"")‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function sha256, which handles sha256.

Line 28: `digest.update(chunk)` This calls ‘digest.update‘ with ‘chunk‘ inside the function sha256, which handles sha256. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 29: `return digest.hexdigest()` This returns ‘digest.hexdigest()‘ to the caller of the function sha256, which handles sha256, ending this invocation. The important operands are digest: the value named ’digest’ in this block; hexdigest: the value named ’hexdigest’ in this block.

Line 32: `def write_split(` This starts function write_split. Its indented body performs write split as part of the file that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning; it runs only when called.

Line 33: `dataset,` Inside the function write_split, which handles write split, this statement advances the host implementation that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning. The important operands are dataset: the value named ’dataset’ in this block.

Line 34: `split: str,` Inside the function write_split, which handles write split, this statement advances the host implementation that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning. The important operands are split: the value named ’split’ in this block; str: the value named ’str’ in this block.

Line 35: `output_dir: Path,` Inside the function write_split, which handles write split, this statement advances the host implementation that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning. The important operands are output_dir: the value named ’output dir’ in this block; Path: the value named ’path’ in this block.

Line 36: `shard_size: int,` Inside the function write_split, which handles write split, this statement advances the host implementation that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning. The important operands are shard_size: the value named ’shard size’ in this block.

Line 37: `) -> list[dict[str, object]]:` Inside the function write_split, which handles write split, this statement advances the host implementation that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning. The important operands are list: the value named ’list’ in this block; dict: the value named ’dict’ in this block; str: the value named ’str’ in this block.

Line 38: `images = np.asarray(dataset.data, dtype=np.uint8)` This assigns ‘np.asarray(dataset.data, dtype=np.uint8)‘ to ‘images ‘ in host memory. Here images means the value named ’images’ in this block. The important operands are asarray: the value named ’asarray’ in this block; dataset: the value named ’dataset’ in this block; data: the value named ’data’ in this block. Context: the function write_split, which handles write split.

Line 39: `labels = np.asarray(dataset.targets, dtype=np.uint8)` This assigns ‘np.asarray(dataset.targets, dtype=np.uint8 to ‘labels ‘ in host memory. Here labels means the value named ’labels’ in this block. The important operands are asarray: the value named ’asarray’ in this block; dataset: the value named ’dataset’ in this block; targets: the value named ’targets’ in this block. Context: the function write_split, which handles write split.

Line 40: `if images.shape != (len(labels), 32, 32, 3):` This executes the following indented host-code branch only when ‘images.shape != (len(labels), 32, 32, 3)‘ is true. The important operands are images: the value named ’images’ in this block; shape: the value named ’shape’ in this block; len: the value named ’len’ in this block. Context: the function write_split, which handles write split.

Line 41: `raise ValueError(f"unexpected official CIFAR-10 {split} shape {images.shape}")` This rejects an invalid state by raising ‘ValueError(f"unexpected official CIFAR-10 {split} shape {images.shape}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 42: `records: list[dict[str, object]] = []` This assigns ‘[]‘ to ‘records‘ in host memory. Here records means the number of descriptor records accepted since program start. The expression is a literal or structural operator and has no hidden software state. Context: the function write_split, which handles write split.

Line 43: `for shard_index, start in enumerate(range(0, len(labels), shard_size)):` This iterates shard_index, start over ‘enumerate(range(0, len(labels), shard_size))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function write_split, which handles write split.

Line 44: `stop = min(start + shard_size, len(labels))` This assigns ‘min(start + shard_size, len(labels))‘ to ‘stop ‘ in host memory. Here stop means the value named ’stop’ in this block. The important operands are min: the value named ’min’ in this block; start: the value named ’start’ in this block; shard_size: the value named ’shard size’ in this block. Context: the function write_split, which handles write split.

Line 45: `target = output_dir / f"cifar10_{split}_{shard_index:03d}.npz"` This assigns ‘output_dir / f"cifar10_{split}_ to ‘target ‘ in host memory. Here target means the value named ’target’ in this block. The important operands are output_dir: the value named ’output dir’ in this block; f: the value named ’f’ in this block; cifar10_: the value named ’cifar10’ in this block. Context: the function write_split, which handles write split.

Line 46: `temporary = target.with_name(target.name + ".tmp")` This assigns ‘target.with_name(target.name + ".tmp")‘ to ‘temporary ‘ in host memory. Here temporary means the value named ’temporary’ in this block. The important operands are target: the value named ’target’ in this block; with_name: the value named ’with name’ in this block; name: the value named ’name’ in this block. Context: the function write_split, which handles write split.

Line 47: `with temporary.open("wb") as stream:` This opens a managed resource scope for ‘temporary.open("wb") as stream‘ so files, tracing, or temporary state are finalized even if the function write_split, which handles write split raises an error.

Line 48: `np.savez_compressed(stream, images=images[start:stop], labels=labels[start:stop])` This calls ‘np.savez_compressed‘ with ‘stream, images=images[start:stop], labels=labels[start:stop]‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 49: `stream.flush()` This calls ‘stream.flush‘ with “ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 50: `os.fsync(stream.fileno())` This calls ‘os.fsync‘ with ‘stream.fileno()‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 51: `os.replace(temporary, target)` This calls ‘os.replace‘ with ‘temporary, target‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 52: `records.append({` This statement continues through source line 59; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘records.append‘ with ‘{ "file": target.name, "samples": stop - start, "first_index": start, "last_index_exclusive": stop, "bytes": target.stat().st_size, "sha256": sha256(target), }‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 53: `"file": target.name,` This is continuation line 2 of the 8-line logical statement that begins at source line 52. Its exact fragment is ‘"file": target.name,‘. The important operands are file: the value named ’file’ in this block; target: the value named ’target’ in this block; name: the value named ’name’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘{ "file": target.name, "samples": stop - start, "first_index": start, "last_index_exclusive": stop, "bytes": target.stat().st_size, "sha256": sha256(target), }‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 54: `"samples": stop - start,` This is continuation line 3 of the 8-line logical statement that begins at source line 52. Its exact fragment is ‘"samples": stop - start,‘. The important operands are samples: the value named ’samples’ in this block; stop: the value named ’stop’ in this block; start: the value named ’start’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘{ "file": target.name, "samples": stop - start, "first_index": start, "last_index_exclusive": stop, "bytes": target.stat().st_size, "sha256": sha256(target), }‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 55: `"first_index": start,` This is continuation line 4 of the 8-line logical statement that begins at source line 52. Its exact fragment is ‘"first_index": start,‘. The important operands are first_index: an integer selecting one tensor element, lane, bank, or state entry; start: the value named ’start’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘{ "file": target.name, "samples": stop - start, "first_index": start, "last_index_exclusive": stop, "bytes": target.stat().st_size, "sha256": sha256(target), }‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 56: `"last_index_exclusive": stop,` This is continuation line 5 of the 8-line logical statement that begins at source line 52. Its exact fragment is ‘"last_index_exclusive": stop,‘. The important operands are last_index_exclusive: the AXI-Stream marker for the final beat of a packet or command payload; stop: the value named ’stop’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘{ "file": target.name, "samples": stop - start, "first_index": start, "last_index_exclusive": stop, "bytes": target.stat().st_size, "sha256": sha256(target), }‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 57: `"bytes": target.stat().st_size,` This is continuation line 6 of the 8-line logical statement that begins at source line 52. Its exact fragment is ‘"bytes": target.stat().st_size,‘. The important operands are bytes: the value named ’bytes’ in this block; target: the value named ’target’ in this block; stat: the value named ’stat’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘{ "file": target.name, "samples": stop - start, "first_index": start, "last_index_exclusive": stop, "bytes": target.stat().st_size, "sha256": sha256(target), }‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 58: `"sha256": sha256(target),` This is continuation line 7 of the 8-line logical statement that begins at source line 52. Its exact fragment is ‘"sha256": sha256(target),‘. The important operands are sha256: the value named ’sha256’ in this block; target: the value named ’target’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘{ "file": target.name, "samples": stop - start, "first_index": start, "last_index_exclusive": stop, "bytes": target.stat().st_size, "sha256": sha256(target), }‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 59: `})` This is continuation line 8 of the 8-line logical statement that begins at source line 52. Its exact fragment is ‘})‘. The expression is a literal or structural operator and has no hidden software state. Read together, the com-

plete operation is: This calls ‘records.append‘ with ‘{ "file": target.name, "samples": stop - start, "first_index": start, "last_index_exclusive": stop, "bytes": target.stat().st_size, "sha256": sha256(target), }‘ inside the function write_split, which handles write split. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 60: `return records` This returns ‘records‘ to the caller of the function write_split, which handles write split, ending this invocation. The important operands are records: the number of descriptor records accepted since program start.

Line 63: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 64: `arguments = parse_arguments()` This assigns ‘parse_arguments()‘ to ‘arguments ‘ in host memory. Here arguments means the value named ’arguments’ in this block. The important operands are parse_arguments: the value named ’parse arguments’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 65: `if arguments.shard_size <= 0:` This executes the following indented host-code branch only when ‘arguments.shard_size <= 0‘ is true. The important operands are arguments: the value named ’arguments’ in this block; shard_size: the value named ’shard size’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 66: `raise ValueError("shard-size must be positive")` This rejects an invalid state by raising ‘ValueError("shard-size must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 67: `try:` This is explicit host-side failure handling inside the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 68: `from torchvision.datasets import CIFAR10` This imports the named Python API so the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 69: `except ImportError as error:` This is explicit host-side failure handling inside the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 70: `raise RuntimeError("torchvision is required to export official CIFAR-10") from error` This rejects an invalid state by raising ‘RuntimeError("torchvision is required to export official CIFAR-10") from error‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 71: `output_dir = arguments.output_dir.expanduser().resolve()` This assigns ‘arguments.output_dir.expanduser().re to ‘output_dir ‘ in host memory. Here output_dir means the value named ’output dir’ in this block. The important operands are arguments: the value named ’arguments’ in this block; output_dir: the value named ’output dir’ in this block; expanduser: the value named ’expanduser’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 72: `output_dir.mkdir(parents=True, exist_ok=True)` This calls ‘output_dir.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 73: `dataset_root = arguments.dataset_root.expanduser().resolve()` This assigns ‘arguments.dataset_root.expandu to ‘dataset_root ‘ in host memory. Here dataset_root means the value named ’dataset root’ in this block. The important operands are arguments: the value named ’arguments’ in this block; dataset_root: the value named ’dataset root’ in this block; expanduser: the value named ’expanduser’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 74: `train = CIFAR10(` This statement continues through source line 75; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘CIFAR10(root=str(dataset_root), train=True, download=not arguments.no_download)‘ to ‘train ‘ in host memory. Here train means the value named ’train’ in this block. The important operands are CIFAR10: the value named ’cifar10’ in this block; root: the value named ’root’ in this block; str: the value named ’str’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 75: `root=str(dataset_root), train=True, download=not arguments.no_download)` This is continuation line 2 of the 2-line logical statement that begins at source line 74. Its exact fragment is ‘root=str(dataset_root), train=True, download=not arguments.no_download)‘. The important operands are root: the value named ’root’ in this block; str: the value named ’str’ in this block; dataset_root: the value named ’dataset root’ in this block. Read together, the complete operation is: This assigns ‘CIFAR10(root=str(dataset_root), train=True, download=not arguments.no_download)‘ to ‘train ‘ in host memory. Here train means the value named ’train’ in this block. The important operands are CIFAR10: the value named ’cifar10’ in this block; root: the value named ’root’ in this block; str: the value named ’str’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 76: `test = CIFAR10(` This statement continues through source line 77; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘CIFAR10(root=str(dataset_root), train=False, download=not arguments.no_download)‘ to ‘test ‘ in host memory. Here test means the value named ’test’ in this block. The important operands are CIFAR10: the value named ’cifar10’ in this block; root: the value named ’root’ in this block; str: the value named ’str’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 77: `root=str(dataset_root), train=False, download=not arguments.no_download)` This is continuation line 2 of the 2-line logical statement that begins at source line 76. Its exact fragment is ‘root=str(dataset_root), train=False, download=not arguments.no_download)‘. The important operands are root: the value named ’root’ in this block; str: the value named ’str’ in this block; dataset_root: the value named ’dataset root’ in this block. Read together, the complete operation is: This assigns ‘CIFAR10(root=str(dataset_root), train=False, download=not arguments.no_download)‘ to ‘test ‘ in host memory. Here test means the value named ’test’ in this block. The important operands are CIFAR10: the value named ’cifar10’ in this block; root: the value named ’root’ in this block; str: the value named ’str’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 78: `manifest = {` This statement continues through source line 89; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "format": "neuraedge-official-cifar10-shards-v1", "created_utc": datetime.now(timezone.utc).isoformat(), "source": "torchvision.datasets.CIFAR10 official Python archive", "image_encoding": "uint8 NHWC RGB", "label_encoding": "uint8 class index 0..9", "shard_size": arguments.shard_size, "splits": { "train": write_split(train, "train", output_dir, arguments.shard_size), "test": write_split(test, "test", output_dir, arguments.shard_size), }, }‘ to ‘manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are format: the value named ’format’ in this block; neuraedge: the value named ’neuraedge’ in this block; official: the value named ’official’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 79: `"format": "neuraedge-official-cifar10-shards-v1",` This is continuation line 2 of the 12-line logical statement that begins at source line 78. Its exact fragment is ‘"format": "neuraedge-official-cifar10-shards-v1",‘. The important operands are format: the value named ’format’ in this block; neuraedge: the value named ’neuraedge’ in this block; official: the value named ’official’ in this block. Read together, the complete operation is: This assigns ‘{ "format": "neuraedge-official-cifar10-shards-v1", "created_utc": datetime.now(timezone.utc).isoformat(), "source": "torchvision.datasets.CIFAR10 official Python archive", "image_encoding": "uint8 NHWC RGB", "label_encoding": "uint8

class index 0..9", "shard_size": arguments.shard_size, "splits": { "train": write_split(train, "train", output_dir, arguments.shard_size), "test": write_split(test, "test", output_dir, arguments.shard_size), }, }‘ to ‘manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are format: the value named ’format’ in this block; neuraedge: the value named ’neuraedge’ in this block; official: the value named ’official’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 80: `"created_utc": datetime.now(timezone.utc).isoformat(),` This is continuation line 3 of the 12-line logical statement that begins at source line 78. Its exact fragment is ‘"created_utc": datetime.now(timezone.utc).isoformat(),‘. The important operands are created_utc: the value named ’created utc’ in this block; datetime: the value named ’datetime’ in this block; now: the value named ’now’ in this block. Read together, the complete operation is: This assigns ‘{ "format": "neuraedge-official-cifar10-shards-v1", "created_utc": datetime.now(timezone.utc).isoformat(), "source": "torchvision.datasets.CIFAR10 official Python archive", "image_encoding": "uint8 NHWC RGB", "label_encoding": "uint8 class index 0..9", "shard_size": arguments.shard_size, "splits": { "train": write_split(train, "train", output_dir, arguments.shard_size), "test": write_split(test, "test", output_dir, arguments.shard_size), }, }‘ to ‘manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are format: the value named ’format’ in this block; neuraedge: the value named ’neuraedge’ in this block; official: the value named ’official’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 81: `"source": "torchvision.datasets.CIFAR10 official Python archive",` This is continuation line 4 of the 12-line logical statement that begins at source line 78. Its exact fragment is ‘"source": "torchvision.datasets.CIFAR10 official Python archive",‘. The important operands are source: the value named ’source’ in this block; torchvision: the value named ’torchvision’ in this block; datasets: the value named ’datasets’ in this block. Read together, the complete operation is: This assigns ‘{ "format": "neuraedge-official-cifar10-shards-v1", "created_utc": datetime.now(timezone.utc).isoformat(), "source": "torchvision.datasets.CIFAR10 official Python archive", "image_encoding": "uint8 NHWC RGB", "label_encoding": "uint8 class index 0..9", "shard_size": arguments.shard_size, "splits": { "train": write_split(train, "train", output_dir, arguments.shard_size), "test": write_split(test, "test", output_dir, arguments.shard_size), }, }‘ to ‘manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are format: the value named ’format’ in this block; neuraedge: the value named ’neuraedge’ in this block; official: the value named ’official’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 82: `"image_encoding": "uint8 NHWC RGB",` This is continuation line 5 of the 12-line logical statement that begins at source line 78. Its exact fragment is ‘"image_encoding": "uint8 NHWC RGB",‘. The important operands are image_encoding: the value named ’image encoding’ in this block; uint8: the value named ’uint8’ in this block; NHWC: the value named ’nhwc’ in this block. Read together, the complete operation is: This assigns ‘{ "format": "neuraedge-official-cifar10-shards-v1", "created_utc": datetime.now(timezone.utc).isoformat(), "source": "torchvision.datasets.CIFAR10 official Python archive", "image_encoding": "uint8 NHWC RGB", "label_encoding": "uint8 class index 0..9", "shard_size": arguments.shard_size, "splits": { "train": write_split(train, "train", output_dir, arguments.shard_size), "test": write_split(test, "test", output_dir, arguments.shard_size), }, }‘ to ‘manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are format: the value named ’format’ in this block; neuraedge: the value named ’neuraedge’ in this block; official: the value named ’official’ in this block. Context: the file whose role is to writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

Line 83: `"label_encoding": "uint8 class index 0..9",` This is continuation line 6 of the 12-line logical statement that begins at source line 78. Its exact fragment is ‘"label_encoding": "uint8 class index 0..9",‘. The important operands are label_encoding: the value named ’label encoding’ in this block; uint8: the value named ’uint8’ in this block; class: the value named ’class’ in this block. The call advances the host-side job that writes deterministic CIFAR-10 training and validation shards for bounded-memory board-side learning.

27 software/export_spikingformer_hardware.py

Role in the complete system: folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

27.1 Beginner architecture map

Dataflow responsibility Checkpoint weights and BatchNorm statistics are folded into affine projections, calibrated, quantized, aligned to 64-byte sections, and hashed. The JSON manifest records offsets, shapes, dtypes, scales, and section digests consumed by both emulator and board runtime.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: BinarySection, ProjectionExport, AlignedBinaryWriter. Functions: quantize_weight_tensor, export_projection, projection_pairs, export_model, parse_arguments, ___init___, append. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

27.2 Complete source

27.3 Line annotations

Line 1: `"""Export the trained Spikingformer into the NeuraEdge binary parameter ABI."""` This is executable documentation attached to the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import argparse` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import hashlib` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `import json` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `from dataclasses import asdict, dataclass` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `from pathlib import Path` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `import numpy as np` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `import torch` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `import torch.nn as nn` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `from neuraedge_golden import quantize_flexible_scale` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `from spikingformer_quantization import quantize_cifar_input_u8` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `from spikingformer_reference import Spikingformer, load_checkpoint` This imports the named Python API so the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `ALIGNMENT = 64` This assigns ‘64‘ to ‘ALIGNMENT ‘ in host memory. Here ALIGNMENT means the value named ’alignment’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 23: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections; it creates no FPGA circuit by itself.

Line 24: `class BinarySection:` This defines class BinarySection, which groups data and methods for binary section. Instances exist in host memory and organize the flow that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 25: `name: str` Inside the class BinarySection, which handles binary section, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are name: the value named ’name’ in this block; str: the value named ’str’ in this block.

Line 26: `offset: int` Inside the class BinarySection, which handles binary section, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are offset: the value named ’offset’ in this block.

Line 27: `length: int` Inside the class BinarySection, which handles binary section, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are length: the value named 'length' in this block.

Line 28: `dtype: str` Inside the class BinarySection, which handles binary section, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are dtype: the value named 'dtype' in this block; str: the value named 'str' in this block.

Line 29: `shape: tuple[int, ...]` Inside the class BinarySection, which handles binary section, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are shape: the value named 'shape' in this block; tuple: the value named 'tuple' in this block.

Line 30: `sha256: str` Inside the class BinarySection, which handles binary section, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are sha256: the value named 'sha256' in this block; str: the value named 'str' in this block.

Line 33: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections; it creates no FPGA circuit by itself.

Line 34: `class ProjectionExport:` This defines class ProjectionExport, which groups data and methods for projection export. Instances exist in host memory and organize the flow that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 35: `name: str` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are name: the value named 'name' in this block; str: the value named 'str' in this block.

Line 36: `source_weight_shape: tuple[int, ...]` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are source_weight_shape: a learned coefficient multiplied by an activation; tuple: the value named 'tuple' in this block.

Line 37: `hardware_matrix_shape: tuple[int, int]` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are hardware_matrix_shape: the value named 'hardware matrix shape' in this block; tuple: the value named 'tuple' in this block.

Line 38: `input_encoding: str` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are input_encoding: the value named 'input encoding' in this block; str: the value named 'str' in this block.

Line 39: `compute_opcode: str` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are compute_opcode: the value named 'compute opcode' in this block; str: the value named 'str' in this block.

Line 40: `output_fractional_bits: int` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are output_fractional_bits: the value named 'output fractional bits' in this block.

Line 41: `weight_scale: float` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are weight_scale: a learned coefficient multiplied by an activation; float: the value named 'float' in this block.

Line 42: `accumulator_factor_minimum: float` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are accumulator_factor_minimum: a widened running sum that prevents intermediate overflow; float: the value named 'float' in this block.

Line 43: `accumulator_factor_maximum: float` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are accumulator_factor_maximum: a widened running sum that prevents intermediate overflow; float: the value named 'float' in this block.

Line 44: `represented_factor_maximum_error: float` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are represented_factor_maximum_error: the value named 'represented factor maximum error' in this block; float: the value named 'float' in this block.

Line 45: `folded_bias_minimum: int` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are folded_bias_minimum: an additive learned offset applied after accumulation.

Line 46: `folded_bias_maximum: int` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are folded_bias_maximum: an additive learned offset applied after accumulation.

Line 47: `sections: tuple[BinarySection, ...]` Inside the class ProjectionExport, which handles projection export, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are sections: the value named 'sections' in this block; tuple: the value named 'tuple' in this block; BinarySection: the value named 'binary section' in this block.

Line 50: `class AlignedBinaryWriter:` This defines class AlignedBinaryWriter, which groups data and methods for aligned binary writer. Instances exist in host memory and organize the flow that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 51: `"""Append typed arrays while retaining deterministic aligned offsets."""` This is executable documentation attached to the class AlignedBinaryWriter, which handles aligned binary writer. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 53: `def __init__(self) -> None:` This starts function ___init___. Its indented body performs init as part of the file that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections; it runs only when called.

Line 54: `self.data = bytearray()` This assigns 'bytearray()' to 'self.data ' in host memory. Here data means the value named 'data' in this block. The important operands are bytearray: the value named 'bytearray' in this block. Context: the function ___init___, which handles init.

Line 55: `self.sections: list[BinarySection] = []` This assigns '[]' to 'self.sections' in host memory. Here sections means the value named 'sections' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 57: `def append(self, name: str, value: np.ndarray) -> BinarySection:` This starts function append. Its indented body performs append as part of the file that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections; it runs only when called.

Line 58: `padding = (-len(self.data)) % ALIGNMENT` This assigns '(-len(self.data)) % ALIGNMENT' to 'padding ' in host memory. Here padding means the value named 'padding' in this block. The important operands are len: the value named 'len' in this block; data: the value named 'data' in this block; ALIGNMENT: the value named 'alignment' in this block. Context: the function append, which handles append.

Line 59: `self.data.extend(b"\x00" * padding)` This calls 'self.data.extend' with 'b"\x00" * padding' inside the function append, which handles append. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 60: `contiguous = np.ascontiguousarray(value)` This assigns 'np.ascontiguousarray(value)' to 'contiguous ' in host memory. Here contiguous means the value named 'contiguous' in this block. The important operands are ascontiguousarray: the value named 'ascontiguousarray' in this block; value: the value named 'value' in this block. Context: the function append, which handles append.

Line 61: `payload = contiguous.tobytes(order="C")` This assigns 'contiguous.tobytes(order="C")' to 'payload ' in host memory. Here payload means stream data belonging to the current command. The important operands are contiguous: the value named 'contiguous' in this block; tobytes: the value named 'tobytes' in this block; order: the value named 'order' in this block. Context: the function append, which handles append.

Line 62: `section = BinarySection(` This statement continues through source line 69; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'BinarySection(name=name, offset=len(self.data), length=len(payload), dtype=contiguous.dtype.str, shape=tuple(contiguous.shape), sha256=hashlib.sha256(payload).hexdigest(),)' to 'section ' in host memory. Here section means the value named 'section' in this block. The important operands are BinarySection: the value named 'binary section' in this block; name: the value named 'name' in this block; offset: the value named 'offset' in this block. Context: the function append, which handles append.

Line 63: `name=name,` This is continuation line 2 of the 8-line logical statement that begins at source line 62. Its exact fragment is 'name=name,'. The important operands are name: the value named 'name' in this block. Read together, the complete operation is: This assigns 'BinarySection(name=name, offset=len(self.data), length=len(payload), dtype=contiguous.dtype.str, shape=tuple(contiguous.shape), sha256=hashlib.sha256(payload).hexdigest(),)' to 'section ' in host memory. Here section means the value named 'section' in this block. The important operands are BinarySection: the value named 'binary section' in this block; name: the value named 'name' in this block; offset: the value named 'offset' in this block. Context: the function append, which handles append.

Line 64: `offset=len(self.data),` This is continuation line 3 of the 8-line logical statement that begins at source line 62. Its exact fragment is 'offset=len(self.data),'. The important operands are offset: the value named 'offset' in this block; len: the value named 'len' in this block; data: the value named 'data' in this block. Read together, the complete operation is: This assigns 'BinarySection(name=name, offset=len(self.data), length=len(payload), dtype=contiguous.dtype.str, shape=tuple(contiguous.shape), sha256=hashlib.sha256(payload).hexdigest(),)' to 'section ' in host memory. Here section means the value named 'section' in this block. The important operands are BinarySection: the value named 'binary section' in this block; name: the value named 'name' in this block; offset: the value named 'offset' in this block. Context: the function append, which handles append.

Line 65: `length=len(payload),` This is continuation line 4 of the 8-line logical statement that begins at source line 62. Its exact fragment is 'length=len(payload),'. The important operands are length: the value named 'length' in this block; len: the value named 'len' in this block; payload: stream data belonging to the current command. Read together, the complete operation is: This assigns 'BinarySection(name=name, offset=len(self.data), length=len(payload), dtype=contiguous.dtype.str, shape=tuple(contiguous.shape), sha256=hashlib.sha256(payload).hexdigest(),)' to 'section ' in host memory. Here section means the value named 'section' in this block. The important operands are BinarySection: the value named 'binary section' in this block; name: the value named 'name' in this block; offset: the value named 'offset' in this block. Context: the function append, which handles append.

Line 66: `dtype=contiguous.dtype.str,` This is continuation line 5 of the 8-line logical statement that begins at source line 62. Its exact fragment is ‘dtype=contiguous.dtype.str,‘. The important operands are dtype: the value named ’dtype’ in this block; contiguous: the value named ’contiguous’ in this block; str: the value named ’str’ in this block. Read together, the complete operation is: This assigns ‘BinarySection(name=name, offset=len(self.data), length=len(payload), dtype=contiguous.dtype.str, shape=tuple(contiguous.shape), sha256=hashlib.sha256(payload).hexdigest(),)‘ to ‘section ‘ in host memory. Here section means the value named ’section’ in this block. The important operands are BinarySection: the value named ’binary section’ in this block; name: the value named ’name’ in this block; offset: the value named ’offset’ in this block. Context: the function append, which handles append.

Line 67: `shape=tuple(contiguous.shape),` This is continuation line 6 of the 8-line logical statement that begins at source line 62. Its exact fragment is ‘shape=tuple(contiguous.shape),‘. The important operands are shape: the value named ’shape’ in this block; tuple: the value named ’tuple’ in this block; contiguous: the value named ’contiguous’ in this block. Read together, the complete operation is: This assigns ‘BinarySection(name=name, offset=len(self.data), length=len(payload), dtype=contiguous.dtype.str, shape=tuple(contiguous.shape), sha256=hashlib.sha256(payload).hexdigest(),)‘ to ‘section ‘ in host memory. Here section means the value named ’section’ in this block. The important operands are BinarySection: the value named ’binary section’ in this block; name: the value named ’name’ in this block; offset: the value named ’offset’ in this block. Context: the function append, which handles append.

Line 68: `sha256=hashlib.sha256(payload).hexdigest(),` This is continuation line 7 of the 8-line logical statement that begins at source line 62. Its exact fragment is ‘sha256=hashlib.sha256(payload).hexdigest(),‘. The important operands are sha256: the value named ’sha256’ in this block; hashlib: the value named ’hashlib’ in this block; payload: stream data belonging to the current command. Read together, the complete operation is: This assigns ‘BinarySection(name=name, offset=len(self.data), length=len(payload), dtype=contiguous.dtype.str, shape=tuple(contiguous.shape), sha256=hashlib.sha256(payload).hexdigest(),)‘ to ‘section ‘ in host memory. Here section means the value named ’section’ in this block. The important operands are BinarySection: the value named ’binary section’ in this block; name: the value named ’name’ in this block; offset: the value named ’offset’ in this block. Context: the function append, which handles append.

Line 69: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 62. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘BinarySection(name=name, offset=len(self.data), length=len(payload), dtype=contiguous.dtype.str, shape=tuple(contiguous.shape), sha256=hashlib.sha256(payload).hexdigest(),)‘ to ‘section ‘ in host memory. Here section means the value named ’section’ in this block. The important operands are BinarySection: the value named ’binary section’ in this block; name: the value named ’name’ in this block; offset: the value named ’offset’ in this block. Context: the function append, which handles append.

Line 70: `self.data.extend(payload)` This calls ‘self.data.extend‘ with ‘payload‘ inside the function append, which handles append. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 71: `self.sections.append(section)` This calls ‘self.sections.append‘ with ‘section‘ inside the function append, which handles append. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 72: `return section` This returns ‘section‘ to the caller of the function append, which handles append, ending this invocation. The important operands are section: the value named ’section’ in this block.

Line 75: `def quantize_weight_tensor(weight: torch.Tensor) -> tuple[torch.Tensor, float]:` This starts function quantize_weight_tensor. Its indented body performs quantize weight tensor as part of the file that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections; it runs only when called.

Line 76: `"""Symmetric signed-int8 quantization used by the measured 95.4% model."""` This is executable documentation attached to the function quantize_weight_tensor, which handles quantize weight tensor. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 78: `maximum = float(weight.detach().abs().amax().item())` This assigns ‘float(weight.detach().abs().amax().item())‘ to ‘maximum ‘ in host memory. Here maximum means the value named ’maximum’ in this block. The important operands are float: the value named ’float’ in this block; weight: a learned coefficient multiplied by an activation; detach: the value named ’detach’ in this block. Context: the function quantize_weight_tensor, which handles quantize weight tensor.

Line 79: `scale = maximum / 127.0 if maximum > 0.0 else 1.0` This assigns ‘maximum / 127.0 if maximum > 0.0 else 1.0‘ to ‘scale ‘ in host memory. Here scale means the real-value spacing represented by one quantized integer step. The important operands are maximum: the value named ’maximum’ in this block. Context: the function quantize_weight_tensor, which handles quantize weight tensor.

Line 80: `integer = torch.round(weight.detach() / scale).clamp(-127, 127).to(torch.int8)` This assigns ‘torch.round(weight.detach() / scale).clamp(-127, 127).to(torch.int8)‘ to ‘integer ‘ in host memory. Here integer means the value named ’integer’ in this block. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; weight: a learned coefficient multiplied by an activation. Context: the function quantize_weight_tensor, which handles quantize weight tensor.

Line 81: `return integer, scale` This returns ‘integer, scale‘ to the caller of the function quantize_weight_tensor, which handles quantize weight tensor, ending this invocation. The important operands are integer: the value named ’integer’ in this block; scale: the real-value spacing represented by one quantized integer step.

Line 84: `def export_projection(` This starts function export_projection. Its indented body performs export projection as part of the file that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections; it runs only when called.

Line 85: `writer: AlignedBinaryWriter,` Inside the function export_projection, which handles export projection, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are writer: the value named ’writer’ in this block; AlignedBinaryWriter: the value named ’aligned binary writer’ in this block.

Line 86: `*,` Inside the function export_projection, which handles export projection, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The expression is a literal or structural operator and has no hidden software state.

Line 87: `name: str,` Inside the function export_projection, which handles export projection, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are name: the value named ’name’ in this block; str: the value named ’str’ in this block.

Line 88: `convolution: nn.Conv1d | nn.Conv2d,` Inside the function export_projection, which handles export projection, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are convolution: the value named ’convolution’ in this block; nn: the value named ’nn’ in this block; Conv1d: the value named ’conv1d’ in this block.

Line 89: `batch_norm: nn.BatchNorm1d | nn.BatchNorm2d,` Inside the function export_projection, which handles export projection, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are batch_norm: the value named ’batch norm’ in this block; nn: the value named ’nn’ in this block; BatchNorm1d: the value named ’batch norm1d’ in this block.

Line 90: `input_scale: float,` Inside the function export_projection, which handles export projection, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are input_scale: the real-value spacing represented by one quantized integer step; float: the value named ’float’ in this block.

Line 91: `fractional_bits: int,` Inside the function export_projection, which handles export projection, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are fractional_bits: the value named 'fractional bits' in this block.

Line 92: `input_encoding: str,` Inside the function export_projection, which handles export projection, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are input_encoding: the value named 'input encoding' in this block; str: the value named 'str' in this block.

Line 93: `compute_opcode: str,` Inside the function export_projection, which handles export projection, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are compute_opcode: the value named 'compute opcode' in this block; str: the value named 'str' in this block.

Line 94: `) -> ProjectionExport:` Inside the function export_projection, which handles export projection, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are ProjectionExport: the value named 'projection export' in this block.

Line 95: `"""Quantize one Conv-BN pair and generate its exact post-accumulator fields."""` This is executable documentation attached to the function export_projection, which handles export projection. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 97: `integer_weight, weight_scale = quantize_weight_tensor(convolution.weight)` This assigns 'quantize_weight_tensor(convolution.weight)' to 'integer_weight, weight_scale ' in host memory. Here integer_weight means a learned coefficient multiplied by an activation. The important operands are quantize_weight_tensor: a learned coefficient multiplied by an activation; convolution: the value named 'convolution' in this block; weight: a learned coefficient multiplied by an activation. Context: the function export_projection, which handles export projection.

Line 98: `output_channels = convolution.out_channels` This assigns 'convolution.out_channels' to 'output_channels ' in host memory. Here output_channels means the value named 'output channels' in this block. The important operands are convolution: the value named 'convolution' in this block; out_channels: the value named 'out channels' in this block. Context: the function export_projection, which handles export projection.

Line 99: `matrix = integer_weight.reshape(output_channels, -1).transpose(0, 1).contiguous()` This assigns 'integer_weight.reshape(output_channels, -1).transpose(0, 1).contiguous()' to 'matrix ' in host memory. Here matrix means the value named 'matrix' in this block. The important operands are integer_weight: a learned coefficient multiplied by an activation; reshape: the value named 'reshape' in this block; output_channels: the value named 'output channels' in this block. Context: the function export_projection, which handles export projection.

Line 100: `batch_norm_scale = batch_norm.weight.detach() / torch.sqrt(` This statement continues through source line 101; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'batch_norm.weight.detach() / torch.sqrt(batch_norm.running_var.detach() + batch_norm.eps)' to 'batch_norm_scale ' in host memory. Here batch_norm_scale means the real-value spacing represented by one quantized integer step. The important operands are batch_norm: the value named 'batch norm' in this block; weight: a learned coefficient multiplied by an activation; detach: the value named 'detach' in this block. Context: the function export_projection, which handles export projection.

Line 101: `batch_norm.running_var.detach() + batch_norm.eps)` This is continuation line 2 of the 2-line logical statement that begins at source line 100. Its exact fragment is 'batch_norm.running_var.detach() + batch_norm.eps)'. The important operands are batch_norm: the value named 'batch norm' in this block; running_var: the value named 'running var' in this block; detach: the value named 'detach' in this block. Read together, the complete operation is: This assigns 'batch_norm.weight.detach() / torch.sqrt(batch_norm.running_var.detach() + batch_norm.eps)' to

‘batch_norm_scale ‘ in host memory. Here batch_norm_scale means the real-value spacing represented by one quantized integer step. The important operands are batch_norm: the value named ’batch norm’ in this block; weight: a learned coefficient multiplied by an activation; detach: the value named ’detach’ in this block. Context: the function export_projection, which handles export projection.

Line 102: `if convolution.bias is None:` This executes the following indented host-code branch only when ‘convolution.bias is None‘ is true. The important operands are convolution: the value named ’convolution’ in this block; bias: an additive learned offset applied after accumulation; is: the value named ’is’ in this block. Context: the function export_projection, which handles export projection.

Line 103: `convolution_bias = torch.zeros_like(batch_norm.running_mean)` This assigns ‘torch.zeros_like(batch_norm.ru to ‘convolution_bias ‘ in host memory. Here convolution_bias means an additive learned offset applied after accumulation. The important operands are torch: the value named ’torch’ in this block; zeros_like: the value named ’zeros like’ in this block; batch_norm: the value named ’batch norm’ in this block. Context: the function export_projection, which handles export projection.

Line 104: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function export_projection, which handles export projection.

Line 105: `convolution_bias = convolution.bias.detach()` This assigns ‘convolution.bias.detach()‘ to ‘convolution_bias ‘ in host memory. Here convolution_bias means an additive learned offset applied after accumulation. The important operands are convolution: the value named ’convolution’ in this block; bias: an additive learned offset applied after accumulation; detach: the value named ’detach’ in this block. Context: the function export_projection, which handles export projection.

Line 106: `folded_bias = (` This statement continues through source line 109; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘((convolution_bias - batch_norm.running_mean.detach()) * batch_norm_scale + batch_norm.bias.detach())‘ to ‘folded_bias ‘ in host memory. Here folded_bias means an additive learned offset applied after accumulation. The important operands are convolution_bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; running_mean: the arithmetic average used by normalization. Context: the function export_projection, which handles export projection.

Line 107: `(convolution_bias - batch_norm.running_mean.detach()) * batch_norm_scale` This is continuation line 2 of the 4-line logical statement that begins at source line 106. Its exact fragment is ‘(convolution_bias - batch_norm.running_m * batch_norm_scale‘. The important operands are convolution_bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; running_mean: the arithmetic average used by normalization. Read together, the complete operation is: This assigns ‘((convolution_bias - batch_norm.running_mean.detach()) * batch_norm_scale + batch_norm.bias.detach())‘ to ‘folded_bias ‘ in host memory. Here folded_bias means an additive learned offset applied after accumulation. The important operands are convolution_bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; running_mean: the arithmetic average used by normalization. Context: the function export_projection, which handles export projection.

Line 108: `+ batch_norm.bias.detach()` This is continuation line 3 of the 4-line logical statement that begins at source line 106. Its exact fragment is ‘+ batch_norm.bias.detach()‘. The important operands are batch_norm: the value named ’batch norm’ in this block; bias: an additive learned offset applied after accumulation; detach: the value named ’detach’ in this block. Read together, the complete operation is: This assigns ‘((convolution_bias - batch_norm.running_mean.detach()) * batch_norm_scale + batch_norm.bias.detach())‘ to ‘folded_bias ‘ in host memory. Here folded_bias means an additive learned offset applied after accumulation. The important operands are convolution_bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; running_mean: the arithmetic average used by normalization. Context: the function export_projection, which handles export projection.

Line 109: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 106. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘((convolution_bias - batch_norm.running_mean.detach()) * batch_norm_scale +

batch_norm.bias.detach())‘ to ‘folded_bias ‘ in host memory. Here folded_bias means an additive learned offset applied after accumulation. The important operands are convolution_bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; running_mean: the arithmetic average used by normalization. Context: the function export_projection, which handles export projection.

Line 110: `output_scale = 1 << fractional_bits` This assigns ‘1 << fractional_bits‘ to ‘output_scale ‘ in host memory. Here output_scale means the real-value spacing represented by one quantized integer step. The important operands are fractional_bits: the value named ’fractional bits’ in this block. Context: the function export_projection, which handles export projection.

Line 111: `accumulator_factor = (` This statement continues through source line 112; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(input_scale * weight_scale * batch_norm_scale * output_scale)‘ to ‘accumulator_factor ‘ in host memory. Here accumulator_factor means a widened running sum that prevents intermediate overflow. The important operands are input_scale: the real-value spacing represented by one quantized integer step; weight_scale: a learned coefficient multiplied by an activation; batch_norm_scale: the real-value spacing represented by one quantized integer step. Context: the function export_projection, which handles export projection.

Line 112: `input_scale * weight_scale * batch_norm_scale * output_scale)` This is continuation line 2 of the 2-line logical statement that begins at source line 111. Its exact fragment is ‘input_scale * weight_scale * batch_norm_scale * output_scale)‘. The important operands are input_scale: the real-value spacing represented by one quantized integer step; weight_scale: a learned coefficient multiplied by an activation; batch_norm_scale: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This assigns ‘(input_scale * weight_scale * batch_norm_scale * output_scale)‘ to ‘accumulator_factor ‘ in host memory. Here accumulator_factor means a widened running sum that prevents intermediate overflow. The important operands are input_scale: the real-value spacing represented by one quantized integer step; weight_scale: a learned coefficient multiplied by an activation; batch_norm_scale: the real-value spacing represented by one quantized integer step. Context: the function export_projection, which handles export projection.

Line 113: `multiplier: list[int] = []` This assigns ‘[]‘ to ‘multiplier‘ in host memory. Here multiplier means the value named ’multiplier’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function export_projection, which handles export projection.

Line 114: `binary_shift: list[int] = []` This assigns ‘[]‘ to ‘binary_shift‘ in host memory. Here binary_shift means the value named ’binary shift’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function export_projection, which handles export projection.

Line 115: `represented: list[float] = []` This assigns ‘[]‘ to ‘represented‘ in host memory. Here represented means the value named ’represented’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function export_projection, which handles export projection.

Line 116: `for value in accumulator_factor.tolist():` This iterates value over ‘accumulator_factor.tolist()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function export_projection, which handles export projection.

Line 117: `q15, shift, represented_value = quantize_flexible_scale(float(value))` This assigns ‘quantize_flexible_sc to ‘q15, shift, represented_value ‘ in host memory. Here q15 means the value named ’q15’ in this block. The important operands are quantize_flexible_scale: the real-value spacing represented by one quantized integer step; float: the value named ’float’ in this block; value: the value named ’value’ in this block. Context: the function export_projection, which handles export projection.

Line 118: `multiplier.append(q15)` This calls ‘multiplier.append‘ with ‘q15‘ inside the function export_projection, which handles export projection. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 119: `binary_shift.append(shift)` This calls ‘binary_shift.append‘ with ‘shift‘ inside the function export_projection, which handles export projection. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 120: `represented.append(represented_value)` This calls ‘represented.append‘ with ‘represented_value‘ inside the function export_projection, which handles export projection. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 121: `bias_integer = torch.round(folded_bias * output_scale).to(torch.int32)` This assigns ‘torch.round(folded_ * output_scale).to(torch.int32)‘ to ‘bias_integer ‘ in host memory. Here bias_integer means an additive learned offset applied after accumulation. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; folded_bias: an additive learned offset applied after accumulation. Context: the function export_projection, which handles export projection.

Line 122: `factor_error = torch.tensor(represented) - accumulator_factor.cpu()` This assigns ‘torch.tensor(represente - accumulator_factor.cpu()‘ to ‘factor_error ‘ in host memory. Here factor_error means the value named ’factor error’ in this block. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block; represented: the value named ’represented’ in this block. Context: the function export_projection, which handles export projection.

Line 124: `sections = (` This statement continues through source line 129; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(writer.append(f"{name}.weight_k_by_n_int8", matrix.cpu().numpy()), writer.append(f"{name}.bias_q{fractional_bits}", bias_integer.cpu().numpy()), writer.append(f"{name}.mult np.asarray(multiplier, dtype="<i2")), writer.append(f"{name}.binary_point_shift", np.asarray(binary_shift, dtype=np.int8)),)‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; f: the value named ’f’ in this block. Context: the function export_projection, which handles export projection.

Line 125: `writer.append(f"{name}.weight_k_by_n_int8", matrix.cpu().numpy()),` This is continuation line 2 of the 6-line logical statement that begins at source line 124. Its exact fragment is ‘writer.append(f"{name}.weight_k_by_n_int8", matrix.cpu().numpy()),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; f: the value named ’f’ in this block. Read together, the complete operation is: This assigns ‘(writer.append(f"{name}.weight_k_by_n_int8", matrix.cpu().numpy()), writer.append(f"{name}.bias_q{fractional_bits}", bias_integer.cpu().numpy()), writer.append(f"{name}.multiplier_q15", np.asarray(multiplier, dtype="<i2")), writer.append(f"{nam np.asarray(binary_shift, dtype=np.int8)),)‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; f: the value named ’f’ in this block. Context: the function export_projection, which handles export projection.

Line 126: `writer.append(f"{name}.bias_q{fractional_bits}", bias_integer.cpu().numpy()),` This is continuation line 3 of the 6-line logical statement that begins at source line 124. Its exact fragment is ‘writer.append(f"{name}.bias_q{fracti bias_integer.cpu().numpy()),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; f: the value named ’f’ in this block. Read together, the complete operation is: This assigns ‘(writer.append(f"{name}.weight_k_by_n_int8", matrix.cpu().numpy()), writer.append(f"{name}.bias_q{fractional_bits}", bias_integer.cpu().numpy()), writer.append(f"{name}.multiplier_q15", np.asarray(multiplier, dtype="<i2")), writer.append(f"{nam np.asarray(binary_shift, dtype=np.int8)),)‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; f: the value named ’f’ in this block. Context: the function export_projection, which handles export projection.

Line 127: `writer.append(f"{name}.multiplier_q15", np.asarray(multiplier, dtype="<i2")),` This is continuation line 4 of the 6-line logical statement that begins at source line 124. Its exact fragment is ‘writer.append(f"{name}.multiplier_q np.asarray(multiplier, dtype="<i2")),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; f: the value named ’f’ in this block. Read together, the complete operation is: This assigns ‘(writer.append(f"{name}.weight_k_by_n_int8", matrix.cpu().numpy()), writer.append(f"{name}.bias_q{fraction bias_integer.cpu().numpy()), writer.append(f"{name}.multiplier_q15", np.asarray(multiplier, dtype="<i2")), writer.append(f"{nam

np.asarray(binary_shift, dtype=np.int8)),)‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; f: the value named ’f’ in this block. Context: the function export_projection, which handles export projection.

Line 128: `writer.append(f"{name}.binary_point_shift", np.asarray(binary_shift, dtype=np.int8)),` This is continuation line 5 of the 6-line logical statement that begins at source line 124. Its exact fragment is ‘writer.append(f"{name}.binar
np.asarray(binary_shift, dtype=np.int8)),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; f: the value named ’f’ in this block. Read together, the complete operation is: This assigns ‘(writer.append(f"{name}.weight_k_by_n_int8", matrix.cpu().numpy()), writer.append(f"{name}.bias_q{fraction
bias_integer.cpu().numpy()), writer.append(f"{name}.multiplier_q15", np.asarray(multiplier, dtype="<i2")), writer.append(f"{nam
np.asarray(binary_shift, dtype=np.int8)),)‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; f: the value named ’f’ in this block. Context: the function export_projection, which handles export projection.

Line 129: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 124. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(writer.append(f"{name}.weight_k_by_n_int8", matrix.cpu().numpy()), writer.append(f"{name}.bias_q{frac
bias_integer.cpu().numpy()), writer.append(f"{name}.multiplier_q15", np.asarray(multiplier, dtype="<i2")), writer.append(f"{nam
np.asarray(binary_shift, dtype=np.int8)),)‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; f: the value named ’f’ in this block. Context: the function export_projection, which handles export projection.

Line 130: `return ProjectionExport(` This statement continues through source line 144; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘ProjectionExport(name=name, source_weight_shape=tuple(convolution.weight.shape), hardware_matrix_shape=tuple(matrix.shape), input_encoding=input_e
compute_opcode=compute_opcode, output_fractional_bits=fractional_bits, weight_scale=weight_scale, accumulator_factor_m
accumulator_factor_maximum=float(accumulator_factor.amax().item()), represented_factor_maximum_error=float(factor_erro
folded_bias_minimum=int(bias_integer.amin().item()), folded_bias_maximum=int(bias_integer.amax().item()), sections=sections,)‘ to the caller of the function export_projection, which handles export projection, ending this invocation. Read together, the complete operation is: This calls ‘pairs.append‘ with ‘(f"block.{index}.mlp.fc{layer}", getattr(block.mlp, f"mlp{layer}_conv"), getattr(block.mlp, f"mlp{layer}_bn"),)‘ inside the function projection_pairs, which handles projection pairs. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 165: `getattr(block.mlp, f"mlp{layer}_bn"),` This is continuation line 4 of the 5-line logical statement that begins at source line 162. Its exact fragment is ‘getattr(block.mlp, f"mlp{layer}_bn"),‘. The important operands are

getattr: the value named 'getattr' in this block; block: the value named 'block' in this block; mlp: the value named 'mlp' in this block. Read together, the complete operation is: This calls ‘pairs.append‘ with ‘(f"block.{index}.mlp.fc{layer}", getattr(block.mlp, f"mlp{layer}_conv"), getattr(block.mlp, f"mlp{layer}_bn"),)‘ inside the function projection_pairs, which handles projection pairs. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 166: `))` This is continuation line 5 of the 5-line logical statement that begins at source line 162. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘pairs.append‘ with ‘(f"block.{index}.mlp.fc{layer}", getattr(block.mlp, f"mlp{layer}_conv"), getattr(block.mlp, f"mlp{layer}_bn"),)‘ inside the function projection_pairs, which handles projection pairs. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 167: `return pairs` This returns ‘pairs‘ to the caller of the function projection_pairs, which handles projection pairs, ending this invocation. The important operands are pairs: the value named 'pairs' in this block.

Line 170: `def export_model(` This starts function export_model. Its indented body performs export model as part of the file that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections; it runs only when called.

Line 171: `checkpoint_path: Path,` Inside the function export_model, which handles export model, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are checkpoint_path: the value named 'checkpoint path' in this block; Path: the value named 'path' in this block.

Line 172: `output_dir: Path,` Inside the function export_model, which handles export model, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are output_dir: the value named 'output dir' in this block; Path: the value named 'path' in this block.

Line 173: `*,` Inside the function export_model, which handles export model, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The expression is a literal or structural operator and has no hidden software state.

Line 174: `fractional_bits: int = 10,` This assigns ‘10,‘ to ‘fractional_bits‘ in host memory. Here fractional_bits means the value named 'fractional bits' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function export_model, which handles export model.

Line 175: `head_activation_scale: float = 0.125,` This assigns ‘0.125,‘ to ‘head_activation_scale‘ in host memory. Here head_activation_scale means an input feature value consumed by a neuron or multiply-accumulate operation. The expression is a literal or structural operator and has no hidden software state. Context: the function export_model, which handles export model.

Line 176: `) -> dict[str, object]:` Inside the function export_model, which handles export model, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are dict: the value named 'dict' in this block; str: the value named 'str' in this block; object: the value named 'object' in this block.

Line 177: `loaded = load_checkpoint(checkpoint_path, device="cpu")` This assigns ‘load_checkpoint(checkpoint_path, device="cpu")‘ to ‘loaded ‘ in host memory. Here loaded means the value named 'loaded' in this block. The important operands are load_checkpoint: the value named 'load checkpoint' in this block; checkpoint_path: the value named 'checkpoint path' in this block; device: the value named 'device' in this block. Context: the function export_model, which handles export model.

Line 178: `model = loaded.model` This assigns ‘loaded.model‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are loaded: the value named ’loaded’ in this block; model: the value named ’model’ in this block. Context: the function export_model, which handles export model.

Line 179: `writer = AlignedBinaryWriter()` This assigns ‘AlignedBinaryWriter()‘ to ‘writer ‘ in host memory. Here writer means the value named ’writer’ in this block. The important operands are AlignedBinaryWriter: the value named ’aligned binary writer’ in this block. Context: the function export_model, which handles export model.

Line 180: `input_probe = torch.zeros(1, 3, 1, 1)` This assigns ‘torch.zeros(1, 3, 1, 1)‘ to ‘input_probe ‘ in host memory. Here input_probe means the value named ’input probe’ in this block. The important operands are torch: the value named ’torch’ in this block; zeros: the value named ’zeros’ in this block. Context: the function export_model, which handles export model.

Line 181: `_, image_scale, image_zero_point = quantize_cifar_input_u8(input_probe)` This assigns ‘quantize_cifar_input_u8(input_probe)‘ to ‘_, image_scale, image_zero_point ‘ in host memory. Here _ means the value named ” in this block. The important operands are quantize_cifar_input_u8: the value named ’quantize cifar input u8’ in this block; input_probe: the value named ’input probe’ in this block. Context: the function export_model, which handles export model.

Line 182: `projections: list[ProjectionExport] = []` This assigns ‘[]‘ to ‘projections‘ in host memory. Here projections means the value named ’projections’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function export_model, which handles export model.

Line 183: `for name, convolution, batch_norm in projection_pairs(model):` This iterates name, convolution, batch_norm over ‘projection_pairs(model)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function export_model, which handles export model.

Line 184: `first_layer = name == "patch_embed.block0"` Inside the function export_model, which handles export model, this statement advances the host implementation that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The important operands are first_layer: the value named ’first layer’ in this block; name: the value named ’name’ in this block; patch_embed: the value named ’patch embed’ in this block.

Line 185: `projections.append(export_projection(` This statement continues through source line 196; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE_DENSE_OUTER" if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 186: `writer,` This is continuation line 2 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘writer,‘. The important operands are writer: the value named ’writer’ in this block. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE_DENSE_OUTER" if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 187: `name=name,` This is continuation line 3 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘name=name,‘. The important operands are name: the value named ’name’ in this block. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else

"binary spike 0/1"), compute_opcode=("COMPUTE_DENSE_OUTER" if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 188: `convolution=convolution,` This is continuation line 4 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘convolution=convolution,‘. The important operands are convolution: the value named ’convolution’ in this block. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:. if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE_DENSE_OUTER" if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 189: `batch_norm=batch_norm,` This is continuation line 5 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘batch_norm=batch_norm,‘. The important operands are batch_norm: the value named ’batch norm’ in this block. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE_DENSE_OUTER" if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 190: `input_scale=image_scale if first_layer else 1.0,` This is continuation line 6 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘input_scale=image_scale if first_layer else 1.0,‘. The important operands are input_scale: the real-value spacing represented by one quantized integer step; image_scale: the real-value spacing represented by one quantized integer step; first_layer: the value named ’first layer’ in this block. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE_DENSE_OUTER" if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 191: `fractional_bits=fractional_bits,` This is continuation line 7 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘fractional_bits=fractional_bits,‘. The important operands are fractional_bits: the value named ’fractional bits’ in this block. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 192: `input_encoding=(` This is continuation line 8 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘input_encoding=(‘. The important operands are input_encoding: the value named ’input encoding’ in this block. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE_DENSE_OUTER" if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 193: `f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}"` This is continuation line 9 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}"‘. The important operands are f: the value named ’f’ in this

block; asymmetric: the value named 'asymmetric' in this block; uint8: the value named 'uint8' in this block. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE_DENSE_OUTER" if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 194: `if first_layer else "binary spike 0/1"),` This is continuation line 10 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘if first_layer else "binary spike 0/1"),‘. The important operands are first_layer: the value named 'first layer' in this block; binary: the value named 'binary' in this block; spike: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 195: `compute_opcode=("COMPUTE_DENSE_OUTER" if first_layer else "COMPUTE_BINARY"),` This is continuation line 11 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘compute_opcode=("COMPUTE_DI if first_layer else "COMPUTE_BINARY"),‘. The important operands are compute_opcode: the value named 'compute opcode' in this block; COMPUTE_DENSE_OUTER: the value named 'compute dense outer' in this block; first_layer: the value named 'first layer' in this block. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 196: `))` This is continuation line 12 of the 12-line logical statement that begins at source line 185. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘projections.append‘ with ‘export_projection(writer, name=name, convolution=convolution, batch_norm=batch_norm, input_scale=image_scale if first_layer else 1.0, fractional_bits=fractional_bits, input_encoding=(f"asymmetric uint8 zero_point={image_zero_point} scale={image_scale:.12g}" if first_layer else "binary spike 0/1"), compute_opcode=("COMPUTE_DENSE_OUTER" if first_layer else "COMPUTE_BINARY"),)‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 198: `head_weight, head_weight_scale = quantize_weight_tensor(model.head.weight)` This assigns ‘quantize_weight_tensor(model.head.weight)‘ to ‘head_weight, head_weight_scale ‘ in host memory. Here head_weight means a learned coefficient multiplied by an activation. The important operands are quantize_weight_tensor: a learned coefficient multiplied by an activation; model: the value named 'model' in this block; head: the value named 'head' in this block. Context: the function export_model, which handles export model.

Line 199: `head_matrix = head_weight.transpose(0, 1).contiguous().cpu().numpy()` This assigns ‘head_weight.transpos 1).contiguous().cpu().numpy()‘ to ‘head_matrix ‘ in host memory. Here head_matrix means the value named 'head matrix' in this block. The important operands are head_weight: a learned coefficient multiplied by an activation; transpose: the value named 'transpose' in this block; contiguous: the value named 'contiguous' in this block. Context: the function export_model, which handles export model.

Line 200: `head_accumulator_scale = head_activation_scale * head_weight_scale` This assigns ‘head_activation_scale * head_weight_scale‘ to ‘head_accumulator_scale ‘ in host memory. Here head_accumulator_scale means a widened running sum that prevents intermediate overflow. The important operands are head_activation_scale: an input feature

value consumed by a neuron or multiply-accumulate operation; head_weight_scale: a learned coefficient multiplied by an activation. Context: the function export_model, which handles export model.

Line 201: `head_bias = torch.round(` This statement continues through source line 202; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘torch.round(model.head.bias.detach() / head_accumulator_scale).to(torch.int32).cpu().numpy()‘ to ‘head_bias ‘ in host memory. Here head_bias means an additive learned offset applied after accumulation. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; model: the value named ’model’ in this block. Context: the function export_model, which handles export model.

Line 202: `model.head.bias.detach() / head_accumulator_scale).to(torch.int32).cpu().numpy()` This is continuation line 2 of the 2-line logical statement that begins at source line 201. Its exact fragment is ‘model.head.bias.detach() / head_accumulator_scale).to(torch.int32).cpu().numpy()‘. The important operands are model: the value named ’model’ in this block; head: the value named ’head’ in this block; bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns ‘torch.round(model.head.bias.detach() / head_accumulator_scale).to(torch.int32).cpu().numpy() to ‘head_bias ‘ in host memory. Here head_bias means an additive learned offset applied after accumulation. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; model: the value named ’model’ in this block. Context: the function export_model, which handles export model.

Line 203: `head_sections = (` This statement continues through source line 206; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(writer.append("head.weight_k_by_n_int8", head_matrix), writer.append("head.bias_accumulator_units", head_bias),)‘ to ‘head_sections ‘ in host memory. Here head_sections means the value named ’head sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; head: the value named ’head’ in this block. Context: the function export_model, which handles export model.

Line 204: `writer.append("head.weight_k_by_n_int8", head_matrix),` This is continuation line 2 of the 4-line logical statement that begins at source line 203. Its exact fragment is ‘writer.append("head.weight_k_by_n_int8", head_matrix),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; head: the value named ’head’ in this block. Read together, the complete operation is: This assigns ‘(writer.append("head.weight_k_by_n_int8", head_matrix), writer.append("head.bias_accumulator_units", head_bias),)‘ to ‘head_sections ‘ in host memory. Here head_sections means the value named ’head sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; head: the value named ’head’ in this block. Context: the function export_model, which handles export model.

Line 205: `writer.append("head.bias_accumulator_units", head_bias),` This is continuation line 3 of the 4-line logical statement that begins at source line 203. Its exact fragment is ‘writer.append("head.bias_accumulator_units", head_bias),‘. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; head: the value named ’head’ in this block. Read together, the complete operation is: This assigns ‘(writer.append("head.weight_k_by_n_int8", head_matrix), writer.append("head.bias_accumulator_units", head_bias),)‘ to ‘head_sections ‘ in host memory. Here head_sections means the value named ’head sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; head: the value named ’head’ in this block. Context: the function export_model, which handles export model.

Line 206: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 203. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(writer.append("head.weight_k_by_n_int8", head_matrix), writer.append("head.bias_accumulator_units", head_bias),)‘ to ‘head_sections ‘ in host memory. Here head_sections means the value named ’head sections’ in this block. The important operands are writer: the value named ’writer’ in this block; append: the value named ’append’ in this block; head: the value named ’head’ in this block. Context: the function export_model, which handles export model.

Line 207: `checkpoint_hash = hashlib.sha256(checkpoint_path.read_bytes()).hexdigest()` This assigns ‘hashlib.sha256(checkpoint_path.read_bytes()).hexdigest()‘ to ‘checkpoint_hash ‘ in host memory. Here checkpoint_hash means the value named ’checkpoint hash’ in this block. The important operands are hashlib: the value named ’hashlib’

in this block; sha256: the value named 'sha256' in this block; checkpoint_path: the value named 'checkpoint path' in this block. Context: the function export_model, which handles export model.

Line 208: `output_dir.mkdir(parents=True, exist_ok=True)` This calls 'output_dir.mkdir' with 'parents=True, exist_ok=True' inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 209: `binary_path = output_dir / "spikingformer_neuraedge_weights.bin"` This assigns 'output_dir / "spikingformer_neuraedge_weights.bin"' to 'binary_path ' in host memory. Here binary_path means the value named 'binary path' in this block. The important operands are output_dir: the value named 'output dir' in this block; spikingformer_neuraedge_weights: a learned coefficient multiplied by an activation; bin: the value named 'bin' in this block. Context: the function export_model, which handles export model.

Line 210: `binary_path.write_bytes(writer.data)` This calls 'binary_path.write_bytes' with 'writer.data' inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 211: `binary_hash = hashlib.sha256(writer.data).hexdigest()` This assigns 'hashlib.sha256(writer.data).hexdigest()' to 'binary_hash ' in host memory. Here binary_hash means the value named 'binary hash' in this block. The important operands are hashlib: the value named 'hashlib' in this block; sha256: the value named 'sha256' in this block; writer: the value named 'writer' in this block. Context: the function export_model, which handles export model.

Line 212: `manifest: dict[str, object] = {` This statement continues through source line 245; the explanation uses the complete expression rather than only the first visual fragment. This assigns '{ "format": "neuraedge-spikingformer-parameters-v1", "checkpoint": str(checkpoint_path.resolve()), "checkpoint_sha256": checkpoint_hash, "checkpoint_epoch": loaded.epoch, "checkpoint_metric_percent": loaded.metric, "binary_file": binary_path.name, "binary_bytes": len(writer.data), "binary_sha256": binary_hash, "alignment_bytes": ALIGNMENT, "fixed_point": { "activation_fractional_bits": fractional_bits, "activation_scale": 1 << fractional_bits, "lif_membrane_bits": 24, "lif_current_bits": 16, "image_input_scale": image_scale, "image_input_zero_point": image_zero_point, "head_activation_scale": head_activation_scale, }, "projections": [asdict(item) for item in projections], "head": { "source_weight_shape": list(model.head.weight.shape), "hardware_matrix_shape": list(head_matrix.shape), "activation_encoding": "signed int8 encoded as uint8 with zero point 128", "weight_encoding": "signed int8 encoded as uint8 with zero point 128", "compute_opcode": "COMPUTE_DENSE_DOT8", "weight_scale": head_weight_scale, "accumulator_scale": head_accumulator_scale, "bias_minimum": int(head_bias.min()), "bias_maximum": int(head_bias.max()), "sections": [asdict(item) for item in head_sections], }, "sections": [asdict(item) for item in writer.sections], }' to 'manifest' in host memory. Here manifest means the value named 'manifest' in this block. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; spikingformer: the value named 'spikingformer' in this block. Context: the function export_model, which handles export model.

Line 213: `"format": "neuraedge-spikingformer-parameters-v1",` This is continuation line 2 of the 34-line logical statement that begins at source line 212. Its exact fragment is '"format": "neuraedge-spikingformer-parameters-v1",'. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; spikingformer: the value named 'spikingformer' in this block. Read together, the complete operation is: This assigns '{ "format": "neuraedge-spikingformer-parameters-v1", "checkpoint": str(checkpoint_path.resolve()), "checkpoint_sha256": checkpoint_hash, "checkpoint_epoch": loaded.epoch, "checkpoint_metric_percent": loaded.metric, "binary_file": binary_path.name, "binary_bytes": len(writer.data), "binary_sha256": binary_hash, "alignment_bytes": ALIGNMENT, "fixed_point": { "activation_fractional_bits": fractional_bits, "activation_scale": 1 << fractional_bits, "lif_membrane_bits": 24, "lif_current_bits": 16, "image_input_scale": image_scale, "image_input_zero_point": image_zero_point, "head_activation_scale": head_activation_scale, }, "projections": [asdict(item) for item in projections], "head": { "source_weight_shape": list(model.head.weight.shape), "hardware_matrix_shape": list(head_matrix.shape), "activation_encoding": "signed int8 encoded as uint8 with zero point 128", "weight_encoding": "signed int8 encoded as uint8 with zero point 128", "compute_opcode": "COMPUTE_DENSE_DOT8", "weight_scale": head_weight_scale, "accumulator_scale": head_accumulator_scale, "bias_minimum": int(head_bias.min()), "bias_maximum": int(head_bias.max()), "sections": [asdict(item) for item in head_sections], }, "sections": [asdict(item) for item in writer.sections], }' to 'manifest' in host memory. Here manifest means the value named 'manifest' in this block. The important operands are format:

the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; spikingformer: the value named 'spikingformer' in this block. Context: the function export_model, which handles export model.

Line 214: `"checkpoint": str(checkpoint_path.resolve()),` This is continuation line 3 of the 34-line logical statement that begins at source line 212. Its exact fragment is '"checkpoint": str(checkpoint_path.resolve()),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "format": "neuraedge-spikingformer-parameters-v1", "checkpoint": str(checkpoint_path.resolve()), "checkpoint_sha256": checkpoint_hash, "checkpoint_epoch": loaded.epoch, "checkpoint_metric_p
loaded.metric, "binary_file": binary_path.name, "binary_bytes": len(writer.data), "binary_sha256": binary_hash, "alignment_bytes": ALIGNMENT, "fixed_point": { "activation_fractional_bits": fractional_bits, "activation_scale": 1 << fractional_bits, "lif_membrane_bits": 24, "lif_current_bits": 16, "image_input_scale": image_scale, "image_input_zero_point": image_zero_point, "head_activation_scale": head_activation_scale, }, "projections": [asdict(item) for item in projections], "head": { "source_weight_shape": list(model.head.weight.shape), "hardware_matrix_shape": list(head_matrix.shape), "activation_encoding": "signed int8 encoded as uint8 with zero point 128", "weight_encoding": "signed int8 encoded as uint8 with zero point 128", "compute_opcode": "COMPUTE_DENSE_DOT8", "weight_scale": head_weight_scale, "accumulator_scale": head_accumulator_scale, "bias_minimum": int(head_bias.min()), "bias_maximum": int(head_bias.max()), "sections": [asdict(item) for item in head_sections], }, "sections": [asdict(item) for item in writer.sections], }‘ to ‘manifest‘ in host memory. Here manifest means the value named 'manifest' in this block. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; spikingformer: the value named 'spikingformer' in this block. Context: the function export_model, which handles export model.

Line 246: `manifest_path = output_dir / "spikingformer_neuraedge_weights.json"` This assigns ‘output_dir / "spikingformer_neuraedge_weights.json"‘ to ‘manifest_path ‘ in host memory. Here manifest_path means the value named 'manifest path' in this block. The important operands are output_dir: the value named 'output dir' in this block; spikingformer_neuraedge_weights: a learned coefficient multiplied by an activation; json: the value named 'json' in this block. Context: the function export_model, which handles export model.

Line 247: `manifest_path.write_text(json.dumps(manifest, indent=2) + "\n", encoding="ascii")` This calls ‘manifest_path.write_text‘ with ‘json.dumps(manifest, indent=2) + "\n", encoding="ascii"‘ inside the function export_model, which handles export model. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 248: `return manifest` This returns ‘manifest‘ to the caller of the function export_model, which handles export model, ending this invocation. The important operands are manifest: the value named 'manifest' in this block.

Line 251: `def parse_arguments() -> argparse.Namespace:` This starts function parse_arguments. Its indented body performs parse arguments as part of the file that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections; it runs only when called.

Line 252: `parser = argparse.ArgumentParser()` This assigns ‘argparse.ArgumentParser()‘ to ‘parser ‘ in host memory. Here parser means the value named 'parser' in this block. The important operands are argparse: the value named 'argparse' in this block; ArgumentParser: the value named 'argument parser' in this block. Context: the function parse_arguments, which handles parse arguments.

Line 253: `parser.add_argument("-checkpoint", required=True, type=Path)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 254: `parser.add_argument("-output-dir", required=True, type=Path)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 255: `parser.add_argument("-fractional-bits", type=int, default=10)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 256: `parser.add_argument("-head-activation-scale", type=float, default=0.125)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 257: `return parser.parse_args()` This returns ‘parser.parse_args()‘ to the caller of the function parse_arguments, which handles parse arguments, ending this invocation. The important operands are parser: the value named ’parser’ in this block; parse_args: the value named ’parse args’ in this block.

Line 260: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 261: `arguments = parse_arguments()` This assigns ‘parse_arguments()‘ to ‘arguments ‘ in host memory. Here arguments means the value named ’arguments’ in this block. The important operands are parse_arguments: the value named ’parse arguments’ in this block. Context: the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 262: `exported = export_model(` This statement continues through source line 267; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘export_model(arguments.checkpoint.resolve(), arguments.output_dir.resolve(), fractional_bits=arguments.fractional_bits, head_activation_scale=arguments.head_activation_s)‘ to ‘exported ‘ in host memory. Here exported means the value named ’exported’ in this block. The important operands are export_model: the value named ’export model’ in this block; arguments: the value named ’arguments’ in this block; checkpoint: the value named ’checkpoint’ in this block. Context: the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 263: `arguments.checkpoint.resolve(),` This is continuation line 2 of the 6-line logical statement that begins at source line 262. Its exact fragment is ‘arguments.checkpoint.resolve(),‘. The important operands are arguments: the value named ’arguments’ in this block; checkpoint: the value named ’checkpoint’ in this block; resolve: the value named ’resolve’ in this block. Read together, the complete operation is: This assigns ‘export_model(arguments.checkpoint.resolve(), arguments.output_dir.resolve(), fractional_bits=arguments.fractional_bits, head_activation_scale=arguments.head_activation_sca)‘ to ‘exported ‘ in host memory. Here exported means the value named ’exported’ in this block. The important operands are export_model: the value named ’export model’ in this block; arguments: the value named ’arguments’ in this block; checkpoint: the value named ’checkpoint’ in this block. Context: the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 264: `arguments.output_dir.resolve(),` This is continuation line 3 of the 6-line logical statement that begins at source line 262. Its exact fragment is ‘arguments.output_dir.resolve(),‘. The important operands are arguments: the value named ’arguments’ in this block; output_dir: the value named ’output dir’ in this block; resolve: the value named ’resolve’ in this block. Read together, the complete operation is: This assigns ‘export_model(arguments.checkpoint.resolve(), arguments.output_dir.resolve(), fractional_bits=arguments.fractional_bits, head_activation_scale=arguments.head_activation_sca)‘ to ‘exported ‘ in host memory. Here exported means the value named ’exported’ in this block. The important operands are export_model: the value named ’export model’ in this block; arguments: the value named ’arguments’ in this block;

checkpoint: the value named 'checkpoint' in this block. Context: the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 265: `fractional_bits=arguments.fractional_bits,` This is continuation line 4 of the 6-line logical statement that begins at source line 262. Its exact fragment is 'fractional_bits=arguments.fractional_bits,'. The important operands are fractional_bits: the value named 'fractional bits' in this block; arguments: the value named 'arguments' in this block. Read together, the complete operation is: This assigns 'export_model(arguments.checkpoint.resolve(), arguments.output_dir.resolve(), fractional_bits=arguments.fractional_bits, head_activation_scale=arguments.head_activation_scale,)' to 'exported ' in host memory. Here exported means the value named 'exported' in this block. The important operands are export_model: the value named 'export model' in this block; arguments: the value named 'arguments' in this block; checkpoint: the value named 'checkpoint' in this block. Context: the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 266: `head_activation_scale=arguments.head_activation_scale,` This is continuation line 5 of the 6-line logical statement that begins at source line 262. Its exact fragment is 'head_activation_scale=arguments.head_activation_scale,'. The important operands are head_activation_scale: an input feature value consumed by a neuron or multiply-accumulate operation; arguments: the value named 'arguments' in this block. Read together, the complete operation is: This assigns 'export_model(arguments.checkpoint.resolve(), arguments.output_dir.resolve(), fractional_bits=arguments.fractional_bits, head_activation_scale=arguments.head_activation_scale,)' to 'exported ' in host memory. Here exported means the value named 'exported' in this block. The important operands are export_model: the value named 'export model' in this block; arguments: the value named 'arguments' in this block; checkpoint: the value named 'checkpoint' in this block. Context: the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 267: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 262. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'export_model(arguments.checkpoint.resolve(), arguments.output_dir.resolve(), fractional_bits=arguments.fractional_bits, head_activation_scale=arguments.head_activation_scale,)' to 'exported ' in host memory. Here exported means the value named 'exported' in this block. The important operands are export_model: the value named 'export model' in this block; arguments: the value named 'arguments' in this block; checkpoint: the value named 'checkpoint' in this block. Context: the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 268: `print(json.dumps({` This statement continues through source line 273; the explanation uses the complete expression rather than only the first visual fragment. This calls 'print' with 'json.dumps({ "binary_file": exported["binary_file"], "binary_bytes": exported["binary_bytes"], "binary_sha256": exported["binary_sha256"], "projection_count": len(exported["projections"]), }, indent=2)' inside the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 269: `"binary_file": exported["binary_file"],` This is continuation line 2 of the 6-line logical statement that begins at source line 268. Its exact fragment is '"binary_file": exported["binary_file"],'. The important operands are binary_file: the value named 'binary file' in this block; exported: the value named 'exported' in this block. Read together, the complete operation is: This calls 'print' with 'json.dumps({ "binary_file": exported["binary_file"], "binary_bytes": exported["binary_bytes"], "binary_sha256": exported["binary_sha256"], "projection_count": len(exported["projections"]), }, indent=2)' inside the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 270: `"binary_bytes": exported["binary_bytes"],` This is continuation line 3 of the 6-line logical statement that begins at source line 268. Its exact fragment is '"binary_bytes": exported["binary_bytes"],'. The important operands are binary_bytes: the value named 'binary bytes' in this block; exported: the value named 'exported' in this block. Read together, the complete operation is: This calls 'print' with 'json.dumps({ "binary_file": exported["binary_file"], "binary_bytes": exported["binary_bytes"], "binary_sha256": exported["binary_sha256"], "projection_count": len(exported["projections"]), }, indent=2)' inside the file whose role is to folds BatchNorm, calibrates

quantizers, and writes aligned hashed hardware parameter sections. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 271: `"binary_sha256": exported["binary_sha256"],` This is continuation line 4 of the 6-line logical statement that begins at source line 268. Its exact fragment is ‘"binary_sha256": exported["binary_sha256"],‘. The important operands are binary_sha256: the value named ’binary sha256’ in this block; exported: the value named ’exported’ in this block. Read together, the complete operation is: This calls ‘print‘ with ‘json.dumps({ "binary_file": exported["binary_file"], "binary_bytes": exported["binary_bytes"], "binary_sha256": exported["binary_sha256"], "projection_count": len(exported["projections"]), }, indent=2)‘ inside the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 272: `"projection_count": len(exported["projections"]),` This is continuation line 5 of the 6-line logical statement that begins at source line 268. Its exact fragment is ‘"projection_count": len(exported["projections"]),‘. The important operands are projection_count: an integer count retained for control or measurable telemetry; len: the value named ’len’ in this block; exported: the value named ’exported’ in this block. Read together, the complete operation is: This calls ‘print‘ with ‘json.dumps({ "binary_file": exported["binary_file"], "binary_bytes": exported["binary_bytes"], "binary_sha256": exported["binary_sha256"], "projection_count": len(exported["projections"]), }, indent=2)‘ inside the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

Line 273: `}, indent=2))` This is continuation line 6 of the 6-line logical statement that begins at source line 268. Its exact fragment is ‘}, indent=2))‘. The important operands are indent: the value named ’indent’ in this block. Read together, the complete operation is: This calls ‘print‘ with ‘json.dumps({ "binary_file": exported["binary_file"], "binary_bytes": exported["binary_bytes"], "binary_sha256": exported["binary_sha256"], "projection_count": len(exported["projection
}, indent=2)‘ inside the file whose role is to folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections. The call advances the host-side job that folds BatchNorm, calibrates quantizers, and writes aligned hashed hardware parameter sections.

28 software/generate_debug_report.py

Role in the complete system: turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

28.1 Beginner architecture map

Dataflow responsibility This evidence builder reads immutable result artifacts instead of rerunning or inventing measurements. It parses VCD transitions and Vivado text tables, plots all standard-test predictions and hardware reports, embeds the native block design, and records every plot's source artifact.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: PlotRecord, VcdSignal. Functions: root_dir, load_json, style_axes, save_figure, text_page, confusion_figure, parse_vcd, choose_wave_signals, waveform_figure, arithmetic_groups, parse_timing_slacks, parse_implementation_summary, parse_clock_timing, parse_utilization_hierarchy, parse_drc_summary, parse_cdc_summ parse_power_report, file_evidence, latex_escape, latex_breakable, write_report_tex, generate, compile_tex, main. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

28.3 Line annotations

Line 1: `"""Generate model, compiler, waveform, timing, utilization, and power plots."""` This is executable documentation attached to the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import argparse` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import hashlib` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `import json` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `import math` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `import re` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `import shutil` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `import subprocess` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `from collections import Counter, defaultdict` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `from pathlib import Path` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `from typing import Callable, Iterable, Sequence` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `import matplotlib.pyplot as plt` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `import numpy as np` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `from matplotlib.backends.backend_pdf import PdfPages` This imports the named Python API so the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `CLASSES = [` This statement continues through source line 25; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘["airplane", "automobile", "bird", "cat", "deer", "dog", "frog", "horse", "ship", "truck",]‘ to ‘CLASSES ‘ in host memory. Here CLASSES means the value named ’classes’ in this block. The important operands are airplane: one parallel arithmetic element within a vector or tensor datapath; automobile: the value named ’automobile’ in this block; bird: the value named ’bird’ in this block. Context: the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 23: `"airplane", "automobile", "bird", "cat", "deer",` This is continuation line 2 of the 4-line logical statement that begins at source line 22. Its exact fragment is ‘"airplane", "automobile", "bird", "cat", "deer",‘. The important operands are airplane: one parallel arithmetic element within a vector or tensor datapath; automobile: the value named ’automobile’ in this block; bird: the value named ’bird’ in this block. Read together, the complete operation is: This assigns ‘["airplane", "automobile", "bird", "cat", "deer", "dog", "frog", "horse", "ship", "truck",]‘ to ‘CLASSES ‘ in host memory. Here CLASSES means the value named ’classes’ in this block. The important operands are airplane: one parallel arithmetic element within a vector or tensor datapath; automobile: the value named ’automobile’ in this block; bird: the value named ’bird’ in this block. Context: the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 24: `"dog", "frog", "horse", "ship", "truck",` This is continuation line 3 of the 4-line logical statement that begins at source line 22. Its exact fragment is ‘"dog", "frog", "horse", "ship", "truck",‘. The important operands are dog: the value named ’dog’ in this block; frog: the value named ’frog’ in this block; horse: the value named ’horse’ in this block. Read together, the complete operation is: This assigns ‘["airplane", "automobile", "bird", "cat", "deer", "dog", "frog", "horse", "ship", "truck",]‘ to ‘CLASSES ‘ in host memory. Here CLASSES means the value named ’classes’ in this block. The important operands are airplane: one parallel arithmetic element within a vector or tensor datapath; automobile: the value named ’automobile’ in this block; bird: the value named ’bird’ in this block. Context: the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 25: `]` This is continuation line 4 of the 4-line logical statement that begins at source line 22. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘["airplane", "automobile", "bird", "cat", "deer", "dog", "frog", "horse", "ship", "truck",]‘ to ‘CLASSES ‘ in host memory. Here CLASSES means the value named ’classes’ in this block. The important operands are airplane: one parallel arithmetic element within a vector or tensor datapath; automobile: the value named ’automobile’ in this block; bird: the value named ’bird’ in this block. Context: the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 26: `COLORS = ["#155e75", "#166534", "#991b1b", "#7c3e00", "#4f46e5", "#374151"]` This assigns ‘["#155e75", "#166534", "#991b1b", "#7c3e00", "#4f46e5", "#374151"]‘ to ‘COLORS ‘ in host memory. Here COLORS means the value named ’colors’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 29: `@dataclass` This decorator changes how the following class or function is constructed. ‘@dataclass‘ is applied at import time on the host and is part of the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it creates no FPGA circuit by itself.

Line 30: `class PlotRecord:` This defines class PlotRecord, which groups data and methods for plot record. Instances exist in host memory and organize the flow that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 31: `filename: str` Inside the class PlotRecord, which handles plot record, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are filename: the value named ’filename’ in this block; str: the value named ’str’ in this block.

Line 32: `title: str` Inside the class PlotRecord, which handles plot record, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are title: the value named 'title' in this block; str: the value named 'str' in this block.

Line 33: `evidence: str` Inside the class PlotRecord, which handles plot record, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are evidence: the value named 'evidence' in this block; str: the value named 'str' in this block.

Line 36: `@dataclass` This decorator changes how the following class or function is constructed. '@dataclass' is applied at import time on the host and is part of the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it creates no FPGA circuit by itself.

Line 37: `class VcdSignal:` This defines class VcdSignal, which groups data and methods for vcd signal. Instances exist in host memory and organize the flow that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 38: `name: str` Inside the class VcdSignal, which handles vcd signal, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are name: the value named 'name' in this block; str: the value named 'str' in this block.

Line 39: `width: int` Inside the class VcdSignal, which handles vcd signal, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are width: the value named 'width' in this block.

Line 40: `transitions: list[tuple[int, float]]` Inside the class VcdSignal, which handles vcd signal, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are transitions: the value named 'transitions' in this block; list: the value named 'list' in this block; tuple: the value named 'tuple' in this block.

Line 43: `def root_dir() -> Path:` This starts function root_dir. Its indented body performs root dir as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 44: `return Path(__file__).resolve().parents[1]` This returns 'Path(___file___).resolve().parents[1]' to the caller of the function root_dir, which handles root dir, ending this invocation. The important operands are Path: the value named 'path' in this block; ___file___: the value named 'file' in this block; resolve: the value named 'resolve' in this block.

Line 47: `def load_json(path: Path) -> dict:` This starts function load_json. Its indented body performs load json as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 48: `return json.loads(path.read_text(encoding="utf-8-sig"))` This returns 'json.loads(path.read_text(encoding="u
8-sig"))' to the caller of the function load_json, which handles load json, ending this invocation. The important operands are json: the value named 'json' in this block; loads: the value named 'loads' in this block; path: the value named 'path' in this block.

Line 51: `def style_axes(axis: plt.Axes, title: str, xlabel: str = "", ylabel: str = "") -> None:` This starts function style_axes. Its indented body performs style axes as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 52: `axis.set_title(title, fontsize=12, fontweight="bold", loc="left")` This calls ‘axis.set_title‘ with ‘title, fontsize=12, fontweight="bold", loc="left"‘ inside the function style_axes, which handles style axes. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 53: `axis.set_xlabel(xlabel)` This calls ‘axis.set_xlabel‘ with ‘xlabel‘ inside the function style_axes, which handles style axes. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 54: `axis.set_ylabel(ylabel)` This calls ‘axis.set_ylabel‘ with ‘ylabel‘ inside the function style_axes, which handles style axes. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 55: `axis.grid(True, axis="y", alpha=0.22, linewidth=0.7)` This calls ‘axis.grid‘ with ‘True, axis="y", alpha=0.22, linewidth=0.7‘ inside the function style_axes, which handles style axes. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 56: `axis.spines[["top", "right"]].set_visible(False)` Inside the function style_axes, which handles style axes, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axis: the value named ’axis’ in this block; spines: the value named ’spines’ in this block; top: the value named ’top’ in this block.

Line 59: `def save_figure(` This starts function save_figure. Its indented body performs save figure as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 60: `figure: plt.Figure,` Inside the function save_figure, which handles save figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are figure: the value named ’figure’ in this block; plt: the value named ’plt’ in this block; Figure: the value named ’figure’ in this block.

Line 61: `output_dir: Path,` Inside the function save_figure, which handles save figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are output_dir: the value named ’output dir’ in this block; Path: the value named ’path’ in this block.

Line 62: `pdf: PdfPages,` Inside the function save_figure, which handles save figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are pdf: the value named ’pdf’ in this block; PdfPages: the value named ’pdf pages’ in this block.

Line 63: `records: list[PlotRecord],` Inside the function save_figure, which handles save figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are records: the number of descriptor records accepted since program start; list: the value named ’list’ in this block; PlotRecord: the value named ’plot record’ in this block.

Line 64: `index: int,` Inside the function save_figure, which handles save figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry.

Line 65: `slug: str,` Inside the function save_figure, which handles save figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are slug: the value named 'slug' in this block; str: the value named 'str' in this block.

Line 66: `title: str,` Inside the function save_figure, which handles save figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are title: the value named 'title' in this block; str: the value named 'str' in this block.

Line 67: `evidence: str,` Inside the function save_figure, which handles save figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are evidence: the value named 'evidence' in this block; str: the value named 'str' in this block.

Line 68: `) -> int:` Inside the function save_figure, which handles save figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The expression is a literal or structural operator and has no hidden software state.

Line 69: `figure.tight_layout()` This calls 'figure.tight_layout' with " inside the function save_figure, which handles save figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 70: `filename = f"{index:02d}_{slug}.png"` This assigns 'f"{index:02d}_{slug}.png"' to 'filename ' in host memory. Here filename means the value named 'filename' in this block. The important operands are f: the value named 'f' in this block; index: an integer selecting one tensor element, lane, bank, or state entry; _: the value named " in this block. Context: the function save_figure, which handles save figure.

Line 71: `figure.savefig(output_dir / filename, dpi=190, bbox_inches="tight")` This calls 'figure.savefig' with 'output_dir / filename, dpi=190, bbox_inches="tight"' inside the function save_figure, which handles save figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 72: `pdf.savefig(figure, bbox_inches="tight")` This calls 'pdf.savefig' with 'figure, bbox_inches="tight"' inside the function save_figure, which handles save figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 73: `plt.close(figure)` This calls 'plt.close' with 'figure' inside the function save_figure, which handles save figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 74: `records.append(PlotRecord(filename, title, evidence))` This calls 'records.append' with 'PlotRecord(filename, title, evidence)' inside the function save_figure, which handles save figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 75: `return index + 1` This returns 'index + 1' to the caller of the function save_figure, which handles save figure, ending this invocation. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry.

Line 78: `def text_page(title: str, lines: Sequence[str]) -> plt.Figure:` This starts function text_page. Its indented body performs text page as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 79: `figure = plt.figure(figsize=(11.69, 8.27))` This assigns ‘plt.figure(figsize=(11.69, 8.27))‘ to ‘figure ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; figure: the value named ’figure’ in this block; figsize: the value named ’figsize’ in this block. Context: the function text_page, which handles text page.

Line 80: `figure.patch.set_facecolor("white")` This calls ‘figure.patch.set_facecolor‘ with ‘"white"‘ inside the function text_page, which handles text page. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 81: `figure.text(0.055, 0.93, title, fontsize=20, fontweight="bold", color="#111827")` This calls ‘figure.text‘ with ‘0.055, 0.93, title, fontsize=20, fontweight="bold", color="#111827"‘ inside the function text_page, which handles text page. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 82: `y = 0.86` This assigns ‘0.86‘ to ‘y ‘ in host memory. Here y means the value named ’y’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function text_page, which handles text page.

Line 83: `for line in lines:` This iterates line over ‘lines‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function text_page, which handles text page.

Line 84: `wrapped = [line[start : start + 125] for start in range(0, len(line), 125)] or [""]` This assigns ‘[line[start : start + 125] for start in range(0, len(line), 125)] or [""]‘ to ‘wrapped ‘ in host memory. Here wrapped means the value named ’wrapped’ in this block. The important operands are line: the value named ’line’ in this block; start: the value named ’start’ in this block; for: the value named ’for’ in this block. Context: the function text_page, which handles text page.

Line 85: `for segment in wrapped:` This iterates segment over ‘wrapped‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function text_page, which handles text page.

Line 86: `figure.text(0.065, y, segment, fontsize=10.5, family="monospace", color="#1f2937")` This calls ‘figure.text‘ with ‘0.065, y, segment, fontsize=10.5, family="monospace", color="#1f2937"‘ inside the function text_page, which handles text page. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 87: `y -= 0.038` Inside the function text_page, which handles text page, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are y: the value named ’y’ in this block.

Line 88: `y -= 0.008` Inside the function text_page, which handles text page, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are y: the value named ’y’ in this block.

Line 89: `return figure` This returns ‘figure‘ to the caller of the function text_page, which handles text page, ending this invocation. The important operands are figure: the value named ’figure’ in this block.

Line 92: `def confusion_figure(matrix: np.ndarray, title: str, signed: bool = False) -> plt.Figure:` This starts function confusion_figure. Its indented body performs confusion figure as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 93: `figure, axis = plt.subplots(figsize=(9.5, 8.2))` This assigns ‘plt.subplots(figsize=(9.5, 8.2))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function confusion_figure, which handles confusion figure.

Line 94: `if signed:` This executes the following indented host-code branch only when ‘signed‘ is true. The expression is a literal or structural operator and has no hidden software state. Context: the function confusion_figure, which handles confusion figure.

Line 95: `limit = max(1, int(np.abs(matrix).max()))` This assigns ‘max(1, int(np.abs(matrix).max()))‘ to ‘limit ‘ in host memory. Here limit means the value named ’limit’ in this block. The important operands are max: the value named ’max’ in this block; abs: the value named ’abs’ in this block; matrix: the value named ’matrix’ in this block. Context: the function confusion_figure, which handles confusion figure.

Line 96: `image = axis.imshow(matrix, cmap="RdBu_r", vmin=-limit, vmax=limit)` This assigns ‘axis.imshow(matrix, cmap="RdBu_r", vmin=-limit, vmax=limit)‘ to ‘image ‘ in host memory. Here image means the value named ’image’ in this block. The important operands are axis: the value named ’axis’ in this block; imshow: the value named ’imshow’ in this block; matrix: the value named ’matrix’ in this block. Context: the function confusion_figure, which handles confusion figure.

Line 97: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function confusion_figure, which handles confusion figure.

Line 98: `image = axis.imshow(matrix, cmap="YlGnBu", vmin=0)` This assigns ‘axis.imshow(matrix, cmap="YlGnBu", vmin=0)‘ to ‘image ‘ in host memory. Here image means the value named ’image’ in this block. The important operands are axis: the value named ’axis’ in this block; imshow: the value named ’imshow’ in this block; matrix: the value named ’matrix’ in this block. Context: the function confusion_figure, which handles confusion figure.

Line 99: `figure.colorbar(image, ax=axis, fraction=0.046, pad=0.04)` This calls ‘figure.colorbar‘ with ‘image, ax=axis, fraction=0.046, pad=0.04‘ inside the function confusion_figure, which handles confusion figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 100: `axis.set_xticks(range(10), CLASSES, rotation=45, ha="right")` This calls ‘axis.set_xticks‘ with ‘range(10), CLASSES, rotation=45, ha="right"‘ inside the function confusion_figure, which handles confusion figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 101: `axis.set_yticks(range(10), CLASSES)` This calls ‘axis.set_yticks‘ with ‘range(10), CLASSES‘ inside the function confusion_figure, which handles confusion figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 102: `axis.set_xlabel("Predicted class")` This calls ‘axis.set_xlabel‘ with ‘"Predicted class"‘ inside the function confusion_figure, which handles confusion figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 103: `axis.set_ylabel("True class")` This calls ‘axis.set_ylabel‘ with ‘"True class"‘ inside the function confusion_figure, which handles confusion figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 104: `axis.set_title(title, fontsize=14, fontweight="bold", loc="left")` This calls ‘axis.set_title‘ with ‘title, fontsize=14, fontweight="bold", loc="left"‘ inside the function confusion_figure, which handles confusion figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 105: `threshold = np.max(np.abs(matrix)) * 0.55` This assigns ‘np.max(np.abs(matrix)) * 0.55‘ to ‘threshold ‘ in host memory. Here threshold means the membrane level at which a neuron emits a spike. The important operands are max: the value named ’max’ in this block; abs: the value named ’abs’ in this block; matrix: the value named ’matrix’ in this block. Context: the function confusion_figure, which handles confusion figure.

Line 106: `for row in range(10):` This iterates row over ‘range(10)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function confusion_figure, which handles confusion figure.

Line 107: `for column in range(10):` This iterates column over ‘range(10)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function confusion_figure, which handles confusion figure.

Line 108: `value = int(matrix[row, column])` This assigns ‘int(matrix[row, column])‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are matrix: the value named ’matrix’ in this block; row: one output-row position processed by the tensor tile; column: one output-feature position processed in parallel. Context: the function confusion_figure, which handles confusion figure.

Line 109: `if value != 0 or not signed:` This executes the following indented host-code branch only when ‘value != 0 or not signed‘ is true. The important operands are value: the value named ’value’ in this block; or: the value named ’or’ in this block; not: the value named ’not’ in this block. Context: the function confusion_figure, which handles confusion figure.

Line 110: `axis.text(column, row, str(value), ha="center", va="center", fontsize=8,` This statement continues through source line 111; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘axis.text‘ with ‘column, row, str(value), ha="center", va="center", fontsize=8, color="white" if abs(value) > threshold else "black"‘ inside the function confusion_figure, which handles confusion figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 111: `color="white" if abs(value) > threshold else "black")` This is continuation line 2 of the 2-line logical statement that begins at source line 110. Its exact fragment is ‘color="white" if abs(value) > threshold else "black")‘. The important operands are color: the value named ’color’ in this block; white: the value named ’white’ in this block; abs: the value named ’abs’ in this block. Read together, the complete operation is: This calls ‘axis.text‘ with ‘column, row, str(value), ha="center", va="center", fontsize=8, color="white" if abs(value) > threshold else "black"‘ inside the function confusion_figure, which handles confusion figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 112: `return figure` This returns ‘figure‘ to the caller of the function confusion_figure, which handles confusion figure, ending this invocation. The important operands are figure: the value named ’figure’ in this block.

Line 115: `def parse_vcd(path: Path) -> tuple[str, dict[str, VcdSignal]]:` This starts function parse_vcd. Its indented body performs parse vcd as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 116: `scopes: list[str] = []` This assigns ‘[]‘ to ‘scopes‘ in host memory. Here scopes means the value named ’scopes’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_vcd, which handles parse vcd.

Line 117: `code_definitions: dict[str, list[tuple[str, int]]] = defaultdict(list)` This assigns ‘defaultdict(list)‘ to ‘code_definitions‘ in host memory. Here code_definitions means the value named ’code definitions’ in this block. The important operands are defaultdict: the value named ’defaultdict’ in this block; list: the value named ’list’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 118: `timescale = "1ps"` This assigns '"1ps"' to 'timescale ' in host memory. Here timescale means the real-value spacing represented by one quantized integer step. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_vcd, which handles parse vcd.

Line 119: `in_definitions = True` This assigns 'True' to 'in_definitions ' in host memory. Here in_definitions means the value named 'in definitions' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_vcd, which handles parse vcd.

Line 120: `selected_codes: set[str] = set()` This assigns 'set()' to 'selected_codes' in host memory. Here selected_codes means the value named 'selected codes' in this block. The important operands are set: the value named 'set' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 121: `transitions: dict[str, list[tuple[int, float]]] = defaultdict(list)` This assigns 'defaultdict(list)' to 'transitions' in host memory. Here transitions means the value named 'transitions' in this block. The important operands are defaultdict: the value named 'defaultdict' in this block; list: the value named 'list' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 122: `current_time = 0` This assigns '0' to 'current_time ' in host memory. Here current_time means the value named 'current time' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_vcd, which handles parse vcd.

Line 124: `with path.open("r", encoding="utf-8", errors="replace") as handle:` This opens a managed resource scope for 'path.open("r", encoding="utf-8", errors="replace") as handle' so files, tracing, or temporary state are finalized even if the function parse_vcd, which handles parse vcd raises an error.

Line 125: `for raw in handle:` This iterates raw over 'handle'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function parse_vcd, which handles parse vcd.

Line 126: `line = raw.strip()` This assigns 'raw.strip()' to 'line ' in host memory. Here line means the value named 'line' in this block. The important operands are raw: the value named 'raw' in this block; strip: the value named 'strip' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 127: `if in_definitions:` This executes the following indented host-code branch only when 'in_definitions' is true. The important operands are in_definitions: the value named 'in definitions' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 128: `if line.startswith("$timescale"):` This executes the following indented host-code branch only when 'line.startswith("$timescale")' is true. The important operands are line: the value named 'line' in this block; startswith: the value named 'startswith' in this block; timescale: the real-value spacing represented by one quantized integer step. Context: the function parse_vcd, which handles parse vcd.

Line 129: `pieces = line.split()` This assigns 'line.split()' to 'pieces ' in host memory. Here pieces means the value named 'pieces' in this block. The important operands are line: the value named 'line' in this block; split: the value named 'split' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 130: `if len(pieces) >= 2 and pieces[1] != "$end":` This executes the following indented host-code branch only when 'len(pieces) >= 2 and pieces[1] != "$end"' is true. The important operands are len: the value named 'len' in this block; pieces: the value named 'pieces' in this block; and: the value named 'and' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 131: `timescale = pieces[1]` This assigns 'pieces[1]' to 'timescale ' in host memory. Here timescale means the real-value spacing represented by one quantized integer step. The important operands are pieces: the value named 'pieces' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 132: `elif line.startswith("$scope"):` This executes the following indented host-code branch only when ‘line.startswith("$scope")‘ is true. The important operands are line: the value named ’line’ in this block; startswith: the value named ’startswith’ in this block; scope: the value named ’scope’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 133: `pieces = line.split()` This assigns ‘line.split()‘ to ‘pieces ‘ in host memory. Here pieces means the value named ’pieces’ in this block. The important operands are line: the value named ’line’ in this block; split: the value named ’split’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 134: `scopes.append(pieces[2])` This calls ‘scopes.append‘ with ‘pieces[2]‘ inside the function parse_vcd, which handles parse vcd. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 135: `elif line.startswith("$upscope"):` This executes the following indented host-code branch only when ‘line.startswith("$upscope")‘ is true. The important operands are line: the value named ’line’ in this block; startswith: the value named ’startswith’ in this block; upscope: the value named ’upscope’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 136: `if scopes:` This executes the following indented host-code branch only when ‘scopes‘ is true. The important operands are scopes: the value named ’scopes’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 137: `scopes.pop()` This calls ‘scopes.pop‘ with “ inside the function parse_vcd, which handles parse vcd. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 138: `elif line.startswith("$var"):` This executes the following indented host-code branch only when ‘line.startswith("$v is true. The important operands are line: the value named ’line’ in this block; startswith: the value named ’startswith’ in this block; var: the value named ’var’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 139: `pieces = line.split()` This assigns ‘line.split()‘ to ‘pieces ‘ in host memory. Here pieces means the value named ’pieces’ in this block. The important operands are line: the value named ’line’ in this block; split: the value named ’split’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 140: `if len(pieces) >= 6:` This executes the following indented host-code branch only when ‘len(pieces) >= 6‘ is true. The important operands are len: the value named ’len’ in this block; pieces: the value named ’pieces’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 141: `width = int(pieces[2])` This assigns ‘int(pieces[2])‘ to ‘width ‘ in host memory. Here width means the value named ’width’ in this block. The important operands are pieces: the value named ’pieces’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 142: `code = pieces[3]` This assigns ‘pieces[3]‘ to ‘code ‘ in host memory. Here code means the value named ’code’ in this block. The important operands are pieces: the value named ’pieces’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 143: `reference = pieces[4]` This assigns ‘pieces[4]‘ to ‘reference ‘ in host memory. Here reference means the value named ’reference’ in this block. The important operands are pieces: the value named ’pieces’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 144: `name = "/" + "/".join([*scopes, reference])` This assigns ‘"/" + "/".join([*scopes, reference])‘ to ‘name ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are join: the value named ’join’ in this block; scopes: the value named ’scopes’ in this block; reference: the value named ’reference’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 145: `code_definitions[code].append((name, width))` Inside the function parse_vcd, which handles parse vcd, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are code_definitions: the value named 'code definitions' in this block; code: the value named 'code' in this block; append: the value named 'append' in this block.

Line 146: `elif line.startswith("$enddefinitions"):` This executes the following indented host-code branch only when 'line.startswith("$enddefinitions")' is true. The important operands are line: the value named 'line' in this block; startswith: the value named 'startswith' in this block; enddefinitions: the value named 'enddefinitions' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 147: `in_definitions = False` This assigns 'False' to 'in_definitions ' in host memory. Here in_definitions means the value named 'in definitions' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_vcd, which handles parse vcd.

Line 148: `selected_codes = set(code_definitions)` This assigns 'set(code_definitions)' to 'selected_codes ' in host memory. Here selected_codes means the value named 'selected codes' in this block. The important operands are set: the value named 'set' in this block; code_definitions: the value named 'code definitions' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 149: `continue` Inside the function parse_vcd, which handles parse vcd, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named 'continue' in this block.

Line 150: `if not line or line.startswith("$"):` This executes the following indented host-code branch only when 'not line or line.startswith("$")' is true. The important operands are not: the value named 'not' in this block; line: the value named 'line' in this block; or: the value named 'or' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 151: `continue` Inside the function parse_vcd, which handles parse vcd, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named 'continue' in this block.

Line 152: `if line.startswith("#"):` This executes the following indented host-code branch only when 'line.startswith("#")' is true. The important operands are line: the value named 'line' in this block; startswith: the value named 'startswith' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 153: `current_time = int(line[1:])` This assigns 'int(line[1:])' to 'current_time ' in host memory. Here current_time means the value named 'current time' in this block. The important operands are line: the value named 'line' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 154: `continue` Inside the function parse_vcd, which handles parse vcd, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named 'continue' in this block.

Line 155: `if line[0] in "01xXzZ":` This executes the following indented host-code branch only when 'line[0] in "01xXzZ"' is true. The important operands are line: the value named 'line' in this block; in: the value named 'in' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 156: `code = line[1:]` This assigns 'line[1:]' to 'code ' in host memory. Here code means the value named 'code' in this block. The important operands are line: the value named 'line' in this block. Context: the function parse_vcd, which handles parse vcd.

Line 157: `if code in selected_codes:` This executes the following indented host-code branch only when ‘code in selected_codes‘ is true. The important operands are code: the value named ’code’ in this block; in: the value named ’in’ in this block; selected_codes: the value named ’selected codes’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 158: `value = float(line[0]) if line[0] in "01" else math.nan` This assigns ‘float(line[0]) if line[0] in "01" else math.nan‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are float: the value named ’float’ in this block; line: the value named ’line’ in this block; in: the value named ’in’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 159: `transitions[code].append((current_time, value))` Inside the function parse_vcd, which handles parse vcd, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are transitions: the value named ’transitions’ in this block; code: the value named ’code’ in this block; append: the value named ’append’ in this block.

Line 160: `elif line[0] in "bBrR":` This executes the following indented host-code branch only when ‘line[0] in "bBrR"‘ is true. The important operands are line: the value named ’line’ in this block; in: the value named ’in’ in this block; bBrR: the value named ’b br r’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 161: `pieces = line.split(maxsplit=1)` This assigns ‘line.split(maxsplit=1)‘ to ‘pieces ‘ in host memory. Here pieces means the value named ’pieces’ in this block. The important operands are line: the value named ’line’ in this block; split: the value named ’split’ in this block; maxsplit: the value named ’maxsplit’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 162: `if len(pieces) != 2:` This executes the following indented host-code branch only when ‘len(pieces) != 2‘ is true. The important operands are len: the value named ’len’ in this block; pieces: the value named ’pieces’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 163: `continue` Inside the function parse_vcd, which handles parse vcd, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named ’continue’ in this block.

Line 164: `encoded, code = pieces` This assigns ‘pieces‘ to ‘encoded, code ‘ in host memory. Here encoded means the value named ’encoded’ in this block. The important operands are pieces: the value named ’pieces’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 165: `if code not in selected_codes:` This executes the following indented host-code branch only when ‘code not in selected_codes‘ is true. The important operands are code: the value named ’code’ in this block; not: the value named ’not’ in this block; in: the value named ’in’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 166: `continue` Inside the function parse_vcd, which handles parse vcd, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named ’continue’ in this block.

Line 167: `digits = encoded[1:]` This assigns ‘encoded[1:]‘ to ‘digits ‘ in host memory. Here digits means the value named ’digits’ in this block. The important operands are encoded: the value named ’encoded’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 168: `if any(character.lower() in "xz" for character in digits):` This executes the following indented host-code branch only when ‘any(character.lower() in "xz" for character in digits)‘ is true. The important operands are any: the value named ’any’ in this block; character: the value named ’character’ in this block; lower: the value named ’lower’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 169: `value = math.nan` This assigns ‘math.nan‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are math: the value named ’math’ in this block; nan: the value named ’nan’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 170: `elif encoded[0].lower() == "b":` This executes the following indented host-code branch only when ‘encoded[0].lower() == "b"‘ is true. The important operands are encoded: the value named ’encoded’ in this block; lower: the value named ’lower’ in this block; b: the value named ’b’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 171: `value = float(int(digits, 2))` This assigns ‘float(int(digits, 2))‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are float: the value named ’float’ in this block; digits: the value named ’digits’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 172: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function parse_vcd, which handles parse vcd.

Line 173: `try:` This is explicit host-side failure handling inside the function parse_vcd, which handles parse vcd; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 174: `value = float(digits)` This assigns ‘float(digits)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are float: the value named ’float’ in this block; digits: the value named ’digits’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 175: `except ValueError:` This is explicit host-side failure handling inside the function parse_vcd, which handles parse vcd; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 176: `value = math.nan` This assigns ‘math.nan‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are math: the value named ’math’ in this block; nan: the value named ’nan’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 177: `transitions[code].append((current_time, value))` Inside the function parse_vcd, which handles parse vcd, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are transitions: the value named ’transitions’ in this block; code: the value named ’code’ in this block; append: the value named ’append’ in this block.

Line 179: `signals: dict[str, VcdSignal] = {}` This assigns ‘{}‘ to ‘signals‘ in host memory. Here signals means the value named ’signals’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_vcd, which handles parse vcd.

Line 180: `for code, definitions in code_definitions.items():` This iterates code, definitions over ‘code_definitions.items
Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function parse_vcd, which handles parse vcd.

Line 181: `values = transitions.get(code, [])` This assigns ‘transitions.get(code, [])‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are transitions: the value named ’transitions’ in this block; get: the value named ’get’ in this block; code: the value named ’code’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 182: `for name, width in definitions:` This iterates name, width over ‘definitions‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function parse_vcd, which handles parse vcd.

Line 183: `signals[name] = VcdSignal(name, width, values)` This assigns ‘VcdSignal(name, width, values)‘ to ‘signals[name] ‘ in host memory. Here signals means the value named ’signals’ in this block. The important operands are VcdSignal: the value named ’vcd signal’ in this block; name: the value named ’name’ in this block; width: the value named ’width’ in this block. Context: the function parse_vcd, which handles parse vcd.

Line 184: `return timescale, signals` This returns ‘timescale, signals‘ to the caller of the function parse_vcd, which handles parse vcd, ending this invocation. The important operands are timescale: the real-value spacing represented by one quantized integer step; signals: the value named ’signals’ in this block.

Line 187: `def choose_wave_signals(signals: dict[str, VcdSignal], limit: int = 10) -> list[VcdSignal]:` This starts function choose_wave_signals. Its indented body performs choose wave signals as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 188: `priority = (` This statement continues through source line 195; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘("program_active", "program_done", "program_error", "state", "command_valid", "input_fifo_count", "s_axis_tvalid", "s_axis_tready", "core_s_valid", "core_s_ready", "issue_valid", "issue_ready", "result_valid", "result_ready", "output_valid", "output_ready", "spike", "membrane", "dense_macs", "spike_adds", "update_count", "result_fifo_count", "m_axis_tlast", "interrupt", "product", "activation", "weight",)‘ to ‘priority ‘ in host memory. Here priority means the value named ’priority’ in this block. The important operands are program_active: the value named ’program active’ in this block; program_done: the value named ’program done’ in this block; program_error: the value named ’program error’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 189: `"program_active", "program_done", "program_error", "state", "command_valid",` This is continuation line 2 of the 8-line logical statement that begins at source line 188. Its exact fragment is ‘"program_active", "program_done", "program_error", "state", "command_valid",‘. The important operands are program_active: the value named ’program active’ in this block; program_done: the value named ’program done’ in this block; program_error: the value named ’program error’ in this block. Read together, the complete operation is: This assigns ‘("program_active", "program_done", "program_error", "state", "command_valid", "input_fifo_count", "s_axis_tvalid", "s_axis_tready", "core_s_valid", "core_s_ready", "issue_valid", "issue_ready", "result_valid", "result_ready", "output_valid", "output_ready", "spike", "membrane", "dense_macs", "spike_adds", "update_count", "result_fifo_count", "m_axis_tlast", "interrupt", "product", "activation", "weight",)‘ to ‘priority ‘ in host memory. Here priority means the value named ’priority’ in this block. The important operands are program_active: the value named ’program active’ in this block; program_done: the value named ’program done’ in this block; program_error: the value named ’program error’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 190: `"input_fifo_count", "s_axis_tvalid", "s_axis_tready", "core_s_valid",` This is continuation line 3 of the 8-line logical statement that begins at source line 188. Its exact fragment is ‘"input_fifo_count", "s_axis_tvalid", "s_axis_tready", "core_s_valid",‘. The important operands are input_fifo_count: an integer count retained for control or measurable telemetry; s_axis_tvalid: the producer’s statement that its current payload is meaningful; s_axis_tready: the consumer’s statement that it can accept a payload this cycle. Read together, the complete operation is: This assigns ‘("program_active", "program_done", "program_error", "state", "command_valid", "input_fifo_count", "s_axis_tvalid", "s_axis_tready", "core_s_valid", "core_s_ready", "issue_valid", "issue_ready", "result_valid", "result_ready", "output_valid", "output_ready", "spike", "membrane", "dense_macs", "spike_adds", "update_count", "result_fifo_count", "m_axis_tlast", "interrupt", "product", "activation", "weight",)‘ to ‘priority ‘ in host memory. Here priority means the value named ’priority’ in this block. The important operands are program_active: the value named ’program active’ in this block; program_done: the value named ’program done’ in this block; program_error: the value named ’program error’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 191: `"core_s_ready", "issue_valid", "issue_ready", "result_valid", "result_ready",` This is continuation line 4 of the 8-line logical statement that begins at source line 188. Its exact fragment is ‘"core_s_ready", "issue_valid", "issue_ready", "result_valid", "result_ready",‘. The important operands are core_s_ready: the consumer’s statement that it can accept a payload this cycle; issue_valid: the producer’s statement that its current payload is meaningful; issue_ready: the consumer’s statement that it can accept a payload this cycle. Read together, the complete operation is: This assigns ‘("program_active", "program_done", "program_error", "state", "command_valid",

"input_fifo_count", "s_axis_tvalid", "s_axis_tready", "core_s_valid", "core_s_ready", "issue_valid", "issue_ready", "result_valid", "result_ready", "output_valid", "output_ready", "spike", "membrane", "dense_macs", "spike_adds", "update_count", "result_fifo_count", "m_axis_tlast", "interrupt", "product", "activation", "weight",)‘ to ‘priority ‘ in host memory. Here priority means the value named ’priority’ in this block. The important operands are program_active: the value named ’program active’ in this block; program_done: the value named ’program done’ in this block; program_error: the value named ’program error’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 192: `"output_valid", "output_ready", "spike", "membrane", "dense_macs", "spike_adds",` This is continuation line 5 of the 8-line logical statement that begins at source line 188. Its exact fragment is ‘"output_valid", "output_ready", "spike", "membrane", "dense_macs", "spike_adds",‘. The important operands are output_valid: the producer’s statement that its current payload is meaningful; output_ready: the consumer’s statement that it can accept a payload this cycle; spike: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns ‘("program_active", "program_done", "program_error", "state", "command_valid", "input_fifo_count", "s_axis_tvalid", "s_axis_tready", "core_s_valid", "core_s_ready", "issue_valid", "issue_ready", "result_valid", "result_ready", "output_valid", "output_ready", "spike", "membrane", "dense_macs", "spike_adds", "update_count", "result_fifo_count", "m_axis_tlast", "interrupt", "product", "activation", "weight",)‘ to ‘priority ‘ in host memory. Here priority means the value named ’priority’ in this block. The important operands are program_active: the value named ’program active’ in this block; program_done: the value named ’program done’ in this block; program_error: the value named ’program error’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 193: `"update_count", "result_fifo_count", "m_axis_tlast", "interrupt", "product",` This is continuation line 6 of the 8-line logical statement that begins at source line 188. Its exact fragment is ‘"update_count", "result_fifo_count", "m_axis_tlast", "interrupt", "product",‘. The important operands are update_count: an integer count retained for control or measurable telemetry; result_fifo_count: an integer count retained for control or measurable telemetry; m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This assigns ‘("program_active", "program_done", "program_error", "state", "command_valid", "input_fifo_count", "s_axis_tvalid", "s_axis_tready", "core_s_valid", "core_s_ready", "issue_valid", "issue_ready", "result_valid", "result_ready", "output_valid", "output_ready", "spike", "membrane", "dense_macs", "spike_adds", "update_count", "result_fifo_count", "m_axis_tlast", "interrupt", "product", "activation", "weight",)‘ to ‘priority ‘ in host memory. Here priority means the value named ’priority’ in this block. The important operands are program_active: the value named ’program active’ in this block; program_done: the value named ’program done’ in this block; program_error: the value named ’program error’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 194: `"activation", "weight",` This is continuation line 7 of the 8-line logical statement that begins at source line 188. Its exact fragment is ‘"activation", "weight",‘. The important operands are activation: an input feature value consumed by a neuron or multiply-accumulate operation; weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘("program_active", "program_done", "program_error", "state", "command_valid", "input_fifo_count", "s_axis_tvalid", "s_axis_tready", "core_s_valid", "core_s_ready", "issue_valid", "issue_ready", "result_valid", "result_ready", "output_valid", "output_ready", "spike", "membrane", "dense_macs", "spike_adds", "update_count", "result_fifo_count", "m_axis_tlast", "interrupt", "product", "activation", "weight",)‘ to ‘priority ‘ in host memory. Here priority means the value named ’priority’ in this block. The important operands are program_active: the value named ’program active’ in this block; program_done: the value named ’program done’ in this block; program_error: the value named ’program error’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 195: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 188. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘("program_active", "program_done", "program_error", "state", "command_valid", "input_fifo_count", "s_axis_tvalid", "s_axis_tready", "core_s_valid", "core_s_ready", "issue_valid", "issue_ready", "result_valid", "result_ready", "output_valid", "output_ready", "spike", "membrane", "dense_macs", "spike_adds", "update_count", "result_fifo_count", "m_axis_tlast", "interrupt", "product", "activation", "weight",)‘ to ‘priority ‘ in host memory. Here priority means the value named ’priority’ in this block. The important operands are program_active: the value named ’program active’ in this block; program_done: the value named ’program done’ in this block; program_error: the value named ’program error’ in this block. Context: the function choose_wave_signals, which handles

choose wave signals.

Line 196: `candidates: list[tuple[int, int, str, VcdSignal]] = []` This assigns '[]' to 'candidates' in host memory. Here candidates means the value named 'candidates' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function choose_wave_signals, which handles choose wave signals.

Line 197: `for signal in signals.values():` This iterates signal over 'signals.values()'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function choose_wave_signals, which handles choose wave signals.

Line 198: `lowered = signal.name.lower()` This assigns 'signal.name.lower()' to 'lowered ' in host memory. Here lowered means the value named 'lowered' in this block. The important operands are signal: the value named 'signal' in this block; name: the value named 'name' in this block; lower: the value named 'lower' in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 199: `leaf = lowered.rsplit("/", 1)[-1]` This assigns 'lowered.rsplit("/", 1)[-1]' to 'leaf ' in host memory. Here leaf means the value named 'leaf' in this block. The important operands are lowered: the value named 'lowered' in this block; rsplit: the value named 'rsplit' in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 200: `if lowered.endswith("/clk") or not signal.transitions:` This executes the following indented host-code branch only when 'lowered.endswith("/clk") or not signal.transitions' is true. The important operands are lowered: the value named 'lowered' in this block; endswith: the value named 'endswith' in this block; clk: the clock that makes all registers advance together. Context: the function choose_wave_signals, which handles choose wave signals.

Line 201: `continue` Inside the function choose_wave_signals, which handles choose wave signals, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named 'continue' in this block.

Line 202: `if leaf in {"clear_state", "lif_clear_state", "clear_counters"}:` This executes the following indented host-code branch only when 'leaf in {"clear_state", "lif_clear_state", "clear_counters"}' is true. The important operands are leaf: the value named 'leaf' in this block; in: the value named 'in' in this block; clear_state: the finite-state-machine phase retained in flip-flops. Context: the function choose_wave_signals, which handles choose wave signals.

Line 203: `continue` Inside the function choose_wave_signals, which handles choose wave signals, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named 'continue' in this block.

Line 204: `matches = [` This statement continues through source line 208; the explanation uses the complete expression rather than only the first visual fragment. Inside the function choose_wave_signals, which handles choose wave signals, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are matches: the value named 'matches' in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named 'for' in this block.

Line 205: `index` This is continuation line 2 of the 5-line logical statement that begins at source line 204. Its exact fragment is 'index'. The important operands are index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: Inside the function choose_wave_signals, which handles choose wave signals, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are matches: the value named 'matches' in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named 'for' in this block.

Line 206: `for index, token in enumerate(priority)` This is continuation line 3 of the 5-line logical statement that begins at source line 204. Its exact fragment is 'for index, token in enumerate(priority)'. The important operands are for: the value named 'for' in this block; index: an integer selecting one tensor element, lane, bank, or state entry; token: the value named 'token' in this block. Read together, the complete operation is: Inside the function choose_wave_signals, which handles choose wave signals, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are matches: the value named 'matches' in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named 'for' in this block.

Line 207: `if leaf == token or leaf == token + "_r" or (token != "state" and token in leaf)` This is continuation line 4 of the 5-line logical statement that begins at source line 204. Its exact fragment is 'if leaf == token or leaf == token + "_r" or (token != "state" and token in leaf)'. The important operands are leaf: the value named 'leaf' in this block; token: the value named 'token' in this block; or: the value named 'or' in this block. Read together, the complete operation is: Inside the function choose_wave_signals, which handles choose wave signals, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are matches: the value named 'matches' in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named 'for' in this block.

Line 208: `]` This is continuation line 5 of the 5-line logical statement that begins at source line 204. Its exact fragment is ']'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function choose_wave_signals, which handles choose wave signals, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are matches: the value named 'matches' in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named 'for' in this block.

Line 209: `if not matches:` This executes the following indented host-code branch only when 'not matches' is true. The important operands are not: the value named 'not' in this block; matches: the value named 'matches' in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 210: `continue` Inside the function choose_wave_signals, which handles choose wave signals, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named 'continue' in this block.

Line 211: `# Prefer DUT registers and shallow hierarchy so plots remain readable.` The comment records this intent: Prefer DUT registers and shallow hierarchy so plots remain readable. It applies inside the function choose_wave_signals, which handles choose wave signals.

Line 212: `hierarchy_penalty = signal.name.count("/")` This assigns 'signal.name.count("/")' to 'hierarchy_penalty ' in host memory. Here hierarchy_penalty means the value named 'hierarchy penalty' in this block. The important operands are signal: the value named 'signal' in this block; name: the value named 'name' in this block; count: the value named 'count' in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 213: `dut_penalty = 0 if "/dut/" in lowered else 2` This assigns '0 if "/dut/" in lowered else 2' to 'dut_penalty ' in host memory. Here dut_penalty means the value named 'dut penalty' in this block. The important operands are dut: the value named 'dut' in this block; in: the value named 'in' in this block; lowered: the value named 'lowered' in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 214: `candidates.append((min(matches), hierarchy_penalty + dut_penalty, signal.name, signal))` This calls 'candidates.append' with '(min(matches), hierarchy_penalty + dut_penalty, signal.name, signal)' inside the function choose_wave_signals, which handles choose wave signals. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 215: `chosen: list[VcdSignal] = []` This assigns '[]' to 'chosen' in host memory. Here chosen means the value named 'chosen' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function choose_wave_signals, which handles choose wave signals.

Line 216: `used_leaf_names: set[str] = set()` This assigns ‘set()‘ to ‘used_leaf_names‘ in host memory. Here used_leaf_names means the value named ’used leaf names’ in this block. The important operands are set: the value named ’set’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 217: `for _, _, _, signal in sorted(candidates):` This iterates _, _, _, signal over ‘sorted(candidates)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function choose_wave_signals, which handles choose wave signals.

Line 218: `leaf = signal.name.rsplit("/", 1)[-1]` This assigns ‘signal.name.rsplit("/", 1)[-1]‘ to ‘leaf ‘ in host memory. Here leaf means the value named ’leaf’ in this block. The important operands are signal: the value named ’signal’ in this block; name: the value named ’name’ in this block; rsplit: the value named ’rsplit’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 219: `if leaf in used_leaf_names:` This executes the following indented host-code branch only when ‘leaf in used_leaf_names‘ is true. The important operands are leaf: the value named ’leaf’ in this block; in: the value named ’in’ in this block; used_leaf_names: the value named ’used leaf names’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 220: `continue` Inside the function choose_wave_signals, which handles choose wave signals, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named ’continue’ in this block.

Line 221: `used_leaf_names.add(leaf)` This calls ‘used_leaf_names.add‘ with ‘leaf‘ inside the function choose_wave_signals, which handles choose wave signals. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 222: `chosen.append(signal)` This calls ‘chosen.append‘ with ‘signal‘ inside the function choose_wave_signals, which handles choose wave signals. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 223: `if len(chosen) == limit:` This executes the following indented host-code branch only when ‘len(chosen) == limit‘ is true. The important operands are len: the value named ’len’ in this block; chosen: the value named ’chosen’ in this block; limit: the value named ’limit’ in this block. Context: the function choose_wave_signals, which handles choose wave signals.

Line 224: `break` Inside the function choose_wave_signals, which handles choose wave signals, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are break: the value named ’break’ in this block.

Line 225: `return chosen` This returns ‘chosen‘ to the caller of the function choose_wave_signals, which handles choose wave signals, ending this invocation. The important operands are chosen: the value named ’chosen’ in this block.

Line 228: `def waveform_figure(vcd_path: Path, title: str) -> tuple[plt.Figure, list[str]]:` This starts function waveform_figure. Its indented body performs waveform figure as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 229: `timescale, signals = parse_vcd(vcd_path)` This assigns ‘parse_vcd(vcd_path)‘ to ‘timescale, signals ‘ in host memory. Here timescale means the real-value spacing represented by one quantized integer step. The important operands are parse_vcd: the value named ’parse vcd’ in this block; vcd_path: the value named ’vcd path’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 230: `selected = choose_wave_signals(signals)` This assigns ‘choose_wave_signals(signals)‘ to ‘selected ‘ in host memory. Here selected means the value named ’selected’ in this block. The important operands are choose_wave_signals: the value named ’choose wave signals’ in this block; signals: the value named ’signals’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 231: `if not selected:` This executes the following indented host-code branch only when ‘not selected‘ is true. The important operands are not: the value named ’not’ in this block; selected: the value named ’selected’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 232: `raise RuntimeError(f"no debug signals selected from {vcd_path}")` This rejects an invalid state by raising ‘RuntimeError(f"no debug signals selected from {vcd_path}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 233: `figure, axes = plt.subplots(len(selected), 1, figsize=(12.5, 1.25 * len(selected) + 1.2), sharex=True)` This assigns ‘plt.subplots(len(selected), 1, figsize=(12.5, 1.25 * len(selected) + 1.2), sharex=True)‘ to ‘figure, axes ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; len: the value named ’len’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 234: `axes_array = np.atleast_1d(axes)` This assigns ‘np.atleast_1d(axes)‘ to ‘axes_array ‘ in host memory. Here axes_array means the value named ’axes array’ in this block. The important operands are atleast_1d: the value named ’atleast 1d’ in this block; axes: the value named ’axes’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 235: `unit_scale = {"1ps": 1e-3, "1ns": 1.0}.get(timescale, 1.0)` This assigns ‘{"1ps": 1e-3, "1ns": 1.0}.get(timescale, 1.0)‘ to ‘unit_scale ‘ in host memory. Here unit_scale means the real-value spacing represented by one quantized integer step. The important operands are get: the value named ’get’ in this block; timescale: the real-value spacing represented by one quantized integer step. Context: the function waveform_figure, which handles waveform figure.

Line 236: `for axis, signal, color in zip(axes_array, selected, COLORS * 3):` This iterates axis, signal, color over ‘zip(axes_array, selected, COLORS * 3)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function waveform_figure, which handles waveform figure.

Line 237: `data = signal.transitions` This assigns ‘signal.transitions‘ to ‘data ‘ in host memory. Here data means the value named ’data’ in this block. The important operands are signal: the value named ’signal’ in this block; transitions: the value named ’transitions’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 238: `if len(data) > 2500:` This executes the following indented host-code branch only when ‘len(data) > 2500‘ is true. The important operands are len: the value named ’len’ in this block; data: the value named ’data’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 239: `stride = math.ceil(len(data) / 2500)` This assigns ‘math.ceil(len(data) / 2500)‘ to ‘stride ‘ in host memory. Here stride means the value named ’stride’ in this block. The important operands are math: the value named ’math’ in this block; ceil: the value named ’ceil’ in this block; len: the value named ’len’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 240: `data = data[::stride]` This assigns ‘data[::stride]‘ to ‘data ‘ in host memory. Here data means the value named ’data’ in this block. The important operands are data: the value named ’data’ in this block; stride: the value named ’stride’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 241: `x = np.asarray([item[0] * unit_scale for item in data], dtype=np.float64)` This assigns ‘np.asarray([item * unit_scale for item in data], dtype=np.float64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are asarray: the value named ’asarray’ in this block; item: the value named ’item’ in this block; unit_scale: the real-value spacing represented by one quantized integer step. Context: the function waveform_figure, which handles waveform figure.

Line 242: `y = np.asarray([item[1] for item in data], dtype=np.float64)` This assigns ‘np.asarray([item[1] for item in data], dtype=np.float64)‘ to ‘y ‘ in host memory. Here y means the value named ’y’ in this block. The important operands are asarray: the value named ’asarray’ in this block; item: the value named ’item’ in this block; for: the value named ’for’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 243: `if signal.width == 1:` This executes the following indented host-code branch only when ‘signal.width == 1‘ is true. The important operands are signal: the value named ’signal’ in this block; width: the value named ’width’ in this block. Context: the function waveform_figure, which handles waveform figure.

Line 244: `axis.step(x, y, where="post", color=color, linewidth=1.2)` This calls ‘axis.step‘ with ‘x, y, where="post", color=color, linewidth=1.2‘ inside the function waveform_figure, which handles waveform figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 245: `axis.set_ylim(-0.2, 1.2)` This calls ‘axis.set_ylim‘ with ‘-0.2, 1.2‘ inside the function waveform_figure, which handles waveform figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 246: `axis.set_yticks([0, 1])` This calls ‘axis.set_yticks‘ with ‘[0, 1]‘ inside the function waveform_figure, which handles waveform figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 247: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function waveform_figure, which handles waveform figure.

Line 248: `axis.step(x, y, where="post", color=color, linewidth=1.05)` This calls ‘axis.step‘ with ‘x, y, where="post", color=color, linewidth=1.05‘ inside the function waveform_figure, which handles waveform figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 249: `axis.set_ylabel(signal.name.rsplit("/", 1)[-1], rotation=0, ha="right", va="center", fontsize=8)` This calls ‘axis.set_ylabel‘ with ‘signal.name.rsplit("/", 1)[-1], rotation=0, ha="right", va="center", fontsize=8‘ inside the function waveform_figure, which handles waveform figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 250: `axis.grid(True, axis="x", alpha=0.18)` This calls ‘axis.grid‘ with ‘True, axis="x", alpha=0.18‘ inside the function waveform_figure, which handles waveform figure. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 251: `axis.spines[["top", "right"]].set_visible(False)` Inside the function waveform_figure, which handles waveform figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axis: the value named ’axis’ in this block; spines: the value named ’spines’ in this block; top: the value named ’top’ in this block.

Line 252: `axes_array[0].set_title(title, fontsize=13, fontweight="bold", loc="left")` Inside the function waveform_figure, which handles waveform figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes_array: the value named ’axes array’ in this block; set_title: the value named ’set title’ in this block; title: the value named ’title’ in this block.

Line 253: `axes_array[-1].set_xlabel(f"Simulation time ({'ns' if unit_scale == 1 else 'ns; VCD timescale ' + timescale...` Inside the function waveform_figure, which handles waveform figure, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes_array: the value named 'axes array' in this block; set_xlabel: the value named 'set xlabel' in this block; f: the value named 'f' in this block.

Line 254: `return figure, [signal.name for signal in selected]` This returns 'figure, [signal.name for signal in selected]' to the caller of the function waveform_figure, which handles waveform figure, ending this invocation. The important operands are figure: the value named 'figure' in this block; signal: the value named 'signal' in this block; name: the value named 'name' in this block.

Line 257: `def arithmetic_groups(operators: Sequence[dict]) -> dict[str, int]:` This starts function arithmetic_groups. Its indented body performs arithmetic groups as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 258: `totals: dict[str, int] = defaultdict(int)` This assigns 'defaultdict(int)' to 'totals' in host memory. Here totals means the value named 'totals' in this block. The important operands are defaultdict: the value named 'defaultdict' in this block. Context: the function arithmetic_groups, which handles arithmetic groups.

Line 259: `for operator in operators:` This iterates operator over 'operators'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function arithmetic_groups, which handles arithmetic groups.

Line 260: `matrix = operator.get("matrix")` This assigns 'operator.get("matrix")' to 'matrix ' in host memory. Here matrix means the value named 'matrix' in this block. The important operands are operator: the value named 'operator' in this block; get: the value named 'get' in this block; matrix: the value named 'matrix' in this block. Context: the function arithmetic_groups, which handles arithmetic groups.

Line 261: `if matrix:` This executes the following indented host-code branch only when 'matrix' is true. The important operands are matrix: the value named 'matrix' in this block. Context: the function arithmetic_groups, which handles arithmetic groups.

Line 262: `totals[matrix["arithmetic"]] += int(matrix["mac_equivalents"])` Inside the function arithmetic_groups, which handles arithmetic groups, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are totals: the value named 'totals' in this block; matrix: the value named 'matrix' in this block; arithmetic: the value named 'arithmetic' in this block.

Line 263: `return dict(totals)` This returns 'dict(totals)' to the caller of the function arithmetic_groups, which handles arithmetic groups, ending this invocation. The important operands are dict: the value named 'dict' in this block; totals: the value named 'totals' in this block.

Line 266: `def parse_timing_slacks(path: Path) -> np.ndarray:` This starts function parse_timing_slacks. Its indented body performs parse timing slacks as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 267: `text = path.read_text(encoding="utf-8", errors="ignore")` This assigns 'path.read_text(encoding="utf-8", errors="ignore")' to 'text ' in host memory. Here text means the value named 'text' in this block. The important operands are path: the value named 'path' in this block; read_text: the value named 'read text' in this block; encoding: the value named 'encoding' in this block. Context: the function parse_timing_slacks, which handles parse timing slacks.

Line 268: `values = [float(value) for value in re.findall(r"Slack \((?:MET|VIOLATED)\)\s*:\s*(-?\d+\.\d+)ns", text)]` This assigns ‘[float(value) for value in re.findall(r"Slack \((?:MET|VIOLATED)\)\s*:\s*(-?\d+\.\d+)ns", text)]‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are float: the value named ’float’ in this block; value: the value named ’value’ in this block; for: the value named ’for’ in this block. Context: the function parse_timing_slacks, which handles parse timing slacks.

Line 269: `return np.asarray(values, dtype=np.float64)` This returns ‘np.asarray(values, dtype=np.float64)‘ to the caller of the function parse_timing_slacks, which handles parse timing slacks, ending this invocation. The important operands are asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block; dtype: the value named ’dtype’ in this block.

Line 272: `def parse_implementation_summary(path: Path) -> dict[str, float]:` This starts function parse_implementa Its indented body performs parse implementation summary as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 273: `result: dict[str, float] = {}` This assigns ‘{}‘ to ‘result‘ in host memory. Here result means the value named ’result’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_implementation_summary, which handles parse implementation summary.

Line 274: `if not path.exists():` This executes the following indented host-code branch only when ‘not path.exists()‘ is true. The important operands are not: the value named ’not’ in this block; path: the value named ’path’ in this block; exists: the value named ’exists’ in this block. Context: the function parse_implementation_summary, which handles parse implementation summary.

Line 275: `return result` This returns ‘result‘ to the caller of the function parse_implementation_summary, which handles parse implementation summary, ending this invocation. The important operands are result: the value named ’result’ in this block.

Line 276: `for raw in path.read_text(encoding="utf-8", errors="ignore").splitlines():` This iterates raw over ‘path.read_text(encoding="utf-8", errors="ignore").splitlines()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function parse_implementation_summary, which handles parse implementation summary.

Line 277: `if "=" not in raw:` This executes the following indented host-code branch only when ‘"=" not in raw‘ is true. The important operands are not: the value named ’not’ in this block; in: the value named ’in’ in this block; raw: the value named ’raw’ in this block. Context: the function parse_implementation_summary, which handles parse implementation summary.

Line 278: `continue` Inside the function parse_implementation_summary, which handles parse implementation summary, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named ’continue’ in this block.

Line 279: `key, value = [part.strip() for part in raw.split("=", 1)]` This assigns ‘[part.strip() for part in raw.split("=", 1)]‘ to ‘key, value ‘ in host memory. Here key means the value named ’key’ in this block. The important operands are part: the value named ’part’ in this block; strip: the value named ’strip’ in this block; for: the value named ’for’ in this block. Context: the function parse_implementation_summary, which handles parse implementation summary.

Line 280: `try:` This is explicit host-side failure handling inside the function parse_implementation_summary, which handles parse implementation summary; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 281: `result[key] = float(value)` This assigns ‘float(value)‘ to ‘result[key] ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are float: the value named ’float’ in this block; value: the value named ’value’ in this block. Context: the function parse_implementation_summary, which handles parse implementation summary.

Line 282: `except ValueError:` This is explicit host-side failure handling inside the function parse_implementation_summary, which handles parse implementation summary; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 283: `continue` Inside the function parse_implementation_summary, which handles parse implementation summary, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named ’continue’ in this block.

Line 284: `return result` This returns ‘result‘ to the caller of the function parse_implementation_summary, which handles parse implementation summary, ending this invocation. The important operands are result: the value named ’result’ in this block.

Line 287: `def parse_clock_timing(path: Path) -> dict[str, tuple[float, float]]:` This starts function parse_clock_timing. Its indented body performs parse clock timing as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 288: `"""Return routed setup/hold slack for each FPGA clock-domain row."""` This is executable documentation attached to the function parse_clock_timing, which handles parse clock timing. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 289: `clocks: dict[str, tuple[float, float]] = {}` This assigns ‘{}‘ to ‘clocks‘ in host memory. Here clocks means the value named ’clocks’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_clock_timing, which handles parse clock timing.

Line 290: `if not path.exists():` This executes the following indented host-code branch only when ‘not path.exists()‘ is true. The important operands are not: the value named ’not’ in this block; path: the value named ’path’ in this block; exists: the value named ’exists’ in this block. Context: the function parse_clock_timing, which handles parse clock timing.

Line 291: `return clocks` This returns ‘clocks‘ to the caller of the function parse_clock_timing, which handles parse clock timing, ending this invocation. The important operands are clocks: the value named ’clocks’ in this block.

Line 292: `for raw in path.read_text(encoding="utf-8", errors="ignore").splitlines():` This iterates raw over ‘path.read_text(encoding="utf-8", errors="ignore").splitlines()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function parse_clock_timing, which handles parse clock timing.

Line 293: `fields = raw.split()` This assigns ‘raw.split()‘ to ‘fields ‘ in host memory. Here fields means the value named ’fields’ in this block. The important operands are raw: the value named ’raw’ in this block; split: the value named ’split’ in this block. Context: the function parse_clock_timing, which handles parse clock timing.

Line 294: `if len(fields) < 10 or not re.fullmatch(r"clk_fpga_\d+", fields[0]):` This executes the following indented host-code branch only when ‘len(fields) $<$ 10 or not re.fullmatch(r"clk_fpga_\d+", fields[0])‘ is true. The important operands are len: the value named ’len’ in this block; fields: the value named ’fields’ in this block; or: the value named ’or’ in this block. Context: the function parse_clock_timing, which handles parse clock timing.

Line 295: `continue` Inside the function parse_clock_timing, which handles parse clock timing, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named 'continue' in this block.

Line 296: `try:` This is explicit host-side failure handling inside the function parse_clock_timing, which handles parse clock timing; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 297: `setup_slack = float(fields[1])` This assigns ‘float(fields[1])‘ to ‘setup_slack ‘ in host memory. Here setup_slack means the value named 'setup slack' in this block. The important operands are float: the value named 'float' in this block; fields: the value named 'fields' in this block. Context: the function parse_clock_timing, which handles parse clock timing.

Line 298: `hold_slack = float(fields[5])` This assigns ‘float(fields[5])‘ to ‘hold_slack ‘ in host memory. Here hold_slack means the value named 'hold slack' in this block. The important operands are float: the value named 'float' in this block; fields: the value named 'fields' in this block. Context: the function parse_clock_timing, which handles parse clock timing.

Line 299: `except ValueError:` This is explicit host-side failure handling inside the function parse_clock_timing, which handles parse clock timing; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 300: `continue` Inside the function parse_clock_timing, which handles parse clock timing, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named 'continue' in this block.

Line 301: `clocks.setdefault(fields[0], (setup_slack, hold_slack))` This calls ‘clocks.setdefault‘ with ‘fields[0], (setup_slack, hold_slack)‘ inside the function parse_clock_timing, which handles parse clock timing. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 302: `return clocks` This returns ‘clocks‘ to the caller of the function parse_clock_timing, which handles parse clock timing, ending this invocation. The important operands are clocks: the value named 'clocks' in this block.

Line 305: `def parse_utilization_hierarchy(path: Path) -> dict[str, dict[str, int]]:` This starts function parse_utilization_hierarchy. Its indented body performs parse utilization hierarchy as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 306: `"""Parse named rows from Vivado’s hierarchical utilization table."""` This is executable documentation attached to the function parse_utilization_hierarchy, which handles parse utilization hierarchy. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 307: `wanted = {` This statement continues through source line 311; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "system_wrapper", "accelerator", "accelerator_control_cdc", "control_interconnect", "dma", "dma_control_cdc", "memory_interconnect", "mm2s_cdc", "s2mm_cdc", }‘ to ‘wanted ‘ in host memory. Here wanted means the value named 'wanted' in this block. The important operands are system_wrapper: the value named 'system wrapper' in this block; accelerator: the value named 'accelerator' in this block; accelerator_control_cdc: the value named 'accelerator control cdc' in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 308: `"system_wrapper", "accelerator", "accelerator_control_cdc",` This is continuation line 2 of the 5-line logical statement that begins at source line 307. Its exact fragment is ‘"system_wrapper", "accelerator", "accelerator_control_cdc",‘. The important operands are system_wrapper: the value named ’system wrapper’ in this block; accelerator: the value named ’accelerator’ in this block; accelerator_control_cdc: the value named ’accelerator control cdc’ in this block. Read together, the complete operation is: This assigns ‘{ "system_wrapper", "accelerator", "accelerator_control_cdc", "control_interconnect", "dma", "dma_control_cdc", "memory_interconnect", "mm2s_cdc", "s2mm_cdc", }‘ to ‘wanted ‘ in host memory. Here wanted means the value named ’wanted’ in this block. The important operands are system_wrapper: the value named ’system wrapper’ in this block; accelerator: the value named ’accelerator’ in this block; accelerator_control_cdc: the value named ’accelerator control cdc’ in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 309: `"control_interconnect", "dma", "dma_control_cdc",` This is continuation line 3 of the 5-line logical statement that begins at source line 307. Its exact fragment is ‘"control_interconnect", "dma", "dma_control_cdc",‘. The important operands are control_interconnect: the value named ’control interconnect’ in this block; dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; dma_control_cdc: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic. Read together, the complete operation is: This assigns ‘{ "system_wrapper", "accelerator", "accelerator_control_cdc", "control_interconnect", "dma", "dma_control_cdc", "memory_interconnect", "mm2s_cdc", "s2mm_cdc", }‘ to ‘wanted ‘ in host memory. Here wanted means the value named ’wanted’ in this block. The important operands are system_wrapper: the value named ’system wrapper’ in this block; accelerator: the value named ’accelerator’ in this block; accelerator_control_cdc: the value named ’accelerator control cdc’ in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 310: `"memory_interconnect", "mm2s_cdc", "s2mm_cdc",` This is continuation line 4 of the 5-line logical statement that begins at source line 307. Its exact fragment is ‘"memory_interconnect", "mm2s_cdc", "s2mm_cdc",‘. The important operands are memory_interconnect: local FPGA storage addressed by surrounding index logic; mm2s_cdc: the value named ’mm2s cdc’ in this block; s2mm_cdc: the value named ’s2mm cdc’ in this block. Read together, the complete operation is: This assigns ‘{ "system_wrapper", "accelerator", "accelerator_control_cdc", "control_interconnect", "dma", "dma_control_cdc", "memory_interconnect", "mm2s_cdc", "s2mm_cdc", }‘ to ‘wanted ‘ in host memory. Here wanted means the value named ’wanted’ in this block. The important operands are system_wrapper: the value named ’system wrapper’ in this block; accelerator: the value named ’accelerator’ in this block; accelerator_control_cdc: the value named ’accelerator control cdc’ in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 311: `}` This is continuation line 5 of the 5-line logical statement that begins at source line 307. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "system_wrapper", "accelerator", "accelerator_control_cdc", "control_interconnect", "dma", "dma_control_cdc", "memory_interconnect", "mm2s_cdc", "s2mm_cdc", }‘ to ‘wanted ‘ in host memory. Here wanted means the value named ’wanted’ in this block. The important operands are system_wrapper: the value named ’system wrapper’ in this block; accelerator: the value named ’accelerator’ in this block; accelerator_control_cdc: the value named ’accelerator control cdc’ in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 312: `rows: dict[str, dict[str, int]] = {}` This assigns ‘{}‘ to ‘rows‘ in host memory. Here rows means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 313: `if not path.exists():` This executes the following indented host-code branch only when ‘not path.exists()‘ is true. The important operands are not: the value named ’not’ in this block; path: the value named ’path’ in this block; exists: the value named ’exists’ in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 314: `return rows` This returns ‘rows‘ to the caller of the function parse_utilization_hierarchy, which handles parse utilization hierarchy, ending this invocation. The important operands are rows: one output-row position processed by the tensor tile.

Line 315: `for raw in path.read_text(encoding="utf-8", errors="ignore").splitlines():` This iterates raw over ‘path.read_text(encoding="utf-8", errors="ignore").splitlines()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 316: `if not raw.startswith("|"):` This executes the following indented host-code branch only when ‘not raw.startswith("|")‘ is true. The important operands are not: the value named ’not’ in this block; raw: the value named ’raw’ in this block; startswith: the value named ’startswith’ in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 317: `continue` Inside the function parse_utilization_hierarchy, which handles parse utilization hierarchy, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named ’continue’ in this block.

Line 318: `fields = [field.strip() for field in raw.split("|")]` This assigns ‘[field.strip() for field in raw.split("|")]‘ to ‘fields ‘ in host memory. Here fields means the value named ’fields’ in this block. The important operands are field: the value named ’field’ in this block; strip: the value named ’strip’ in this block; for: the value named ’for’ in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 319: `if len(fields) < 12 or fields[1] not in wanted:` This executes the following indented host-code branch only when ‘len(fields) < 12 or fields[1] not in wanted‘ is true. The important operands are len: the value named ’len’ in this block; fields: the value named ’fields’ in this block; or: the value named ’or’ in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 320: `continue` Inside the function parse_utilization_hierarchy, which handles parse utilization hierarchy, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named ’continue’ in this block.

Line 321: `try:` This is explicit host-side failure handling inside the function parse_utilization_hierarchy, which handles parse utilization hierarchy; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 322: `rows[fields[1]] = {` This statement continues through source line 326; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "lut": int(fields[3]), "ff": int(fields[7]), "bram36": int(fields[8]), "bram18": int(fields[9]), "dsp": int(fields[10]), }‘ to ‘rows[fields[1]] ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are lut: the value named ’lut’ in this block; fields: the value named ’fields’ in this block; ff: the value named ’ff’ in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 323: `"lut": int(fields[3]), "ff": int(fields[7]),` This is continuation line 2 of the 5-line logical statement that begins at source line 322. Its exact fragment is ‘"lut": int(fields[3]), "ff": int(fields[7]),‘. The important operands are lut: the value named ’lut’ in this block; fields: the value named ’fields’ in this block; ff: the value named ’ff’ in this block. Read together, the complete operation is: This assigns ‘{ "lut": int(fields[3]), "ff": int(fields[7]), "bram36": int(fields[8]), "bram18": int(fields[9]), "dsp": int(fields[10]), }‘ to ‘rows[fields[1]] ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are lut: the value named ’lut’ in this block; fields: the value named ’fields’ in this block; ff: the value named ’ff’ in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 324: `"bram36": int(fields[8]), "bram18": int(fields[9]),` This is continuation line 3 of the 5-line logical statement that begins at source line 322. Its exact fragment is ‘"bram36": int(fields[8]), "bram18": int(fields[9]),‘. The important operands are bram36: the value named ’bram36’ in this block; fields: the value named ’fields’ in this block; bram18: the value named ’bram18’ in this block. Read together, the complete operation is: This assigns ‘{ "lut": int(fields[3]), "ff": int(fields[7]), "bram36": int(fields[8]), "bram18": int(fields[9]), "dsp": int(fields[10]), }‘ to ‘rows[fields[1]]

‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are lut: the value named 'lut' in this block; fields: the value named 'fields' in this block; ff: the value named 'ff' in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 325: `"dsp": int(fields[10]),` This is continuation line 4 of the 5-line logical statement that begins at source line 322. Its exact fragment is ‘"dsp": int(fields[10]),‘. The important operands are dsp: the value named 'dsp' in this block; fields: the value named 'fields' in this block. Read together, the complete operation is: This assigns ‘{ "lut": int(fields[3]), "ff": int(fields[7]), "bram36": int(fields[8]), "bram18": int(fields[9]), "dsp": int(fields[10]), }‘ to ‘rows[fields[1]] ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are lut: the value named 'lut' in this block; fields: the value named 'fields' in this block; ff: the value named 'ff' in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 326: `}` This is continuation line 5 of the 5-line logical statement that begins at source line 322. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘{ "lut": int(fields[3]), "ff": int(fields[7]), "bram36": int(fields[8]), "bram18": int(fields[9]), "dsp": int(fields[10]), }‘ to ‘rows[fields[1]] ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are lut: the value named 'lut' in this block; fields: the value named 'fields' in this block; ff: the value named 'ff' in this block. Context: the function parse_utilization_hierarchy, which handles parse utilization hierarchy.

Line 327: `except ValueError:` This is explicit host-side failure handling inside the function parse_utilization_hierarchy, which handles parse utilization hierarchy; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 328: `continue` Inside the function parse_utilization_hierarchy, which handles parse utilization hierarchy, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are continue: the value named 'continue' in this block.

Line 329: `return rows` This returns ‘rows‘ to the caller of the function parse_utilization_hierarchy, which handles parse utilization hierarchy, ending this invocation. The important operands are rows: one output-row position processed by the tensor tile.

Line 332: `def parse_drc_summary(path: Path) -> list[tuple[str, str, str, int]]:` This starts function parse_drc_summary. Its indented body performs parse drc summary as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 333: `"""Parse DRC rule, severity, description, and count from the summary table."""` This is executable documentation attached to the function parse_drc_summary, which handles parse drc summary. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 334: `if not path.exists():` This executes the following indented host-code branch only when ‘not path.exists()‘ is true. The important operands are not: the value named 'not' in this block; path: the value named 'path' in this block; exists: the value named 'exists' in this block. Context: the function parse_drc_summary, which handles parse drc summary.

Line 335: `return []` This returns ‘[]‘ to the caller of the function parse_drc_summary, which handles parse drc summary, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 336: `pattern = re.compile(` This statement continues through source line 338; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘re.compile(r"^\|\s*([A-Z]+-\d+)\s*\|\s*(\w+)\s*\|\s*(.*?)
)‘ to ‘pattern ‘ in host memory. Here pattern means the value named 'pattern' in this block. The important operands

are re: the value named 're' in this block; compile: the value named 'compile' in this block; r: the value named 'r' in this block. Context: the function parse_drc_summary, which handles parse drc summary.

Line 337: `r"^\|\s*([A-Z]+-\d+)\s*\|\s*(\w+)\s*\|\s*(.*?)\s*\|\s*(\d+)\s*\|$"` This is continuation line 2 of the 3-line logical statement that begins at source line 336. Its exact fragment is 'r"^\|\s*([A-Z]+-\d+)\s*\|\s*(\w+)\s*\|\s*(.*?)\s
The important operands are r: the value named 'r' in this block; s: the value named 's' in this block; A: the value named 'a' in this block. Read together, the complete operation is: This assigns 're.compile(r"^\|\s*([A-Z]+-\d+)\s*\|\s*(\w+)\s*\|\s*(.*?)\s
)' to 'pattern ' in host memory. Here pattern means the value named 'pattern' in this block. The important operands are re: the value named 're' in this block; compile: the value named 'compile' in this block; r: the value named 'r' in this block. Context: the function parse_drc_summary, which handles parse drc summary.

Line 338: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 336. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 're.compile(r"^\|\s*([A-Z]+-\d+)\s*\|\s*(\w+)\s*\|\s*(.*?)\s*\|\s*(\d+)\s*\|$")' to 'pattern ' in host memory. Here pattern means the value named 'pattern' in this block. The important operands are re: the value named 're' in this block; compile: the value named 'compile' in this block; r: the value named 'r' in this block. Context: the function parse_drc_summary, which handles parse drc summary.

Line 339: `rows: list[tuple[str, str, str, int]] = []` This assigns '[]' to 'rows' in host memory. Here rows means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_drc_summary, which handles parse drc summary.

Line 340: `for raw in path.read_text(encoding="utf-8", errors="ignore").splitlines():` This iterates raw over 'path.read_text(encoding="utf-8", errors="ignore").splitlines()'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function parse_drc_summary, which handles parse drc summary.

Line 341: `match = pattern.match(raw)` This assigns 'pattern.match(raw)' to 'match ' in host memory. Here match means the value named 'match' in this block. The important operands are pattern: the value named 'pattern' in this block; match: the value named 'match' in this block; raw: the value named 'raw' in this block. Context: the function parse_drc_summary, which handles parse drc summary.

Line 342: `if match:` This executes the following indented host-code branch only when 'match' is true. The important operands are match: the value named 'match' in this block. Context: the function parse_drc_summary, which handles parse drc summary.

Line 343: `rows.append((match.group(1), match.group(2), match.group(3), int(match.group(4))))` This calls 'rows.append' with '(match.group(1), match.group(2), match.group(3), int(match.group(4)))' inside the function parse_drc_summa
which handles parse drc summary. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 344: `return rows` This returns 'rows' to the caller of the function parse_drc_summary, which handles parse drc summary, ending this invocation. The important operands are rows: one output-row position processed by the tensor tile.

Line 347: `def parse_cdc_summary(path: Path) -> list[tuple[str, str, int, str]]:` This starts function parse_cdc_summary. Its indented body performs parse cdc summary as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 348: `"""Parse the compact CDC classification table before detailed paths."""` This is executable documentation attached to the function parse_cdc_summary, which handles parse cdc summary. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 349: `if not path.exists():` This executes the following indented host-code branch only when ‘not path.exists()‘ is true. The important operands are not: the value named ’not’ in this block; path: the value named ’path’ in this block; exists: the value named ’exists’ in this block. Context: the function parse_cdc_summary, which handles parse cdc summary.

Line 350: `return []` This returns ‘[]‘ to the caller of the function parse_cdc_summary, which handles parse cdc summary, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 351: `pattern = re.compile(r"^(CDC-\d+)\s+(\w+)\s+(\d+)\s+(.+)$")` This assigns ‘re.compile(r"^(CDC-\d+)\s+(\w+)\s+(\d+)\s+(.+)$")‘ to ‘pattern ‘ in host memory. Here pattern means the value named ’pattern’ in this block. The important operands are re: the value named ’re’ in this block; compile: the value named ’compile’ in this block; r: the value named ’r’ in this block. Context: the function parse_cdc_summary, which handles parse cdc summary.

Line 352: `rows: list[tuple[str, str, int, str]] = []` This assigns ‘[]‘ to ‘rows‘ in host memory. Here rows means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function parse_cdc_summary, which handles parse cdc summary.

Line 353: `for raw in path.read_text(encoding="utf-8", errors="ignore").splitlines():` This iterates raw over ‘path.read_text(encoding="utf-8", errors="ignore").splitlines()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function parse_cdc_summary, which handles parse cdc summary.

Line 354: `match = pattern.match(raw.strip())` This assigns ‘pattern.match(raw.strip())‘ to ‘match ‘ in host memory. Here match means the value named ’match’ in this block. The important operands are pattern: the value named ’pattern’ in this block; match: the value named ’match’ in this block; raw: the value named ’raw’ in this block. Context: the function parse_cdc_summary, which handles parse cdc summary.

Line 355: `if match:` This executes the following indented host-code branch only when ‘match‘ is true. The important operands are match: the value named ’match’ in this block. Context: the function parse_cdc_summary, which handles parse cdc summary.

Line 356: `rows.append((match.group(1), match.group(2), int(match.group(3)), match.group(4)))` This calls ‘rows.append‘ with ‘(match.group(1), match.group(2), int(match.group(3)), match.group(4))‘ inside the function parse_cdc_summa which handles parse cdc summary. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 357: `elif rows:` This executes the following indented host-code branch only when ‘rows‘ is true. The important operands are rows: one output-row position processed by the tensor tile. Context: the function parse_cdc_summary, which handles parse cdc summary.

Line 358: `break` Inside the function parse_cdc_summary, which handles parse cdc summary, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are break: the value named ’break’ in this block.

Line 359: `return rows` This returns ‘rows‘ to the caller of the function parse_cdc_summary, which handles parse cdc summary, ending this invocation. The important operands are rows: one output-row position processed by the tensor tile.

Line 362: `def parse_power_report(path: Path) -> dict[str, object]:` This starts function parse_power_report. Its indented body performs parse power report as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 363: `"""Extract explicit Vivado power totals, resources, hierarchy, and confidence."""` This is executable documentation attached to the function parse_power_report, which handles parse power report. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 364: `if not path.exists():` This executes the following indented host-code branch only when ‘not path.exists()‘ is true. The important operands are not: the value named ’not’ in this block; path: the value named ’path’ in this block; exists: the value named ’exists’ in this block. Context: the function parse_power_report, which handles parse power report.

Line 365: `return {}` This returns ‘{}‘ to the caller of the function parse_power_report, which handles parse power report, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 366: `text = path.read_text(encoding="utf-8", errors="ignore")` This assigns ‘path.read_text(encoding="utf-8", errors="ignore")‘ to ‘text ‘ in host memory. Here text means the value named ’text’ in this block. The important operands are path: the value named ’path’ in this block; read_text: the value named ’read text’ in this block; encoding: the value named ’encoding’ in this block. Context: the function parse_power_report, which handles parse power report.

Line 368: `def number(label: str) -> float | None:` This starts function number. Its indented body performs number as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 369: `match = re.search(rf"^\|\s*{re.escape(label)}\s*\|\s*([0-9.]+)", text, re.MULTILINE)` This assigns ‘re.search(rf"^\|\s*{re.escape(label)}\s*\|\s*([0-9.]+)", text, re.MULTILINE)‘ to ‘match ‘ in host memory. Here match means the value named ’match’ in this block. The important operands are re: the value named ’re’ in this block; search: the value named ’search’ in this block; rf: the value named ’rf’ in this block. Context: the function number, which handles number.

Line 370: `return float(match.group(1)) if match else None` This returns ‘float(match.group(1)) if match else None‘ to the caller of the function number, which handles number, ending this invocation. The important operands are float: the value named ’float’ in this block; match: the value named ’match’ in this block; group: the value named ’group’ in this block.

Line 372: `confidence_match = re.search(` This statement continues through source line 374; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘re.search(r"^\|\s*Confidence Level\s*\|\s*(\w+)", text, re.MULTILINE)‘ to ‘confidence_match ‘ in host memory. Here confidence_match means the value named ’confidence match’ in this block. The important operands are re: the value named ’re’ in this block; search: the value named ’search’ in this block; r: the value named ’r’ in this block. Context: the function parse_power_report, which handles parse power report.

Line 373: `r"^\|\s*Confidence Level\s*\|\s*(\w+)", text, re.MULTILINE` This is continuation line 2 of the 3-line logical statement that begins at source line 372. Its exact fragment is ‘r"^\|\s*Confidence Level\s*\|\s*(\w+)", text, re.MULTILINE‘. The important operands are r: the value named ’r’ in this block; s: the value named ’s’ in this block; Confidence: the value named ’confidence’ in this block. Read together, the complete operation is: This assigns ‘re.search(r"^\|\s*Confidence Level\s*\|\s*(\w+)", text, re.MULTILINE)‘ to ‘confidence_match ‘ in host memory. Here confidence_match means the value named ’confidence match’ in this block. The important operands are re: the value named ’re’ in this block; search: the value named ’search’ in this block; r: the value named ’r’ in this block. Context: the function parse_power_report, which handles parse power report.

Line 374: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 372. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘re.search(r"^\|\s*Confidence Level\s*\|\s*(\w+)", text, re.MULTILINE)‘ to ‘confidence_match ‘ in host memory. Here confidence_match means the value named ’confidence match’ in this block. The important operands are re: the value named ’re’ in this block; search: the value named ’search’ in this block; r: the value named ’r’ in this block. Context: the function parse_power_report, which handles parse power report.

Line 375: `matched_match = re.search(` This statement continues through source line 377; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘re.search(r"^\|\s*Design Nets Matched\s*\|\s*([^|]+)", text, re.MULTILINE)‘ to ‘matched_match ‘ in host memory. Here matched_match means the value named ’matched match’ in this block. The important operands are re: the value named ’re’ in this block; search: the value named ’search’ in this block; r: the value named ’r’ in this block. Context: the function parse_power_report, which handles parse power report.

Line 376: `r"^\|\s*Design Nets Matched\s*\|\s*([^|]+)", text, re.MULTILINE` This is continuation line 2 of the 3-line logical statement that begins at source line 375. Its exact fragment is ‘r"^\|\s*Design Nets Matched\s*\|\s*([^|]+)", text, re.MULTILINE‘. The important operands are r: the value named ’r’ in this block; s: the value named ’s’ in this block; Design: the value named ’design’ in this block. Read together, the complete operation is: This assigns ‘re.search(r"^\|\s*Design Nets Matched\s*\|\s*([^|]+)", text, re.MULTILINE)‘ to ‘matched_match ‘ in host memory. Here matched_match means the value named ’matched match’ in this block. The important operands are re: the value named ’re’ in this block; search: the value named ’search’ in this block; r: the value named ’r’ in this block. Context: the function parse_power_report, which handles parse power report.

Line 377: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 375. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘re.search(r"^\|\s*Design Nets Matched\s*\|\s*([^|]+)", text, re.MULTILINE)‘ to ‘matched_match ‘ in host memory. Read together, the complete operation is: This returns ‘{ "total": number("Total On-Chip Power (W)"), "dynamic": number("Dynamic (W)"), "static": number("Device Static (W)"), "confidence": confidence_match.group(1) if confidence_match else "unknown", "matched": matched_match.group(1).strip() if matched_match else "not reported", "resources": resources, "hierarchy": hierarchy, }‘ to the caller of the function parse_power_report, which handles parse power report, ending this invocation. The important operands are total: the value named 'total' in this block; number: the value named 'number' in this block; Total: the value named 'total' in this block.

Line 408: `def file_evidence(path: Path) -> tuple[int, str]:` This starts function file_evidence. Its indented body performs file evidence as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 409: `digest = hashlib.sha256()` This assigns ‘hashlib.sha256()‘ to ‘digest ‘ in host memory. Here digest means the value named 'digest' in this block. The important operands are hashlib: the value named 'hashlib' in this block; sha256: the value named 'sha256' in this block. Context: the function file_evidence, which handles file evidence.

Line 410: `with path.open("rb") as handle:` This opens a managed resource scope for ‘path.open("rb") as handle‘ so files, tracing, or temporary state are finalized even if the function file_evidence, which handles file evidence raises an error.

Line 411: `for chunk in iter(lambda: handle.read(1024 * 1024), b""):` This iterates chunk over ‘iter(lambda: handle.read(1024 * 1024), b"")‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function file_evidence, which handles file evidence.

Line 412: `digest.update(chunk)` This calls ‘digest.update‘ with ‘chunk‘ inside the function file_evidence, which handles file evidence. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 413: `return path.stat().st_size, digest.hexdigest()` This returns ‘path.stat().st_size, digest.hexdigest()‘ to the caller of the function file_evidence, which handles file evidence, ending this invocation. The important operands are path: the value named 'path' in this block; stat: the value named 'stat' in this block; st_size: the value named 'st size' in this block.

Line 416: `def latex_escape(value: str) -> str:` This starts function latex_escape. Its indented body performs latex escape as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 417: `replacements = {` This statement continues through source line 421; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", }‘ to ‘replacements ‘ in host memory. Here replacements means the value named 'replacements' in this block. The important

operands are r: the value named 'r' in this block; textbackslash: the value named 'textbackslash' in this block; _: the value named '' in this block. Context: the function latex_escape, which handles latex escape.

Line 418: `"\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$",` This is continuation line 2 of the 5-line logical statement that begins at source line 417. Its exact fragment is `'"\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$",'`. The important operands are r: the value named 'r' in this block; textbackslash: the value named 'textbackslash' in this block. Read together, the complete operation is: This assigns `'{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"\_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", }'` to 'replacements ' in host memory. Here replacements means the value named 'replacements' in this block. The important operands are r: the value named 'r' in this block; textbackslash: the value named 'textbackslash' in this block; _: the value named '' in this block. Context: the function latex_escape, which handles latex escape.

Line 419: `"#": r"\#", "_": r"\_", "{": r"\{", "}": r"\},` This is continuation line 3 of the 5-line logical statement that begins at source line 417. Its exact fragment is `'"#": r"\#", "_": r"\_", "{": r"\{", "}": r"\},'`. The important operands are r: the value named 'r' in this block; _: the value named '' in this block. Read together, the complete operation is: This assigns `'{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"\_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", }'` to 'replacements ' in host memory. Here replacements means the value named 'replacements' in this block. The important operands are r: the value named 'r' in this block; textbackslash: the value named 'textbackslash' in this block; _: the value named '' in this block. Context: the function latex_escape, which handles latex escape.

Line 420: `"~": r"\textasciitilde{}", "^": r"\textasciicircum{}",` This is continuation line 4 of the 5-line logical statement that begins at source line 417. Its exact fragment is `'"~": r"\textasciitilde{}", "^": r"\textasciicircum{}",'`. The important operands are r: the value named 'r' in this block; textasciitilde: the value named 'textasciitilde' in this block; textasciicircum: the value named 'textasciicircum' in this block. Read together, the complete operation is: This assigns `'{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"\_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", }'` to 'replacements ' in host memory. Here replacements means the value named 'replacements' in this block. The important operands are r: the value named 'r' in this block; textbackslash: the value named 'textbackslash' in this block; _: the value named '' in this block. Context: the function latex_escape, which handles latex escape.

Line 421: `}` This is continuation line 5 of the 5-line logical statement that begins at source line 417. Its exact fragment is `'}'`. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns `'{ "\\": r"\textbackslash{}", "&": r"\&", "%": r"\%", "$": r"\$", "#": r"\#", "_": r"\_", "{": r"\{", "}": r"\}", "~": r"\textasciitilde{}", "^": r"\textasciicircum{}", }'` to 'replacements ' in host memory. Here replacements means the value named 'replacements' in this block. The important operands are r: the value named 'r' in this block; textbackslash: the value named 'textbackslash' in this block; _: the value named '' in this block. Context: the function latex_escape, which handles latex escape.

Line 422: `return "".join(replacements.get(character, character) for character in value)` This returns `'"".join(replacements.get(character, character) for character in value)'` to the caller of the function latex_escape, which handles latex escape, ending this invocation. The important operands are join: the value named 'join' in this block; replacements: the value named 'replacements' in this block; get: the value named 'get' in this block.

Line 425: `def latex_breakable(value: str) -> str:` This starts function latex_breakable. Its indented body performs latex breakable as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 426: `"""Escape provenance text while adding legal line-break opportunities."""` This is executable documentation attached to the function latex_breakable, which handles latex breakable. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 427: `escaped = latex_escape(value)` This assigns `'latex_escape(value)'` to 'escaped ' in host memory. Here escaped means the value named 'escaped' in this block. The important operands are latex_escape: the value named

'latex escape' in this block; value: the value named 'value' in this block. Context: the function latex_breakable, which handles latex breakable.

Line 428: `escaped = escaped.replace(r"\textbackslash{}", r"\textbackslash{}\allowbreak{}")` This assigns 'escaped.replace(r"\textbackslash{}", r"\textbackslash{}\allowbreak{}")' to 'escaped ' in host memory. Here escaped means the value named 'escaped' in this block. The important operands are escaped: the value named 'escaped' in this block; replace: the value named 'replace' in this block; r: the value named 'r' in this block. Context: the function latex_breakable, which handles latex breakable.

Line 429: `escaped = escaped.replace(r"\_", r"\_\allowbreak{}")` This assigns 'escaped.replace(r"_", r"_\allowbreak{}
to 'escaped ' in host memory. Here escaped means the value named 'escaped' in this block. The important operands are escaped: the value named 'escaped' in this block; replace: the value named 'replace' in this block; r: the value named 'r' in this block. Context: the function latex_breakable, which handles latex breakable.

Line 430: `escaped = escaped.replace("/", r"/\allowbreak{}")` This assigns 'escaped.replace("/", r"/\allowbreak{}")' to 'escaped ' in host memory. Here escaped means the value named 'escaped' in this block. The important operands are escaped: the value named 'escaped' in this block; replace: the value named 'replace' in this block; r: the value named 'r' in this block. Context: the function latex_breakable, which handles latex breakable.

Line 431: `escaped = escaped.replace(";", r";\allowbreak{}")` This assigns 'escaped.replace(";", r";\allowbreak{}")' to 'escaped ' in host memory. Here escaped means the value named 'escaped' in this block. The important operands are escaped: the value named 'escaped' in this block; replace: the value named 'replace' in this block; r: the value named 'r' in this block. Context: the function latex_breakable, which handles latex breakable.

Line 432: `escaped = escaped.replace(", ", r",\allowbreak{} ")` This assigns 'escaped.replace(", ", r",\allowbreak{}
")' to 'escaped ' in host memory. Here escaped means the value named 'escaped' in this block. The important operands are escaped: the value named 'escaped' in this block; replace: the value named 'replace' in this block; r: the value named 'r' in this block. Context: the function latex_breakable, which handles latex breakable.

Line 433: `return escaped` This returns 'escaped' to the caller of the function latex_breakable, which handles latex breakable, ending this invocation. The important operands are escaped: the value named 'escaped' in this block.

Line 436: `def write_report_tex(` This starts function write_report_tex. Its indented body performs write report tex as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 437: `output_dir: Path,` Inside the function write_report_tex, which handles write report tex, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are output_dir: the value named 'output dir' in this block; Path: the value named 'path' in this block.

Line 438: `records: Sequence[PlotRecord],` Inside the function write_report_tex, which handles write report tex, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are records: the number of descriptor records accepted since program start; Sequence: the value named 'sequence' in this block; PlotRecord: the value named 'plot record' in this block.

Line 439: `block_design_filename: str | None,` Inside the function write_report_tex, which handles write report tex, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are block_design_filename: the value named 'block design filename' in this block; str: the value named 'str' in this block; None: the value named 'none' in this block.

Line 440: `) -> Path:` Inside the function write_report_tex, which handles write report tex, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are Path: the value named 'path' in this block.

Line 441: `tex_path = output_dir / "neuraedge_deep_debug_report.tex"` This assigns 'output_dir / "neuraedge_deep_deb to 'tex_path ' in host memory. Here tex_path means the value named 'tex path' in this block. The important operands are output_dir: the value named 'output dir' in this block; neuraedge_deep_debug_report: the value named 'neuraedge deep debug report' in this block; tex: the value named 'tex' in this block. Context: the function write_report_tex, which handles write report tex.

Line 442: `lines = [` This statement continues through source line 461; the explanation uses the complete expression rather than only the first visual fragment. This assigns '[r"\documentclass[10pt]{article}", r"\usepackage[margin=0.65in]{geometry} r"\usepackage[T1]{fontenc}", r"\usepackage{lmodern}", r"\usepackage{graphicx}", r"\usepackage{pdfpages}", r"\usepackage[hideli r"\setlength{\parindent}{0pt}", r"\setlength{\parskip}{5pt}", r"\title{NeuraEdge Universal: Deep Debug Plots and Waveforms}", r"\author{Generated from CIFAR-10, XSim, compiler, and Vivado artifacts}", r"\date{\today}", r"\begin{document} r"\maketitle", r"\tableofcontents", r"\clearpage", r"\section{Evidence rule}", "Every page names its source artifact. Line 480: `]` This is continuation line 9 of the 10-line logical statement that begins at source line 472. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘lines.extend‘ with ‘ [r"\clearpage", rf"\section{{{latex_escape(record.title)}}}", rf"\begin{{sloppypar}}\small\textbf{{Evidence:}} {latex_breakable(record.evidence)}\end{{sloppypar}}", r"\begin{center}", rf"\includegraphics[width=0.98\textwidth,height=0.78\textheight,keepaspectratio]{{plots/{record.filename}}}", r"\end{center}",] ‘ inside the function write_report_tex, which handles write report tex. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 481: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 472. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘lines.extend‘ with ‘ [r"\clearpage", rf"\section{{{latex_escape(record.title)}}}", rf"\begin{{sloppypar}}\small\textbf{{Evidence:}} {latex_breakable(record.evidence)}\end{{sloppypar}}", r"\begin{center}", rf"\includegraphics[width=0.98\textwidth,height=0.78\textheight,keepaspectratio]{{plots/{record.filename}}}", r"\end{center}",] ‘ inside the function write_report_tex, which handles write report tex. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 482: `lines.append(r"\end{document}")` This calls ‘lines.append‘ with ‘r"\end{document}"‘ inside the function write_report_tex, which handles write report tex. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 483: `tex_path.write_text("\n".join(lines) + "\n", encoding="utf-8")` This calls ‘tex_path.write_text‘ with ‘"\n".join(lines) + "\n", encoding="utf-8"‘ inside the function write_report_tex, which handles write report tex. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 484: `return tex_path` This returns ‘tex_path‘ to the caller of the function write_report_tex, which handles write report tex, ending this invocation. The important operands are tex_path: the value named ’tex path’ in this block.

Line 487: `def generate(` This starts function generate. Its indented body performs generate as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 488: `output_dir: Path,` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are output_dir: the value named ’output dir’ in this block; Path: the value named ’path’ in this block.

Line 489: `timing_dir: Path | None,` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are timing_dir: the value named ’timing dir’ in this block; Path: the value named ’path’ in this block; None: the value named ’none’ in this block.

Line 490: `waveform_dir: Path | None = None,` This assigns ‘None,‘ to ‘waveform_dir‘ in host memory. Here waveform_dir means the value named ’waveform dir’ in this block. The important operands are None: the value named ’none’ in this block. Context: the function generate, which handles generate.

Line 491: `saif_power_report: Path | None = None,` This assigns 'None,' to 'saif_power_report' in host memory. Here saif_power_report means the value named 'saif power report' in this block. The important operands are None: the value named 'none' in this block. Context: the function generate, which handles generate.

Line 492: `block_design: Path | None = None,` This assigns 'None,' to 'block_design' in host memory. Here block_design means the value named 'block design' in this block. The important operands are None: the value named 'none' in this block. Context: the function generate, which handles generate.

Line 493: `) -> tuple[Path, Path, Path]:` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are tuple: the value named 'tuple' in this block; Path: the value named 'path' in this block.

Line 494: `root = root_dir()` This assigns 'root_dir()' to 'root ' in host memory. Here root means the value named 'root' in this block. The important operands are root_dir: the value named 'root dir' in this block. Context: the function generate, which handles generate.

Line 495: `timing_dir = timing_dir or root / "outputs/pynq_full"` This assigns 'timing_dir or root / "outputs/pynq_full"' to 'timing_dir ' in host memory. Here timing_dir means the value named 'timing dir' in this block. The important operands are timing_dir: the value named 'timing dir' in this block; or: the value named 'or' in this block; root: the value named 'root' in this block. Context: the function generate, which handles generate.

Line 496: `waveform_dir = waveform_dir or root / "outputs/waveforms_final"` This assigns 'waveform_dir or root / "outputs/waveforms_final"' to 'waveform_dir ' in host memory. Here waveform_dir means the value named 'waveform dir' in this block. The important operands are waveform_dir: the value named 'waveform dir' in this block; or: the value named 'or' in this block; root: the value named 'root' in this block. Context: the function generate, which handles generate.

Line 497: `saif_power_report = saif_power_report or (` This statement continues through source line 499; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'saif_power_report or (root / "outputs/power_activity_full/vivado_reports/routed_saif_power.rpt")' to 'saif_power_report ' in host memory. Here saif_power_report means the value named 'saif power report' in this block. The important operands are saif_power_report: the value named 'saif power report' in this block; or: the value named 'or' in this block; root: the value named 'root' in this block. Context: the function generate, which handles generate.

Line 498: `root / "outputs/power_activity_full/vivado_reports/routed_saif_power.rpt"` This is continuation line 2 of the 3-line logical statement that begins at source line 497. Its exact fragment is 'root / "outputs/power_activity_full/viv The important operands are root: the value named 'root' in this block; outputs: the value named 'outputs' in this block; power_activity_full: the value named 'power activity full' in this block. Read together, the complete operation is: This assigns 'saif_power_report or (root / "outputs/power_activity_full/vivado_reports/routed_saif_power.rpt")' to 'saif_power_report ' in host memory. Here saif_power_report means the value named 'saif power report' in this block. The important operands are saif_power_report: the value named 'saif power report' in this block; or: the value named 'or' in this block; root: the value named 'root' in this block. Context: the function generate, which handles generate.

Line 499: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 497. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'saif_power_report or (root / "outputs/power_activity_full/vivado_reports/routed_saif_power.rpt")' to 'saif_power_report ' in host memory. Here saif_power_report means the value named 'saif power report' in this block. The important operands are saif_power_report: the value named 'saif power report' in this block; or: the value named 'or' in this block; root: the value named 'root' in this block. Context: the function generate, which handles generate.

Line 500: `block_design = block_design or root / "outputs/pynq_full/neuraedge_pynq_block_design.pdf"` This assigns 'block_design or root / "outputs/pynq_full/neuraedge_pynq_block_design.pdf"' to 'block_design ' in host memory. Here block_design means the value named 'block design' in this block. The important operands are

block_design: the value named 'block design' in this block; or: the value named 'or' in this block; root: the value named 'root' in this block. Context: the function generate, which handles generate.

Line 501: `output_dir.mkdir(parents=True, exist_ok=True)` This calls ‘output_dir.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 502: `plot_dir = output_dir / "plots"` This assigns ‘output_dir / "plots"‘ to ‘plot_dir ‘ in host memory. Here plot_dir means the value named 'plot dir' in this block. The important operands are output_dir: the value named 'output dir' in this block; plots: the value named 'plots' in this block. Context: the function generate, which handles generate.

Line 503: `plot_dir.mkdir(parents=True, exist_ok=True)` This calls ‘plot_dir.mkdir‘ with ‘parents=True, exist_ok=True‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 504: `pdf_path = output_dir / "neuraedge_deep_debug_plots.pdf"` This assigns ‘output_dir / "neuraedge_deep_debu
to ‘pdf_path ‘ in host memory. Here pdf_path means the value named 'pdf path' in this block. The important operands are output_dir: the value named 'output dir' in this block; neuraedge_deep_debug_plots: the value named 'neuraedge deep debug plots' in this block; pdf: the value named 'pdf' in this block. Context: the function generate, which handles generate.

Line 505: `records: list[PlotRecord] = []` This assigns ‘[]‘ to ‘records‘ in host memory. Here records means the number of descriptor records accepted since program start. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 506: `index = 1` This assigns ‘1‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 508: `reference = load_json(root / "outputs/spikingformer_reference/spikingformer_evaluation.json")`
This assigns ‘load_json(root / "outputs/spikingformer_reference/spikingformer_evaluation.json")‘ to ‘reference ‘ in host memory. Here reference means the value named 'reference' in this block. The important operands are load_json: the value named 'load json' in this block; root: the value named 'root' in this block; outputs: the value named 'outputs' in this block. Context: the function generate, which handles generate.

Line 509: `quantized = load_json(root / "outputs/spikingformer_hw_q10_tensor_exact/spikingformer_evaluation.js`
This assigns ‘load_json(root / "outputs/spikingformer_hw_q10_tensor_exact/spikingformer_evaluation.json")‘ to ‘quantized ‘ in host memory. Here quantized means the value named 'quantized' in this block. The important operands are load_json: the value named 'load json' in this block; root: the value named 'root' in this block; outputs: the value named 'outputs' in this block. Context: the function generate, which handles generate.

Line 510: `execution = load_json(root / "outputs/spikingformer_reference/spikingformer_execution_manifest.json`
This assigns ‘load_json(root / "outputs/spikingformer_reference/spikingformer_execution_manifest.json")‘ to ‘execution ‘ in host memory. Here execution means the value named 'execution' in this block. The important operands are load_json: the value named 'load json' in this block; root: the value named 'root' in this block; outputs: the value named 'outputs' in this block. Context: the function generate, which handles generate.

Line 511: `parameters = load_json(root / "outputs/spikingformer_hardware_parameters/spikingformer_neuraedge_we`
This assigns ‘load_json(root / "outputs/spikingformer_hardware_parameters/spikingformer_neuraedge_weights.json")‘ to ‘parameters ‘ in host memory. Here parameters means the value named 'parameters' in this block. The important operands are load_json: the value named 'load json' in this block; root: the value named 'root' in this block; outputs: the value named 'outputs' in this block. Context: the function generate, which handles generate.

Line 512: `compiler_benchmark = load_json(root / "outputs/benchmarks/compiler_block3_memory.json")` This assigns ‘load_json(root / "outputs/benchmarks/compiler_block3_memory.json")‘ to ‘compiler_benchmark ‘ in host memory. Here compiler_benchmark means the value named ’compiler benchmark’ in this block. The important operands are load_json: the value named ’load json’ in this block; root: the value named ’root’ in this block; outputs: the value named ’outputs’ in this block. Context: the function generate, which handles generate.

Line 513: `training_coverage_path = root / "outputs/training/spikingformer_training_coverage.json"` This assigns ‘root / "outputs/training/spikingformer_training_coverage.json"‘ to ‘training_coverage_path ‘ in host memory. Here training_coverage_path means the value named ’training coverage path’ in this block. The important operands are root: the value named ’root’ in this block; outputs: the value named ’outputs’ in this block; training: the value named ’training’ in this block. Context: the function generate, which handles generate.

Line 514: `training_coverage = (` This statement continues through source line 516; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(load_json(training_coverage_path) if training_coverage_path.exists() else None)‘ to ‘training_coverage ‘ in host memory. Here training_coverage means the value named ’training coverage’ in this block. The important operands are load_json: the value named ’load json’ in this block; training_coverage_path: the value named ’training coverage path’ in this block; exists: the value named ’exists’ in this block. Context: the function generate, which handles generate.

Line 515: `load_json(training_coverage_path) if training_coverage_path.exists() else None` This is continuation line 2 of the 3-line logical statement that begins at source line 514. Its exact fragment is ‘load_json(training_coverage_path if training_coverage_path.exists() else None‘. The important operands are load_json: the value named ’load json’ in this block; training_coverage_path: the value named ’training coverage path’ in this block; exists: the value named ’exists’ in this block. Read together, the complete operation is: This assigns ‘(load_json(training_coverage_path) if training_coverage_path.exists() else None)‘ to ‘training_coverage ‘ in host memory. Here training_coverage means the value named ’training coverage’ in this block. The important operands are load_json: the value named ’load json’ in this block; training_coverage_path: the value named ’training coverage path’ in this block; exists: the value named ’exists’ in this block. Context: the function generate, which handles generate.

Line 516: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 514. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(load_json(training_coverage_path) if training_coverage_path.exists() else None)‘ to ‘training_coverage ‘ in host memory. Here training_coverage means the value named ’training coverage’ in this block. The important operands are load_json: the value named ’load json’ in this block; training_coverage_path: the value named ’training coverage path’ in this block; exists: the value named ’exists’ in this block. Context: the function generate, which handles generate.

Line 517: `forward_validation_path = root / "outputs/regression/real_full_graph_forward_validation.json"` This assigns ‘root / "outputs/regression/real_full_graph_forward_validation.json"‘ to ‘forward_validation_path ‘ in host memory. Here forward_validation_path means the producer’s statement that its current payload is meaningful. The important operands are root: the value named ’root’ in this block; outputs: the value named ’outputs’ in this block; regression: the value named ’regression’ in this block. Context: the function generate, which handles generate.

Line 518: `forward_validation = (` This statement continues through source line 520; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(load_json(forward_validation_path) if forward_validation_path.exists() else None)‘ to ‘forward_validation ‘ in host memory. Here forward_validation means the producer’s statement that its current payload is meaningful. The important operands are load_json: the value named ’load json’ in this block; forward_validation_path: the producer’s statement that its current payload is meaningful; exists: the value named ’exists’ in this block. Context: the function generate, which handles generate.

Line 519: `load_json(forward_validation_path) if forward_validation_path.exists() else None` This is continuation line 2 of the 3-line logical statement that begins at source line 518. Its exact fragment is ‘load_json(forward_validation_pat if forward_validation_path.exists() else None‘. The important operands are load_json: the value named ’load json’ in this block; forward_validation_path: the producer’s statement that its current payload is meaningful; exists: the value named ’exists’ in this block. Read together, the complete operation is: This assigns ‘(load_json(forward_validation_path) if forward_validation_path.exists() else None)‘ to ‘forward_validation ‘ in host memory. Here forward_validation means

the producer's statement that its current payload is meaningful. The important operands are load_json: the value named 'load json' in this block; forward_validation_path: the producer's statement that its current payload is meaningful; exists: the value named 'exists' in this block. Context: the function generate, which handles generate.

Line 520: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 518. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(load_json(forward_validation_path) if forward_validation_path.exists() else None)' to 'forward_validation ' in host memory. Here forward_validation means the producer's statement that its current payload is meaningful. The important operands are load_json: the value named 'load json' in this block; forward_validation_path: the producer's statement that its current payload is meaningful; exists: the value named 'exists' in this block. Context: the function generate, which handles generate.

Line 521: `shard_manifest_path = root / "outputs/cifar10_shards/cifar10_shards_manifest.json"` This assigns 'root / "outputs/cifar10_shards/cifar10_shards_manifest.json"' to 'shard_manifest_path ' in host memory. Here shard_manifest_path means the value named 'shard manifest path' in this block. The important operands are root: the value named 'root' in this block; outputs: the value named 'outputs' in this block; cifar10_shards: the value named 'cifar10 shards' in this block. Context: the function generate, which handles generate.

Line 522: `shard_manifest = load_json(shard_manifest_path) if shard_manifest_path.exists() else None` This assigns 'load_json(shard_manifest_path) if shard_manifest_path.exists() else None' to 'shard_manifest ' in host memory. Here shard_manifest means the value named 'shard manifest' in this block. The important operands are load_json: the value named 'load json' in this block; shard_manifest_path: the value named 'shard manifest path' in this block; exists: the value named 'exists' in this block. Context: the function generate, which handles generate.

Line 523: `float_npz = np.load(root / "outputs/spikingformer_reference/spikingformer_predictions.npz")` This assigns 'np.load(root / "outputs/spikingformer_reference/spikingformer_predictions.npz")' to 'float_npz ' in host memory. Here float_npz means the value named 'float npz' in this block. The important operands are load: the value named 'load' in this block; root: the value named 'root' in this block; outputs: the value named 'outputs' in this block. Context: the function generate, which handles generate.

Line 524: `quant_npz = np.load(root / "outputs/spikingformer_hw_q10_tensor_exact/spikingformer_predictions.npz` This assigns 'np.load(root / "outputs/spikingformer_hw_q10_tensor_exact/spikingformer_predictions.npz")' to 'quant_npz ' in host memory. Here quant_npz means the value named 'quant npz' in this block. The important operands are load: the value named 'load' in this block; root: the value named 'root' in this block; outputs: the value named 'outputs' in this block. Context: the function generate, which handles generate.

Line 525: `summary_path = timing_dir / "full_implementation_summary.txt"` This assigns 'timing_dir / "full_implementa to 'summary_path ' in host memory. Here summary_path means the value named 'summary path' in this block. The important operands are timing_dir: the value named 'timing dir' in this block; full_implementation_summary: the value named 'full implementation summary' in this block; txt: the value named 'txt' in this block. Context: the function generate, which handles generate.

Line 526: `if not summary_path.exists():` This executes the following indented host-code branch only when 'not summary_path.exists()' is true. The important operands are not: the value named 'not' in this block; summary_path: the value named 'summary path' in this block; exists: the value named 'exists' in this block. Context: the function generate, which handles generate.

Line 527: `summary_path = timing_dir / "implementation_summary.txt"` This assigns 'timing_dir / "implementation_summary.txt"' to 'summary_path ' in host memory. Here summary_path means the value named 'summary path' in this block. The important operands are timing_dir: the value named 'timing dir' in this block; implementation_summary: the value named 'implementation summary' in this block; txt: the value named 'txt' in this block. Context: the function generate, which handles generate.

Line 528: `implementation = parse_implementation_summary(summary_path)` This assigns ‘parse_implementation_summary to ‘implementation ‘ in host memory. Here implementation means the value named ’implementation’ in this block. The important operands are parse_implementation_summary: the value named ’parse implementation summary’ in this block; summary_path: the value named ’summary path’ in this block. Context: the function generate, which handles generate.

Line 529: `vectorless_power_path = timing_dir / "full_vectorless_power.rpt"` This assigns ‘timing_dir / "full_vectorless_power.rpt"‘ to ‘vectorless_power_path ‘ in host memory. Here vectorless_power_path means the value named ’vectorless power path’ in this block. The important operands are timing_dir: the value named ’timing dir’ in this block; full_vectorless_power: the value named ’full vectorless power’ in this block; rpt: the value named ’rpt’ in this block. Context: the function generate, which handles generate.

Line 530: `if not vectorless_power_path.exists():` This executes the following indented host-code branch only when ‘not vectorless_power_path.exists()‘ is true. The important operands are not: the value named ’not’ in this block; vectorless_power_path: the value named ’vectorless power path’ in this block; exists: the value named ’exists’ in this block. Context: the function generate, which handles generate.

Line 531: `vectorless_power_path = timing_dir / "routed_vectorless_power.rpt"` This assigns ‘timing_dir / "routed_vectorless_power.rpt"‘ to ‘vectorless_power_path ‘ in host memory. Here vectorless_power_path means the value named ’vectorless power path’ in this block. The important operands are timing_dir: the value named ’timing dir’ in this block; routed_vectorless_power: the value named ’routed vectorless power’ in this block; rpt: the value named ’rpt’ in this block. Context: the function generate, which handles generate.

Line 532: `vectorless_power = parse_power_report(vectorless_power_path)` This assigns ‘parse_power_report(vectorless_ to ‘vectorless_power ‘ in host memory. Here vectorless_power means the value named ’vectorless power’ in this block. The important operands are parse_power_report: the value named ’parse power report’ in this block; vectorless_power_path: the value named ’vectorless power path’ in this block. Context: the function generate, which handles generate.

Line 533: `saif_power = parse_power_report(saif_power_report)` This assigns ‘parse_power_report(saif_power_report)‘ to ‘saif_power ‘ in host memory. Here saif_power means the value named ’saif power’ in this block. The important operands are parse_power_report: the value named ’parse power report’ in this block; saif_power_report: the value named ’saif power report’ in this block. Context: the function generate, which handles generate.

Line 534: `block_design_filename: str | None = None` This assigns ‘None‘ to ‘block_design_filename‘ in host memory. Here block_design_filename means the value named ’block design filename’ in this block. The important operands are None: the value named ’none’ in this block. Context: the function generate, which handles generate.

Line 535: `if block_design.exists():` This executes the following indented host-code branch only when ‘block_design.exists()‘ is true. The important operands are block_design: the value named ’block design’ in this block; exists: the value named ’exists’ in this block. Context: the function generate, which handles generate.

Line 536: `copied_block_design = output_dir / "pynq-block-design.pdf"` This assigns ‘output_dir / "pynq-block-design.pdf"‘ to ‘copied_block_design ‘ in host memory. Here copied_block_design means the value named ’copied block design’ in this block. The important operands are output_dir: the value named ’output dir’ in this block; pynq: the value named ’pynq’ in this block; block: the value named ’block’ in this block. Context: the function generate, which handles generate.

Line 537: `shutil.copy2(block_design, copied_block_design)` This calls ‘shutil.copy2‘ with ‘block_design, copied_block_de inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 538: `block_design_filename = copied_block_design.name` This assigns ‘copied_block_design.name‘ to ‘block_design_ ‘ in host memory. Here block_design_filename means the value named ’block design filename’ in this block. The important operands are copied_block_design: the value named ’copied block design’ in this block; name: the value named ’name’ in this block. Context: the function generate, which handles generate.

Line 540: `with PdfPages(pdf_path) as pdf:` This opens a managed resource scope for 'PdfPages(pdf_path) as pdf' so files, tracing, or temporary state are finalized even if the function generate, which handles generate raises an error.

Line 541: `summary_lines = [` This statement continues through source line 550; the explanation uses the complete expression rather than only the first visual fragment. Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are summary_lines: the value named 'summary lines' in this block; f: the value named 'f' in this block; Dataset: the value named 'dataset' in this block.

Line 542: `f"Dataset: {reference['dataset']} ({reference['samples']:,} samples)",` This is continuation line 2 of the 10-line logical statement that begins at source line 541. Its exact fragment is 'f"Dataset: {reference['dataset']} ({reference['samples']:,} samples)",'. The important operands are f: the value named 'f' in this block; Dataset: the value named 'dataset' in this block; reference: the value named 'reference' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are summary_lines: the value named 'summary lines' in this block; f: the value named 'f' in this block; Dataset: the value named 'dataset' in this block.

Line 543: `f"Checkpoint: {reference['correct']:,}/{reference['samples']:,} = {reference['top1_accuracy_percen`
This is continuation line 3 of the 10-line logical statement that begins at source line 541. Its exact fragment is 'f"Checkpoint: {reference['correct']:,}/{reference['samples']:,} = {reference['top1_accuracy_percent']:.2f}%",'. The important operands are f: the value named 'f' in this block; Checkpoint: the value named 'checkpoint' in this block; reference: the value named 'reference' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are summary_lines: the value named 'summary lines' in this block; f: the value named 'f' in this block; Dataset: the value named 'dataset' in this block.

Line 544: `f"Exported integer arithmetic: {quantized['correct']:,}/{quantized['samples']:,} = {quantized['top`
This is continuation line 4 of the 10-line logical statement that begins at source line 541. Its exact fragment is 'f"Exported integer arithmetic: {quantized['correct']:,}/{quantized['samples']:,} = {quantized['top1_accuracy_percent']:.2f}%",'. The important operands are f: the value named 'f' in this block; Exported: the value named 'exported' in this block; integer: the value named 'integer' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are summary_lines: the value named 'summary lines' in this block; f: the value named 'f' in this block; Dataset: the value named 'dataset' in this block.

Line 545: `f"Prediction disagreements: {int(np.count_nonzero(float_npz['predictions'] != quant_npz['predictio`
This is continuation line 5 of the 10-line logical statement that begins at source line 541. Its exact fragment is 'f"Prediction disagreements: {int(np.count_nonzero(float_npz['predictions'] != quant_npz['predictions'])):,}",'. The important operands are f: the value named 'f' in this block; Prediction: the class index with the greatest classifier score; disagreements: the value named 'disagreements' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are summary_lines: the value named 'summary lines' in this block; f: the value named 'f' in this block; Dataset: the value named 'dataset' in this block.

f"Host trace elapsed time: {forward_validation['elapsed_seconds']:.3f} s",]' to 'validation_lines ' in host memory. Here validation_lines means the producer's statement that its current payload is meaningful. The important operands are f: the value named 'f' in this block; Result: the value named 'result' in this block; forward_validation: the producer's statement that its current payload is meaningful. Context: the function generate, which handles generate.

Line 575: `f"Host trace elapsed time: {forward_validation['elapsed_seconds']:.3f} s",` This is continuation line 9 of the 10-line logical statement that begins at source line 567. Its exact fragment is 'f"Host trace elapsed time: {forward_validation['elapsed_seconds']:.3f} s",'. The important operands are f: the value named 'f' in this block; Host: the value named 'host' in this block; trace: the value named 'trace' in this block. Read together, the complete operation is: This assigns '[f"Result: {forward_validation['result']}", f"Official CIFAR-10 fixture: {forward_validation['dataset_sample']}", f"Label / predicted class: {forward_validation['label']} / {forward_validation['predicted_clas
f"Complete graph commands: {forward_validation['command_count']:,}", f"Input / output stream beats: {forward_validation['inpu
/ {forward_validation['output_beats']:,}", f"Maximum logit delta from archived 10,000-image evaluation: {forward_validation['max
f"Parameter bytes / SHA-256: {forward_validation['parameter_binary_bytes']:,} / {forward_validation['parameter_binary_sha25
f"Host trace elapsed time: {forward_validation['elapsed_seconds']:.3f} s",]' to 'validation_lines ' in host memory. Here validation_lines means the producer's statement that its current payload is meaningful. The important operands are f: the value named 'f' in this block; Result: the value named 'result' in this block; forward_validation: the producer's

statement that its current payload is meaningful. Context: the function generate, which handles generate.

Line 576: `]` This is continuation line 10 of the 10-line logical statement that begins at source line 567. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘[f"Result: {forward_validation['result']}", f"Official CIFAR-10 fixture: {forward_validation['dataset_sample']}", f"Label / predicted class: {forward_validation['label']} / {forward_validation['predicted_clas f"Complete graph commands: {forward_validation['command_count']:,}", f"Input / output stream beats: {forward_validation['inpu / {forward_validation['output_beats']:,}", f"Maximum logit delta from archived 10,000-image evaluation: {forward_validation['max f"Parameter bytes / SHA-256: {forward_validation['parameter_binary_bytes']:,} / {forward_validation['parameter_binary_sha25 f"Host trace elapsed time: {forward_validation['elapsed_seconds']:.3f} s",]‘ to ‘validation_lines ‘ in host memory. Here validation_lines means the producer’s statement that its current payload is meaningful. The important operands are f: the value named ’f’ in this block; Result: the value named ’result’ in this block; forward_validation: the producer’s statement that its current payload is meaningful. Context: the function generate, which handles generate.

Line 577: `figure = text_page("Complete Exported-Graph Trace Validation", validation_lines)` This assigns ‘text_page("Complete Exported-Graph Trace Validation", validation_lines)‘ to ‘figure ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are text_page: the value named ’text page’ in this block; Complete: the value named ’complete’ in this block; Exported: the value named ’exported’ in this block. Context: the function generate, which handles generate.

Line 578: `index = save_figure(` This statement continues through source line 581; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "full_graph_validation", "Complete exported-graph trace validation", str(forward_validation_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 579: `figure, plot_dir, pdf, records, index, "full_graph_validation",` This is continuation line 2 of the 4-line logical statement that begins at source line 578. Its exact fragment is ‘figure, plot_dir, pdf, records, index, "full_graph_validation",‘. The important operands are figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block; pdf: the value named ’pdf’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "full_graph_validation", "Complete exported-graph trace validation", str(forward_validation_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 580: `"Complete exported-graph trace validation", str(forward_validation_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 578. Its exact fragment is ‘"Complete exported-graph trace validation", str(forward_validation_path),‘. The important operands are Complete: the value named ’complete’ in this block; exported: the value named ’exported’ in this block; graph: the value named ’graph’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "full_graph_validation", "Complete exported-graph trace validation", str(forward_validation_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 581: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 578. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "full_graph_validation", "Complete exported-graph trace validation", str(forward_validation_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 583: `artifact_lines: list[str] = []` This assigns '[]' to 'artifact_lines' in host memory. Here artifact_lines means the value named 'artifact lines' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 584: `for artifact_name in (` This line opens or closes a multi-line Python expression inside the function generate, which handles generate; the neighboring lines supply its arguments or elements.

Line 585: `"neuraedge_pynq_full.bit", "neuraedge_pynq_full.hwh",` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are neuraedge_pynq_full: the value named 'neuraedge pynq full' in this block; bit: the value named 'bit' in this block; hwh: the value named 'hwh' in this block.

Line 586: `"neuraedge_pynq_full.xsa", "neuraedge_pynq_full_routed.dcp",` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are neuraedge_pynq_full: the value named 'neuraedge pynq full' in this block; xsa: the value named 'xsa' in this block; neuraedge_pynq_full_routed: the value named 'neuraedge pynq full routed' in this block.

Line 587: `):` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The expression is a literal or structural operator and has no hidden software state.

Line 588: `artifact_path = timing_dir / artifact_name` This assigns 'timing_dir / artifact_name' to 'artifact_path ' in host memory. Here artifact_path means the value named 'artifact path' in this block. The important operands are timing_dir: the value named 'timing dir' in this block; artifact_name: the value named 'artifact name' in this block. Context: the function generate, which handles generate.

Line 589: `if artifact_path.exists():` This executes the following indented host-code branch only when 'artifact_path.exists()' is true. The important operands are artifact_path: the value named 'artifact path' in this block; exists: the value named 'exists' in this block. Context: the function generate, which handles generate.

Line 590: `size, digest = file_evidence(artifact_path)` This assigns 'file_evidence(artifact_path)' to 'size, digest ' in host memory. Here size means the value named 'size' in this block. The important operands are file_evidence: the value named 'file evidence' in this block; artifact_path: the value named 'artifact path' in this block. Context: the function generate, which handles generate.

Line 591: `artifact_lines.append(f"{artifact_name}: {size:,} bytes")` This calls 'artifact_lines.append' with 'f"{artifact_name}: {size:,} bytes"' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 592: `artifact_lines.append(f" SHA-256 {digest}")` This calls 'artifact_lines.append' with 'f" SHA-256 {digest}"' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 593: `if artifact_lines:` This executes the following indented host-code branch only when 'artifact_lines' is true. The important operands are artifact_lines: the value named 'artifact lines' in this block. Context: the function generate, which handles generate.

Line 594: `figure = text_page("Final PYNQ Deliverable Integrity", artifact_lines)` This assigns 'text_page("Final PYNQ Deliverable Integrity", artifact_lines)' to 'figure ' in host memory. Here figure means the value named 'figure' in this block. The important operands are text_page: the value named 'text page' in this block; Final: the value named 'final' in this block; PYNQ: the value named 'pynq' in this block. Context: the function generate, which handles generate.

Line 595: `index = save_figure(` This statement continues through source line 598; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "artifact_integrity", "Final PYNQ artifact integrity", str(timing_dir),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 596: `figure, plot_dir, pdf, records, index, "artifact_integrity",` This is continuation line 2 of the 4-line logical statement that begins at source line 595. Its exact fragment is ‘figure, plot_dir, pdf, records, index, "artifact_integrity",‘. The important operands are figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block; pdf: the value named ’pdf’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "artifact_integrity", "Final PYNQ artifact integrity", str(timing_dir),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 597: `"Final PYNQ artifact integrity", str(timing_dir),` This is continuation line 3 of the 4-line logical statement that begins at source line 595. Its exact fragment is ‘"Final PYNQ artifact integrity", str(timing_dir),‘. The important operands are Final: the value named ’final’ in this block; PYNQ: the value named ’pynq’ in this block; artifact: the value named ’artifact’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "artifact_integrity", "Final PYNQ artifact integrity", str(timing_dir),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 598: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 595. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "artifact_integrity", "Final PYNQ artifact integrity", str(timing_dir),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 600: `float_cm = np.asarray(reference["confusion_matrix_rows_true_columns_predicted"], dtype=np.int64)` This assigns ‘np.asarray(reference["confusion_matrix_rows_true_columns_predicted"], dtype=np.int64)‘ to ‘float_cm ‘ in host memory. Here float_cm means the value named ’float cm’ in this block. The important operands are asarray: the value named ’asarray’ in this block; reference: the value named ’reference’ in this block; confusion_matrix_rows_true_columns_pre one output-row position processed by the tensor tile. Context: the function generate, which handles generate.

Line 601: `quant_cm = np.asarray(quantized["confusion_matrix_rows_true_columns_predicted"], dtype=np.int64)` This assigns ‘np.asarray(quantized["confusion_matrix_rows_true_columns_predicted"], dtype=np.int64)‘ to ‘quant_cm ‘ in host memory. Here quant_cm means the value named ’quant cm’ in this block. The important operands are asarray: the value named ’asarray’ in this block; quantized: the value named ’quantized’ in this block; confusion_matrix_rows_true_columns one output-row position processed by the tensor tile. Context: the function generate, which handles generate.

Line 602: `for slug, title, matrix, signed in (` This line opens or closes a multi-line Python expression inside the function generate, which handles generate; the neighboring lines supply its arguments or elements.

Line 603: `("float_confusion", "Checkpoint confusion matrix: 10,000 images", float_cm, False),` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are float_confusion: the value named ’float confusion’ in this block; Checkpoint: the value named ’checkpoint’ in this block; confusion: the value named ’confusion’ in this block.

Line 604: `("quant_confusion", "Exported integer confusion matrix:  10,000 images", quant_cm, False),` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are quant_confusion: the value named 'quant confusion' in this block; Exported: the value named 'exported' in this block; integer: the value named 'integer' in this block.

Line 605: `("confusion_delta", "Integer minus checkpoint confusion counts", quant_cm - float_cm, True),` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are confusion_delta: the value named 'confusion delta' in this block; Integer: the value named 'integer' in this block; minus: the value named 'minus' in this block.

Line 606: `):` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The expression is a literal or structural operator and has no hidden software state.

Line 607: `index = save_figure(confusion_figure(matrix, title, signed), plot_dir, pdf, records, index, slug, title,` This statement continues through source line 608; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'save_figure(confusion_figure(matrix, title, signed), plot_dir, pdf, records, index, slug, title, "full CIFAR-10 prediction NPZ/JSON")' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; confusion_figure: the value named 'confusion figure' in this block; matrix: the value named 'matrix' in this block. Context: the function generate, which handles generate.

Line 608: `"full CIFAR-10 prediction NPZ/JSON")` This is continuation line 2 of the 2-line logical statement that begins at source line 607. Its exact fragment is '"full CIFAR-10 prediction NPZ/JSON")'. The important operands are full: the value named 'full' in this block; CIFAR: the value named 'cifar' in this block; prediction: the class index with the greatest classifier score. Read together, the complete operation is: This assigns 'save_figure(confusion_figure(matrix, title, signed), plot_dir, pdf, records, index, slug, title, "full CIFAR-10 prediction NPZ/JSON")' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; confusion_figure: the value named 'confusion figure' in this block; matrix: the value named 'matrix' in this block. Context: the function generate, which handles generate.

Line 610: `figure, axis = plt.subplots(figsize=(11, 5.8))` This assigns 'plt.subplots(figsize=(11, 5.8))' to 'figure, axis ' in host memory. Here figure means the value named 'figure' in this block. The important operands are plt: the value named 'plt' in this block; subplots: the value named 'subplots' in this block; figsize: the value named 'figsize' in this block. Context: the function generate, which handles generate.

Line 611: `x = np.arange(10)` This assigns 'np.arange(10)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are arange: the value named 'arange' in this block. Context: the function generate, which handles generate.

Line 612: `width = 0.39` This assigns '0.39' to 'width ' in host memory. Here width means the value named 'width' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 613: `float_acc = np.diag(float_cm) / float_cm.sum(axis=1) * 100` This assigns 'np.diag(float_cm) / float_cm.sum(axis=1) * 100' to 'float_acc ' in host memory. Here float_acc means the value named 'float acc' in this block. The important operands are diag: the value named 'diag' in this block; float_cm: the value named 'float cm' in this block; sum: the value named 'sum' in this block. Context: the function generate, which handles generate.

Line 614: `quant_acc = np.diag(quant_cm) / quant_cm.sum(axis=1) * 100` This assigns 'np.diag(quant_cm) / quant_cm.sum(axis=1) * 100' to 'quant_acc ' in host memory. Here quant_acc means the value named 'quant acc' in this block. The important operands are diag: the value named 'diag' in this block; quant_cm: the value named 'quant cm' in this block; sum: the value named 'sum' in this block. Context: the function generate, which handles generate.

Line 615: `axis.bar(x - width / 2, float_acc, width, label="checkpoint", color=COLORS[0])` This calls ‘axis.bar‘ with ‘x - width / 2, float_acc, width, label="checkpoint", color=COLORS[0]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 616: `axis.bar(x + width / 2, quant_acc, width, label="integer export", color=COLORS[1])` This calls ‘axis.bar‘ with ‘x + width / 2, quant_acc, width, label="integer export", color=COLORS[1]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 617: `axis.set_xticks(x, CLASSES, rotation=32, ha="right")` This calls ‘axis.set_xticks‘ with ‘x, CLASSES, rotation=32, ha="right"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 618: `axis.set_ylim(80, 100)` This calls ‘axis.set_ylim‘ with ‘80, 100‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 619: `axis.legend(frameon=False)` This calls ‘axis.legend‘ with ‘frameon=False‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 620: `style_axes(axis, "Per-class top-1 accuracy", ylabel="Accuracy (%)")` This calls ‘style_axes‘ with ‘axis, "Per-class top-1 accuracy", ylabel="Accuracy (%)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 621: `index = save_figure(figure, plot_dir, pdf, records, index, "class_accuracy", "Per-class top-1 accuracy",` This statement continues through source line 622; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "class_accuracy", "Per-class top-1 accuracy", "full CIFAR-10 confusion matrices")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 622: `"full CIFAR-10 confusion matrices")` This is continuation line 2 of the 2-line logical statement that begins at source line 621. Its exact fragment is ‘"full CIFAR-10 confusion matrices")‘. The important operands are full: the value named ’full’ in this block; CIFAR: the value named ’cifar’ in this block; confusion: the value named ’confusion’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "class_accuracy", "Per-class top-1 accuracy", "full CIFAR-10 confusion matrices")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 624: `labels = float_npz["labels"].astype(np.int64)` This assigns ‘float_npz["labels"].astype(np.int64)‘ to ‘labels ‘ in host memory. Here labels means the value named ’labels’ in this block. The important operands are float_npz: the value named ’float npz’ in this block; labels: the value named ’labels’ in this block; astype: the value named ’astype’ in this block. Context: the function generate, which handles generate.

Line 625: `float_logits = float_npz["logits"].astype(np.float64)` This assigns ‘float_npz["logits"].astype(np.float64)‘ to ‘float_logits ‘ in host memory. Here float_logits means the ten unnormalized classifier scores used for argmax. The important operands are float_npz: the value named ’float npz’ in this block; logits: the ten unnormalized classifier scores used for argmax; astype: the value named ’astype’ in this block. Context: the function generate, which handles generate.

Line 626: `quant_logits = quant_npz["logits"].astype(np.float64)` This assigns ‘quant_npz["logits"].astype(np.float64)‘ to ‘quant_logits ‘ in host memory. Here quant_logits means the ten unnormalized classifier scores used for argmax. The important operands are quant_npz: the value named ’quant npz’ in this block; logits: the ten unnormalized classifier scores used for argmax; astype: the value named ’astype’ in this block. Context: the function generate, which handles generate.

Line 627: `float_sorted = np.sort(float_logits, axis=1)` This assigns ‘np.sort(float_logits, axis=1)‘ to ‘float_sorted ‘ in host memory. Here float_sorted means the value named ’float sorted’ in this block. The important operands are sort: the value named ’sort’ in this block; float_logits: the ten unnormalized classifier scores used for argmax; axis: the value named ’axis’ in this block. Context: the function generate, which handles generate.

Line 628: `quant_sorted = np.sort(quant_logits, axis=1)` This assigns ‘np.sort(quant_logits, axis=1)‘ to ‘quant_sorted ‘ in host memory. Here quant_sorted means the value named ’quant sorted’ in this block. The important operands are sort: the value named ’sort’ in this block; quant_logits: the ten unnormalized classifier scores used for argmax; axis: the value named ’axis’ in this block. Context: the function generate, which handles generate.

Line 629: `float_margin = float_sorted[:, -1] - float_sorted[:, -2]` This assigns ‘float_sorted[:, -1] - float_sorted[:, -2]‘ to ‘float_margin ‘ in host memory. Here float_margin means the value named ’float margin’ in this block. The important operands are float_sorted: the value named ’float sorted’ in this block. Context: the function generate, which handles generate.

Line 630: `quant_margin = quant_sorted[:, -1] - quant_sorted[:, -2]` This assigns ‘quant_sorted[:, -1] - quant_sorted[:, -2]‘ to ‘quant_margin ‘ in host memory. Here quant_margin means the value named ’quant margin’ in this block. The important operands are quant_sorted: the value named ’quant sorted’ in this block. Context: the function generate, which handles generate.

Line 631: `figure, axis = plt.subplots(figsize=(10.8, 5.8))` This assigns ‘plt.subplots(figsize=(10.8, 5.8))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 632: `axis.hist(float_margin, bins=100, density=True, alpha=0.58, label="checkpoint", color=COLORS[0])` This calls ‘axis.hist‘ with ‘float_margin, bins=100, density=True, alpha=0.58, label="checkpoint", color=COLORS[0]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 633: `axis.hist(quant_margin, bins=100, density=True, alpha=0.52, label="integer export", color=COLORS[2]` This calls ‘axis.hist‘ with ‘quant_margin, bins=100, density=True, alpha=0.52, label="integer export", color=COLORS[2]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 634: `axis.set_xlim(0, np.percentile(np.concatenate([float_margin, quant_margin]), 99.5))` This calls ‘axis.set_xlim‘ with ‘0, np.percentile(np.concatenate([float_margin, quant_margin]), 99.5)‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 635: `axis.legend(frameon=False)` This calls ‘axis.legend‘ with ‘frameon=False‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 636: `style_axes(axis, "Top-1 versus runner-up confidence margin", "Logit margin", "Probability density")` This calls ‘style_axes‘ with ‘axis, "Top-1 versus runner-up confidence margin", "Logit margin", "Probability density"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 637: `index = save_figure(figure, plot_dir, pdf, records, index, "margin_distribution", "Classifier margin distri...` This statement continues through source line 638; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "margin_distribution", "Classifier margin distribution", "all 10,000 checkpoint and integer logits")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 638: `"all 10,000 checkpoint and integer logits")` This is continuation line 2 of the 2-line logical statement that begins at source line 637. Its exact fragment is ‘"all 10,000 checkpoint and integer logits")‘. The important operands are all: the value named ’all’ in this block; checkpoint: the value named ’checkpoint’ in this block; and: the value named ’and’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "margin_distribution", "Classifier margin distribution", "all 10,000 checkpoint and integer logits")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 640: `logit_error = quant_logits - float_logits` This assigns ‘quant_logits - float_logits‘ to ‘logit_error ‘ in host memory. Here logit_error means the value named ’logit error’ in this block. The important operands are quant_logits: the ten unnormalized classifier scores used for argmax; float_logits: the ten unnormalized classifier scores used for argmax. Context: the function generate, which handles generate.

Line 641: `figure, axes = plt.subplots(1, 2, figsize=(12, 5))` This assigns ‘plt.subplots(1, 2, figsize=(12, 5))‘ to ‘figure, axes ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 642: `axes[0].hist(logit_error.ravel(), bins=150, color=COLORS[4], alpha=0.8)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; hist: the value named ’hist’ in this block; logit_error: the value named ’logit error’ in this block.

Line 643: `style_axes(axes[0], "All logit errors", "Integer - checkpoint logit", "Count")` This calls ‘style_axes‘ with ‘axes[0], "All logit errors", "Integer - checkpoint logit", "Count"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 644: `axes[1].boxplot([logit_error[:, index] for index in range(10)], tick_labels=CLASSES, showfliers=Fal` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; boxplot: the value named ’boxplot’ in this block; logit_error: the value named ’logit error’ in this block.

Line 645: `axes[1].tick_params(axis="x", rotation=40)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; tick_params: the value named ’tick params’ in this block; axis: the value named ’axis’ in this block.

Line 646: `style_axes(axes[1], "Error by output class", ylabel="Logit error")` This calls ‘style_axes‘ with ‘axes[1], "Error by output class", ylabel="Logit error"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 647: `index = save_figure(figure, plot_dir, pdf, records, index, "logit_error", "Integer-export logit error",` This statement continues through source line 648; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "logit_error", "Integer-export logit error", "paired 10,000 x 10 logit arrays")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 648: `"paired 10,000 x 10 logit arrays")` This is continuation line 2 of the 2-line logical statement that begins at source line 647. Its exact fragment is ‘"paired 10,000 x 10 logit arrays")‘. The important operands are paired: the value named ’paired’ in this block; x: the value named ’x’ in this block; logit: the value named ’logit’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "logit_error", "Integer-export logit error", "paired 10,000 x 10 logit arrays")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 650: `disagreements = float_npz["predictions"] != quant_npz["predictions"]` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are disagreements: the value named ’disagreements’ in this block; float_npz: the value named ’float npz’ in this block; predictions: the class index with the greatest classifier score.

Line 651: `transition = np.zeros((10, 10), dtype=np.int64)` This assigns ‘np.zeros((10, 10), dtype=np.int64)‘ to ‘transition ‘ in host memory. Here transition means the value named ’transition’ in this block. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function generate, which handles generate.

Line 652: `for before, after in zip(float_npz["predictions"][disagreements], quant_npz["predictions"][disagree` This iterates before, after over ‘zip(float_npz["predictions"][disagreements], quant_npz["predictions"][disagreements])‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate, which handles generate.

Line 653: `transition[int(before), int(after)] += 1` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are transition: the value named ’transition’ in this block; before: the value named ’before’ in this block; after: the value named ’after’ in this block.

Line 654: `index = save_figure(confusion_figure(transition, "Prediction changes: checkpoint class to integer class"),` This statement continues through source line 656; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(confusion_figure(transition, "Prediction changes: checkpoint class to integer class"), plot_dir, pdf, records, index, "prediction_changes", "Prediction disagreement transitions", f"{int(disagreements.sum())} changed predictions from paired NPZ files")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; confusion_figure: the value named ’confusion figure’ in this block; transition: the value named ’transition’ in this block. Context: the function generate, which handles generate.

Line 655: `plot_dir, pdf, records, index, "prediction_changes", "Prediction disagreement transitions",` This is continuation line 2 of the 3-line logical statement that begins at source line 654. Its exact fragment is ‘plot_dir, pdf, records, index, "prediction_changes", "Prediction disagreement transitions",‘. The important operands are plot_dir: the value named ’plot dir’ in this block; pdf: the value named ’pdf’ in this block; records: the number of descriptor records accepted since program start. Read together, the complete operation is: This assigns ‘save_figure(confusion_figure(transition, "Prediction changes: checkpoint class to integer class"), plot_dir, pdf, records, index, "prediction_changes", "Prediction disagreement transitions", f"{int(disagreements.sum())} changed predictions from paired NPZ files")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands

are save_figure: the value named 'save figure' in this block; confusion_figure: the value named 'confusion figure' in this block; transition: the value named 'transition' in this block. Context: the function generate, which handles generate.

Line 656: `f"{int(disagreements.sum())} changed predictions from paired NPZ files")` This is continuation line 3 of the 3-line logical statement that begins at source line 654. Its exact fragment is 'f"{int(disagreements.sum())} changed predictions from paired NPZ files")'. The important operands are f: the value named 'f' in this block; disagreements: the value named 'disagreements' in this block; sum: the value named 'sum' in this block. Read together, the complete operation is: This assigns 'save_figure(confusion_figure(transition, "Prediction changes: checkpoint class to integer class"), plot_dir, pdf, records, index, "prediction_changes", "Prediction disagreement transitions", f"{int(disagreements.sum())} changed predictions from paired NPZ files")' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; confusion_figure: the value named 'confusion figure' in this block; transition: the value named 'transition' in this block. Context: the function generate, which handles generate.

Line 658: `activation_stats = reference["activation_statistics"]` This assigns 'reference["activation_statistics"]' to 'activation_stats ' in host memory. Here activation_stats means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are reference: the value named 'reference' in this block; activation_statistics: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function generate, which handles generate.

Line 659: `spike_items = [(name, values) for name, values in activation_stats.items() if values["is_spike"]]` This assigns '[(name, values) for name, values in activation_stats.items() if values["is_spike"]]' to 'spike_items ' in host memory. Here spike_items means a binary event produced when a neuron crosses its threshold. The important operands are name: the value named 'name' in this block; values: the value named 'values' in this block; for: the value named 'for' in this block. Context: the function generate, which handles generate.

Line 660: `spike_items.sort(key=lambda item: item[1]["nonzero_fraction"], reverse=True)` This calls 'spike_items.so with 'key=lambda item: item[1]["nonzero_fraction"], reverse=True' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 661: `figure, axis = plt.subplots(figsize=(12, 8))` This assigns 'plt.subplots(figsize=(12, 8))' to 'figure, axis ' in host memory. Here figure means the value named 'figure' in this block. The important operands are plt: the value named 'plt' in this block; subplots: the value named 'subplots' in this block; figsize: the value named 'figsize' in this block. Context: the function generate, which handles generate.

Line 662: `names = [item[0] for item in spike_items]` This assigns '[item[0] for item in spike_items]' to 'names ' in host memory. Here names means the value named 'names' in this block. The important operands are item: the value named 'item' in this block; for: the value named 'for' in this block; in: the value named 'in' in this block. Context: the function generate, which handles generate.

Line 663: `rates = [item[1]["nonzero_fraction"] * 100 for item in spike_items]` This assigns '[item[1]["nonzero_fracti * 100 for item in spike_items]' to 'rates ' in host memory. Here rates means the value named 'rates' in this block. The important operands are item: the value named 'item' in this block; nonzero_fraction: the value named 'nonzero fraction' in this block; for: the value named 'for' in this block. Context: the function generate, which handles generate.

Line 664: `axis.barh(np.arange(len(names)), rates, color=COLORS[0])` This calls 'axis.barh' with 'np.arange(len(names)), rates, color=COLORS[0]' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 665: `axis.set_yticks(np.arange(len(names)), names, fontsize=7)` This calls 'axis.set_yticks' with 'np.arange(len(na names, fontsize=7' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 666: `axis.invert_yaxis()` This calls ‘axis.invert_yaxis‘ with “ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 667: `style_axes(axis, "Measured spike density by activation", "Nonzero spike fraction (%)")` This calls ‘style_axes‘ with ‘axis, "Measured spike density by activation", "Nonzero spike fraction (%)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 668: `index = save_figure(figure, plot_dir, pdf, records, index, "spike_density", "Measured spike density",` This statement continues through source line 669; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "spike_density", "Measured spike density", "streaming activation statistics over all CIFAR-10 test images")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 669: `"streaming activation statistics over all CIFAR-10 test images")` This is continuation line 2 of the 2-line logical statement that begins at source line 668. Its exact fragment is ‘"streaming activation statistics over all CIFAR-10 test images")‘. The important operands are streaming: the value named ’streaming’ in this block; activation: an input feature value consumed by a neuron or multiply-accumulate operation; statistics: the value named ’statistics’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "spike_density", "Measured spike density", "streaming activation statistics over all CIFAR-10 test images")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 671: `figure, axis = plt.subplots(figsize=(11, 6.2))` This assigns ‘plt.subplots(figsize=(11, 6.2))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 672: `qkv_names = [name for name in activation_stats if re.search(r"block\.\d+\.attn\.[qkv]_lif$", name)]` This assigns ‘[name for name in activation_stats if re.search(r"block\.\d+\.attn\.[qkv]_lif$", name)]‘ to ‘qkv_names ‘ in host memory. Here qkv_names means the value named ’qkv names’ in this block. The important operands are name: the value named ’name’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function generate, which handles generate.

Line 673: `x = np.arange(4)` This assigns ‘np.arange(4)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are arange: the value named ’arange’ in this block. Context: the function generate, which handles generate.

Line 674: `for offset, suffix, color in ((-0.25, "q_lif", COLORS[0]), (0, "k_lif", COLORS[1]), (0.25, "v_lif", COLORS[...` This iterates offset, suffix, color over ‘((-0.25, "q_lif", COLORS[0]), (0, "k_lif", COLORS[1]), (0.25, "v_lif", COLORS[2]))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate, which handles generate.

Line 675: `values = [activation_stats[f"block.{block}.attn.{suffix}"]["nonzero_fraction"] * 100 for block in range(4)]` This assigns ‘[activation_stats[f"block.{block}.attn.{suffix}"]["nonzero_fraction"] * 100 for block in range(4)]‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are activation_stats: an input feature value consumed by a neuron or multiply-accumulate operation; f: the value named ’f’ in this block; block: the value named ’block’ in this block. Context: the function generate, which handles generate.

Line 676: `axis.bar(x + offset, values, 0.24, label=suffix[0].upper(), color=color)` This calls ‘axis.bar‘ with ‘x + offset, values, 0.24, label=suffix[0].upper(), color=color‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 677: `axis.set_xticks(x, [f"Transformer block {block}" for block in range(4)])` This calls ‘axis.set_xticks‘ with ‘x, [f"Transformer block {block}" for block in range(4)]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 678: `axis.legend(frameon=False)` This calls ‘axis.legend‘ with ‘frameon=False‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 679: `style_axes(axis, "Q/K/V spike density across depth", ylabel="Spike density (%)")` This calls ‘style_axes‘ with ‘axis, "Q/K/V spike density across depth", ylabel="Spike density (%)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 680: `index = save_figure(figure, plot_dir, pdf, records, index, "qkv_density", "Q/K/V spike density",` This statement continues through source line 681; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "qkv_density", "Q/K/V spike density", "full-test streaming activation statistics")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 681: `"full-test streaming activation statistics")` This is continuation line 2 of the 2-line logical statement that begins at source line 680. Its exact fragment is ‘"full-test streaming activation statistics")‘. The important operands are full: the value named ’full’ in this block; test: the value named ’test’ in this block; streaming: the value named ’streaming’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "qkv_density", "Q/K/V spike density", "full-test streaming activation statistics")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 683: `nonspike_items = [(name, values) for name, values in activation_stats.items() if not values["is_spi` This assigns ‘[(name, values) for name, values in activation_stats.items() if not values["is_spike"]]‘ to ‘nonspike_items ‘ in host memory. Here nonspike_items means a binary event produced when a neuron crosses its threshold. The important operands are name: the value named ’name’ in this block; values: the value named ’values’ in this block; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 684: `figure, axis = plt.subplots(figsize=(12, 7))` This assigns ‘plt.subplots(figsize=(12, 7))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 685: `names = [item[0] for item in nonspike_items]` This assigns ‘[item[0] for item in nonspike_items]‘ to ‘names ‘ in host memory. Here names means the value named ’names’ in this block. The important operands are item: the value named ’item’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function generate, which handles generate.

Line 686: `means = np.asarray([item[1]["mean"] for item in nonspike_items])` This assigns ‘np.asarray([item[1]["mean"] for item in nonspike_items])‘ to ‘means ‘ in host memory. Here means means the arithmetic average used by normaliza-

tion. The important operands are asarray: the value named 'asarray' in this block; item: the value named 'item' in this block; mean: the arithmetic average used by normalization. Context: the function generate, which handles generate.

Line 687: `stds = np.asarray([item[1]["standard_deviation"] for item in nonspike_items])` This assigns 'np.asarray([item[1]["standard_deviation"] for item in nonspike_items])' to 'stds ' in host memory. Here stds means the value named 'stds' in this block. The important operands are asarray: the value named 'asarray' in this block; item: the value named 'item' in this block; standard_deviation: the value named 'standard deviation' in this block. Context: the function generate, which handles generate.

Line 688: `axis.errorbar(np.arange(len(names)), means, yerr=stds, fmt="o", markersize=3, capsize=2, color=COLO` This calls 'axis.errorbar' with 'np.arange(len(names)), means, yerr=stds, fmt="o", markersize=3, capsize=2, color=COLORS[4]' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 689: `axis.axhline(0, color="#111827", linewidth=0.8)` This calls 'axis.axhline' with '0, color="#111827", linewidth=0.8' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 690: `axis.set_xticks(np.arange(len(names)), names, rotation=75, ha="right", fontsize=6.5)` This calls 'axis.set_xticks' with 'np.arange(len(names)), names, rotation=75, ha="right", fontsize=6.5' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 691: `style_axes(axis, "Non-spiking activation mean and one standard deviation", ylabel="Activation value")` This calls 'style_axes' with 'axis, "Non-spiking activation mean and one standard deviation", ylabel="Activation value"' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 692: `index = save_figure(figure, plot_dir, pdf, records, index, "activation_moments", "Activation mean and spread",` This statement continues through source line 693; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'save_figure(figure, plot_dir, pdf, records, index, "activation_moments", "Activation mean and spread", "full-test streaming activation moments")' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 693: `"full-test streaming activation moments")` This is continuation line 2 of the 2-line logical statement that begins at source line 692. Its exact fragment is '"full-test streaming activation moments")'. The important operands are full: the value named 'full' in this block; test: the value named 'test' in this block; streaming: the value named 'streaming' in this block. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "activation_moments", "Activation mean and spread", "full-test streaming activation moments")' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 695: `operators = execution["operators"]` This assigns 'execution["operators"]' to 'operators ' in host memory. Here operators means the value named 'operators' in this block. The important operands are execution: the value named 'execution' in this block; operators: the value named 'operators' in this block. Context: the function generate, which handles generate.

Line 696: `operator_names = [operator["name"] for operator in operators if operator.get("matrix")]` This assigns '[operator["name"] for operator in operators if operator.get("matrix")]' to 'operator_names ' in host memory. Here operator_names means the value named 'operator names' in this block. The important operands are operator: the value named 'operator' in this block; name: the value named 'name' in this block; for: the value named 'for' in this block. Context: the function generate, which handles generate.

Line 697: `macs = np.asarray([operator["matrix"]["mac_equivalents"] for operator in operators if operator.get(` This assigns ‘np.asarray([operator["matrix"]["mac_equivalents"] for operator in operators if operator.get("matrix")])‘ to ‘macs ‘ in host memory. Here macs means the value named ’macs’ in this block. The important operands are asarray: the value named ’asarray’ in this block; operator: the value named ’operator’ in this block; matrix: the value named ’matrix’ in this block. Context: the function generate, which handles generate.

Line 698: `commands = np.asarray([operator["matrix"]["commands"] for operator in operators if operator.get("ma` This assigns ‘np.asarray([operator["matrix"]["commands"] for operator in operators if operator.get("matrix")])‘ to ‘commands ‘ in host memory. Here commands means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are asarray: the value named ’asarray’ in this block; operator: the value named ’operator’ in this block; matrix: the value named ’matrix’ in this block. Context: the function generate, which handles generate.

Line 699: `input_bytes = np.asarray([operator["matrix"]["input_stream_bytes"] for operator in operators if operator.ge...` This assigns ‘np.asarray([operator["matrix"]["input_stream_bytes"] for operator in operators if operator.get("matrix")])‘ to ‘input_bytes ‘ in host memory. Here input_bytes means the value named ’input bytes’ in this block. The important operands are asarray: the value named ’asarray’ in this block; operator: the value named ’operator’ in this block; matrix: the value named ’matrix’ in this block. Context: the function generate, which handles generate.

Line 700: `output_bytes = np.asarray([operator["matrix"]["output_stream_bytes"] for operator in operators if operator....` This assigns ‘np.asarray([operator["matrix"]["output_stream_bytes"] for operator in operators if operator.get("matrix")])‘ to ‘output_bytes ‘ in host memory. Here output_bytes means the value named ’output bytes’ in this block. The important operands are asarray: the value named ’asarray’ in this block; operator: the value named ’operator’ in this block; matrix: the value named ’matrix’ in this block. Context: the function generate, which handles generate.

Line 701: `for values, slug, title, ylabel, log_scale in (` This line opens or closes a multi-line Python expression inside the function generate, which handles generate; the neighboring lines supply its arguments or elements.

Line 702: `(macs, "operator_macs", "Model work by learned operator", "MAC equivalents", True),` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are macs: the value named ’macs’ in this block; operator_macs: the value named ’operator macs’ in this block; Model: the value named ’model’ in this block.

Line 703: `(commands, "operator_commands", "Tile commands by learned operator", "Commands", True),` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are commands: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operator_commands: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Tile: the value named ’tile’ in this block.

Line 704: `):` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The expression is a literal or structural operator and has no hidden software state.

Line 705: `figure, axis = plt.subplots(figsize=(12, 7))` This assigns ‘plt.subplots(figsize=(12, 7))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 706: `order = np.argsort(values)` This assigns ‘np.argsort(values)‘ to ‘order ‘ in host memory. Here order means the value named ’order’ in this block. The important operands are argsort: the value named ’argsort’ in this block; values: the value named ’values’ in this block. Context: the function generate, which handles generate.

Line 707: `axis.barh(np.arange(len(order)), values[order], color=COLORS[0 if slug.endswith("macs") else 1])` This calls ‘axis.barh‘ with ‘np.arange(len(order)), values[order], color=COLORS[0 if slug.endswith("macs") else 1]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 708: `axis.set_yticks(np.arange(len(order)), [operator_names[item] for item in order], fontsize=7)` This calls ‘axis.set_yticks‘ with ‘np.arange(len(order)), [operator_names[item] for item in order], fontsize=7‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 709: `if log_scale:` This executes the following indented host-code branch only when ‘log_scale‘ is true. The important operands are log_scale: the real-value spacing represented by one quantized integer step. Context: the function generate, which handles generate.

Line 710: `axis.set_xscale("log")` This calls ‘axis.set_xscale‘ with ‘"log"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 711: `style_axes(axis, title, ylabel)` This calls ‘style_axes‘ with ‘axis, title, ylabel‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 712: `index = save_figure(figure, plot_dir, pdf, records, index, slug, title,` This statement continues through source line 713; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, slug, title, "execution manifest generated from exported tensor shapes")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 713: `"execution manifest generated from exported tensor shapes")` This is continuation line 2 of the 2-line logical statement that begins at source line 712. Its exact fragment is ‘"execution manifest generated from exported tensor shapes")‘. The important operands are execution: the value named ’execution’ in this block; manifest: the value named ’manifest’ in this block; generated: the value named ’generated’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, slug, title, "execution manifest generated from exported tensor shapes")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 715: `figure, axis = plt.subplots(figsize=(12, 7))` This assigns ‘plt.subplots(figsize=(12, 7))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 716: `order = np.argsort(input_bytes + output_bytes)` This assigns ‘np.argsort(input_bytes + output_bytes)‘ to ‘order ‘ in host memory. Here order means the value named ’order’ in this block. The important operands are argsort: the value named ’argsort’ in this block; input_bytes: the value named ’input bytes’ in this block; output_bytes: the value named ’output bytes’ in this block. Context: the function generate, which handles generate.

Line 717: `axis.barh(np.arange(len(order)), input_bytes[order] / 1e6, label="input", color=COLORS[0])` This calls ‘axis.barh‘ with ‘np.arange(len(order)), input_bytes[order] / 1e6, label="input", color=COLORS[0]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 718: `axis.barh(np.arange(len(order)), output_bytes[order] / 1e6, left=input_bytes[order] / 1e6,` This statement continues through source line 719; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘axis.barh‘ with ‘np.arange(len(order)), output_bytes[order] / 1e6, left=input_bytes[order] / 1e6, label="output", color=COLORS[3]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 719: `label="output", color=COLORS[3])` This is continuation line 2 of the 2-line logical statement that begins at source line 718. Its exact fragment is ‘label="output", color=COLORS[3])‘. The important operands are label: the value named ’label’ in this block; output: the value named ’output’ in this block; color: the value named ’color’ in this block. Read together, the complete operation is: This calls ‘axis.barh‘ with ‘np.arange(len(order)), output_bytes[order] / 1e6, left=input_bytes[order] / 1e6, label="output", color=COLORS[3]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 720: `axis.set_yticks(np.arange(len(order)), [operator_names[item] for item in order], fontsize=7)` This calls ‘axis.set_yticks‘ with ‘np.arange(len(order)), [operator_names[item] for item in order], fontsize=7‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 721: `axis.legend(frameon=False)` This calls ‘axis.legend‘ with ‘frameon=False‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 722: `style_axes(axis, "Raw tile-stream traffic by learned operator", "Traffic (MB per image)")` This calls ‘style_axes‘ with ‘axis, "Raw tile-stream traffic by learned operator", "Traffic (MB per image)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 723: `index = save_figure(figure, plot_dir, pdf, records, index, "operator_traffic", "Operator stream traffic",` This statement continues through source line 724; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "operator_traffic", "Operator stream traffic", "execution manifest; excludes inter-layer DDR spill")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 724: `"execution manifest; excludes inter-layer DDR spill")` This is continuation line 2 of the 2-line logical statement that begins at source line 723. Its exact fragment is ‘"execution manifest; excludes inter-layer DDR spill")‘. The important operands are execution: the value named ’execution’ in this block; manifest: the value named ’manifest’ in this block; excludes: the value named ’excludes’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "operator_traffic", "Operator stream traffic", "execution manifest; excludes inter-layer DDR spill")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 726: `arithmetic = arithmetic_groups(operators)` This assigns ‘arithmetic_groups(operators)‘ to ‘arithmetic ‘ in host memory. Here arithmetic means the value named ’arithmetic’ in this block. The important operands are arithmetic_groups: the value named ’arithmetic groups’ in this block; operators: the value named ’operators’ in this block. Context: the function generate, which handles generate.

Line 727: `figure, axis = plt.subplots(figsize=(8, 6))` This assigns ‘plt.subplots(figsize=(8, 6))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 728: `axis.pie(list(arithmetic.values()), labels=list(arithmetic), autopct="%1.1f%%", colors=COLORS[: len(arithme...` This statement continues through source line 729; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘axis.pie‘ with ‘list(arithmetic.values()), labels=list(arithmetic), autopct="%1.1f%%", colors=COLORS[: len(arithmetic)], startangle=90, wedgeprops={"linewidth": 0.7, "edgecolor": "white"}‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 729: `startangle=90, wedgeprops={"linewidth": 0.7, "edgecolor": "white"})` This is continuation line 2 of the 2-line logical statement that begins at source line 728. Its exact fragment is ‘startangle=90, wedgeprops={"linewidth": 0.7, "edgecolor": "white"})‘. The important operands are startangle: the value named ’startangle’ in this block; wedgeprops: the value named ’wedgeprops’ in this block; linewidth: the value named ’linewidth’ in this block. Read together, the complete operation is: This calls ‘axis.pie‘ with ‘list(arithmetic.values()), labels=list(arithmetic), autopct="%1.1f%%", colors=COLORS[: len(arithmetic)], startangle=90, wedgeprops={"linewidth": 0.7, "edgecolor": "white"}‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 730: `axis.set_title("MAC-equivalent share by arithmetic mode", fontsize=13, fontweight="bold")` This calls ‘axis.set_title‘ with ‘"MAC-equivalent share by arithmetic mode", fontsize=13, fontweight="bold"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 731: `index = save_figure(figure, plot_dir, pdf, records, index, "arithmetic_share", "Arithmetic mode share",` This statement continues through source line 732; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "arithmetic_share", "Arithmetic mode share", "execution manifest model-equivalent operation counts")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 732: `"execution manifest model-equivalent operation counts")` This is continuation line 2 of the 2-line logical statement that begins at source line 731. Its exact fragment is ‘"execution manifest model-equivalent operation counts")‘. The important operands are execution: the value named ’execution’ in this block; manifest: the value named ’manifest’ in this block; model: the value named ’model’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "arithmetic_share", "Arithmetic mode share", "execution manifest model-equivalent operation counts")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 734: `matrix_records = [(operator["name"], operator["matrix"]) for operator in operators if operator.get(` This assigns ‘[(operator["name"], operator["matrix"]) for operator in operators if operator.get("matrix")]‘ to ‘matrix_records ‘ in host memory. Here matrix_records means the number of descriptor records accepted since program start. The important operands are operator: the value named ’operator’ in this block; name: the value named ’name’ in this block; matrix: the value named ’matrix’ in this block. Context: the function generate, which handles generate.

Line 735: `figure, axis = plt.subplots(figsize=(9.5, 6.5))` This assigns ‘plt.subplots(figsize=(9.5, 6.5))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 736: `for arithmetic_name in sorted({item[1]["arithmetic"] for item in matrix_records}):` This iterates arithmetic_name over ‘sorted({item[1]["arithmetic"] for item in matrix_records})‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate, which handles generate.

Line 737: `subset = [item for item in matrix_records if item[1]["arithmetic"] == arithmetic_name]` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are subset: the value named 'subset' in this block; item: the value named 'item' in this block; for: the value named 'for' in this block.

Line 738: `axis.scatter([item[1]["reduction"] for item in subset], [item[1]["columns"] for item in subset],` This statement continues through source line 739; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘axis.scatter‘ with ‘[item[1]["reduction"] for item in subset], [item[1]["columns"] for item in subset], s=[max(25, math.sqrt(item[1]["rows"])) for item in subset], label=arithmetic_name, alpha=0.75‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 739: `s=[max(25, math.sqrt(item[1]["rows"])) for item in subset], label=arithmetic_name, alpha=0.75)` This is continuation line 2 of the 2-line logical statement that begins at source line 738. Its exact fragment is ‘s=[max(25, math.sqrt(item[1]["rows"])) for item in subset], label=arithmetic_name, alpha=0.75)‘. The important operands are s: the value named 's' in this block; max: the value named 'max' in this block; math: the value named 'math' in this block. Read together, the complete operation is: This calls ‘axis.scatter‘ with ‘[item[1]["reduction"] for item in subset], [item[1]["columns"] for item in subset], s=[max(25, math.sqrt(item[1]["rows"])) for item in subset], label=arithmetic_name, alpha=0.75‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 740: `axis.set_xscale("log")` This calls ‘axis.set_xscale‘ with ‘"log"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 741: `axis.set_yscale("log")` This calls ‘axis.set_yscale‘ with ‘"log"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 742: `axis.legend(frameon=False)` This calls ‘axis.legend‘ with ‘frameon=False‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 743: `style_axes(axis, "Matrix shape landscape", "Reduction K", "Output columns N")` This calls ‘style_axes‘ with ‘axis, "Matrix shape landscape", "Reduction K", "Output columns N"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 744: `index = save_figure(figure, plot_dir, pdf, records, index, "matrix_shapes", "Matrix shape landscape",` This statement continues through source line 745; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "matrix_shapes", "Matrix shape landscape", "execution manifest; marker area tracks output-row count")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 745: `"execution manifest; marker area tracks output-row count")` This is continuation line 2 of the 2-line logical statement that begins at source line 744. Its exact fragment is ‘"execution manifest; marker area tracks output-row count")‘. The important operands are execution: the value named 'execution' in this block; manifest: the value named 'manifest' in this block; marker: the value named 'marker' in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "matrix_shapes", "Matrix shape landscape", "execution manifest; marker area tracks output-row count")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 747: `projection_names = [projection["name"] for projection in parameters["projections"]]` This assigns ‘[projection["name"] for projection in parameters["projections"]]‘ to ‘projection_names ‘ in host memory. Here projection_names means the value named ’projection names’ in this block. The important operands are projection: the value named ’projection’ in this block; name: the value named ’name’ in this block; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 748: `weight_scales = [projection["weight_scale"] for projection in parameters["projections"]]` This assigns ‘[projection["weight_scale"] for projection in parameters["projections"]]‘ to ‘weight_scales ‘ in host memory. Here weight_scales means a learned coefficient multiplied by an activation. The important operands are projection: the value named ’projection’ in this block; weight_scale: a learned coefficient multiplied by an activation; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 749: `factor_errors = [projection["represented_factor_maximum_error"] for projection in parameters["proje` This assigns ‘[projection["represented_factor_maximum_error"] for projection in parameters["projections"]]‘ to ‘factor_errors ‘ in host memory. Here factor_errors means the value named ’factor errors’ in this block. The important operands are projection: the value named ’projection’ in this block; represented_factor_maximum_error: the value named ’represented factor maximum error’ in this block; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 750: `figure, axes = plt.subplots(2, 1, figsize=(12, 8), sharex=True)` This assigns ‘plt.subplots(2, 1, figsize=(12, 8), sharex=True)‘ to ‘figure, axes ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 751: `axes[0].plot(weight_scales, marker="o", markersize=3, color=COLORS[0])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; plot: the value named ’plot’ in this block; weight_scales: a learned coefficient multiplied by an activation.

Line 752: `axes[0].set_yscale("log")` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; set_yscale: the real-value spacing represented by one quantized integer step; log: the value named ’log’ in this block.

Line 753: `style_axes(axes[0], "Per-projection INT8 weight scale", ylabel="Scale")` This calls ‘style_axes‘ with ‘axes[0], "Per-projection INT8 weight scale", ylabel="Scale"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 754: `axes[1].plot(factor_errors, marker="o", markersize=3, color=COLORS[2])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; plot: the value named ’plot’ in this block; factor_errors: the value named ’factor errors’ in this block.

Line 755: `axes[1].set_yscale("log")` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; set_yscale: the real-value spacing represented by one quantized integer step; log: the value named ’log’ in this block.

Line 756: `axes[1].set_xticks(range(len(projection_names)), projection_names, rotation=75, ha="right", fontsize=6.5)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and

PDFs. The important operands are axes: the value named 'axes' in this block; set_xticks: the value named 'set xticks' in this block; range: the value named 'range' in this block.

Line 757: `style_axes(axes[1], "Maximum represented requantization-factor error", ylabel="Absolute factor error")` This calls ‘style_axes‘ with ‘axes[1], "Maximum represented requantization-factor error", ylabel="Absolute factor error"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 758: `index = save_figure(figure, plot_dir, pdf, records, index, "projection_quantization", "Projection quantizat...` This statement continues through source line 759; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "projection_quantization", "Projection quantization diagnostics", "hashed hardware parameter manifest")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 759: `"hashed hardware parameter manifest")` This is continuation line 2 of the 2-line logical statement that begins at source line 758. Its exact fragment is ‘"hashed hardware parameter manifest")‘. The important operands are hashed: the value named 'hashed' in this block; hardware: the value named 'hardware' in this block; parameter: the value named 'parameter' in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "projection_quantization", "Projection quantization diagnostics", "hashed hardware parameter manifest")‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 761: `binary_path = root / "outputs/spikingformer_hardware_parameters" / parameters["binary_file"]` This assigns ‘root / "outputs/spikingformer_hardware_parameters" / parameters["binary_file"]‘ to ‘binary_path ‘ in host memory. Here binary_path means the value named 'binary path' in this block. The important operands are root: the value named 'root' in this block; outputs: the value named 'outputs' in this block; spikingformer_hardware_parameters: the value named 'spikingformer hardware parameters' in this block. Context: the function generate, which handles generate.

Line 762: `binary = binary_path.read_bytes()` This assigns ‘binary_path.read_bytes()‘ to ‘binary ‘ in host memory. Here binary means the value named 'binary' in this block. The important operands are binary_path: the value named 'binary path' in this block; read_bytes: the value named 'read bytes' in this block. Context: the function generate, which handles generate.

Line 763: `all_weights: list[np.ndarray] = []` This assigns ‘[]‘ to ‘all_weights‘ in host memory. Here all_weights means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 764: `for projection in parameters["projections"]:` This iterates projection over ‘parameters["projections"]‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate, which handles generate.

Line 765: `section = projection["sections"][0]` This assigns ‘projection["sections"][0]‘ to ‘section ‘ in host memory. Here section means the value named 'section' in this block. The important operands are projection: the value named 'projection' in this block; sections: the value named 'sections' in this block. Context: the function generate, which handles generate.

Line 766: `if "weight" in section["name"] and section["dtype"] == "|i1":` This executes the following indented host-code branch only when ‘"weight" in section["name"] and section["dtype"] == "|i1"‘ is true. The important operands are weight: a learned coefficient multiplied by an activation; in: the value named 'in' in this block; section: the value named 'section' in this block. Context: the function generate, which handles generate.

Line 767: `all_weights.append(np.frombuffer(binary, dtype=np.int8, count=section["length"], offset=section["of` This calls ‘all_weights.append‘ with ‘np.frombuffer(binary, dtype=np.int8, count=section["length"], offset=section["offset"])‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 768: `head_section = parameters["head"]["sections"][0]` This assigns ‘parameters["head"]["sections"][0]‘ to ‘head_section ‘ in host memory. Here head_section means the value named ’head section’ in this block. The important operands are parameters: the value named ’parameters’ in this block; head: the value named ’head’ in this block; sections: the value named ’sections’ in this block. Context: the function generate, which handles generate.

Line 769: `all_weights.append(np.frombuffer(binary, dtype=np.int8, count=head_section["length"], offset=head_s` This calls ‘all_weights.append‘ with ‘np.frombuffer(binary, dtype=np.int8, count=head_section["length"], offset=head_section["offs inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 770: `weight_values = np.concatenate(all_weights)` This assigns ‘np.concatenate(all_weights)‘ to ‘weight_values ‘ in host memory. Here weight_values means a learned coefficient multiplied by an activation. The important operands are concatenate: the value named ’concatenate’ in this block; all_weights: a learned coefficient multiplied by an activation. Context: the function generate, which handles generate.

Line 771: `figure, axes = plt.subplots(1, 2, figsize=(12, 5.2))` This assigns ‘plt.subplots(1, 2, figsize=(12, 5.2))‘ to ‘figure, axes ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 772: `axes[0].hist(weight_values, bins=np.arange(-128.5, 128.5), color=COLORS[0])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; hist: the value named ’hist’ in this block; weight_values: a learned coefficient multiplied by an activation.

Line 773: `axes[0].set_yscale("log")` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; set_yscale: the real-value spacing represented by one quantized integer step; log: the value named ’log’ in this block.

Line 774: `style_axes(axes[0], "All exported INT8 weights", "Integer weight", "Count (log)")` This calls ‘style_axes‘ with ‘axes[0], "All exported INT8 weights", "Integer weight", "Count (log)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 775: `unique, counts = np.unique(weight_values, return_counts=True)` This assigns ‘np.unique(weight_values, return_counts=True)‘ to ‘unique, counts ‘ in host memory. Here unique means the value named ’unique’ in this block. The important operands are unique: the value named ’unique’ in this block; weight_values: a learned coefficient multiplied by an activation; return_counts: the value named ’return counts’ in this block. Context: the function generate, which handles generate.

Line 776: `top = np.argsort(counts)[-20:]` This assigns ‘np.argsort(counts)[-20:]‘ to ‘top ‘ in host memory. Here top means the value named ’top’ in this block. The important operands are argsort: the value named ’argsort’ in this block; counts: the value named ’counts’ in this block. Context: the function generate, which handles generate.

Line 777: `axes[1].bar(unique[top].astype(str), counts[top], color=COLORS[1])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes:

the value named 'axes' in this block; bar: the value named 'bar' in this block; unique: the value named 'unique' in this block.

Line 778: `axes[1].tick_params(axis="x", rotation=60)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; tick_params: the value named 'tick params' in this block; axis: the value named 'axis' in this block.

Line 779: `style_axes(axes[1], "Twenty most frequent codes", "Integer weight", "Count")` This calls 'style_axes' with 'axes[1], "Twenty most frequent codes", "Integer weight", "Count"' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 780: `index = save_figure(figure, plot_dir, pdf, records, index, "weight_distribution", "Exported weight distribu...` This statement continues through source line 781; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'save_figure(figure, plot_dir, pdf, records, index, "weight_distribution", "Exported weight distribution", "direct section views from the SHA-256-checked parameter binary")' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 781: `"direct section views from the SHA-256-checked parameter binary")` This is continuation line 2 of the 2-line logical statement that begins at source line 780. Its exact fragment is '"direct section views from the SHA-256-checked parameter binary")'. The important operands are direct: the value named 'direct' in this block; section: the value named 'section' in this block; views: the value named 'views' in this block. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "weight_distribution", "Exported weight distribution", "direct section views from the SHA-256-checked parameter binary")' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 783: `figure, axes = plt.subplots(1, 2, figsize=(11, 5))` This assigns 'plt.subplots(1, 2, figsize=(11, 5))' to 'figure, axes ' in host memory. Here figure means the value named 'figure' in this block. The important operands are plt: the value named 'plt' in this block; subplots: the value named 'subplots' in this block; figsize: the value named 'figsize' in this block. Context: the function generate, which handles generate.

Line 784: `names = ["scalar packer", "vectorized packer"]` This assigns '["scalar packer", "vectorized packer"]' to 'names ' in host memory. Here names means the value named 'names' in this block. The important operands are scalar: the value named 'scalar' in this block; packer: the value named 'packer' in this block; vectorized: the value named 'vectorized' in this block. Context: the function generate, which handles generate.

Line 785: `seconds = [95.601, compiler_benchmark["compile_seconds"]]` This assigns '[95.601, compiler_benchmark["comp to 'seconds ' in host memory. Here seconds means the value named 'seconds' in this block. The important operands are compiler_benchmark: the value named 'compiler benchmark' in this block; compile_seconds: the value named 'compile seconds' in this block. Context: the function generate, which handles generate.

Line 786: `peaks = [71.468169, compiler_benchmark["tracemalloc_peak_bytes"] / 1e6]` This assigns '[71.468169, compiler_benchmark["tracemalloc_peak_bytes"] / 1e6]' to 'peaks ' in host memory. Here peaks means the value named 'peaks' in this block. The important operands are compiler_benchmark: the value named 'compiler benchmark' in this block; tracemalloc_peak_bytes: the value named 'tracemalloc peak bytes' in this block. Context: the function generate, which handles generate.

Line 787: `axes[0].bar(names, seconds, color=[COLORS[2], COLORS[1]])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests,

XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; bar: the value named 'bar' in this block; names: the value named 'names' in this block.

Line 788: `axes[0].set_yscale("log")` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; set_yscale: the real-value spacing represented by one quantized integer step; log: the value named 'log' in this block.

Line 789: `style_axes(axes[0], "Block-3 compile time", ylabel="Seconds (log)")` This calls 'style_axes' with 'axes[0], "Block-3 compile time", ylabel="Seconds (log)"' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 790: `axes[1].bar(names, peaks, color=[COLORS[2], COLORS[1]])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; bar: the value named 'bar' in this block; names: the value named 'names' in this block.

Line 791: `style_axes(axes[1], "Peak traced memory", ylabel="MB")` This calls 'style_axes' with 'axes[1], "Peak traced memory", ylabel="MB"' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 792: `index = save_figure(figure, plot_dir, pdf, records, index, "compiler_benchmark", "Largest-layer compiler be...` This statement continues through source line 793; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'save_figure(figure, plot_dir, pdf, records, index, "compiler_benchmark", "Largest-layer compiler benchmark", "recorded scalar baseline and outputs/benchmarks/compiler_block3_memory.json")' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 793: `"recorded scalar baseline and outputs/benchmarks/compiler_block3_memory.json")` This is continuation line 2 of the 2-line logical statement that begins at source line 792. Its exact fragment is '"recorded scalar baseline and outputs/benchmarks/compiler_block3_memory.json")'. The important operands are recorded: the value named 'recorded' in this block; scalar: the value named 'scalar' in this block; baseline: the value named 'baseline' in this block. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "compiler_benchmark", "Largest-layer compiler benchmark", "recorded scalar baseline and outputs/benchmarks/compiler_block3_memo to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 795: `if training_coverage:` This executes the following indented host-code branch only when 'training_coverage' is true. The important operands are training_coverage: the value named 'training coverage' in this block. Context: the function generate, which handles generate.

Line 796: `training_summary = training_coverage["summary"]` This assigns 'training_coverage["summary"]' to 'training_summary ' in host memory. Here training_summary means the value named 'training summary' in this block. The important operands are training_coverage: the value named 'training coverage' in this block; summary: the value named 'summary' in this block. Context: the function generate, which handles generate.

Line 797: `semantics = training_coverage["training_semantics"]` This assigns 'training_coverage["training_semantics"]' to 'semantics ' in host memory. Here semantics means the value named 'semantics' in this block. The important operands are training_coverage: the value named 'training coverage' in this block; training_semantics: the value named 'training semantics' in this block. Context: the function generate, which handles generate.

Line 798: `training_lines = [` This statement continues through source line 810; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘[f"Target: {semantics['target_graph']}", f"Execution operators covered: {training_summary['covered_execution_operator_count']}/{training_summary['execution_operator_count']} uncovered {training_summary['uncovered_operator_count']}", f"Learned affine groups / dynamic attention products: {training_summary['learned_affine_group_count']} / {training_summary['dynamic_attention_matmul_count']}", f"Trainable deployed parameter elements: {training_summary['trainable_deployed_parameter_elements']:,}", f"Backward partial tiles / signed multiplications: {training_summary['total_backward_partial_tiles']:,} / {(training_summary['learned_backward_m + training_summary['dynamic_backward_multiplications']):,}", f"Fabric SGDW update commands: {training_summary['sgdw_up f"Quantizer derivative: {semantics['quantizer_gradient']}", f"LIF derivative: {semantics['lif_gradient']}", f"Temporal schedule: {semantics['temporal_method']}", f"Optimizer: {semantics['optimizer']}", f"Parameter residency: {semantics['parameter_residency']}",]‘ to ‘training_lines ‘ in host memory. Here training_lines means the value named ’training lines’ in this block. The important operands are f: the value named ’f’ in this block; Target: the value named ’target’ in this block; semantics: the value named ’semantics’ in this block. Context: the function generate, which handles generate.

Line 799: `f"Target: {semantics['target_graph']}",` This is continuation line 2 of the 13-line logical statement that begins at source line 798. Its exact fragment is ‘f"Target: {semantics['target_graph']}",‘. The important operands are f: the value named ’f’ in this block; Target: the value named ’target’ in this block; semantics: the value named ’semantics’ in this block. Read together, the complete operation is: This assigns ‘[f"Target: {semantics['target_graph']}", f"Execution operators covered: {training_summary['covered_execution_operator_count']}/{training_summary['execution_operator_count']} uncovered {training_summary['uncovered_operator_count']}", f"Learned affine groups / dynamic attention products: {training_summary['learned_affine_group_count']} / {training_summary['dynamic_attention_matmul_count']}", f"Trainable deployed parameter elements: {training_summary['trainable_deployed_parameter_elements']:,}", f"Backward partial tiles / signed multiplications: {training_summary['total_backward_partial_tiles']:,} / {(training_summary['learned_backward_m + training_summary['dynamic_backward_multiplications']):,}", f"Fabric SGDW update commands: {training_summary['sgdw_up f"Quantizer derivative: {semantics['quantizer_gradient']}", f"LIF derivative: {semantics['lif_gradient']}", f"Temporal schedule: {semantics['temporal_method']}", f"Optimizer: {semantics['optimizer']}", f"Parameter residency: {semantics['parameter_residency']}",]‘ to ‘training_lines ‘ in host memory. Here training_lines means the value named ’training lines’ in this block. The important operands are f: the value named ’f’ in this block; Target: the value named ’target’ in this block; semantics: the value named ’semantics’ in this block. Context: the function generate, which handles generate.

Line 800: `f"Execution operators covered: {training_summary['covered_execution_operator_count']}/{training_su`
This is continuation line 3 of the 13-line logical statement that begins at source line 798. Its exact fragment is ‘f"Execution operators covered: {training_summary['covered_execution_operator_count']}/{training_summary['execution_operator_count']} uncovered {training_summary['uncovered_operator_count']}",‘. Context: the function generate, which handles generate.

Line 811: `figure = text_page("Full-Backbone Training Schedule", training_lines)` This assigns ‘text_page("Full-Backbone Training Schedule", training_lines)‘ to ‘figure ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are text_page: the value named ’text page’ in this block; Full: the value named ’full’ in this block; Backbone: the value named ’backbone’ in this block. Context: the function generate, which handles generate.

Line 812: `index = save_figure(` This statement continues through source line 815; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_schedule", "Full-backbone training schedule and numeric contract", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 813: `figure, plot_dir, pdf, records, index, "training_schedule",` This is continuation line 2 of the 4-line logical statement that begins at source line 812. Its exact fragment is ‘figure, plot_dir, pdf, records, index,

"training_schedule",‘. The important operands are figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block; pdf: the value named ’pdf’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_schedule", "Full-backbone training schedule and numeric contract", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 814: `"Full-backbone training schedule and numeric contract", str(training_coverage_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 812. Its exact fragment is ‘"Full-backbone training schedule and numeric contract", str(training_coverage_path),‘. The important operands are Full: the value named ’full’ in this block; backbone: the value named ’backbone’ in this block; training: the value named ’training’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_schedule", "Full-backbone training schedule and numeric contract", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 815: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 812. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_schedule", "Full-backbone training schedule and numeric contract", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 817: `learned = training_coverage["learned_affine_coverage"]` This assigns ‘training_coverage["learned_affine_cov to ‘learned ‘ in host memory. Here learned means the value named ’learned’ in this block. The important operands are training_coverage: the value named ’training coverage’ in this block; learned_affine_coverage: the value named ’learned affine coverage’ in this block. Context: the function generate, which handles generate.

Line 818: `learned_names = [item["name"] for item in learned]` This assigns ‘[item["name"] for item in learned]‘ to ‘learned_names ‘ in host memory. Here learned_names means the value named ’learned names’ in this block. The important operands are item: the value named ’item’ in this block; name: the value named ’name’ in this block; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 819: `weight_elements = np.asarray([item["weight_elements"] for item in learned], dtype=np.int64)` This assigns ‘np.asarray([item["weight_elements"] for item in learned], dtype=np.int64)‘ to ‘weight_elements ‘ in host memory. Here weight_elements means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; item: the value named ’item’ in this block; weight_elements: a learned coefficient multiplied by an activation. Context: the function generate, which handles generate.

Line 820: `bias_elements = np.asarray([item["bias_elements"] for item in learned], dtype=np.int64)` This assigns ‘np.asarray([item["bias_elements"] for item in learned], dtype=np.int64)‘ to ‘bias_elements ‘ in host memory. Here bias_elements means an additive learned offset applied after accumulation. The important operands are asarray: the value named ’asarray’ in this block; item: the value named ’item’ in this block; bias_elements: an additive learned offset applied after accumulation. Context: the function generate, which handles generate.

Line 821: `order = np.argsort(weight_elements + bias_elements)` This assigns ‘np.argsort(weight_elements + bias_elements)‘ to ‘order ‘ in host memory. Here order means the value named ’order’ in this block. The important operands are argsort: the value named ’argsort’ in this block; weight_elements: a learned coefficient multiplied by an activation; bias_elements: an additive learned offset applied after accumulation. Context: the function generate, which handles generate.

Line 822: `figure, axis = plt.subplots(figsize=(12, 8.5))` This assigns ‘plt.subplots(figsize=(12, 8.5))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 823: `axis.barh(np.arange(len(order)), weight_elements[order], label="weight", color=COLORS[0])` This calls ‘axis.barh‘ with ‘np.arange(len(order)), weight_elements[order], label="weight", color=COLORS[0]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 824: `axis.barh(` This statement continues through source line 827; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘axis.barh‘ with ‘ np.arange(len(order)), bias_elements[order], left=weight_elements[order], label="bias", color=COLORS[3], ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 825: `np.arange(len(order)), bias_elements[order], left=weight_elements[order],` This is continuation line 2 of the 4-line logical statement that begins at source line 824. Its exact fragment is ‘np.arange(len(order)), bias_elements[order], left=weight_elements[order],‘. The important operands are arange: the value named ’arange’ in this block; len: the value named ’len’ in this block; order: the value named ’order’ in this block. Read together, the complete operation is: This calls ‘axis.barh‘ with ‘ np.arange(len(order)), bias_elements[order], left=weight_elements[order], label="bias", color=COLORS[3], ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 826: `label="bias", color=COLORS[3],` This is continuation line 3 of the 4-line logical statement that begins at source line 824. Its exact fragment is ‘label="bias", color=COLORS[3],‘. The important operands are label: the value named ’label’ in this block; bias: an additive learned offset applied after accumulation; color: the value named ’color’ in this block. Read together, the complete operation is: This calls ‘axis.barh‘ with ‘ np.arange(len(order)), bias_elements[order], left=weight_elements[order], label="bias", color=COLORS[3], ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 827: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 824. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘axis.barh‘ with ‘ np.arange(len(order)), bias_elements[order], left=weight_elements[order], label="bias", color=COLORS[3], ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 828: `axis.set_yticks(np.arange(len(order)), [learned_names[item] for item in order], fontsize=7)` This calls ‘axis.set_yticks‘ with ‘np.arange(len(order)), [learned_names[item] for item in order], fontsize=7‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 829: `axis.set_xscale("log")` This calls ‘axis.set_xscale‘ with ‘"log"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 830: `axis.legend(frameon=False)` This calls ‘axis.legend‘ with ‘frameon=False‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 831: `style_axes(axis, "Trainable deployed parameters by affine group", "Parameter elements (log)")` This calls ‘style_axes‘ with ‘axis, "Trainable deployed parameters by affine group", "Parameter elements (log)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 832: `index = save_figure(` This statement continues through source line 835; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_parameters", "Trainable deployed parameter distribution", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 833: `figure, plot_dir, pdf, records, index, "training_parameters",` This is continuation line 2 of the 4-line logical statement that begins at source line 832. Its exact fragment is ‘figure, plot_dir, pdf, records, index, "training_parameters",‘. The important operands are figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block; pdf: the value named ’pdf’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_parameters", "Trainable deployed parameter distribution", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 834: `"Trainable deployed parameter distribution", str(training_coverage_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 832. Its exact fragment is ‘"Trainable deployed parameter distribution", str(training_coverage_path),‘. The important operands are Trainable: the value named ’trainable’ in this block; deployed: the value named ’deployed’ in this block; parameter: the value named ’parameter’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_parameters", "Trainable deployed parameter distribution", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 835: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 832. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_parameters", "Trainable deployed parameter distribution", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 837: `backward_tiles = np.asarray(` This statement continues through source line 839; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.asarray([item["backward_partial_tiles"] for item in learned], dtype=np.int64)‘ to ‘backward_tiles ‘ in host memory. Here backward_tiles means the value named ’backward tiles’ in this block. The important operands are asarray: the value named ’asarray’ in this block; item: the value named ’item’ in this block; backward_partial_tiles: the value named ’backward partial tiles’ in this block. Context: the function generate, which handles generate.

Line 838: `[item["backward_partial_tiles"] for item in learned], dtype=np.int64` This is continuation line 2 of the 3-line logical statement that begins at source line 837. Its exact fragment is ‘[item["backward_partial_tiles"] for item in learned], dtype=np.int64‘. The important operands are item: the value named ’item’ in this block; backward_partial_tiles: the value named ’backward partial tiles’ in this block; for: the value named ’for’ in this block. Read together, the complete operation is: This assigns ‘np.asarray([item["backward_partial_tiles"] for item in learned], dtype=np.int64)‘ to ‘backward_tiles ‘ in host memory. Here backward_tiles means the value named ’backward tiles’ in this block. The important operands are asarray: the value named ’asarray’ in this block; item: the value named ’item’ in this block; backward_partial_tiles: the value named ’backward partial tiles’ in this block. Context: the function generate, which handles generate.

Line 839: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 837. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.asarray([item["backward_partial_tiles"] for item in learned], dtype=np.int64)‘ to ‘backward_tiles ‘ in host memory. Here backward_tiles means the value named ’backward tiles’ in this block. The important operands are asarray: the value named ’asarray’ in this block; item: the value named ’item’ in this block; backward_partial_tiles: the value named ’backward partial tiles’ in this block. Context: the function generate, which handles generate.

Line 840: `backward_multiplies = np.asarray(` This statement continues through source line 842; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.asarray([item["backward_multiplications"] for item in learned], dtype=np.int64)‘ to ‘backward_multiplies ‘ in host memory. Here backward_multiplies means the value named ’backward multiplies’ in this block. The important operands are asarray: the value named ’asarray’ in this block; item: the value named ’item’ in this block; backward_multiplications: the value named ’backward multiplications’ in this block. Context: the function generate, which handles generate.

Line 841: `[item["backward_multiplications"] for item in learned], dtype=np.int64` This is continuation line 2 of the 3-line logical statement that begins at source line 840. Its exact fragment is ‘[item["backward_multiplications"] for item in learned], dtype=np.int64‘. The important operands are item: the value named ’item’ in this block; backward_multiplications: the value named ’backward multiplications’ in this block; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 843: `order = np.argsort(backward_multiplies)` This assigns ‘np.argsort(backward_multiplies)‘ to ‘order ‘ in host memory. Here order means the value named ’order’ in this block. The important operands are argsort: the value named ’argsort’ in this block; backward_multiplies: the value named ’backward multiplies’ in this block. Context: the function generate, which handles generate.

Line 844: `figure, axes = plt.subplots(1, 2, figsize=(14, 9), sharey=True)` This assigns ‘plt.subplots(1, 2, figsize=(14, 9), sharey=True)‘ to ‘figure, axes ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 845: `y = np.arange(len(order))` This assigns ‘np.arange(len(order))‘ to ‘y ‘ in host memory. Here y means the value named ’y’ in this block. The important operands are arange: the value named ’arange’ in this block; len: the value named ’len’ in this block; order: the value named ’order’ in this block. Context: the function generate, which handles generate.

Line 846: `axes[0].barh(y, backward_tiles[order], color=COLORS[1])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; barh: the value named ’barh’ in this block; y: the value named ’y’ in this block.

Line 847: `axes[0].set_yticks(y, [learned_names[item] for item in order], fontsize=7)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions,

compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; set_yticks: the value named 'set yticks' in this block; y: the value named 'y' in this block.

Line 848: `axes[0].set_xscale("log")` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; set_xscale: the real-value spacing represented by one quantized integer step; log: the value named 'log' in this block.

Line 849: `style_axes(axes[0], "Backward partial tiles", "Tiles per sample (log)")` This calls ‘style_axes‘ with ‘axes[0], "Backward partial tiles", "Tiles per sample (log)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 850: `axes[1].barh(y, backward_multiplies[order], color=COLORS[2])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; barh: the value named 'barh' in this block; y: the value named 'y' in this block.

Line 851: `axes[1].set_xscale("log")` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; set_xscale: the real-value spacing represented by one quantized integer step; log: the value named 'log' in this block.

Line 852: `style_axes(axes[1], "Signed backward multiplications", "Multiplications per sample (log)")` This calls ‘style_axes‘ with ‘axes[1], "Signed backward multiplications", "Multiplications per sample (log)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 853: `index = save_figure(` This statement continues through source line 856; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_backward_work", "Exact learned-layer backward work", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 854: `figure, plot_dir, pdf, records, index, "training_backward_work",` This is continuation line 2 of the 4-line logical statement that begins at source line 853. Its exact fragment is ‘figure, plot_dir, pdf, records, index, "training_backward_work",‘. The important operands are figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block; pdf: the value named 'pdf' in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_backward_work", "Exact learned-layer backward work", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 855: `"Exact learned-layer backward work", str(training_coverage_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 853. Its exact fragment is ‘"Exact learned-layer backward work", str(training_coverage_path),‘. The important operands are Exact: the value named 'exact' in this block; learned: the value named 'learned' in this block; layer: the value named 'layer' in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_backward_work", "Exact learned-layer backward work", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 856: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 853. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_backward_work", "Exact learned-layer backward work", str(training_coverage_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 858: `backward_sites = {` This statement continues through source line 865; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "affine dX/dW/dB": training_summary["learned_affine_group_
"dynamic QK/AV": training_summary["dynamic_attention_matmul_count"], "LIF surrogate": training_summary["lif_node_coun
"max-pool scatter": training_summary["maxpool_backward_count"], "residual fan-out": training_summary["residual_gradient_fa
"global pool": 1, }‘ to ‘backward_sites ‘ in host memory. Here backward_sites means the value named ’backward sites’ in this block. The important operands are affine: the value named ’affine’ in this block; dX: the value named ’d x’ in this block; dW: the value named ’d w’ in this block. Context: the function generate, which handles generate.

Line 859: `"affine dX/dW/dB": training_summary["learned_affine_group_count"],` This is continuation line 2 of the 8-line logical statement that begins at source line 858. Its exact fragment is ‘"affine dX/dW/dB": training_summary["learned_affine_group_count"],‘. The important operands are affine: the value named ’affine’ in this block; dX: the value named ’d x’ in this block; dW: the value named ’d w’ in this block. Read together, the complete operation is: This assigns ‘{ "affine dX/dW/dB": training_summary["learned_affine_group_count"], "dynamic QK/AV": training_summary["dynamic_attention_matmul_count"], "LIF surrogate": training_summary["lif_node_count"], "max-pool scatter": training_summary["maxpool_backward_count"], "residual fan-out": training_summary["residual_gradient_fanout_coun
"global pool": 1, }‘ to ‘backward_sites ‘ in host memory. Here backward_sites means the value named ’backward sites’ in this block. The important operands are affine: the value named ’affine’ in this block; dX: the value named ’d x’ in this block; dW: the value named ’d w’ in this block. Context: the function generate, which handles generate.

Line 860: `"dynamic QK/AV": training_summary["dynamic_attention_matmul_count"],` This is continuation line 3 of the 8-line logical statement that begins at source line 858. Its exact fragment is ‘"dynamic QK/AV": training_summary["dynamic_attention_matmul_count"],‘. The important operands are dynamic: the value named ’dynamic’ in this block; QK: the value named ’qk’ in this block; AV: the value named ’av’ in this block. Read together, the complete operation is: This assigns ‘{ "affine dX/dW/dB": training_summary["learned_affine_group_count"], "dynamic QK/AV": training_summary["dynamic_attention_matmul_count"], "LIF surrogate": training_summary["lif_node_count"], "max-pool scatter": training_summary["maxpool_backward_count"], "residual fan-out": training_summary["residual_gradient_fanout_
"global pool": 1, }‘ to ‘backward_sites ‘ in host memory. Here backward_sites means the value named ’backward sites’ in this block. The important operands are affine: the value named ’affine’ in this block; dX: the value named ’d x’ in this block; dW: the value named ’d w’ in this block. Context: the function generate, which handles generate.

Line 861: `"LIF surrogate": training_summary["lif_node_count"],` This is continuation line 4 of the 8-line logical statement that begins at source line 858. Its exact fragment is ‘"LIF surrogate": training_summary["lif_node_count"],‘. The important operands are LIF: the value named ’lif’ in this block; surrogate: the value named ’surrogate’ in this block; training_summary: the value named ’training summary’ in this block. Read together, the complete operation is: This assigns ‘{ "affine dX/dW/dB": training_summary["learned_affine_group_count"], "dynamic QK/AV": training_summary["dynamic_attention_matmul_count"], "LIF surrogate": training_summary["lif_node_count"], "max-pool scatter": training_summary["maxpool_backward_count"], "residual fan-out": training_summary["residual_gradient_fanout_coun
"global pool": 1, }‘ to ‘backward_sites ‘ in host memory. Here backward_sites means the value named ’backward sites’ in this block. The important operands are affine: the value named ’affine’ in this block; dX: the value named ’d x’ in this block; dW: the value named ’d w’ in this block. Context: the function generate, which handles generate.

Line 862: `"max-pool scatter": training_summary["maxpool_backward_count"],` This is continuation line 5 of the 8-line logical statement that begins at source line 858. Its exact fragment is ‘"max-pool scatter": training_summary["maxpool_ba
The important operands are max: the value named ’max’ in this block; pool: the value named ’pool’ in this block; scatter: the value named ’scatter’ in this block. Read together, the complete operation is: This assigns ‘{ "affine dX/dW/dB": training_summary["learned_affine_group_count"], "dynamic QK/AV": training_summary["dynamic_attention_matmul_count"], "LIF surrogate": training_summary["lif_node_count"], "max-pool scatter": training_summary["maxpool_backward_count"], "residual fan-out": training_summary["residual_gradient_fanout_count"], "global pool": 1, }‘ to ‘backward_sites ‘ in host memory. Here backward_sites means the value named ’backward sites’ in this block. The important operands are

affine: the value named 'affine' in this block; dX: the value named 'd x' in this block; dW: the value named 'd w' in this block. Context: the function generate, which handles generate.

Line 863: `"residual fan-out": training_summary["residual_gradient_fanout_count"],` This is continuation line 6 of the 8-line logical statement that begins at source line 858. Its exact fragment is '"residual fan-out": training_summary["residual_gradient_fanout_count"],'. The important operands are residual: the value named 'residual' in this block; fan: the value named 'fan' in this block; out: the value named 'out' in this block. Read together, the complete operation is: This assigns '{ "affine dX/dW/dB": training_summary["learned_affine_group_count"], "dynamic QK/AV": training_summary["dynamic_attention_matmul_count"], "LIF surrogate": training_summary["lif_node_count"], "max-pool scatter": training_summary["maxpool_backward_count"], "residual fan-out": training_summary["residual_gradient_fanout_ "global pool": 1, }' to 'backward_sites ' in host memory. Here backward_sites means the value named 'backward sites' in this block. The important operands are affine: the value named 'affine' in this block; dX: the value named 'd x' in this block; dW: the value named 'd w' in this block. Context: the function generate, which handles generate.

Line 864: `"global pool": 1,` This is continuation line 7 of the 8-line logical statement that begins at source line 858. Its exact fragment is '"global pool": 1,'. The important operands are global: the value named 'global' in this block; pool: the value named 'pool' in this block. Read together, the complete operation is: This assigns '{ "affine dX/dW/dB": training_summary["learned_affine_group_count"], "dynamic QK/AV": training_summary["dynamic_attention_matmul_count"], "LIF surrogate": training_summary["lif_node_count"], "max-pool scatter": training_summary["maxpool_backward_count"], "residual fan-out": training_summary["residual_gradient_fanout_count"], "global pool": 1, }' to 'backward_sites ' in host memory. Here backward_sites means the value named 'backward sites' in this block. The important operands are affine: the value named 'affine' in this block; dX: the value named 'd x' in this block; dW: the value named 'd w' in this block. Context: the function generate, which handles generate.

Line 865: `}` This is continuation line 8 of the 8-line logical statement that begins at source line 858. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '{ "affine dX/dW/dB": training_summary["learned_affine_group_count"], "dynamic QK/AV": training_summary["dynamic_attention_matmul_count"], "LIF surrogate": training_summary["lif_node_count"], "max-pool scatter": training_summary["maxpool_backward_count"], "residual fan-out": training_summary["residual_gradient_fanout_ "global pool": 1, }' to 'backward_sites ' in host memory. Here backward_sites means the value named 'backward sites' in this block. The important operands are affine: the value named 'affine' in this block; dX: the value named 'd x' in this block; dW: the value named 'd w' in this block. Context: the function generate, which handles generate.

Line 866: `figure, axes = plt.subplots(1, 2, figsize=(12.5, 5.8))` This assigns 'plt.subplots(1, 2, figsize=(12.5, 5.8))' to 'figure, axes ' in host memory. Here figure means the value named 'figure' in this block. The important operands are plt: the value named 'plt' in this block; subplots: the value named 'subplots' in this block; figsize: the value named 'figsize' in this block. Context: the function generate, which handles generate.

Line 867: `axes[0].bar(` This statement continues through source line 870; the explanation uses the complete expression rather than only the first visual fragment. Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; bar: the value named 'bar' in this block; arange: the value named 'arange' in this block.

Line 868: `np.arange(len(backward_sites)), list(backward_sites.values()),` This is continuation line 2 of the 4-line logical statement that begins at source line 867. Its exact fragment is 'np.arange(len(backward_sites)), list(backward_sites.values()),'. The important operands are arange: the value named 'arange' in this block; len: the value named 'len' in this block; backward_sites: the value named 'backward sites' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; bar: the value named 'bar' in this block; arange: the value named 'arange' in this block.

Line 869: `color=COLORS[:len(backward_sites)],` This is continuation line 3 of the 4-line logical statement that begins at source line 867. Its exact fragment is 'color=COLORS[:len(backward_sites)],'. The important operands are color: the value named 'color' in this block; COLORS: the value named 'colors' in this block; len: the value named

'len' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; bar: the value named 'bar' in this block; arange: the value named 'arange' in this block.

Line 870: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 867. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; bar: the value named 'bar' in this block; arange: the value named 'arange' in this block.

Line 871: `axes[0].set_xticks(` This statement continues through source line 873; the explanation uses the complete expression rather than only the first visual fragment. Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; set_xticks: the value named 'set xticks' in this block; arange: the value named 'arange' in this block.

Line 872: `np.arange(len(backward_sites)), list(backward_sites), rotation=35, ha="right"` This is continuation line 2 of the 3-line logical statement that begins at source line 871. Its exact fragment is 'np.arange(len(backward_sites)), list(backward_sites), rotation=35, ha="right"'. The important operands are arange: the value named 'arange' in this block; len: the value named 'len' in this block; backward_sites: the value named 'backward sites' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; set_xticks: the value named 'set xticks' in this block; arange: the value named 'arange' in this block.

Line 873: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 871. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; set_xticks: the value named 'set xticks' in this block; arange: the value named 'arange' in this block.

Line 874: `style_axes(axes[0], "Implemented backward sites", ylabel="Site count")` This calls 'style_axes' with 'axes[0], "Implemented backward sites", ylabel="Site count"' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 875: `work_labels = ["learned affine", "dynamic attention"]` This assigns '["learned affine", "dynamic attention"]' to 'work_labels ' in host memory. Here work_labels means the value named 'work labels' in this block. The important operands are learned: the value named 'learned' in this block; affine: the value named 'affine' in this block; dynamic: the value named 'dynamic' in this block. Context: the function generate, which handles generate.

Line 876: `work_values = [` This statement continues through source line 879; the explanation uses the complete expression rather than only the first visual fragment. This assigns '[training_summary["learned_backward_multiplications"], training_summary["dynamic_backward_multiplications"],]' to 'work_values ' in host memory. Here work_values means the value named 'work values' in this block. The important operands are training_summary: the value named 'training summary' in this block; learned_backward_multiplications: the value named 'learned backward multiplications' in this block; dynamic_backward_multiplications: the value named 'dynamic backward multiplications' in this block. Context: the function generate, which handles generate.

Line 877: `training_summary["learned_backward_multiplications"],` This is continuation line 2 of the 4-line logical statement that begins at source line 876. Its exact fragment is 'training_summary["learned_backward_multiplications"],'. The important operands are training_summary: the value named 'training summary' in this block; learned_backward_multiplicatio

the value named 'learned backward multiplications' in this block. Read together, the complete operation is: This assigns '[training_summary["learned_backward_multiplications"], training_summary["dynamic_backward_multiplications"],]' to 'work_values ' in host memory. Here work_values means the value named 'work values' in this block. The important operands are training_summary: the value named 'training summary' in this block; learned_backward_multiplications: the value named 'learned backward multiplications' in this block; dynamic_backward_multiplications: the value named 'dynamic backward multiplications' in this block. Context: the function generate, which handles generate.

Line 878: `training_summary["dynamic_backward_multiplications"],` This is continuation line 3 of the 4-line logical statement that begins at source line 876. Its exact fragment is 'training_summary["dynamic_backward_multiplications"],'. The important operands are training_summary: the value named 'training summary' in this block; dynamic_backward_multiplicati the value named 'dynamic backward multiplications' in this block. Read together, the complete operation is: This assigns '[training_summary["learned_backward_multiplications"], training_summary["dynamic_backward_multiplications"],]' to 'work_values ' in host memory. Here work_values means the value named 'work values' in this block. The important operands are training_summary: the value named 'training summary' in this block; learned_backward_multiplications: the value named 'learned backward multiplications' in this block; dynamic_backward_multiplications: the value named 'dynamic backward multiplications' in this block. Context: the function generate, which handles generate.

Line 879: `]` This is continuation line 4 of the 4-line logical statement that begins at source line 876. Its exact fragment is ']'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '[training_summary["learned_backward_multiplications"], training_summary["dynamic_backward_multiplica]' to 'work_values ' in host memory. Here work_values means the value named 'work values' in this block. The important operands are training_summary: the value named 'training summary' in this block; learned_backward_multiplications: the value named 'learned backward multiplications' in this block; dynamic_backward_multiplications: the value named 'dynamic backward multiplications' in this block. Context: the function generate, which handles generate.

Line 880: `axes[1].pie(` This statement continues through source line 883; the explanation uses the complete expression rather than only the first visual fragment. Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; pie: the value named 'pie' in this block; work_values: the value named 'work values' in this block.

Line 881: `work_values, labels=work_labels, autopct="%1.2f%%", colors=[COLORS[0], COLORS[3]],` This is continuation line 2 of the 4-line logical statement that begins at source line 880. Its exact fragment is 'work_values, labels=work_labels, autopct="%1.2f%%", colors=[COLORS[0], COLORS[3]],'. The important operands are work_values: the value named 'work values' in this block; labels: the value named 'labels' in this block; work_labels: the value named 'work labels' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; pie: the value named 'pie' in this block; work_values: the value named 'work values' in this block.

Line 882: `startangle=90, wedgeprops={"linewidth": 0.7, "edgecolor": "white"},` This is continuation line 3 of the 4-line logical statement that begins at source line 880. Its exact fragment is 'startangle=90, wedgeprops={"linewidth": 0.7, "edgecolor": "white"},'. The important operands are startangle: the value named 'startangle' in this block; wedgeprops: the value named 'wedgeprops' in this block; linewidth: the value named 'linewidth' in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; pie: the value named 'pie' in this block; work_values: the value named 'work values' in this block.

Line 883: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 880. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; pie: the value named 'pie' in this block; work_values: the value named 'work values' in this block.

Line 884: `axes[1].set_title("Backward multiplication share", fontsize=13, fontweight="bold")` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; set_title: the value named 'set title' in this block; Backward: the value named 'backward' in this block.

Line 885: `index = save_figure(` This statement continues through source line 888; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'save_figure(figure, plot_dir, pdf, records, index, "training_operator_coverage", "Backward operator coverage and work composition", str(training_coverage_path),)' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 886: `figure, plot_dir, pdf, records, index, "training_operator_coverage",` This is continuation line 2 of the 4-line logical statement that begins at source line 885. Its exact fragment is 'figure, plot_dir, pdf, records, index, "training_operator_coverage",'. The important operands are figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block; pdf: the value named 'pdf' in this block. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "training_operator_coverage", "Backward operator coverage and work composition", str(training_coverage_path),)' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 887: `"Backward operator coverage and work composition", str(training_coverage_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 885. Its exact fragment is '"Backward operator coverage and work composition", str(training_coverage_path),'. The important operands are Backward: the value named 'backward' in this block; operator: the value named 'operator' in this block; coverage: the value named 'coverage' in this block. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "training_operator_coverage", "Backward operator coverage and work composition", str(training_coverage_path),)' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. Context: the function generate, which handles generate.

Line 888: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 885. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "training_operator_coverage", "Backward operator coverage and work composition", str(training_coverage_path),)' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 890: `if shard_manifest:` This executes the following indented host-code branch only when 'shard_manifest' is true. The important operands are shard_manifest: the value named 'shard manifest' in this block. Context: the function generate, which handles generate.

Line 891: `split_names: list[str] = []` This assigns '[]' to 'split_names' in host memory. Here split_names means the value named 'split names' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 892: `shard_indices: list[int] = []` This assigns '[]' to 'shard_indices' in host memory. Here shard_indices means the value named 'shard indices' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 893: `shard_sizes: list[float] = []` This assigns '[]' to 'shard_sizes' in host memory. Here shard_sizes means the value named 'shard sizes' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 894: `for split_name, shards in shard_manifest["splits"].items():` This iterates split_name, shards over ‘shard_manifest["splits"].items()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate, which handles generate.

Line 895: `for shard_index, shard in enumerate(shards):` This iterates shard_index, shard over ‘enumerate(shards)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate, which handles generate.

Line 896: `split_names.append(split_name)` This calls ‘split_names.append‘ with ‘split_name‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 897: `shard_indices.append(shard_index)` This calls ‘shard_indices.append‘ with ‘shard_index‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 898: `shard_sizes.append(shard["bytes"] / 1e6)` This calls ‘shard_sizes.append‘ with ‘shard["bytes"] / 1e6‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 899: `figure, axis = plt.subplots(figsize=(11.5, 5.8))` This assigns ‘plt.subplots(figsize=(11.5, 5.8))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 900: `for color_index, split_name in enumerate(sorted(set(split_names))):` This iterates color_index, split_name over ‘enumerate(sorted(set(split_names)))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate, which handles generate.

Line 901: `selected = [index for index, name in enumerate(split_names) if name == split_name]` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are selected: the value named ’selected’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named ’for’ in this block.

Line 902: `axis.plot(` This statement continues through source line 906; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘axis.plot‘ with ‘ [shard_indices[index] for index in selected], [shard_sizes[index] for index in selected], marker="o", markersize=3, label=split_name, color=COLORS[color_index], ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 903: `[shard_indices[index] for index in selected],` This is continuation line 2 of the 5-line logical statement that begins at source line 902. Its exact fragment is ‘[shard_indices[index] for index in selected],‘. The important operands are shard_indices: the value named ’shard indices’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named ’for’ in this block. Read together, the complete operation is: This calls ‘axis.plot‘ with ‘ [shard_indices[index] for index in selected], [shard_sizes[index] for index in selected], marker="o", markersize=3, label=split_name, color=COLORS[color_index], ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 904: `[shard_sizes[index] for index in selected],` This is continuation line 3 of the 5-line logical statement that begins at source line 902. Its exact fragment is ‘[shard_sizes[index] for index in selected],‘. The important operands are shard_sizes: the value named ’shard sizes’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named ’for’ in this block. Read together, the complete operation is: This calls

‘axis.plot‘ with ‘ [shard_indices[index] for index in selected], [shard_sizes[index] for index in selected], marker="o", markersize=3, label=split_name, color=COLORS[color_index], ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 905: `marker="o", markersize=3, label=split_name, color=COLORS[color_index],` This is continuation line 4 of the 5-line logical statement that begins at source line 902. Its exact fragment is ‘marker="o", markersize=3, label=split_name, color=COLORS[color_index],‘. The important operands are marker: the value named ’marker’ in this block; o: the value named ’o’ in this block; markersize: the value named ’markersize’ in this block. Read together, the complete operation is: This calls ‘axis.plot‘ with ‘ [shard_indices[index] for index in selected], [shard_sizes[index] for index in selected], marker="o", markersize=3, label=split_name, color=COLORS[color_index], ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 906: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 902. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘axis.plot‘ with ‘ [shard_indices[index] for index in selected], [shard_sizes[index] for index in selected], marker="o", markersize=3, label=split_name, color=COLORS[color_index], ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 907: `axis.legend(frameon=False)` This calls ‘axis.legend‘ with ‘frameon=False‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 908: `style_axes(axis, "Official CIFAR-10 shard sizes", "Shard index", "Compressed NPZ size (MB)")` This calls ‘style_axes‘ with ‘axis, "Official CIFAR-10 shard sizes", "Shard index", "Compressed NPZ size (MB)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 909: `index = save_figure(` This statement continues through source line 912; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_dataset_shards", "Deterministic CIFAR-10 board-training shards", str(shard_manifest_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 910: `figure, plot_dir, pdf, records, index, "training_dataset_shards",` This is continuation line 2 of the 4-line logical statement that begins at source line 909. Its exact fragment is ‘figure, plot_dir, pdf, records, index, "training_dataset_shards",‘. The important operands are figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block; pdf: the value named ’pdf’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_dataset_shards", "Deterministic CIFAR-10 board-training shards", str(shard_manifest_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 911: `"Deterministic CIFAR-10 board-training shards", str(shard_manifest_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 909. Its exact fragment is ‘"Deterministic CIFAR-10 board-training shards", str(shard_manifest_path),‘. The important operands are Deterministic: the value named ’deterministic’ in this block; CIFAR: the value named ’cifar’ in this block; board: the value named ’board’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_dataset_shards", "Deterministic CIFAR-10 board-training shards", str(shard_manifest_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 912: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 909. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "training_dataset_shards", "Deterministic CIFAR-10 board-training shards", str(shard_manifest_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 914: `waveform_manifest_path = waveform_dir / "waveform_manifest.json"` This assigns ‘waveform_dir / "waveform_manifest.json"‘ to ‘waveform_manifest_path ‘ in host memory. Here waveform_manifest_path means the value named ’waveform manifest path’ in this block. The important operands are waveform_dir: the value named ’waveform dir’ in this block; waveform_manifest: the value named ’waveform manifest’ in this block; json: the value named ’json’ in this block. Context: the function generate, which handles generate.

Line 915: `if waveform_manifest_path.exists():` This executes the following indented host-code branch only when ‘waveform_manifest_path.exists()‘ is true. The important operands are waveform_manifest_path: the value named ’waveform manifest path’ in this block; exists: the value named ’exists’ in this block. Context: the function generate, which handles generate.

Line 916: `waveform_manifest = load_json(waveform_manifest_path)` This assigns ‘load_json(waveform_manifest_path)‘ to ‘waveform_manifest ‘ in host memory. Here waveform_manifest means the value named ’waveform manifest’ in this block. The important operands are load_json: the value named ’load json’ in this block; waveform_manifest_path: the value named ’waveform manifest path’ in this block. Context: the function generate, which handles generate.

Line 917: `for capture in waveform_manifest["captures"]:` This iterates capture over ‘waveform_manifest["captures"]‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate, which handles generate.

Line 918: `vcd_path = waveform_dir / capture["vcd"]` This assigns ‘waveform_dir / capture["vcd"]‘ to ‘vcd_path ‘ in host memory. Here vcd_path means the value named ’vcd path’ in this block. The important operands are waveform_dir: the value named ’waveform dir’ in this block; capture: the value named ’capture’ in this block; vcd: the value named ’vcd’ in this block. Context: the function generate, which handles generate.

Line 919: `figure, selected_names = waveform_figure(vcd_path, f"XSim: {capture['testbench']}")` This assigns ‘waveform_figure(vcd_path, f"XSim: {capture['testbench']}")‘ to ‘figure, selected_names ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are waveform_figure: the value named ’waveform figure’ in this block; vcd_path: the value named ’vcd path’ in this block; f: the value named ’f’ in this block. Context: the function generate, which handles generate.

Line 920: `evidence = (` This statement continues through source line 923; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(f"Vivado 2026.1 XSim VCD, requested window {capture['duration']} {capture['unit']}; " f"signals: {', '.join(name.rsplit('/', 1)[-1] for name in selected_names)}")‘ to ‘evidence ‘ in host memory. Here evidence means the value named ’evidence’ in this block. The important operands are f: the value named ’f’ in this block; Vivado: the value named ’vivado’ in this block; XSim: the value named ’xsim’ in this block. Context: the function generate, which handles generate.

Line 921: `f"Vivado 2026.1 XSim VCD, requested window {capture['duration']} {capture['unit']}; "` This is continuation line 2 of the 4-line logical statement that begins at source line 920. Its exact fragment is ‘f"Vivado 2026.1 XSim VCD, requested window {capture['duration']} {capture['unit']}; "‘. The important operands are f: the value named ’f’ in this block; Vivado: the value named ’vivado’ in this block; XSim: the value named ’xsim’ in this block. Read together, the complete operation is: This assigns ‘(f"Vivado 2026.1 XSim VCD, requested window {capture['duration']} {capture['unit']}; " f"signals: {', '.join(name.rsplit('/', 1)[-1] for name in selected_names)}")‘ to ‘evidence ‘ in host memory. Here evidence means the value named ’evidence’ in this block. The important operands are f: the value named ’f’ in this block; Vivado: the value named ’vivado’ in this block; XSim: the value named ’xsim’ in this block. Context: the function generate, which handles generate.

Line 922: `f"signals: {', '.join(name.rsplit('/', 1)[-1] for name in selected_names)}"` This is continuation line 3 of the 4-line logical statement that begins at source line 920. Its exact fragment is ‘f"signals: {', '.join(name.rsplit('/', 1)[-1] for name in selected_names)}"‘. The important operands are f: the value named ’f’ in this block; signals: the value named ’signals’ in this block; join: the value named ’join’ in this block. Read together, the complete operation is: This assigns ‘(f"Vivado 2026.1 XSim VCD, requested window {capture['duration']} {capture['unit']}; " f"signals: {', '.join(name.rsplit('/', 1)[-1] for name in selected_names)}")‘ to ‘evidence ‘ in host memory. Here evidence means the value named ’evidence’ in this block. The important operands are f: the value named ’f’ in this block; Vivado: the value named ’vivado’ in this block; XSim: the value named ’xsim’ in this block. Context: the function generate, which handles generate.

Line 923: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 920. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(f"Vivado 2026.1 XSim VCD, requested window {capture['duration']} {capture['unit']}; " f"signals: {', '.join(name.rsplit('/', 1)[-1] for name in selected_names)}")‘ to ‘evidence ‘ in host memory. Here evidence means the value named ’evidence’ in this block. The important operands are f: the value named ’f’ in this block; Vivado: the value named ’vivado’ in this block; XSim: the value named ’xsim’ in this block. Context: the function generate, which handles generate.

Line 924: `index = save_figure(figure, plot_dir, pdf, records, index,` This statement continues through source line 926; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, f"wave_{capture['testbench'].removeprefix('tb_neuraedge_')}", f"Waveform: {capture['testbench']}", evidence)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 925: `f"wave_{capture['testbench'].removeprefix('tb_neuraedge_')}",` This is continuation line 2 of the 3-line logical statement that begins at source line 924. Its exact fragment is ‘f"wave_{capture['testbench'].removeprefix('tb_neuraedg
The important operands are f: the value named ’f’ in this block; wave_: the value named ’wave’ in this block; capture: the value named ’capture’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, f"wave_{capture['testbench'].removeprefix('tb_neuraedge_')}", f"Waveform: {capture['testbench']}", evidence)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 926: `f"Waveform: {capture['testbench']}", evidence)` This is continuation line 3 of the 3-line logical statement that begins at source line 924. Its exact fragment is ‘f"Waveform: {capture['testbench']}", evidence)‘. The important operands are f: the value named ’f’ in this block; Waveform: the value named ’waveform’ in this block; capture: the value named ’capture’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, f"wave_{capture['testbench'].removeprefix('tb_neuraedge_')}", f"Waveform: {capture['testbench']}", evidence)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 928: `if timing_dir is not None and timing_dir.exists():` This executes the following indented host-code branch only when ‘timing_dir is not None and timing_dir.exists()‘ is true. The important operands are timing_dir: the value named ’timing dir’ in this block; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function generate, which handles generate.

Line 929: `timing_summary_path = timing_dir / "full_routed_timing_summary.rpt"` This assigns ‘timing_dir / "full_routed_timing_summary.rpt"‘ to ‘timing_summary_path ‘ in host memory. Here timing_summary_path means the value named ’timing summary path’ in this block. The important operands are timing_dir: the value named ’timing dir’ in this block; full_routed_timing_summary: the value named ’full routed timing summary’ in this block; rpt: the value named ’rpt’ in this block. Context: the function generate, which handles generate.

Line 930: `if not timing_summary_path.exists():` This executes the following indented host-code branch only when ‘not timing_summary_path.exists()‘ is true. The important operands are not: the value named ’not’ in this block; timing_summary_path: the value named ’timing summary path’ in this block; exists: the value named ’exists’ in this block. Context: the function generate, which handles generate.

Line 931: `timing_summary_path = timing_dir / "routed_timing_summary.rpt"` This assigns ‘timing_dir / "routed_timing_ to ‘timing_summary_path ‘ in host memory. Here timing_summary_path means the value named ’timing summary path’ in this block. The important operands are timing_dir: the value named ’timing dir’ in this block; routed_timing_summary: the value named ’routed timing summary’ in this block; rpt: the value named ’rpt’ in this block. Context: the function generate, which handles generate.

Line 932: `clock_timing = parse_clock_timing(timing_summary_path)` This assigns ‘parse_clock_timing(timing_summary_ to ‘clock_timing ‘ in host memory. Here clock_timing means the value named ’clock timing’ in this block. The important operands are parse_clock_timing: the value named ’parse clock timing’ in this block; timing_summary_path: the value named ’timing summary path’ in this block. Context: the function generate, which handles generate.

Line 933: `if clock_timing:` This executes the following indented host-code branch only when ‘clock_timing‘ is true. The important operands are clock_timing: the value named ’clock timing’ in this block. Context: the function generate, which handles generate.

Line 934: `names = sorted(clock_timing)` This assigns ‘sorted(clock_timing)‘ to ‘names ‘ in host memory. Here names means the value named ’names’ in this block. The important operands are sorted: the value named ’sorted’ in this block; clock_timing: the value named ’clock timing’ in this block. Context: the function generate, which handles generate.

Line 935: `setup = [clock_timing[name][0] for name in names]` This assigns ‘[clock_timing[name][0] for name in names]‘ to ‘setup ‘ in host memory. Here setup means the value named ’setup’ in this block. The important operands are clock_timing: the value named ’clock timing’ in this block; name: the value named ’name’ in this block; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 936: `hold = [clock_timing[name][1] for name in names]` This assigns ‘[clock_timing[name][1] for name in names]‘ to ‘hold ‘ in host memory. Here hold means the value named ’hold’ in this block. The important operands are clock_timing: the value named ’clock timing’ in this block; name: the value named ’name’ in this block; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 937: `figure, axes = plt.subplots(1, 2, figsize=(11.5, 5.2))` This assigns ‘plt.subplots(1, 2, figsize=(11.5, 5.2))‘ to ‘figure, axes ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 938: `axes[0].bar(names, setup, color=COLORS[: len(names)])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; bar: the value named ’bar’ in this block; names: the value named ’names’ in this block.

Line 939: `axes[0].axhline(0, color=COLORS[2], linewidth=1.0)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; axhline: the value named ’axhline’ in this block; color: the value named ’color’ in this block.

Line 940: `style_axes(axes[0], "Setup slack by clock domain", ylabel="WNS (ns)")` This calls ‘style_axes‘ with ‘axes[0], "Setup slack by clock domain", ylabel="WNS (ns)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 941: `axes[1].bar(names, hold, color=COLORS[: len(names)])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; bar: the value named 'bar' in this block; names: the value named 'names' in this block.

Line 942: `axes[1].axhline(0, color=COLORS[2], linewidth=1.0)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; axhline: the value named 'axhline' in this block; color: the value named 'color' in this block.

Line 943: `style_axes(axes[1], "Hold slack by clock domain", ylabel="WHS (ns)")` This calls ‘style_axes‘ with ‘axes[1], "Hold slack by clock domain", ylabel="WHS (ns)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 944: `index = save_figure(` This statement continues through source line 947; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "clock_domain_timing", "Routed timing by clock domain", str(timing_summary_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 945: `figure, plot_dir, pdf, records, index, "clock_domain_timing",` This is continuation line 2 of the 4-line logical statement that begins at source line 944. Its exact fragment is ‘figure, plot_dir, pdf, records, index, "clock_domain_timing",‘. The important operands are figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block; pdf: the value named 'pdf' in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "clock_domain_timing", "Routed timing by clock domain", str(timing_summary_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 946: `"Routed timing by clock domain", str(timing_summary_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 944. Its exact fragment is ‘"Routed timing by clock domain", str(timing_summary_path),‘. The important operands are Routed: the value named 'routed' in this block; timing: the value named 'timing' in this block; by: the value named 'by' in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "clock_domain_timing", "Routed timing by clock domain", str(timing_summary_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 947: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 944. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "clock_domain_timing", "Routed timing by clock domain", str(timing_summary_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 949: `utilization_path = timing_dir / "full_routed_utilization_hierarchical.rpt"` This assigns ‘timing_dir / "full_routed_utilization_hierarchical.rpt"‘ to ‘utilization_path ‘ in host memory. Here utilization_path means the value named 'utilization path' in this block. The important operands are timing_dir: the value named 'timing dir' in this block; full_routed_utilization_hierarchical: the value named 'full routed utilization hierarchical' in this block; rpt: the value named 'rpt' in this block. Context: the function generate, which handles generate.

Line 950: `if not utilization_path.exists():` This executes the following indented host-code branch only when ‘not utilization_path.exists()‘ is true. The important operands are not: the value named ’not’ in this block; utilization_path: the value named ’utilization path’ in this block; exists: the value named ’exists’ in this block. Context: the function generate, which handles generate.

Line 951: `utilization_path = timing_dir / "routed_utilization_hierarchical.rpt"` This assigns ‘timing_dir / "routed_utilization_hierarchical.rpt"‘ to ‘utilization_path ‘ in host memory. Here utilization_path means the value named ’utilization path’ in this block. The important operands are timing_dir: the value named ’timing dir’ in this block; routed_utilization_hierarchical: the value named ’routed utilization hierarchical’ in this block; rpt: the value named ’rpt’ in this block. Context: the function generate, which handles generate.

Line 952: `utilization = parse_utilization_hierarchy(utilization_path)` This assigns ‘parse_utilization_hierarchy(utili to ‘utilization ‘ in host memory. Here utilization means the value named ’utilization’ in this block. The important operands are parse_utilization_hierarchy: the value named ’parse utilization hierarchy’ in this block; utilization_path: the value named ’utilization path’ in this block. Context: the function generate, which handles generate.

Line 953: `if "system_wrapper" in utilization:` This executes the following indented host-code branch only when ‘"system_wrapper" in utilization‘ is true. The important operands are system_wrapper: the value named ’system wrapper’ in this block; in: the value named ’in’ in this block; utilization: the value named ’utilization’ in this block. Context: the function generate, which handles generate.

Line 954: `top = utilization["system_wrapper"]` This assigns ‘utilization["system_wrapper"]‘ to ‘top ‘ in host memory. Here top means the value named ’top’ in this block. The important operands are utilization: the value named ’utilization’ in this block; system_wrapper: the value named ’system wrapper’ in this block. Context: the function generate, which handles generate.

Line 955: `labels_resource = ["LUT", "FF", "DSP48", "BRAM tile"]` This assigns ‘["LUT", "FF", "DSP48", "BRAM tile"]‘ to ‘labels_resource ‘ in host memory. Here labels_resource means the value named ’labels resource’ in this block. The important operands are LUT: the value named ’lut’ in this block; FF: the value named ’ff’ in this block; DSP48: the value named ’dsp48’ in this block. Context: the function generate, which handles generate.

Line 956: `counts_resource = [top["lut"], top["ff"], top["dsp"], top["bram36"] + top["bram18"] / 2]` This assigns ‘[top["lut"], top["ff"], top["dsp"], top["bram36"] + top["bram18"] / 2]‘ to ‘counts_resource ‘ in host memory. Here counts_resource means the value named ’counts resource’ in this block. The important operands are top: the value named ’top’ in this block; lut: the value named ’lut’ in this block; ff: the value named ’ff’ in this block. Context: the function generate, which handles generate.

Line 957: `capacities = [53_200, 106_400, 220, 140]` This assigns ‘[53_200, 106_400, 220, 140]‘ to ‘capacities ‘ in host memory. Here capacities means the value named ’capacities’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate, which handles generate.

Line 958: `percents = [100 * count / capacity for count, capacity in zip(counts_resource, capacities)]` This assigns ‘[100 * count / capacity for count, capacity in zip(counts_resource, capacities)]‘ to ‘percents ‘ in host memory. Here percents means the value named ’percents’ in this block. The important operands are count: the value named ’count’ in this block; capacity: the value named ’capacity’ in this block; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 959: `figure, axes = plt.subplots(1, 2, figsize=(11.5, 5.2))` This assigns ‘plt.subplots(1, 2, figsize=(11.5, 5.2))‘ to ‘figure, axes ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 960: `axes[0].bar(labels_resource, counts_resource, color=COLORS[:4])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; bar: the value named 'bar' in this block; labels_resource: the value named 'labels resource' in this block.

Line 961: `axes[0].set_yscale("log")` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; set_yscale: the real-value spacing represented by one quantized integer step; log: the value named 'log' in this block.

Line 962: `style_axes(axes[0], "Implemented primitive use", ylabel="Count (log scale)")` This calls 'style_axes' with 'axes[0], "Implemented primitive use", ylabel="Count (log scale)"' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 963: `axes[1].bar(labels_resource, percents, color=COLORS[:4])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; bar: the value named 'bar' in this block; labels_resource: the value named 'labels resource' in this block.

Line 964: `axes[1].set_ylim(0, 100)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; set_ylim: the value named 'set ylim' in this block.

Line 965: `for position, value in enumerate(percents):` This iterates position, value over 'enumerate(percents)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate, which handles generate.

Line 966: `axes[1].text(position, value + 1.5, f"{value:.1f}%", ha="center", fontsize=9)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; text: the value named 'text' in this block; position: the value named 'position' in this block.

Line 967: `style_axes(axes[1], "PYNQ-Z2 device utilization", ylabel="Available resources used (%)")` This calls 'style_axes' with 'axes[1], "PYNQ-Z2 device utilization", ylabel="Available resources used (%)"' inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 968: `index = save_figure(` This statement continues through source line 971; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'save_figure(figure, plot_dir, pdf, records, index, "full_routed_resources", "Full PYNQ routed resource utilization", str(utilization_path),)' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 969: `figure, plot_dir, pdf, records, index, "full_routed_resources",` This is continuation line 2 of the 4-line logical statement that begins at source line 968. Its exact fragment is 'figure, plot_dir, pdf, records, index, "full_routed_resources",'. The important operands are figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block; pdf: the value named 'pdf' in this block. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "full_routed_resources", "Full PYNQ routed resource utilization", str(utilization_path),)' to 'index ' in host memory. Here index means an integer selecting one tensor element,

lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 970: `"Full PYNQ routed resource utilization", str(utilization_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 968. Its exact fragment is '"Full PYNQ routed resource utilization", str(utilization_path),'. The important operands are Full: the value named 'full' in this block; PYNQ: the value named 'pynq' in this block; routed: the value named 'routed' in this block. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "full_routed_resources", "Full PYNQ routed resource utilization", str(utilization_path),)' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 971: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 968. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "full_routed_resources", "Full PYNQ routed resource utilization", str(utilization_path),)' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 973: `hierarchy_order = [` This statement continues through source line 978; the explanation uses the complete expression rather than only the first visual fragment. This assigns '[name for name in ("accelerator", "dma", "control_interconnect", "memory_interconnect", "accelerator_control_cdc", "dma_control_cdc", "mm2s_cdc", "s2mm_cdc",) if name in utilization]' to 'hierarchy_order ' in host memory. Here hierarchy_order means the value named 'hierarchy order' in this block. The important operands are name: the value named 'name' in this block; for: the value named 'for' in this block; in: the value named 'in' in this block. Context: the function generate, which handles generate.

Line 974: `name for name in (` This is continuation line 2 of the 6-line logical statement that begins at source line 973. Its exact fragment is 'name for name in ('. The important operands are name: the value named 'name' in this block; for: the value named 'for' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This assigns '[name for name in ("accelerator", "dma", "control_interconnect", "memory_interconnect", "accelerator_control_cdc", "dma_control_cdc", "mm2s_cdc", "s2mm_cdc",) if name in utilization]' to 'hierarchy_order ' in host memory. Here hierarchy_order means the value named 'hierarchy order' in this block. The important operands are name: the value named 'name' in this block; for: the value named 'for' in this block; in: the value named 'in' in this block. Context: the function generate, which handles generate.

Line 975: `"accelerator", "dma", "control_interconnect", "memory_interconnect",` This is continuation line 3 of the 6-line logical statement that begins at source line 973. Its exact fragment is '"accelerator", "dma", "control_interconnect", "memory_interconnect",'. The important operands are accelerator: the value named 'accelerator' in this block; dma: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; control_interconnect: the value named 'control interconnect' in this block. Read together, the complete operation is: This assigns '[name for name in ("accelerator", "dma", "control_interconnect", "memory_interconnect", "accelerator_control_cdc", "dma_control_cdc", "mm2s_cdc", "s2mm_cdc",) if name in utilization]' to 'hierarchy_order ' in host memory. Here hierarchy_order means the value named 'hierarchy order' in this block. The important operands are name: the value named 'name' in this block; for: the value named 'for' in this block; in: the value named 'in' in this block. Context: the function generate, which handles generate.

Line 976: `"accelerator_control_cdc", "dma_control_cdc", "mm2s_cdc", "s2mm_cdc",` This is continuation line 4 of the 6-line logical statement that begins at source line 973. Its exact fragment is '"accelerator_control_cdc", "dma_control_cdc", "mm2s_cdc", "s2mm_cdc",'. The important operands are accelerator_control_cdc: the value named 'accelerator control cdc' in this block; dma_control_cdc: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic; mm2s_cdc: the value named 'mm2s cdc' in this block. Read together, the complete operation is: This assigns '[name for name in ("accelerator", "dma", "control_interconnect", "memory_interconnect", "accelerator_control_cdc", "dma_control_cdc", "mm2s_cdc", "s2mm_cdc",) if name in utilization]' to 'hierarchy_order

‘ in host memory. Here hierarchy_order means the value named ’hierarchy order’ in this block. The important operands are name: the value named ’name’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function generate, which handles generate.

Line 977: `) if name in utilization` This is continuation line 5 of the 6-line logical statement that begins at source line 973. Its exact fragment is ‘) if name in utilization‘. The important operands are name: the value named ’name’ in this block; in: the value named ’in’ in this block; utilization: the value named ’utilization’ in this block. Read together, the complete operation is: This assigns ‘[name for name in ("accelerator", "dma", "control_interconnect", "memory_interconnect", "accelerator_control_cdc", "dma_control_cdc", "mm2s_cdc", "s2mm_cdc",) if name in utilization]‘ to ‘hierarchy_order ‘ in host memory. Here hierarchy_order means the value named ’hierarchy order’ in this block. The important operands are name: the value named ’name’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function generate, which handles generate.

Line 978: `]` This is continuation line 6 of the 6-line logical statement that begins at source line 973. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘[name for name in ("accelerator", "dma", "control_interconnect", "memory_interconnect", "accelerator_control_cdc", "dma_control_cdc", "mm2s_cdc", "s2mm_cdc",) if name in utilization]‘ to ‘hierarchy_order ‘ in host memory. Here hierarchy_order means the value named ’hierarchy order’ in this block. The important operands are name: the value named ’name’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function generate, which handles generate.

Line 979: `figure, axes = plt.subplots(2, 2, figsize=(12, 8.2))` This assigns ‘plt.subplots(2, 2, figsize=(12, 8.2))‘ to ‘figure, axes ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 980: `for axis, key, title in zip(` This line opens or closes a multi-line Python expression inside the function generate, which handles generate; the neighboring lines supply its arguments or elements.

Line 981: `axes.ravel(), ("lut", "ff", "dsp", "bram36"),` This calls ‘axes.ravel‘ with ‘), ("lut", "ff", "dsp", "bram36"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 982: `("LUTs", "Flip-flops", "DSP48 blocks", "RAMB36 blocks"),` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are LUTs: the value named ’luts’ in this block; Flip: the value named ’flip’ in this block; flops: the value named ’flops’ in this block.

Line 983: `):` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The expression is a literal or structural operator and has no hidden software state.

Line 984: `values = [utilization[name][key] for name in hierarchy_order]` This assigns ‘[utilization[name][key] for name in hierarchy_order]‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are utilization: the value named ’utilization’ in this block; name: the value named ’name’ in this block; key: the value named ’key’ in this block. Context: the function generate, which handles generate.

Line 985: `axis.barh(np.arange(len(hierarchy_order)), values, color=COLORS[0])` This calls ‘axis.barh‘ with ‘np.arange(len(hierarchy_order)), values, color=COLORS[0]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 986: `axis.set_yticks(np.arange(len(hierarchy_order)), hierarchy_order, fontsize=8)` This calls ‘axis.set_ytick with ‘np.arange(len(hierarchy_order)), hierarchy_order, fontsize=8‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 987: `axis.invert_yaxis()` This calls ‘axis.invert_yaxis‘ with “ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 988: `style_axes(axis, title, xlabel="Primitive count")` This calls ‘style_axes‘ with ‘axis, title, xlabel="Primitive count"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 989: `index = save_figure(` This statement continues through source line 992; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "resource_hierarchy", "Resource use by full-system hierarchy", str(utilization_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 990: `figure, plot_dir, pdf, records, index, "resource_hierarchy",` This is continuation line 2 of the 4-line logical statement that begins at source line 989. Its exact fragment is ‘figure, plot_dir, pdf, records, index, "resource_hierarchy",‘. The important operands are figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block; pdf: the value named ’pdf’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "resource_hierarchy", "Resource use by full-system hierarchy", str(utilization_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 991: `"Resource use by full-system hierarchy", str(utilization_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 989. Its exact fragment is ‘"Resource use by full-system hierarchy", str(utilization_path),‘. The important operands are Resource: the value named ’resource’ in this block; use: the value named ’use’ in this block; by: the value named ’by’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "resource_hierarchy", "Resource use by full-system hierarchy", str(utilization_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 992: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 989. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "resource_hierarchy", "Resource use by full-system hierarchy", str(utilization_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 994: `drc_path = timing_dir / "full_drc.rpt"` This assigns ‘timing_dir / "full_drc.rpt"‘ to ‘drc_path ‘ in host memory. Here drc_path means the value named ’drc path’ in this block. The important operands are timing_dir: the value named ’timing dir’ in this block; full_drc: the value named ’full drc’ in this block; rpt: the value named ’rpt’ in this block. Context: the function generate, which handles generate.

Line 995: `drc_rows = parse_drc_summary(drc_path)` This assigns ‘parse_drc_summary(drc_path)‘ to ‘drc_rows ‘ in host memory. Here drc_rows means one output-row position processed by the tensor tile. The important operands

are parse_drc_summary: the value named 'parse drc summary' in this block; drc_path: the value named 'drc path' in this block. Context: the function generate, which handles generate.

Line 996: `if drc_rows:` This executes the following indented host-code branch only when ‘drc_rows‘ is true. The important operands are drc_rows: one output-row position processed by the tensor tile. Context: the function generate, which handles generate.

Line 997: `figure, axis = plt.subplots(figsize=(11, 6.2))` This assigns ‘plt.subplots(figsize=(11, 6.2))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named 'figure' in this block. The important operands are plt: the value named 'plt' in this block; subplots: the value named 'subplots' in this block; figsize: the value named 'figsize' in this block. Context: the function generate, which handles generate.

Line 998: `labels_drc = [f"{rule}: {description}" for rule, _, description, _ in drc_rows]` This assigns ‘[f"{rule}: {description}" for rule, _, description, _ in drc_rows]‘ to ‘labels_drc ‘ in host memory. Here labels_drc means the value named 'labels drc' in this block. The important operands are f: the value named 'f' in this block; rule: the value named 'rule' in this block; description: the value named 'description' in this block. Context: the function generate, which handles generate.

Line 999: `counts_drc = [count for _, _, _, count in drc_rows]` This assigns ‘[count for _, _, _, count in drc_rows]‘ to ‘counts_drc ‘ in host memory. Here counts_drc means the value named 'counts drc' in this block. The important operands are count: the value named 'count' in this block; for: the value named 'for' in this block; _: the value named '' in this block. Context: the function generate, which handles generate.

Line 1000: `axis.barh(np.arange(len(drc_rows)), counts_drc, color=COLORS[3])` This calls ‘axis.barh‘ with ‘np.arange(len(drc_rows)), counts_drc, color=COLORS[3]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1001: `axis.set_yticks(np.arange(len(drc_rows)), labels_drc, fontsize=8)` This calls ‘axis.set_yticks‘ with ‘np.arange(len(drc_rows)), labels_drc, fontsize=8‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1002: `axis.invert_yaxis()` This calls ‘axis.invert_yaxis‘ with ‘‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1003: `axis.set_xscale("log")` This calls ‘axis.set_xscale‘ with ‘"log"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1004: `style_axes(axis, "Vivado DRC advisory classification", "Reported checks (log scale)")` This calls ‘style_axes‘ with ‘axis, "Vivado DRC advisory classification", "Reported checks (log scale)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1005: `index = save_figure(` This statement continues through source line 1008; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "drc_classification", "DRC warning classification", str(drc_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 1006: `figure, plot_dir, pdf, records, index, "drc_classification",` This is continuation line 2 of the 4-line logical statement that begins at source line 1005. Its exact fragment is ‘figure, plot_dir, pdf, records, index, "drc_classification",‘. The important operands are figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block; pdf: the value named ’pdf’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "drc_classification", "DRC warning classification", str(drc_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 1007: `"DRC warning classification", str(drc_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 1005. Its exact fragment is ‘"DRC warning classification", str(drc_path),‘. The important operands are DRC: the value named ’drc’ in this block; warning: the value named ’warning’ in this block; classification: the value named ’classification’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "drc_classification", "DRC warning classification", str(drc_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 1008: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1005. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "drc_classification", "DRC warning classification", str(drc_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 1010: `cdc_path = timing_dir / "full_cdc.rpt"` This assigns ‘timing_dir / "full_cdc.rpt"‘ to ‘cdc_path ‘ in host memory. Here cdc_path means the value named ’cdc path’ in this block. The important operands are timing_dir: the value named ’timing dir’ in this block; full_cdc: the value named ’full cdc’ in this block; rpt: the value named ’rpt’ in this block. Context: the function generate, which handles generate.

Line 1011: `cdc_rows = parse_cdc_summary(cdc_path)` This assigns ‘parse_cdc_summary(cdc_path)‘ to ‘cdc_rows ‘ in host memory. Here cdc_rows means one output-row position processed by the tensor tile. The important operands are parse_cdc_summary: the value named ’parse cdc summary’ in this block; cdc_path: the value named ’cdc path’ in this block. Context: the function generate, which handles generate.

Line 1012: `if cdc_rows:` This executes the following indented host-code branch only when ‘cdc_rows‘ is true. The important operands are cdc_rows: one output-row position processed by the tensor tile. Context: the function generate, which handles generate.

Line 1013: `figure, axis = plt.subplots(figsize=(10.5, 5.4))` This assigns ‘plt.subplots(figsize=(10.5, 5.4))‘ to ‘figure, axis ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 1014: `labels_cdc = [f"{rule} {severity}\n{description}" for rule, severity, _, description in cdc_rows]` This assigns ‘[f"{rule} {severity}\n{description}" for rule, severity, _, description in cdc_rows]‘ to ‘labels_cdc ‘ in host memory. Here labels_cdc means the value named ’labels cdc’ in this block. The important operands are f: the value named ’f’ in this block; rule: the value named ’rule’ in this block; severity: the value named ’severity’ in this block. Context: the function generate, which handles generate.

Line 1015: `counts_cdc = [count for _, _, count, _ in cdc_rows]` This assigns ‘[count for _, _, count, _ in cdc_rows]‘ to ‘counts_cdc ‘ in host memory. Here counts_cdc means the value named ’counts cdc’ in this block. The important operands are count: the value named ’count’ in this block; for: the value named ’for’ in this block; _: the value named ” in this block. Context: the function generate, which handles generate.

Line 1016: `axis.bar(labels_cdc, counts_cdc, color=[COLORS[1], COLORS[3]][: len(cdc_rows)])` This calls ‘axis.bar‘ with ‘labels_cdc, counts_cdc, color=[COLORS[1], COLORS[3]][: len(cdc_rows)]‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1017: `style_axes(axis, "Vivado clock-domain crossing classification", ylabel="Reported crossings")` This calls ‘style_axes‘ with ‘axis, "Vivado clock-domain crossing classification", ylabel="Reported crossings"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1018: `index = save_figure(` This statement continues through source line 1021; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "cdc_classification", "Clock-domain crossing classification", str(cdc_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 1019: `figure, plot_dir, pdf, records, index, "cdc_classification",` This is continuation line 2 of the 4-line logical statement that begins at source line 1018. Its exact fragment is ‘figure, plot_dir, pdf, records, index, "cdc_classification",‘. The important operands are figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block; pdf: the value named ’pdf’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "cdc_classification", "Clock-domain crossing classification", str(cdc_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 1020: `"Clock-domain crossing classification", str(cdc_path),` This is continuation line 3 of the 4-line logical statement that begins at source line 1018. Its exact fragment is ‘"Clock-domain crossing classification", str(cdc_path),‘. The important operands are Clock: the value named ’clock’ in this block; domain: the value named ’domain’ in this block; crossing: the value named ’crossing’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "cdc_classification", "Clock-domain crossing classification", str(cdc_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 1021: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1018. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "cdc_classification", "Clock-domain crossing classification", str(cdc_path),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 1023: `if vectorless_power and saif_power:` This executes the following indented host-code branch only when ‘vectorless_power and saif_power‘ is true. The important operands are vectorless_power: the value named ’vectorless power’ in this block; and: the value named ’and’ in this block; saif_power: the value named ’saif power’ in this block. Context: the function generate, which handles generate.

Line 1024: `labels_power = ["Total", "Dynamic", "Static"]` This assigns ‘["Total", "Dynamic", "Static"]‘ to ‘labels_power ‘ in host memory. Here labels_power means the value named ’labels power’ in this block. The important operands are Total: the value named ’total’ in this block; Dynamic: the value named ’dynamic’ in this block; Static: the value named ’static’ in this block. Context: the function generate, which handles generate.

Line 1025: `vector_values = [vectorless_power[key] for key in ("total", "dynamic", "static")]` This assigns ‘[vectorless_power[key] for key in ("total", "dynamic", "static")]‘ to ‘vector_values ‘ in host memory. Here vector_values means the value named ’vector values’ in this block. The important operands are vectorless_power: the value named ’vectorless power’ in this block; key: the value named ’key’ in this block; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 1026: `saif_values = [saif_power[key] for key in ("total", "dynamic", "static")]` This assigns ‘[saif_power[ke
for key in ("total", "dynamic", "static")]‘ to ‘saif_values ‘ in host memory. Here saif_values means the value named ’saif values’ in this block. The important operands are saif_power: the value named ’saif power’ in this block; key: the value named ’key’ in this block; for: the value named ’for’ in this block. Context: the function generate, which handles generate.

Line 1027: `x = np.arange(len(labels_power))` This assigns ‘np.arange(len(labels_power))‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are arange: the value named ’arange’ in this block; len: the value named ’len’ in this block; labels_power: the value named ’labels power’ in this block. Context: the function generate, which handles generate.

Line 1028: `figure, axes = plt.subplots(1, 2, figsize=(12, 5.5))` This assigns ‘plt.subplots(1, 2, figsize=(12, 5.5))‘ to ‘figure, axes ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are plt: the value named ’plt’ in this block; subplots: the value named ’subplots’ in this block; figsize: the value named ’figsize’ in this block. Context: the function generate, which handles generate.

Line 1029: `axes[0].bar(x - 0.2, vector_values, 0.4, label="vectorless", color=COLORS[3])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; bar: the value named ’bar’ in this block; x: the value named ’x’ in this block.

Line 1030: `axes[0].bar(x + 0.2, saif_values, 0.4, label="SAIF annotated", color=COLORS[1])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; bar: the value named ’bar’ in this block; x: the value named ’x’ in this block.

Line 1031: `axes[0].set_xticks(x, labels_power)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; set_xticks: the value named ’set xticks’ in this block; x: the value named ’x’ in this block.

Line 1032: `axes[0].legend(frameon=False)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; legend: the value named ’legend’ in this block; frameon: the value named ’frameon’ in this block.

Line 1033: `style_axes(axes[0], "Full-system Vivado power estimates", ylabel="Power (W)")` This calls ‘style_axes‘ with ‘axes[0], "Full-system Vivado power estimates", ylabel="Power (W)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1034: `hierarchy_order = [` This statement continues through source line 1037; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘[name for name in ("accelerator", "dma", "mm2s_cdc", "s2mm_cdc") if name in vectorless_power["hierarchy"] and name in saif_power["hierarchy"]]‘ to ‘hierarchy_order ‘ in host memory. Here hierarchy_order means the value named ’hierarchy order’ in this block. The important operands are name: the value named ’name’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function generate, which handles generate.

Line 1035: `name for name in ("accelerator", "dma", "mm2s_cdc", "s2mm_cdc")` This is continuation line 2 of the 4-line logical statement that begins at source line 1034. Its exact fragment is ‘name for name in ("accelerator", "dma", "mm2s_cdc", "s2mm_cdc")‘. The important operands are name: the value named ’name’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘[name for name in ("accelerator", "dma", "mm2s_cdc", "s2mm_cdc") if name in vectorless_power["hierarchy"] and name in saif_power["hierarchy"]]‘ to ‘hierarchy_order ‘ in host memory. Here hierarchy_order means the value named ’hierarchy order’ in this block. The important operands are name: the value named ’name’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function generate, which handles generate.

Line 1036: `if name in vectorless_power["hierarchy"] and name in saif_power["hierarchy"]` This is continuation line 3 of the 4-line logical statement that begins at source line 1034. Its exact fragment is ‘if name in vectorless_power["hierarchy"] and name in saif_power["hierarchy"]‘. The important operands are name: the value named ’name’ in this block; in: the value named ’in’ in this block; vectorless_power: the value named ’vectorless power’ in this block. Read together, the complete operation is: This assigns ‘[name for name in ("accelerator", "dma", "mm2s_cdc", "s2mm_cdc") if name in vectorless_power["hierarchy"] and name in saif_power["hierarchy"]]‘ to ‘hierarchy_order ‘ in host memory. Here hierarchy_order means the value named ’hierarchy order’ in this block. The important operands are name: the value named ’name’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function generate, which handles generate.

Line 1037: `]` This is continuation line 4 of the 4-line logical statement that begins at source line 1034. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘[name for name in ("accelerator", "dma", "mm2s_cdc", "s2mm_cdc") if name in vectorless_power["hierarchy"] and name in saif_power["hierarchy"]]‘ to ‘hierarchy_order ‘ in host memory. Here hierarchy_order means the value named ’hierarchy order’ in this block. The important operands are name: the value named ’name’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Context: the function generate, which handles generate.

Line 1038: `hierarchy_x = np.arange(len(hierarchy_order))` This assigns ‘np.arange(len(hierarchy_order))‘ to ‘hierarchy_x ‘ in host memory. Here hierarchy_x means the value named ’hierarchy x’ in this block. The important operands are arange: the value named ’arange’ in this block; len: the value named ’len’ in this block; hierarchy_order: the value named ’hierarchy order’ in this block. Context: the function generate, which handles generate.

Line 1039: `axes[1].bar(` This statement continues through source line 1043; the explanation uses the complete expression rather than only the first visual fragment. Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; bar: the value named ’bar’ in this block; hierarchy_x: the value named ’hierarchy x’ in this block.

Line 1040: `hierarchy_x - 0.2,` This is continuation line 2 of the 5-line logical statement that begins at source line 1039. Its exact fragment is ‘hierarchy_x - 0.2,‘. The important operands are hierarchy_x: the value named ’hierarchy x’ in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named ’axes’ in this block; bar: the value named ’bar’ in this block; hierarchy_x: the value named ’hierarchy x’ in this block.

Line 1041: `[vectorless_power["hierarchy"][name] for name in hierarchy_order],` This is continuation line 3 of the 5-line logical statement that begins at source line 1039. Its exact fragment is ‘[vectorless_power["hierarchy"][name] for name in hierarchy_order],‘. The important operands are vectorless_power: the value named ’vectorless power’ in this block; hierarchy: the value named ’hierarchy’ in this block; name: the value named ’name’ in this block. Read together, the complete operation is: Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are f: the value named ’f’ in this block; Vectorless: the value named ’vectorless’ in this block; total: the value named ’total’ in this block. Context: the function generate, which handles generate.

Line 1062: `"Captured tests do not initialize every memory location; Vivado reports X-state warnings for untouched stor...` This is continuation line 5 of the 7-line logical statement that begins at source line 1058. Its exact fragment is ‘"Captured tests do not initialize every memory location; Vivado reports X-state warnings for untouched storage.",‘. The important operands are Captured: the value named ’captured’ in this block; tests: the value named ’tests’ in this block; do: the value named ’do’ in this block. Read together, the complete operation is: This assigns

‘[f"Vectorless: total {vectorless_power['total']:.3f} W, dynamic {vectorless_power['dynamic']:.3f} W, confidence {vectorless_power['confidence']}", f"SAIF: total {saif_power['total']:.3f} W, dynamic {saif_power['dynamic']:.3f} W, confidence {saif_power['confidence']}", f"SAIF implementation nets matched: {saif_power['matched']}", "Captured tests do not initialize every memory location; Vivado reports X-state warnings for untouched storage.", "These are tool estimates for the routed design, not measurements from a PYNQ-Z2 power rail.",]‘ to ‘power_lines ‘ in host memory. Here power_lines means the value named ’power lines’ in this block. The important operands are f: the value named ’f’ in this block; Vectorless: the value named ’vectorless’ in this block; total: the value named ’total’ in this block. Context: the function generate, which handles generate.

Line 1063: `"These are tool estimates for the routed design, not measurements from a PYNQ-Z2 power rail.",` This is continuation line 6 of the 7-line logical statement that begins at source line 1058. Its exact fragment is ‘"These are tool estimates for the routed design, not measurements from a PYNQ-Z2 power rail.",‘. The important operands are These: the value named ’these’ in this block; are: the value named ’are’ in this block; tool: the value named ’tool’ in this block. Read together, the complete operation is: This assigns ‘[f"Vectorless: total {vectorless_power['total']:.3f} W, dynamic {vectorless_power['dynamic']:.3f} W, confidence {vectorless_power['confidence']}", f"SAIF: total {saif_power['total']:.3f} W, dynamic {saif_power['dynamic']:.3f} W, confidence {saif_power['confidence']}", f"SAIF implementation nets matched: {saif_power['matched']}", "Captured tests do not initialize every memory location; Vivado reports X-state warnings for untouched storage.", "These are tool estimates for the routed design, not measurements from a PYNQ-Z2 power rail.",]‘ to ‘power_lines ‘ in host memory. Here power_lines means the value named ’power lines’ in this block. The important operands are f: the value named ’f’ in this block; Vectorless: the value named ’vectorless’ in this block; total: the value named ’total’ in this block. Context: the function generate, which handles generate.

Line 1064: `]` This is continuation line 7 of the 7-line logical statement that begins at source line 1058. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘[f"Vectorless: total {vectorless_power['total']:.3f} W, dynamic {vectorless_power['dynamic']:.3f} W, confidence {vectorless_power['confidence']}", f"SAIF: total {saif_power['total']:.3f} W, dynamic {saif_power['dynamic']:.3f} W, confidence {saif_power['confidence']}", f"SAIF implementation nets matched: {saif_power['matched']}", "Captured tests do not initialize every memory location; Vivado reports X-state warnings for untouched storage.", "These are tool estimates for the routed design, not measurements from a PYNQ-Z2 power rail.",]‘ to ‘power_lines ‘ in host memory. Here power_lines means the value named ’power lines’ in this block. The important operands are f: the value named ’f’ in this block; Vectorless: the value named ’vectorless’ in this block; total: the value named ’total’ in this block. Context: the function generate, which handles generate.

Line 1065: `figure = text_page("Power Evidence and Confidence Boundary", power_lines)` This assigns ‘text_page("Po Evidence and Confidence Boundary", power_lines)‘ to ‘figure ‘ in host memory. Here figure means the value named ’figure’ in this block. The important operands are text_page: the value named ’text page’ in this block; Power: the value named ’power’ in this block; Evidence: the value named ’evidence’ in this block. Context: the function generate, which handles generate.

Line 1066: `index = save_figure(` This statement continues through source line 1069; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "power_confidence", "Power confidence and annotation coverage", str(saif_power_report),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 1067: `figure, plot_dir, pdf, records, index, "power_confidence",` This is continuation line 2 of the 4-line logical statement that begins at source line 1066. Its exact fragment is ‘figure, plot_dir, pdf, records, index, "power_confidence",‘. The important operands are figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block; pdf: the value named ’pdf’ in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "power_confidence", "Power confidence and annotation coverage", str(saif_power_report),)‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named ’save figure’ in this block; figure: the value named ’figure’ in this block; plot_dir: the value named ’plot dir’ in this block. Context: the function generate, which handles generate.

Line 1068: `"Power confidence and annotation coverage", str(saif_power_report),` This is continuation line 3 of the 4-line logical statement that begins at source line 1066. Its exact fragment is '"Power confidence and annotation coverage", str(saif_power_report),'. The important operands are Power: the value named 'power' in this block; confidence: the value named 'confidence' in this block; and: the value named 'and' in this block. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "power_confidence", "Power confidence and annotation coverage", str(saif_power_report),)' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 1069: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1066. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'save_figure(figure, plot_dir, pdf, records, index, "power_confidence", "Power confidence and annotation coverage", str(saif_power_report),)' to 'index ' in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 1071: `timing_path = timing_dir / "full_routed_timing_paths_250.rpt"` This assigns 'timing_dir / "full_routed_ti
to 'timing_path ' in host memory. Here timing_path means the value named 'timing path' in this block. The important operands are timing_dir: the value named 'timing dir' in this block; full_routed_timing_paths_250: the value named 'full routed timing paths 250' in this block; rpt: the value named 'rpt' in this block. Context: the function generate, which handles generate.

Line 1072: `if not timing_path.exists():` This executes the following indented host-code branch only when 'not timing_path.exists()' is true. The important operands are not: the value named 'not' in this block; timing_path: the value named 'timing path' in this block; exists: the value named 'exists' in this block. Context: the function generate, which handles generate.

Line 1073: `timing_path = timing_dir / "routed_timing_paths_250.rpt"` This assigns 'timing_dir / "routed_timing_paths
to 'timing_path ' in host memory. Here timing_path means the value named 'timing path' in this block. The important operands are timing_dir: the value named 'timing dir' in this block; routed_timing_paths_250: the value named 'routed timing paths 250' in this block; rpt: the value named 'rpt' in this block. Context: the function generate, which handles generate.

Line 1074: `if timing_path.exists():` This executes the following indented host-code branch only when 'timing_path.exists()' is true. The important operands are timing_path: the value named 'timing path' in this block; exists: the value named 'exists' in this block. Context: the function generate, which handles generate.

Line 1075: `slacks = parse_timing_slacks(timing_path)` This assigns 'parse_timing_slacks(timing_path)' to 'slacks ' in host memory. Here slacks means the value named 'slacks' in this block. The important operands are parse_timing_slacks: the value named 'parse timing slacks' in this block; timing_path: the value named 'timing path' in this block. Context: the function generate, which handles generate.

Line 1076: `if slacks.size:` This executes the following indented host-code branch only when 'slacks.size' is true. The important operands are slacks: the value named 'slacks' in this block; size: the value named 'size' in this block. Context: the function generate, which handles generate.

Line 1077: `figure, axes = plt.subplots(1, 2, figsize=(11, 5))` This assigns 'plt.subplots(1, 2, figsize=(11, 5))' to 'figure, axes ' in host memory. Here figure means the value named 'figure' in this block. The important operands are plt: the value named 'plt' in this block; subplots: the value named 'subplots' in this block; figsize: the value named 'figsize' in this block. Context: the function generate, which handles generate.

Line 1078: `axes[0].hist(slacks, bins=min(40, max(8, slacks.size // 5)), color=COLORS[0])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; hist: the value named 'hist' in this block; slacks: the value named 'slacks' in this block.

Line 1079: `axes[0].axvline(0, color=COLORS[2], linewidth=1.2)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; axvline: the value named 'axvline' in this block; color: the value named 'color' in this block.

Line 1080: `style_axes(axes[0], "Reported routed path slack", "Setup slack (ns)", "Path count")` This calls ‘style_axes‘ with ‘axes[0], "Reported routed path slack", "Setup slack (ns)", "Path count"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1081: `axes[1].plot(np.sort(slacks), color=COLORS[4])` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; plot: the value named 'plot' in this block; sort: the value named 'sort' in this block.

Line 1082: `axes[1].axhline(0, color=COLORS[2], linewidth=1.2)` Inside the function generate, which handles generate, this statement advances the host implementation that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The important operands are axes: the value named 'axes' in this block; axhline: the value named 'axhline' in this block; color: the value named 'color' in this block.

Line 1083: `style_axes(axes[1], "Sorted critical-path slack", "Path rank", "Setup slack (ns)")` This calls ‘style_axes‘ with ‘axes[1], "Sorted critical-path slack", "Path rank", "Setup slack (ns)"‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1084: `index = save_figure(figure, plot_dir, pdf, records, index, "routed_timing", "Routed timing path distribution",` This statement continues through source line 1085; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "routed_timing", "Routed timing path distribution", str(timing_path))‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 1085: `str(timing_path))` This is continuation line 2 of the 2-line logical statement that begins at source line 1084. Its exact fragment is ‘str(timing_path))‘. The important operands are str: the value named 'str' in this block; timing_path: the value named 'timing path' in this block. Read together, the complete operation is: This assigns ‘save_figure(figure, plot_dir, pdf, records, index, "routed_timing", "Routed timing path distribution", str(timing_path))‘ to ‘index ‘ in host memory. Here index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are save_figure: the value named 'save figure' in this block; figure: the value named 'figure' in this block; plot_dir: the value named 'plot dir' in this block. Context: the function generate, which handles generate.

Line 1087: `tex_path = write_report_tex(output_dir, records, block_design_filename)` This assigns ‘write_report_tex
records, block_design_filename)‘ to ‘tex_path ‘ in host memory. Here tex_path means the value named 'tex path' in this block. The important operands are write_report_tex: the value named 'write report tex' in this block; output_dir: the value named 'output dir' in this block; records: the number of descriptor records accepted since program start. Context: the function generate, which handles generate.

Line 1088: `manifest_path = output_dir / "neuraedge_debug_plot_manifest.json"` This assigns ‘output_dir / "neuraedge_debug_plot_manifest.json"‘ to ‘manifest_path ‘ in host memory. Here manifest_path means the value named ’manifest path’ in this block. The important operands are output_dir: the value named ’output dir’ in this block; neuraedge_debug_plot_manifest: the value named ’neuraedge debug plot manifest’ in this block; json: the value named ’json’ in this block. Context: the function generate, which handles generate.

Line 1089: `manifest_path.write_text(` This statement continues through source line 1103; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘manifest_path.write_text‘ with ‘ json.dumps({ "format": "neuraedge-deep-debug-v1", "plot_count": len(records), "plots": [record.___dict___ for record in records], "multipage_pdf": pdf_path.name, "latex": tex_path.name, "native_vivado_block_design": block_design_filename, }, indent=2,) + "\n", encoding="utf-8", ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1090: `json.dumps(` This is continuation line 2 of the 15-line logical statement that begins at source line 1089. Its exact fragment is ‘json.dumps(‘. The important operands are json: the value named ’json’ in this block; dumps: the value named ’dumps’ in this block. Read together, the complete operation is: This calls ‘manifest_path.write_text‘ with ‘ json.dumps({ "format": "neuraedge-deep-debug-v1", "plot_count": len(records), "plots": [record.___dict___ for record in records], "multipage_pdf": pdf_path.name, "latex": tex_path.name, "native_vivado_block_design": block_design_filename, }, indent=2,) + "\n", encoding="utf-8", ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1091: `{` This is continuation line 3 of the 15-line logical statement that begins at source line 1089. Its exact fragment is ‘{‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘manifest_path.write_text‘ with ‘ json.dumps({ "format": "neuraedge-deep-debug-v1", "plot_count": len(records), "plots": [record.___dict___ for record in records], "multipage_pdf": pdf_path.name, "latex": tex_path.name, "native_vivado_block_design": block_design_filename, }, indent=2,) + "\n", encoding="utf-8", ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1092: `"format": "neuraedge-deep-debug-v1",` This is continuation line 4 of the 15-line logical statement that begins at source line 1089. Its exact fragment is ‘"format": "neuraedge-deep-debug-v1",‘. The important operands are format: the value named ’format’ in this block; neuraedge: the value named ’neuraedge’ in this block; deep: the value named ’deep’ in this block. Read together, the complete operation is: This calls ‘manifest_path.write_text‘ with ‘ json.dumps({ "format": "neuraedge-deep-debug-v1", "plot_count": len(records), "plots": [record.___dict___ for record in records], "multipage_pdf": pdf_path.name, "latex": tex_path.name, "native_vivado_block_design": block_design_filename, }, indent=2,) + "\n", encoding="utf-8", ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1093: `"plot_count": len(records),` This is continuation line 5 of the 15-line logical statement that begins at source line 1089. Its exact fragment is ‘"plot_count": len(records),‘. The important operands are plot_count: an integer count retained for control or measurable telemetry; len: the value named ’len’ in this block; records: the number of descriptor records accepted since program start. Read together, the complete operation is: This calls ‘manifest_path.write_text‘ with ‘ json.dumps({ "format": "neuraedge-deep-debug-v1", "plot_count": len(records), "plots": [record.___dict___ for record in records], "multipage_pdf": pdf_path.name, "latex": tex_path.name, "native_vivado_block_design": block_design_filena }, indent=2,) + "\n", encoding="utf-8", ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1094: `"plots": [record.__dict__ for record in records],` This is continuation line 6 of the 15-line logical statement that begins at source line 1089. Its exact fragment is ‘"plots": [record.___dict___ for record in records],‘. The important operands are plots: the value named ’plots’ in this block; record: the value named ’record’ in this block; ___dict___: the value named ’dict’ in this block. Read together, the complete operation is: This calls ‘manifest_path.write_text‘ with ‘ json.dumps({ "format": "neuraedge-deep-debug-v1", "plot_count": len(records),

"plots": [record.___dict___ for record in records], "multipage_pdf": pdf_path.name, "latex": tex_path.name, "native_vivado_block_design": block_design_filename, }, indent=2,) + "\n", encoding="utf-8", ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1095: `"multipage_pdf": pdf_path.name,` This is continuation line 7 of the 15-line logical statement that begins at source line 1089. Its exact fragment is ‘"multipage_pdf": pdf_path.name,‘. The important operands are multipage_pdf: the value named ’multipage pdf’ in this block; pdf_path: the value named ’pdf path’ in this block; name: the value named ’name’ in this block. Read together, the complete operation is: This calls ‘manifest_path.write_text‘ with ‘ json.dumps({ "format": "neuraedge-deep-debug-v1", "plot_count": len(records), "plots": [record.___dict___ for record in records], "multipage_pdf": pdf_path.name, "latex": tex_path.name, "native_vivado_block_design": block_design_filename, }, indent=2,) + "\n", encoding="utf-8", ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1096: `"latex": tex_path.name,` This is continuation line 8 of the 15-line logical statement that begins at source line 1089. Its exact fragment is ‘"latex": tex_path.name,‘. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1102: `encoding="utf-8",` This is continuation line 14 of the 15-line logical statement that begins at source line 1089. Its exact fragment is ‘encoding="utf-8",‘. The important operands are encoding: the value named ’encoding’ in this block; utf: the value named ’utf’ in this block. Read together, the complete operation is: This calls ‘manifest_path.write_text‘ with ‘ json.dumps({ "format": "neuraedge-deep-debug-v1", "plot_count": len(records), "plots": [record.___dict___ for record in records], "multipage_pdf": pdf_path.name, "latex": tex_path.name, "native_vivado_block_design": block_design_filename, }, indent=2,) + "\n", encoding="utf-8", ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1103: `)` This is continuation line 15 of the 15-line logical statement that begins at source line 1089. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘manifest_path.write_text‘ with ‘ json.dumps({ "format": "neuraedge-deep-debug-v1", "plot_count": len(records), "plots": [record.___dict___ for record in records], "multipage_pdf": pdf_path.name, "latex": tex_path.name, "native_vivado_block_design": block_design_filename, }, indent=2,) + "\n", encoding="utf-8", ‘ inside the function generate, which handles generate. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1104: `return pdf_path, tex_path, manifest_path` This returns ‘pdf_path, tex_path, manifest_path‘ to the caller of the function generate, which handles generate, ending this invocation. The important operands are pdf_path: the value named ’pdf path’ in this block; tex_path: the value named ’tex path’ in this block; manifest_path: the value named ’manifest path’ in this block.

Line 1107: `def compile_tex(tex_path: Path, pdflatex: str) -> Path:` This starts function compile_tex. Its indented body performs compile tex as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 1108: `for _ in range(2):` This iterates _ over ‘range(2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_tex, which handles compile tex.

Line 1109: `subprocess.run([pdflatex, "-interaction=nonstopmode", "-halt-on-error", tex_path.name],` This statement continues through source line 1110; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘subprocess.run‘ with ‘[pdflatex, "-interaction=nonstopmode", "-halt-on-error", tex_path.name], cwd=tex_path.parent, check=True‘ inside the function compile_tex, which handles compile tex. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1110: `cwd=tex_path.parent, check=True)` This is continuation line 2 of the 2-line logical statement that begins at source line 1109. Its exact fragment is ‘cwd=tex_path.parent, check=True)‘. The important operands are cwd: the value named ’cwd’ in this block; tex_path: the value named ’tex path’ in this block; parent: the value named ’parent’ in this block. Read together, the complete operation is: This calls ‘subprocess.run‘ with ‘[pdflatex, "-interaction=nonstopmode", "-halt-on-error", tex_path.name], cwd=tex_path.parent, check=True‘ inside the function compile_tex, which handles compile tex. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1111: `return tex_path.with_suffix(".pdf")` This returns ‘tex_path.with_suffix(".pdf")‘ to the caller of the function compile_tex, which handles compile tex, ending this invocation. The important operands are tex_path: the value named ’tex path’ in this block; with_suffix: the value named ’with suffix’ in this block; pdf: the value named ’pdf’ in this block.

Line 1114: `def main() -> None:` This starts function main. Its indented body performs main as part of the file that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs; it runs only when called.

Line 1115: `parser = argparse.ArgumentParser(description=__doc__)` This assigns ‘argparse.ArgumentParser(description= to ‘parser ‘ in host memory. Here parser means the value named ’parser’ in this block. The important operands are argparse: the value named ’argparse’ in this block; ArgumentParser: the value named ’argument parser’ in this block; description: the value named ’description’ in this block. Context: the function main, which handles main.

Line 1116: `parser.add_argument("-output-dir", type=Path, default=root_dir() / "outputs/deep_debug")` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 1117: `parser.add_argument("-timing-dir", type=Path)` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 1118: `parser.add_argument("-waveform-dir", type=Path)` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 1119: `parser.add_argument("-saif-power-report", type=Path)` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 1120: `parser.add_argument("-block-design", type=Path)` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 1121: `parser.add_argument("-compile", action="store_true")` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 1122: `parser.add_argument("-pdflatex", default="pdflatex")` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 1123: `args = parser.parse_args()` This assigns ‘parser.parse_args()‘ to ‘args ‘ in host memory. Here args means the value named ’args’ in this block. The important operands are parser: the value named ’parser’ in this block; parse_args: the value named ’parse args’ in this block. Context: the function main, which handles main.

Line 1124: `pdf_path, tex_path, manifest_path = generate(` This statement continues through source line 1130; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘generate(args.output_dir.resolv args.timing_dir.resolve() if args.timing_dir else None, args.waveform_dir.resolve() if args.waveform_dir else None, args.saif_power_ if args.saif_power_report else None, args.block_design.resolve() if args.block_design else None,)‘ to ‘pdf_path, tex_path, manifest_path ‘ in host memory. Here pdf_path means the value named ’pdf path’ in this block. The important operands are generate: the value named ’generate’ in this block; args: the value named ’args’ in this block; output_dir: the value named ’output dir’ in this block. Context: the function main, which handles main.

Line 1125: `args.output_dir.resolve(),` This is continuation line 2 of the 7-line logical statement that begins at source line 1124. Its exact fragment is 'args.output_dir.resolve(),'. The important operands are args: the value named 'args' in this block; output_dir: the value named 'output dir' in this block; resolve: the value named 'resolve' in this block. Read together, the complete operation is: This assigns 'generate(args.output_dir.resolve(), args.timing_dir.resolve() if args.timing_dir else None, args.waveform_dir.resolve() if args.waveform_dir else None, args.saif_power_report.resolve() if args.saif_power_report else None, args.block_design.resolve() if args.block_design else None,)' to 'pdf_path, tex_path, manifest_path ' in host memory. The important operands are generate: the value named 'generate' in this block; args: the value named 'args' in this block; output_dir: the value named 'output dir' in this block. Context: the function main, which handles main.

Line 1130: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1124. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'generate(args.output_dir.resolve(), args.timing_dir.resolve() if args.timing_dir else None,

args.waveform_dir.resolve() if args.waveform_dir else None, args.saif_power_report.resolve() if args.saif_power_report else None, args.block_design.resolve() if args.block_design else None,)‘ to ‘pdf_path, tex_path, manifest_path ‘ in host memory. Here pdf_path means the value named ’pdf path’ in this block. The important operands are generate: the value named ’generate’ in this block; args: the value named ’args’ in this block; output_dir: the value named ’output dir’ in this block. Context: the function main, which handles main.

Line 1131: `print(f"plots_pdf={pdf_path}")` This calls ‘print‘ with ‘f"plots_pdf={pdf_path}"‘ inside the function main, which handles main. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1132: `print(f"latex={tex_path}")` This calls ‘print‘ with ‘f"latex={tex_path}"‘ inside the function main, which handles main. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1133: `print(f"manifest={manifest_path}")` This calls ‘print‘ with ‘f"manifest={manifest_path}"‘ inside the function main, which handles main. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1134: `if args.compile:` This executes the following indented host-code branch only when ‘args.compile‘ is true. The important operands are args: the value named ’args’ in this block; compile: the value named ’compile’ in this block. Context: the function main, which handles main.

Line 1135: `print(f"report_pdf={compile_tex(tex_path, args.pdflatex)}")` This calls ‘print‘ with ‘f"report_pdf={compile
args.pdflatex)}"‘ inside the function main, which handles main. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1138: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

Line 1139: `main()` This calls ‘main‘ with “ inside the file whose role is to turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs. The call advances the host-side job that turns full-test predictions, compiler manifests, XSim waveforms, and final Vivado reports into auditable plots and PDFs.

29 software/generate_operator_fixtures.py

Role in the complete system: builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

29.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: none. Functions: pack_signed, write_hex, generate_vector_cases, generate_optimizer_cases, generate_layernorm_cases, generate_softmax_cases, main. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

29.2 Complete source

29.3 Line annotations

Line 1: `"""Generate deterministic cross-language fixtures for vector and optimizer RTL."""` This is executable documentation attached to the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import argparse` This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import json` This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from pathlib import Path` This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `import numpy as np` This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `from math import isqrt` This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `from neuraedge_golden import (` This statement continues through source line 19; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `VectorOperation,` This is continuation line 2 of the 7-line logical statement that begins at source line 13. Its exact fragment is 'VectorOperation,'. The important operands are VectorOperation: the value named 'vector operation' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `integer_layer_norm,` This is continuation line 3 of the 7-line logical statement that begins at source line 13. Its exact fragment is 'integer_layer_norm,'. The important operands are integer_layer_norm: the value named 'integer layer norm' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `log_int_softmax_q15,` This is continuation line 4 of the 7-line logical statement that begins at source line 13. Its exact fragment is 'log_int_softmax_q15,'. The important operands are log_int_softmax_q15: the value named 'log int softmax q15' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `sgd_momentum_step,` This is continuation line 5 of the 7-line logical statement that begins at source line 13. Its exact fragment is 'sgd_momentum_step,'. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `vector_alu,` This is continuation line 6 of the 7-line logical statement that begins at source line 13. Its exact fragment is 'vector_alu,'. The important operands are vector_alu: the value named 'vector alu' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 13. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `def pack_signed(values: np.ndarray, bits: int) -> int:` This starts function pack_signed. Its indented body performs pack signed as part of the file that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests; it runs only when called.

Line 23: `packed = 0` This assigns '0' to 'packed ' in host memory. Here packed means the value named 'packed' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function pack_signed, which handles pack signed.

Line 24: `mask = (1 << bits) - 1` This assigns '(1 << bits) - 1' to 'mask ' in host memory. Here mask means the value named 'mask' in this block. The important operands are bits: the value named 'bits' in this block. Context: the function pack_signed, which handles pack signed.

Line 25: `for lane, value in enumerate(np.asarray(values, dtype=np.int64).reshape(-1)):` This iterates lane, value over 'enumerate(np.asarray(values, dtype=np.int64).reshape(-1))'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function pack_signed, which handles pack signed.

Line 26: `packed |= (int(value) & mask) << (lane * bits)` Inside the function pack_signed, which handles pack signed, this statement advances the host implementation that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The important operands are packed: the value named 'packed' in this block; value: the value named 'value' in this block; mask: the value named 'mask' in this block.

Line 27: `return packed` This returns 'packed' to the caller of the function pack_signed, which handles pack signed, ending this invocation. The important operands are packed: the value named 'packed' in this block.

Line 30: `def write_hex(path: Path, values: list[int], width_bits: int) -> None:` This starts function write_hex. Its indented body performs write hex as part of the file that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests; it runs only when called.

Line 31: `digits = (width_bits + 3) // 4` This assigns '(width_bits + 3) // 4' to 'digits ' in host memory. Here digits means the value named 'digits' in this block. The important operands are width_bits: the value named 'width bits' in this block. Context: the function write_hex, which handles write hex.

Line 32: `path.write_text("".join(f"{value & ((1 << width_bits) - 1):0{digits}x}\n" for value in values))` This calls 'path.write_text' with '"".join(f"{value & ((1 << width_bits) - 1):0{digits}x}\n" for value in values)' inside the function write_hex, which handles write hex. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 35: `def generate_vector_cases(rng: np.random.Generator, count_per_operation: int) -> dict[str, list[int]]:` This starts function generate_vector_cases. Its indented body performs generate vector cases as part of the file that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests; it runs only when called.

Line 36: `commands: list[int] = []` This assigns '[]' to 'commands' in host memory. Here commands means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_vector_cases, which handles generate vector cases.

Line 37: `operands_a: list[int] = []` This assigns '[]' to 'operands_a' in host memory. Here operands_a means the value named 'operands a' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_vector_cases, which handles generate vector cases.

Line 38: `operands_b: list[int] = []` This assigns '[]' to 'operands_b' in host memory. Here operands_b means the value named 'operands b' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_vector_cases, which handles generate vector cases.

Line 39: `expected: list[int] = []` This assigns '[]' to 'expected' in host memory. Here expected means the value named 'expected' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_vector_cases, which handles generate vector cases.

Line 40: `boundaries = np.array(` This statement continues through source line 42; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.array([-(1 << 31), -32768, -129, -1, 0, 1, 32767, (1 << 31) - 1], dtype=np.int64)' to 'boundaries ' in host memory. Here boundaries means the value named 'boundaries' in this block. The important operands are array: the value named 'array' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 41: `[-(1 << 31), -32768, -129, -1, 0, 1, 32767, (1 << 31) - 1], dtype=np.int64` This is continuation line 2 of the 3-line logical statement that begins at source line 40. Its exact fragment is '[-(1 << 31), -32768, -129, -1, 0, 1, 32767, (1 << 31) - 1], dtype=np.int64'. The important operands are dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Read together, the complete operation is: This assigns 'np.array([-(1 << 31), -32768, -129, -1, 0, 1, 32767, (1 << 31) - 1], dtype=np.int64)' to 'boundaries ' in host memory. Here boundaries means the value named 'boundaries' in this block. The important operands are array: the value named 'array' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 42: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 40. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.array([-(1 << 31), -32768, -129, -1, 0, 1, 32767, (1 << 31) - 1], dtype=np.int64)' to 'boundaries ' in host memory. Here boundaries means the value named 'boundaries' in this block. The important operands are array: the value named 'array' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 44: `for operation in VectorOperation:` This iterates operation over 'VectorOperation'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate_vector_cases, which handles generate vector cases.

Line 45: `for case_index in range(count_per_operation):` This iterates case_index over 'range(count_per_operation)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate_vector_cases, which handles generate vector cases.

Line 46: `if case_index == 0:` This executes the following indented host-code branch only when 'case_index == 0' is true. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function generate_vector_cases, which handles generate vector cases.

Line 47: `a = boundaries.copy()` This assigns 'boundaries.copy()' to 'a ' in host memory. Here a means the value named 'a' in this block. The important operands are boundaries: the value named 'boundaries' in this block; copy: the value named 'copy' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 48: `b = boundaries[::-1].copy()` This assigns 'boundaries[::-1].copy()' to 'b ' in host memory. Here b means the value named 'b' in this block. The important operands are boundaries: the value named 'boundaries' in this block; copy: the value named 'copy' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 49: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function generate_vector_cases, which handles generate vector cases.

Line 50: `a = rng.integers(-(1 << 20), 1 << 20, size=8, dtype=np.int64)` This assigns ‘rng.integers(-(1 << 20), 1 << 20, size=8, dtype=np.int64)‘ to ‘a ‘ in host memory. Here a means the value named ’a’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 51: `b = rng.integers(-(1 << 20), 1 << 20, size=8, dtype=np.int64)` This assigns ‘rng.integers(-(1 << 20), 1 << 20, size=8, dtype=np.int64)‘ to ‘b ‘ in host memory. Here b means the value named ’b’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 53: `multiplier = int(rng.integers(-32768, 32768))` This assigns ‘int(rng.integers(-32768, 32768))‘ to ‘multiplier ‘ in host memory. Here multiplier means the value named ’multiplier’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 54: `if operation == VectorOperation.FLEX_REQUANTIZE:` This executes the following indented host-code branch only when ‘operation == VectorOperation.FLEX_REQUANTIZE‘ is true. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function generate_vector_cases, which handles generate vector cases.

Line 55: `right_shift = int(rng.integers(-15, 16))` This assigns ‘int(rng.integers(-15, 16))‘ to ‘right_shift ‘ in host memory. Here right_shift means the value named ’right shift’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 56: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function generate_vector_cases, which handles generate vector cases.

Line 57: `right_shift = int(rng.integers(0, 8))` This assigns ‘int(rng.integers(0, 8))‘ to ‘right_shift ‘ in host memory. Here right_shift means the value named ’right shift’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 58: `zero_point = int(rng.integers(-128, 128))` This assigns ‘int(rng.integers(-128, 128))‘ to ‘zero_point ‘ in host memory. Here zero_point means the integer code representing real numeric zero in affine quantization. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 59: `threshold = int(rng.integers(1, 4097))` This assigns ‘int(rng.integers(1, 4097))‘ to ‘threshold ‘ in host memory. Here threshold means the membrane level at which a neuron emits a spike. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 60: `window = int(rng.integers(0, 4097))` This assigns ‘int(rng.integers(0, 4097))‘ to ‘window ‘ in host memory. Here window means the value named ’window’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 61: `clamp_minimum = int(rng.integers(-32768, 0))` This assigns ‘int(rng.integers(-32768, 0))‘ to ‘clamp_minimum ‘ in host memory. Here clamp_minimum means the value named ’clamp minimum’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 62: `clamp_maximum = int(rng.integers(0, 32768))` This assigns ‘int(rng.integers(0, 32768))‘ to ‘clamp_maximum ‘ in host memory. Here clamp_maximum means the value named ’clamp maximum’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 63: `result = vector_alu(` This statement continues through source line 74; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=cla clamp_maximum=clamp_maximum,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; operation: the value named ’operation’ in this block; a: the value named ’a’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 64: `operation,` This is continuation line 2 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘operation,‘. The important operands are operation: the value named ’operation’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; operation: the value named ’operation’ in this block; a: the value named ’a’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 65: `a,` This is continuation line 3 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘a,‘. The important operands are a: the value named ’a’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; operation: the value named ’operation’ in this block; a: the value named ’a’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 66: `b,` This is continuation line 4 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘b,‘. The important operands are b: the value named ’b’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; operation: the value named ’operation’ in this block; a: the value named ’a’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 67: `multiplier_q15=multiplier,` This is continuation line 5 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘multiplier_q15=multiplier,‘. The important operands are multiplier_q15: the value named ’multiplier q15’ in this block; multiplier: the value named ’multiplier’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maxi)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; operation: the value named ’operation’ in this block; a: the value named ’a’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 68: `right_shift=right_shift,` This is continuation line 6 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘right_shift=right_shift,‘. The important operands are right_shift: the value named ’right shift’ in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation,

a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘result ‘ in host memory. Here result means the value named 'result' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; a: the value named 'a' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 69: `output_zero_point=zero_point,` This is continuation line 7 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘output_zero_point=zero_point,‘. The important operands are output_zero_point: the integer code representing real numeric zero in affine quantization; zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘result ‘ in host memory. Here result means the value named 'result' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; a: the value named 'a' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 70: `threshold=threshold,` This is continuation line 8 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘threshold=threshold,‘. The important operands are threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘result ‘ in host memory. Here result means the value named 'result' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; a: the value named 'a' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 71: `surrogate_window=window,` This is continuation line 9 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘surrogate_window=window,‘. The important operands are surrogate_window: the value named 'surrogate window' in this block; window: the value named 'window' in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maxi
)‘ to ‘result ‘ in host memory. Here result means the value named 'result' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; a: the value named 'a' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 72: `clamp_minimum=clamp_minimum,` This is continuation line 10 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘clamp_minimum=clamp_minimum,‘. The important operands are clamp_minimum: the value named 'clamp minimum' in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘result ‘ in host memory. Here result means the value named 'result' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; a: the value named 'a' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 73: `clamp_maximum=clamp_maximum,` This is continuation line 11 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘clamp_maximum=clamp_maximum,‘. The important operands are clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,)‘ to ‘result ‘ in host memory. Here result means the value named 'result' in this block. The important operands are vector_alu: the value named 'vector alu' in this block; operation: the value named 'operation' in this block; a: the value named 'a' in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 74: `)` This is continuation line 12 of the 12-line logical statement that begins at source line 63. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘vector_alu(operation, a, b, multiplier_q15=multiplier, right_shift=right_shift, output_zero_point=zero_point, threshold=threshold, surrogate_window=window, clamp_minimum=clamp_minimum, clamp_maxi

)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are vector_alu: the value named ’vector alu’ in this block; operation: the value named ’operation’ in this block; a: the value named ’a’ in this block. Context: the function generate_vector_cases, which handles generate vector cases.

Line 76: `command = 0` This assigns ‘0‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_vector_cases, which handles generate vector cases.

Line 77: `command |= int(operation)` Inside the function generate_vector_cases, which handles generate vector cases, this statement advances the host implementation that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operation: the value named ’operation’ in this block.

Line 78: `command |= (multiplier & 0xFFFF) << 4` Inside the function generate_vector_cases, which handles generate vector cases, this statement advances the host implementation that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; multiplier: the value named ’multiplier’ in this block.

Line 79: `command |= (right_shift & 0x1F) << 20` Inside the function generate_vector_cases, which handles generate vector cases, this statement advances the host implementation that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; right_shift: the value named ’right shift’ in this block.

Line 80: `command |= (zero_point & 0xFFFF) << 25` Inside the function generate_vector_cases, which handles generate vector cases, this statement advances the host implementation that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; zero_point: the integer code representing real numeric zero in affine quantization.

Line 81: `command |= (threshold & 0xFFFFFFFF) << 41` Inside the function generate_vector_cases, which handles generate vector cases, this statement advances the host implementation that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; threshold: the membrane level at which a neuron emits a spike.

Line 82: `command |= window << 73` Inside the function generate_vector_cases, which handles generate vector cases, this statement advances the host implementation that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; window: the value named ’window’ in this block.

Line 83: `command |= (clamp_minimum & 0xFFFFFFFF) << 105` Inside the function generate_vector_cases, which handles generate vector cases, this statement advances the host implementation that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; clamp_minimum: the value named ’clamp minimum’ in this block.

Line 84: `command |= (clamp_maximum & 0xFFFFFFFF) << 137` Inside the function generate_vector_cases, which handles generate vector cases, this statement advances the host implementation that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; clamp_maximum: the value named ’clamp maximum’ in this block.

Line 85: `commands.append(command)` This calls ‘commands.append‘ with ‘command‘ inside the function generate_vector_cases, which handles generate vector cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 86: `operands_a.append(pack_signed(a, 32))` This calls ‘operands_a.append‘ with ‘pack_signed(a, 32)‘ inside the function generate_vector_cases, which handles generate vector cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 87: `operands_b.append(pack_signed(b, 32))` This calls ‘operands_b.append‘ with ‘pack_signed(b, 32)‘ inside the function generate_vector_cases, which handles generate vector cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 88: `expected.append(pack_signed(result, 32))` This calls ‘expected.append‘ with ‘pack_signed(result, 32)‘ inside the function generate_vector_cases, which handles generate vector cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 89: `return {"commands": commands, "a": operands_a, "b": operands_b, "expected": expected}` This returns ‘{"commands": commands, "a": operands_a, "b": operands_b, "expected": expected}‘ to the caller of the function generate_vector_cases, which handles generate vector cases, ending this invocation. The important operands are commands: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; a: the value named ’a’ in this block; operands_a: the value named ’operands a’ in this block.

Line 92: `def generate_optimizer_cases(rng: np.random.Generator, case_count: int) -> dict[str, list[int]]:` This starts function generate_optimizer_cases. Its indented body performs generate optimizer cases as part of the file that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests; it runs only when called.

Line 93: `parameters: list[int] = []` This assigns ‘[]‘ to ‘parameters‘ in host memory. Here parameters means the value named ’parameters’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 94: `weights: list[int] = []` This assigns ‘[]‘ to ‘weights‘ in host memory. Here weights means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 95: `gradients: list[int] = []` This assigns ‘[]‘ to ‘gradients‘ in host memory. Here gradients means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 96: `velocities: list[int] = []` This assigns ‘[]‘ to ‘velocities‘ in host memory. Here velocities means the value named ’velocities’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 97: `expected_weights: list[int] = []` This assigns ‘[]‘ to ‘expected_weights‘ in host memory. Here expected_weights means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 98: `expected_velocities: list[int] = []` This assigns ‘[]‘ to ‘expected_velocities‘ in host memory. Here expected_velocities means the value named ’expected velocities’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 100: `for case_index in range(case_count):` This iterates case_index over ‘range(case_count)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate_optimizer_cases, which handles generate optimizer cases.

Line 101: `if case_index == 0:` This executes the following indented host-code branch only when ‘case_index == 0‘ is true. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 102: `weight = np.array([-32768, -32767, -1, 0, 1, 32766, 32767, 123], dtype=np.int64)` This assigns ‘np.array([-32768, -32767, -1, 0, 1, 32766, 32767, 123], dtype=np.int64)‘ to ‘weight ‘ in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 103: `gradient = np.array([-(1 << 23), -(1 << 20), -1, 0, 1, 1 << 20, (1 << 23) - 1, -999])` This assigns ‘np.array([-(1 << 23), -(1 << 20), -1, 0, 1, 1 << 20, (1 << 23) - 1, -999])‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are array: the value named ’array’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 104: `velocity = gradient[::-1].copy()` This assigns ‘gradient[::-1].copy()‘ to ‘velocity ‘ in host memory. Here velocity means the momentum history retained by the SGD optimizer. The important operands are gradient: the signed loss derivative used to update a learned parameter; copy: the value named ’copy’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 105: `elif case_index == 1:` This executes the following indented host-code branch only when ‘case_index == 1‘ is true. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 106: `# This case distinguishes SGDW from coupled L2: decay changes the` The comment records this intent: This case distinguishes SGDW from coupled L2: decay changes the It applies inside the function generate_optimizer_cases, which handles generate optimizer cases.

Line 107: `# weight direction but must not be retained in the velocity.` The comment records this intent: weight direction but must not be retained in the velocity. It applies inside the function generate_optimizer_cases, which handles generate optimizer cases.

Line 108: `weight = np.full(8, 1000, dtype=np.int64)` This assigns ‘np.full(8, 1000, dtype=np.int64)‘ to ‘weight ‘ in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are full: the value named ’full’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 109: `gradient = np.zeros(8, dtype=np.int64)` This assigns ‘np.zeros(8, dtype=np.int64)‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are zeros: the value named ’zeros’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 110: `velocity = np.full(8, 1000, dtype=np.int64)` This assigns ‘np.full(8, 1000, dtype=np.int64)‘ to ‘velocity ‘ in host memory. Here velocity means the momentum history retained by the SGD optimizer. The important operands are full: the value named ’full’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 111: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function generate_optimizer_cases, which handles generate optimizer cases.

Line 112: `weight = rng.integers(-32768, 32768, size=8, dtype=np.int64)` This assigns ‘rng.integers(-32768, 32768, size=8, dtype=np.int64)‘ to ‘weight ‘ in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 113: `gradient = rng.integers(-(1 << 23), 1 << 23, size=8, dtype=np.int64)` This assigns ‘rng.integers(-(1 << 23), 1 << 23, size=8, dtype=np.int64)‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 114: `velocity = rng.integers(-(1 << 23), 1 << 23, size=8, dtype=np.int64)` This assigns ‘rng.integers(-(1 << 23), 1 << 23, size=8, dtype=np.int64)‘ to ‘velocity ‘ in host memory. Here velocity means the momentum history retained by the SGD optimizer. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 115: `if case_index == 1:` This executes the following indented host-code branch only when ‘case_index == 1‘ is true. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 116: `learning_rate = 65536` This assigns ‘65536‘ to ‘learning_rate ‘ in host memory. Here learning_rate means the fixed-point multiplier controlling update magnitude. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 117: `momentum = 65536` This assigns ‘65536‘ to ‘momentum ‘ in host memory. Here momentum means the value named ’momentum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 118: `weight_decay = 65536` This assigns ‘65536‘ to ‘weight_decay ‘ in host memory. Here weight_decay means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 119: `update_right_shift = 16` This assigns ‘16‘ to ‘update_right_shift ‘ in host memory. Here update_right_shift means the value named ’update right shift’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 120: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function generate_optimizer_cases, which handles generate optimizer cases.

Line 121: `learning_rate = int(rng.integers(1, 131072))` This assigns ‘int(rng.integers(1, 131072))‘ to ‘learning_rate ‘ in host memory. Here learning_rate means the fixed-point multiplier controlling update magnitude. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 122: `momentum = int(rng.integers(0, 65537))` This assigns ‘int(rng.integers(0, 65537))‘ to ‘momentum ‘ in host memory. Here momentum means the value named ’momentum’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 123: `weight_decay = int(rng.integers(0, 65537))` This assigns ‘int(rng.integers(0, 65537))‘ to ‘weight_decay ‘ in host memory. Here weight_decay means a learned coefficient multiplied by an activation. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 124: `update_right_shift = 16 if case_index == 0 else int(rng.integers(0, 32))` Inside the function generate_optimizer_cases, which handles generate optimizer cases, this statement advances the host implementation that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The important operands are update_right_shift: the value named 'update right shift' in this block; case_index: an integer selecting one tensor element, lane, bank, or state entry; rng: the value named 'rng' in this block.

Line 125: `next_weight, next_velocity = sgd_momentum_step(` This statement continues through source line 133; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'sgd_momentum_step(weight, gradient, velocity, learning_rate, momentum, weight_decay, update_right_shift,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weight: a learned coefficient multiplied by an activation; gradient: the signed loss derivative used to update a learned parameter. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 126: `weight,` This is continuation line 2 of the 9-line logical statement that begins at source line 125. Its exact fragment is 'weight,'. The important operands are weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'sgd_momentum_step(weight, gradient, velocity, learning_rate, momentum, weight_decay, update_right_shift,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weight: a learned coefficient multiplied by an activation; gradient: the signed loss derivative used to update a learned parameter. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 127: `gradient,` This is continuation line 3 of the 9-line logical statement that begins at source line 125. Its exact fragment is 'gradient,'. The important operands are gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'sgd_momentum_step(weight, gradient, velocity, learning_rate, momentum, weight_decay, update_right_shift,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weight: a learned coefficient multiplied by an activation; gradient: the signed loss derivative used to update a learned parameter. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 128: `velocity,` This is continuation line 4 of the 9-line logical statement that begins at source line 125. Its exact fragment is 'velocity,'. The important operands are velocity: the momentum history retained by the SGD optimizer. Read together, the complete operation is: This assigns 'sgd_momentum_step(weight, gradient, velocity, learning_rate, momentum, weight_decay, update_right_shift,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weight: a learned coefficient multiplied by an activation; gradient: the signed loss derivative used to update a learned parameter. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 129: `learning_rate,` This is continuation line 5 of the 9-line logical statement that begins at source line 125. Its exact fragment is 'learning_rate,'. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns 'sgd_momentum_step(weight, gradient, velocity, learning_rate, momentum, weight_decay, update_right_shift,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weight: a learned coefficient multiplied by an activation; gradient: the signed loss derivative used to update a learned parameter. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 130: `momentum,` This is continuation line 6 of the 9-line logical statement that begins at source line 125. Its exact fragment is 'momentum,'. The important operands are momentum: the value named 'momentum' in this block. Read together, the complete operation is: This assigns 'sgd_momentum_step(weight, gradient, velocity, learning_rate, momentum, weight_decay, update_right_shift,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weight: a learned coefficient multiplied by an activation; gradient: the signed

loss derivative used to update a learned parameter. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 131: `weight_decay,` This is continuation line 7 of the 9-line logical statement that begins at source line 125. Its exact fragment is 'weight_decay,'. The important operands are weight_decay: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'sgd_momentum_step(weight, gradient, velocity, learning_rate, momentum, weight_decay, update_right_shift,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weight: a learned coefficient multiplied by an activation; gradient: the signed loss derivative used to update a learned parameter. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 132: `update_right_shift,` This is continuation line 8 of the 9-line logical statement that begins at source line 125. Its exact fragment is 'update_right_shift,'. The important operands are update_right_shift: the value named 'update right shift' in this block. Read together, the complete operation is: This assigns 'sgd_momentum_step(weight, gradient, velocity, learning_rate, momentum, weight_decay, update_right_shift,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weight: a learned coefficient multiplied by an activation; gradient: the signed loss derivative used to update a learned parameter. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 133: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 125. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_momentum_step(weight, gradient, velocity, learning_rate, momentum, weight_decay, update_right_shift,)' to 'next_weight, next_velocity ' in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are sgd_momentum_step: the value named 'sgd momentum step' in this block; weight: a learned coefficient multiplied by an activation; gradient: the signed loss derivative used to update a learned parameter. Context: the function generate_optimizer_cases, which handles generate optimizer cases.

Line 134: `parameters.append(` This statement continues through source line 139; the explanation uses the complete expression rather than only the first visual fragment. This calls 'parameters.append' with ' learning_rate | (momentum << 18) | (weight_decay << 35) | (update_right_shift << 52) ' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 135: `learning_rate` This is continuation line 2 of the 6-line logical statement that begins at source line 134. Its exact fragment is 'learning_rate'. The important operands are learning_rate: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This calls 'parameters.append' with ' learning_rate | (momentum << 18) | (weight_decay << 35) | (update_right_shift << 52) ' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 136: `| (momentum << 18)` This is continuation line 3 of the 6-line logical statement that begins at source line 134. Its exact fragment is '| (momentum << 18)'. The important operands are momentum: the value named 'momentum' in this block. Read together, the complete operation is: This calls 'parameters.append' with ' learning_rate | (momentum << 18) | (weight_decay << 35) | (update_right_shift << 52) ' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 137: `| (weight_decay << 35)` This is continuation line 4 of the 6-line logical statement that begins at source line 134. Its exact fragment is '| (weight_decay << 35)'. The important operands are weight_decay: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls 'parameters.append' with ' learning_rate | (momentum << 18) | (weight_decay << 35) | (update_right_shift << 52) ' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 138: `| (update_right_shift << 52)` This is continuation line 5 of the 6-line logical statement that begins at source line 134. Its exact fragment is '| (update_right_shift << 52)'. The important operands are update_right_shift: the value named 'update right shift' in this block. Read together, the complete operation is: This calls 'parameters.append' with ' learning_rate | (momentum << 18) | (weight_decay << 35) | (update_right_shift << 52) ' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 139: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 134. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'parameters.append' with ' learning_rate | (momentum << 18) | (weight_decay << 35) | (update_right_shift << 52) ' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 140: `weights.append(pack_signed(weight, 16))` This calls 'weights.append' with 'pack_signed(weight, 16)' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 141: `gradients.append(pack_signed(gradient, 24))` This calls 'gradients.append' with 'pack_signed(gradient, 24)' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 142: `velocities.append(pack_signed(velocity, 24))` This calls 'velocities.append' with 'pack_signed(velocity, 24)' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 143: `expected_weights.append(pack_signed(next_weight, 16))` This calls 'expected_weights.append' with 'pack_signed(next_weight, 16)' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 144: `expected_velocities.append(pack_signed(next_velocity, 24))` This calls 'expected_velocities.append' with 'pack_signed(next_velocity, 24)' inside the function generate_optimizer_cases, which handles generate optimizer cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 145: `return {` This statement continues through source line 152; the explanation uses the complete expression rather than only the first visual fragment. This returns '{ "parameters": parameters, "weights": weights, "gradients": gradients, "velocities": velocities, "expected_weights": expected_weights, "expected_velocities": expected_velocities, }' to the caller of the function generate_optimizer_cases, which handles generate optimizer cases, ending this invocation. The important operands are parameters: the value named 'parameters' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter.

Line 146: `"parameters": parameters,` This is continuation line 2 of the 8-line logical statement that begins at source line 145. Its exact fragment is '"parameters": parameters,'. The important operands are parameters: the value named 'parameters' in this block. Read together, the complete operation is: This returns '{ "parameters": parameters, "weights": weights, "gradients": gradients, "velocities": velocities, "expected_weights": expected_weights, "expected_velocities": expected_velocities, }' to the caller of the function generate_optimizer_cases, which handles generate optimizer cases, ending this invocation. The important operands are parameters: the value named 'parameters' in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter.

Line 147: `"weights": weights,` This is continuation line 3 of the 8-line logical statement that begins at source line 145. Its exact fragment is '"weights": weights,'. The important operands are weights: a learned coefficient multiplied by an activation. Read together, the complete operation is: This returns '{ "parameters": parameters, "weights": weights, "gradients": gradients, "velocities": velocities, "expected_weights": expected_weights, "expected_velocities":

expected_velocities, }‘ to the caller of the function generate_optimizer_cases, which handles generate optimizer cases, ending this invocation. The important operands are parameters: the value named ’parameters’ in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter.

Line 148: `"gradients": gradients,` This is continuation line 4 of the 8-line logical statement that begins at source line 145. Its exact fragment is ‘"gradients": gradients,‘. The important operands are gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This returns ‘{ "parameters": parameters, "weights": weights, "gradients": gradients, "velocities": velocities, "expected_weights": expected_weights, "expected_velocities": expected_velocities, }‘ to the caller of the function generate_optimizer_cases, which handles generate optimizer cases, ending this invocation. The important operands are parameters: the value named ’parameters’ in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter.

Line 149: `"velocities": velocities,` This is continuation line 5 of the 8-line logical statement that begins at source line 145. Its exact fragment is ‘"velocities": velocities,‘. The important operands are velocities: the value named ’velocities’ in this block. Read together, the complete operation is: This returns ‘{ "parameters": parameters, "weights": weights, "gradients": gradients, "velocities": velocities, "expected_weights": expected_weights, "expected_velocities": expected_velocities, }‘ to the caller of the function generate_optimizer_cases, which handles generate optimizer cases, ending this invocation. The important operands are parameters: the value named ’parameters’ in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter.

Line 150: `"expected_weights": expected_weights,` This is continuation line 6 of the 8-line logical statement that begins at source line 145. Its exact fragment is ‘"expected_weights": expected_weights,‘. The important operands are expected_weights: a learned coefficient multiplied by an activation. Read together, the complete operation is: This returns ‘{ "parameters": parameters, "weights": weights, "gradients": gradients, "velocities": velocities, "expected_weights": expected_weights, "expected_velocities": expected_velocities, }‘ to the caller of the function generate_optimizer_cases, which handles generate optimizer cases, ending this invocation. The important operands are parameters: the value named ’parameters’ in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter.

Line 151: `"expected_velocities": expected_velocities,` This is continuation line 7 of the 8-line logical statement that begins at source line 145. Its exact fragment is ‘"expected_velocities": expected_velocities,‘. The important operands are expected_velocities: the value named ’expected velocities’ in this block. Read together, the complete operation is: This returns ‘{ "parameters": parameters, "weights": weights, "gradients": gradients, "velocities": velocities, "expected_weights": expected_weights, "expected_velocities": expected_velocities, }‘ to the caller of the function generate_optimizer_cases, which handles generate optimizer cases, ending this invocation. The important operands are parameters: the value named ’parameters’ in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter.

Line 152: `}` This is continuation line 8 of the 8-line logical statement that begins at source line 145. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘{ "parameters": parameters, "weights": weights, "gradients": gradients, "velocities": velocities, "expected_weights": expected_weights, "expected_velocities": expected_velocities, }‘ to the caller of the function generate_optimizer_cases, which handles generate optimizer cases, ending this invocation. The important operands are parameters: the value named ’parameters’ in this block; weights: a learned coefficient multiplied by an activation; gradients: the signed loss derivative used to update a learned parameter.

Line 155: `def generate_layernorm_cases(rng: np.random.Generator) -> dict[str, list[int]]:` This starts function generate_layernorm_cases. Its indented body performs generate layernorm cases as part of the file that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests; it runs only when called.

Line 156: `descriptors: list[int] = []` This assigns ‘[]‘ to ‘descriptors‘ in host memory. Here descriptors means a DMA record header plus one command and its declared payload. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 157: `values: list[int] = []` This assigns '[]' to 'values' in host memory. Here values means the value named 'values' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 158: `gammas: list[int] = []` This assigns '[]' to 'gammas' in host memory. Here gammas means the learned multiplicative LayerNorm parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 159: `betas: list[int] = []` This assigns '[]' to 'betas' in host memory. Here betas means the learned additive LayerNorm parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 160: `expected: list[int] = []` This assigns '[]' to 'expected' in host memory. Here expected means the value named 'expected' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 161: `debug: list[int] = []` This assigns '[]' to 'debug' in host memory. Here debug means the value named 'debug' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 162: `lengths = [1, 4, 7, 32, 64, 127, 384, 1536]` This assigns '[1, 4, 7, 32, 64, 127, 384, 1536]' to 'lengths ' in host memory. Here lengths means the value named 'lengths' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 164: `for case_index, length in enumerate(lengths):` This iterates case_index, length over 'enumerate(lengths)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate_layernorm_cases, which handles generate layernorm cases.

Line 165: `epsilon = 1 + case_index * 3` This assigns '1 + case_index * 3' to 'epsilon ' in host memory. Here epsilon means the value named 'epsilon' in this block. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 166: `if case_index == 0:` This executes the following indented host-code branch only when 'case_index == 0' is true. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 167: `x = np.array([17], dtype=np.int64)` This assigns 'np.array([17], dtype=np.int64)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are array: the value named 'array' in this block; dtype: the value named 'dtype' in this block; int64: the value named 'int64' in this block. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 168: `elif case_index == 1:` This executes the following indented host-code branch only when 'case_index == 1' is true. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 169: `x = np.full(length, -91, dtype=np.int64)` This assigns 'np.full(length, -91, dtype=np.int64)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are full: the value named 'full' in this block; length: the value named 'length' in this block; dtype: the value named 'dtype' in this block. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 170: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function generate_layernorm_cases, which handles generate layernorm cases.

Line 171: `x = rng.integers(-8192, 8193, size=length, dtype=np.int64)` This assigns ‘rng.integers(-8192, 8193, size=length, dtype=np.int64)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 172: `gamma = rng.integers(8192, 49153, size=length, dtype=np.int64)` This assigns ‘rng.integers(8192, 49153, size=length, dtype=np.int64)‘ to ‘gamma ‘ in host memory. Here gamma means the learned multiplicative LayerNorm parameter. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 173: `beta = rng.integers(-2048, 2049, size=length, dtype=np.int64)` This assigns ‘rng.integers(-2048, 2049, size=length, dtype=np.int64)‘ to ‘beta ‘ in host memory. Here beta means the learned additive LayerNorm parameter. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 174: `output = integer_layer_norm(x, gamma, beta, epsilon)` This assigns ‘integer_layer_norm(x, gamma, beta, epsilon)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are integer_layer_norm: the value named ’integer layer norm’ in this block; x: the value named ’x’ in this block; gamma: the learned multiplicative LayerNorm parameter. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 175: `mean = int(x.sum() // length)` This assigns ‘int(x.sum() // length)‘ to ‘mean ‘ in host memory. Here mean means the arithmetic average used by normalization. The important operands are x: the value named ’x’ in this block; sum: the value named ’sum’ in this block; length: the value named ’length’ in this block. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 176: `centered = x - mean` This assigns ‘x - mean‘ to ‘centered ‘ in host memory. Here centered means the value named ’centered’ in this block. The important operands are x: the value named ’x’ in this block; mean: the arithmetic average used by normalization. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 177: `variance = int((centered * centered).sum() // length)` This assigns ‘int((centered * centered).sum() // length)‘ to ‘variance ‘ in host memory. Here variance means the average squared distance from the mean. The important operands are centered: the value named ’centered’ in this block; sum: the value named ’sum’ in this block; length: the value named ’length’ in this block. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 178: `sigma = max(1, isqrt(variance + epsilon))` This assigns ‘max(1, isqrt(variance + epsilon))‘ to ‘sigma ‘ in host memory. Here sigma means the value named ’sigma’ in this block. The important operands are max: the value named ’max’ in this block; isqrt: the value named ’isqrt’ in this block; variance: the average squared distance from the mean. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 179: `reciprocal = ((1 << 31) - 1) // sigma` This assigns ‘((1 << 31) - 1) // sigma‘ to ‘reciprocal ‘ in host memory. Here reciprocal means the value named ’reciprocal’ in this block. The important operands are sigma: the value named ’sigma’ in this block. Context: the function generate_layernorm_cases, which handles generate layernorm cases.

Line 181: `descriptors.append(length | (epsilon << 12))` This calls ‘descriptors.append‘ with ‘length | (epsilon << 12)‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 182: `values.extend(int(value) for value in x)` This calls ‘values.extend‘ with ‘int(value) for value in x‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 183: `gammas.extend(int(value) for value in gamma)` This calls ‘gammas.extend‘ with ‘int(value) for value in gamma‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 184: `betas.extend(int(value) for value in beta)` This calls ‘betas.extend‘ with ‘int(value) for value in beta‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 185: `expected.extend(int(value) for value in output)` This calls ‘expected.extend‘ with ‘int(value) for value in output‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 186: `debug.append(` This statement continues through source line 191; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘debug.append‘ with ‘ (mean & 0xFFFFFFFF) | (variance << 32) | (sigma << 64) | (reciprocal << 96) ‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 187: `(mean & 0xFFFFFFFF)` This is continuation line 2 of the 6-line logical statement that begins at source line 186. Its exact fragment is ‘(mean & 0xFFFFFFFF)‘. The important operands are mean: the arithmetic average used by normalization. Read together, the complete operation is: This calls ‘debug.append‘ with ‘ (mean & 0xFFFFFFFF) | (variance << 32) | (sigma << 64) | (reciprocal << 96) ‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 188: `| (variance << 32)` This is continuation line 3 of the 6-line logical statement that begins at source line 186. Its exact fragment is ‘| (variance << 32)‘. The important operands are variance: the average squared distance from the mean. Read together, the complete operation is: This calls ‘debug.append‘ with ‘ (mean & 0xFFFFFFFF) | (variance << 32) | (sigma << 64) | (reciprocal << 96) ‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 189: `| (sigma << 64)` This is continuation line 4 of the 6-line logical statement that begins at source line 186. Its exact fragment is ‘| (sigma << 64)‘. The important operands are sigma: the value named ’sigma’ in this block. Read together, the complete operation is: This calls ‘debug.append‘ with ‘ (mean & 0xFFFFFFFF) | (variance << 32) | (sigma << 64) | (reciprocal << 96) ‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 190: `| (reciprocal << 96)` This is continuation line 5 of the 6-line logical statement that begins at source line 186. Its exact fragment is ‘| (reciprocal << 96)‘. The important operands are reciprocal: the value named ’reciprocal’ in this block. Read together, the complete operation is: This calls ‘debug.append‘ with ‘ (mean & 0xFFFFFFFF) | (variance << 32) | (sigma << 64) | (reciprocal << 96) ‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 191: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 186. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘debug.append‘ with ‘ (mean & 0xFFFFFFFF) | (variance << 32) | (sigma << 64) | (reciprocal << 96) ‘ inside the function generate_layernorm_cases, which handles generate layernorm cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 192: `return {` This statement continues through source line 200; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘{ "descriptors": descriptors, "values": values, "gammas": gammas, "betas": betas, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_layernorm_cases, which handles generate layernorm cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; values: the value named ’values’ in this block; gammas: the learned multiplicative LayerNorm parameter.

Line 193: `"descriptors": descriptors,` This is continuation line 2 of the 9-line logical statement that begins at source line 192. Its exact fragment is ‘"descriptors": descriptors,‘. The important operands are descriptors: a DMA record header plus one command and its declared payload. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "values": values, "gammas": gammas, "betas": betas, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_layernorm_cases, which handles generate layernorm cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; values: the value named ’values’ in this block; gammas: the learned multiplicative LayerNorm parameter.

Line 194: `"values": values,` This is continuation line 3 of the 9-line logical statement that begins at source line 192. Its exact fragment is ‘"values": values,‘. The important operands are values: the value named ’values’ in this block. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "values": values, "gammas": gammas, "betas": betas, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_layernorm_cases, which handles generate layernorm cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; values: the value named ’values’ in this block; gammas: the learned multiplicative LayerNorm parameter.

Line 195: `"gammas": gammas,` This is continuation line 4 of the 9-line logical statement that begins at source line 192. Its exact fragment is ‘"gammas": gammas,‘. The important operands are gammas: the learned multiplicative LayerNorm parameter. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "values": values, "gammas": gammas, "betas": betas, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_layernorm_cases, which handles generate layernorm cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; values: the value named ’values’ in this block; gammas: the learned multiplicative LayerNorm parameter.

Line 196: `"betas": betas,` This is continuation line 5 of the 9-line logical statement that begins at source line 192. Its exact fragment is ‘"betas": betas,‘. The important operands are betas: the learned additive LayerNorm parameter. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "values": values, "gammas": gammas, "betas": betas, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_layernorm_cases, which handles generate layernorm cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; values: the value named ’values’ in this block; gammas: the learned multiplicative LayerNorm parameter.

Line 197: `"expected": expected,` This is continuation line 6 of the 9-line logical statement that begins at source line 192. Its exact fragment is ‘"expected": expected,‘. The important operands are expected: the value named ’expected’ in this block. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "values": values, "gammas": gammas, "betas": betas, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_layernorm_cases, which handles generate layernorm cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; values: the value named ’values’ in this block; gammas: the learned multiplicative LayerNorm parameter.

Line 198: `"debug": debug,` This is continuation line 7 of the 9-line logical statement that begins at source line 192. Its exact fragment is ‘"debug": debug,‘. The important operands are debug: the value named ’debug’ in this block. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "values": values, "gammas": gammas, "betas": betas, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_layernorm_cases, which handles generate layernorm cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; values: the value named ’values’ in this block; gammas: the learned multiplicative LayerNorm parameter.

Line 199: `"lengths": lengths,` This is continuation line 8 of the 9-line logical statement that begins at source line 192. Its exact fragment is ‘"lengths": lengths,‘. The important operands are lengths: the value named ’lengths’ in this block. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "values": values, "gammas": gammas, "betas": betas, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_layernorm_cases, which handles generate layernorm cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; values: the value named ’values’ in this block; gammas: the learned multiplicative LayerNorm parameter.

Line 200: `}` This is continuation line 9 of the 9-line logical statement that begins at source line 192. Its exact fragment is ‘}‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "values": values, "gammas": gammas, "betas": betas, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_layernorm_cases, which handles generate layernorm cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; values: the value named ’values’ in this block; gammas: the learned multiplicative LayerNorm parameter.

Line 203: `def generate_softmax_cases(rng: np.random.Generator) -> dict[str, list[int]]:` This starts function generate_softmax_cases. Its indented body performs generate softmax cases as part of the file that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests; it runs only when called.

Line 204: `descriptors: list[int] = []` This assigns ‘[]‘ to ‘descriptors‘ in host memory. Here descriptors means a DMA record header plus one command and its declared payload. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 205: `scores: list[int] = []` This assigns ‘[]‘ to ‘scores‘ in host memory. Here scores means the value named ’scores’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 206: `expected: list[int] = []` This assigns ‘[]‘ to ‘expected‘ in host memory. Here expected means the value named ’expected’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 207: `debug: list[int] = []` This assigns ‘[]‘ to ‘debug‘ in host memory. Here debug means the value named ’debug’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 208: `lengths = [1, 4, 7, 32, 64, 127, 256]` This assigns ‘[1, 4, 7, 32, 64, 127, 256]‘ to ‘lengths ‘ in host memory. Here lengths means the value named ’lengths’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 210: `for case_index, length in enumerate(lengths):` This iterates case_index, length over ‘enumerate(lengths)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function generate_softmax_cases, which handles generate softmax cases.

Line 211: `difference_shift = case_index % 8` This assigns ‘case_index % 8‘ to ‘difference_shift ‘ in host memory. Here difference_shift means the value named ’difference shift’ in this block. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 212: `if case_index == 0:` This executes the following indented host-code branch only when ‘case_index == 0‘ is true. The important operands are case_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 213: `score = np.array([123], dtype=np.int64)` This assigns ‘np.array([123], dtype=np.int64)‘ to ‘score ‘ in host memory. Here score means the value named ’score’ in this block. The important operands are array: the value named ’array’ in this block; dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 214: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function generate_softmax_cases, which handles generate softmax cases.

Line 215: `score = rng.integers(-(1 << 18), 1 << 18, size=length, dtype=np.int64)` This assigns ‘rng.integers(-(1 << 18), 1 << 18, size=length, dtype=np.int64)‘ to ‘score ‘ in host memory. Here score means the value named ’score’ in this block. The important operands are rng: the value named ’rng’ in this block; integers: the value named ’integers’ in this block; size: the value named ’size’ in this block. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 216: `probability = log_int_softmax_q15(score, difference_shift)` This assigns ‘log_int_softmax_q15(score, difference_shift)‘ to ‘probability ‘ in host memory. Here probability means the value named ’probability’ in this block. The important operands are log_int_softmax_q15: the value named ’log int softmax q15’ in this block; score: the value named ’score’ in this block; difference_shift: the value named ’difference shift’ in this block. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 217: `difference = score.max() - score` This assigns ‘score.max() - score‘ to ‘difference ‘ in host memory. Here difference means the value named ’difference’ in this block. The important operands are score: the value named ’score’ in this block; max: the value named ’max’ in this block. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 218: `exponent = np.minimum(difference >> difference_shift, 15)` This assigns ‘np.minimum(difference >> difference_shift, 15)‘ to ‘exponent ‘ in host memory. Here exponent means the value named ’exponent’ in this block. The important operands are minimum: the value named ’minimum’ in this block; difference: the value named ’difference’ in this block; difference_shift: the value named ’difference shift’ in this block. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 219: `unnormalized = 1 << (15 - exponent)` This assigns ‘1 << (15 - exponent)‘ to ‘unnormalized ‘ in host memory. Here unnormalized means the value named ’unnormalized’ in this block. The important operands are exponent: the value named ’exponent’ in this block. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 220: `denominator = int(unnormalized.sum())` This assigns ‘int(unnormalized.sum())‘ to ‘denominator ‘ in host memory. Here denominator means the value named ’denominator’ in this block. The important operands are unnormalized: the value named ’unnormalized’ in this block; sum: the value named ’sum’ in this block. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 221: `reciprocal = ((1 << 31) - 1) // denominator` This assigns ‘((1 << 31) - 1) // denominator‘ to ‘reciprocal ‘ in host memory. Here reciprocal means the value named ’reciprocal’ in this block. The important operands are denominator: the value named ’denominator’ in this block. Context: the function generate_softmax_cases, which handles generate softmax cases.

Line 223: `descriptors.append(length | (difference_shift << 9))` This calls ‘descriptors.append‘ with ‘length | (difference_shift << 9)‘ inside the function generate_softmax_cases, which handles generate softmax cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 224: `scores.extend(int(value) for value in score)` This calls ‘scores.extend‘ with ‘int(value) for value in score‘ inside the function generate_softmax_cases, which handles generate softmax cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 225: `expected.extend(int(value) for value in probability)` This calls ‘expected.extend‘ with ‘int(value) for value in probability‘ inside the function generate_softmax_cases, which handles generate softmax cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 226: `debug.append((int(score.max()) & 0xFFFFFF) | (denominator << 24) | (reciprocal << 48))` This calls ‘debug.append‘ with ‘(int(score.max()) & 0xFFFFFF) | (denominator << 24) | (reciprocal << 48)‘ inside the function generate_softmax_cases, which handles generate softmax cases. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 227: `return {` This statement continues through source line 233; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘{ "descriptors": descriptors, "scores": scores, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_softmax_cases, which handles generate softmax cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; scores: the value named ’scores’ in this block; expected: the value named ’expected’ in this block.

Line 228: `"descriptors": descriptors,` This is continuation line 2 of the 7-line logical statement that begins at source line 227. Its exact fragment is ‘"descriptors": descriptors,‘. The important operands are descriptors: a DMA record header plus one command and its declared payload. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "scores": scores, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_softmax_cases, which handles generate softmax cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; scores: the value named ’scores’ in this block; expected: the value named ’expected’ in this block.

Line 229: `"scores": scores,` This is continuation line 3 of the 7-line logical statement that begins at source line 227. Its exact fragment is ‘"scores": scores,‘. The important operands are scores: the value named ’scores’ in this block. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "scores": scores, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_softmax_cases, which handles generate softmax cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; scores: the value named ’scores’ in this block; expected: the value named ’expected’ in this block.

Line 230: `"expected": expected,` This is continuation line 4 of the 7-line logical statement that begins at source line 227. Its exact fragment is ‘"expected": expected,‘. The important operands are expected: the value named ’expected’ in this block. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "scores": scores, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_softmax_cases, which handles generate softmax cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; scores: the value named ’scores’ in this block; expected: the value named ’expected’ in this block.

Line 231: `"debug": debug,` This is continuation line 5 of the 7-line logical statement that begins at source line 227. Its exact fragment is ‘"debug": debug,‘. The important operands are debug: the value named ’debug’ in this block. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "scores": scores, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_softmax_cases, which handles generate softmax cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; scores: the value named ’scores’ in this block; expected: the value named ’expected’ in this block.

Line 232: `"lengths": lengths,` This is continuation line 6 of the 7-line logical statement that begins at source line 227. Its exact fragment is ‘"lengths": lengths,‘. The important operands are lengths: the value named ’lengths’ in this block. Read together, the complete operation is: This returns ‘{ "descriptors": descriptors, "scores": scores, "expected": expected, "debug": debug, "lengths": lengths, }‘ to the caller of the function generate_softmax_cases, which handles generate softmax cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; scores: the value named ’scores’ in this block; expected: the value named ’expected’ in this block.

Line 233: `}` This is continuation line 7 of the 7-line logical statement that begins at source line 227. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns '{ "descriptors": descriptors, "scores": scores, "expected": expected, "debug": debug, "lengths": lengths, }' to the caller of the function generate_softmax_cases, which handles generate softmax cases, ending this invocation. The important operands are descriptors: a DMA record header plus one command and its declared payload; scores: the value named 'scores' in this block; expected: the value named 'expected' in this block.

Line 236: `def main() -> None:` This starts function main. Its indented body performs main as part of the file that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests; it runs only when called.

Line 237: `parser = argparse.ArgumentParser()` This assigns 'argparse.ArgumentParser()' to 'parser ' in host memory. Here parser means the value named 'parser' in this block. The important operands are argparse: the value named 'argparse' in this block; ArgumentParser: the value named 'argument parser' in this block. Context: the function main, which handles main.

Line 238: `parser.add_argument("-output-dir", type=Path, default=Path("tb/fixtures"))` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 239: `parser.add_argument("-vector-count-per-operation", type=int, default=24)` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 240: `parser.add_argument("-optimizer-cases", type=int, default=128)` This declares a command-line option for the function main, which handles main. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 241: `args = parser.parse_args()` This assigns 'parser.parse_args()' to 'args ' in host memory. Here args means the value named 'args' in this block. The important operands are parser: the value named 'parser' in this block; parse_args: the value named 'parse args' in this block. Context: the function main, which handles main.

Line 242: `args.output_dir.mkdir(parents=True, exist_ok=True)` This calls 'args.output_dir.mkdir' with 'parents=True, exist_ok=True' inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 243: `rng = np.random.default_rng(20260711)` This assigns 'np.random.default_rng(20260711)' to 'rng ' in host memory. Here rng means the value named 'rng' in this block. The important operands are random: the value named 'random' in this block; default_rng: the value named 'default rng' in this block. Context: the function main, which handles main.

Line 245: `vector = generate_vector_cases(rng, args.vector_count_per_operation)` This assigns 'generate_vector_case
args.vector_count_per_operation)' to 'vector ' in host memory. Here vector means the value named 'vector' in this block. The important operands are generate_vector_cases: the value named 'generate vector cases' in this block; rng: the value named 'rng' in this block; args: the value named 'args' in this block. Context: the function main, which handles main.

Line 246: `optimizer = generate_optimizer_cases(rng, args.optimizer_cases)` This assigns 'generate_optimizer_cases(r
args.optimizer_cases)' to 'optimizer ' in host memory. Here optimizer means the value named 'optimizer' in this block. The important operands are generate_optimizer_cases: the value named 'generate optimizer cases' in this block; rng: the value named 'rng' in this block; args: the value named 'args' in this block. Context: the function main, which handles main.

Line 247: `layernorm = generate_layernorm_cases(rng)` This assigns 'generate_layernorm_cases(rng)' to 'layernorm ' in host memory. Here layernorm means the value named 'layernorm' in this block. The important operands are generate_layernorm_cases: the value named 'generate layernorm cases' in this block; rng: the value named 'rng' in this block. Context: the function main, which handles main.

Line 248: `softmax = generate_softmax_cases(rng)` This assigns ‘generate_softmax_cases(rng)‘ to ‘softmax ‘ in host memory. Here softmax means the value named ’softmax’ in this block. The important operands are generate_softmax_cases: the value named ’generate softmax cases’ in this block; rng: the value named ’rng’ in this block. Context: the function main, which handles main.

Line 249: `write_hex(args.output_dir / "vector_commands.mem", vector["commands"], 192)` This calls ‘write_hex‘ with ‘args.output_dir / "vector_commands.mem", vector["commands"], 192‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 250: `write_hex(args.output_dir / "vector_a.mem", vector["a"], 256)` This calls ‘write_hex‘ with ‘args.output_dir / "vector_a.mem", vector["a"], 256‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 251: `write_hex(args.output_dir / "vector_b.mem", vector["b"], 256)` This calls ‘write_hex‘ with ‘args.output_dir / "vector_b.mem", vector["b"], 256‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 252: `write_hex(args.output_dir / "vector_expected.mem", vector["expected"], 256)` This calls ‘write_hex‘ with ‘args.output_dir / "vector_expected.mem", vector["expected"], 256‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 253: `write_hex(args.output_dir / "optimizer_parameters.mem", optimizer["parameters"], 64)` This calls ‘write_hex‘ with ‘args.output_dir / "optimizer_parameters.mem", optimizer["parameters"], 64‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 254: `write_hex(args.output_dir / "optimizer_weights.mem", optimizer["weights"], 128)` This calls ‘write_hex‘ with ‘args.output_dir / "optimizer_weights.mem", optimizer["weights"], 128‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 255: `write_hex(args.output_dir / "optimizer_gradients.mem", optimizer["gradients"], 192)` This calls ‘write_hex‘ with ‘args.output_dir / "optimizer_gradients.mem", optimizer["gradients"], 192‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 256: `write_hex(args.output_dir / "optimizer_velocities.mem", optimizer["velocities"], 192)` This calls ‘write_hex‘ with ‘args.output_dir / "optimizer_velocities.mem", optimizer["velocities"], 192‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 257: `write_hex(args.output_dir / "optimizer_expected_weights.mem", optimizer["expected_weights"], 128)` This calls ‘write_hex‘ with ‘args.output_dir / "optimizer_expected_weights.mem", optimizer["expected_weights"], 128‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 258: `write_hex(args.output_dir / "optimizer_expected_velocities.mem", optimizer["expected_velocities"], 192)` This calls ‘write_hex‘ with ‘args.output_dir / "optimizer_expected_velocities.mem", optimizer["expected_velocities"], 192‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 259: `write_hex(args.output_dir / "layernorm_cases.mem", layernorm["descriptors"], 64)` This calls ‘write_hex‘ with ‘args.output_dir / "layernorm_cases.mem", layernorm["descriptors"], 64‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 260: `write_hex(args.output_dir / "layernorm_values.mem", layernorm["values"], 24)` This calls ‘write_hex‘ with ‘args.output_dir / "layernorm_values.mem", layernorm["values"], 24‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 261: `write_hex(args.output_dir / "layernorm_gammas.mem", layernorm["gammas"], 24)` This calls ‘write_hex‘ with ‘args.output_dir / "layernorm_gammas.mem", layernorm["gammas"], 24‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 262: `write_hex(args.output_dir / "layernorm_betas.mem", layernorm["betas"], 24)` This calls ‘write_hex‘ with ‘args.output_dir / "layernorm_betas.mem", layernorm["betas"], 24‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 263: `write_hex(args.output_dir / "layernorm_expected.mem", layernorm["expected"], 32)` This calls ‘write_hex‘ with ‘args.output_dir / "layernorm_expected.mem", layernorm["expected"], 32‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 264: `write_hex(args.output_dir / "layernorm_debug.mem", layernorm["debug"], 128)` This calls ‘write_hex‘ with ‘args.output_dir / "layernorm_debug.mem", layernorm["debug"], 128‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 265: `write_hex(args.output_dir / "softmax_cases.mem", softmax["descriptors"], 32)` This calls ‘write_hex‘ with ‘args.output_dir / "softmax_cases.mem", softmax["descriptors"], 32‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 266: `write_hex(args.output_dir / "softmax_scores.mem", softmax["scores"], 24)` This calls ‘write_hex‘ with ‘args.output_dir / "softmax_scores.mem", softmax["scores"], 24‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 267: `write_hex(args.output_dir / "softmax_expected.mem", softmax["expected"], 16)` This calls ‘write_hex‘ with ‘args.output_dir / "softmax_expected.mem", softmax["expected"], 16‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 268: `write_hex(args.output_dir / "softmax_debug.mem", softmax["debug"], 80)` This calls ‘write_hex‘ with ‘args.output_dir / "softmax_debug.mem", softmax["debug"], 80‘ inside the function main, which handles main. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 270: `manifest = {` This statement continues through source line 280; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ "seed": 20260711, "vector_cases": len(vector["commands"]), "vector_cases_per_operation": args.vector_count_per_operation, "optimizer_cases": len(optimizer["parameters"]), "layernorm_cases": len(layernorm["lengths"]), "layernorm_samples": len(layernorm["values"]), "softmax_cases": len(softmax["lengths"])

"softmax_samples": len(softmax["scores"]), "rounding": "nearest, ties away from zero", }‘ to ‘manifest ‘ in host memory. Here manifest means the value named ’manifest’ in this block. Line 294: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

Line 295: `main()` This calls ‘main‘ with “ inside the file whose role is to builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests. The call advances the host-side job that builds independent LayerNorm, softmax, vector, optimizer, and LUT vectors for RTL tests.

30 software/generate_source_reference.py

Role in the complete system: generates this source-reference volume and its source-integrity manifest.

30.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to generates this source-reference volume and its source-integrity manifest.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: SourceEntry, StatementSpan. Functions: project_root, source_entries, inferred_file_purpose, humanize, identifier_meaning, summarize_expression, python_contexts, _joined_statement, python_statement_spans, sv_statement_spans, sv_contexts, explain_sv_line, explain_python_line, explain_script_line, latex_escape, source_archite annotation_tex, generate, compile_pdf, main. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

30.2 Complete source

```
"""Generate an auditable, context-aware line-by-line source reference.

The generated TeX contains the complete source text and one explanation for
every nonblank line.  Explanations use the enclosing Python function or RTL
process, known accelerator signal meanings, and the exact left/right sides of
assignments.  A JSON manifest records every included file and SHA-256 digest so
the PDF can be checked against the source tree that produced it.

FILE_DATAFLOWS = {
    "rtl/neuraedge_activation_buffer.sv": "A load command writes activation bytes into addressed entries. During compute, the scheduler presents reduction indices and this memory returns one activation vector per selected row; keeping the tile local avoids rereading DDR for every output column.",
    "rtl/neuraedge_activation_lut8.sv": "Software first streams address/value pairs into the 256-entry table. A later execute command reads eight addresses in parallel, returns eight programmed nonlinear values, and counts only newly initialized addresses so duplicate writes cannot falsely report a complete table.",
    "rtl/neuraedge_active_index_buffer.sv": "While activations load, the tensor core tests whether a reduction position is all zero across active rows. Only nonzero positions are written here; compute later walks this compact list, so sparse positions remove issue cycles rather than performing useless zero arithmetic.",
    "rtl/neuraedge_alpha_xnor.sv": "The input stream supplies packed query and key spike masks. The block counts matching one bits and matching zero bits, weights zero matches by programmable alpha, accumulates across chunks, and emits one fixed-point attention score under valid/ready backpressure.",
    "rtl/neuraedge_buffered_tensor_core.sv": "This is the tile-level controller around memories and the physical array. Commands are predecoded, validated, and then routed through activation load, weight load, sparse-index formation, issue FIFO, accumulation, and ordered result output states. A two-entry skid FIFO reserves one beat for registered READY latency, decouples the tile's 128-entry result store from parent backpressure, and delays command completion until the buffered final result is actually transferred.",
    "rtl/neuraedge_descriptor_sequencer.sv": "A DMA record header declares one command's payload and result lengths. The sequencer captures both halves of the 128-bit command, forwards exactly the declared payload, counts accepted results, regenerates final TLAST, and drains malformed packets so the next descriptor starts aligned.",
    "rtl/neuraedge_integer_layernorm.sv": "The block first stores a vector while accumulating its sum and squared sum. It derives integer mean and variance, invokes the iterative square-root and divider, applies per-element gamma and beta, saturates the result, and preserves output data whenever downstream ready is low.",
    "rtl/neuraedge_isqrt64.sv": "One iteration examines the next two radicand bits, shifts the partial remainder, conditionally subtracts the trial divisor, and appends one root bit. After 32 iterations the 32-bit result is exactly floor(sqrt(radicand)); a widened subtraction bit makes borrow detection explicit.",
    "rtl/neuraedge_lif_bank.sv": "Each of 32 lanes reads persistent membrane state, applies the leak shift, adds signed input current, compares against threshold, emits a spike, and writes either reset or integrated membrane back. Segmented counters avoid a long telemetry carry chain on the 200 MHz datapath.",
    "rtl/neuraedge_linear_backward8.sv": "A command declares up to eight rows, input features, and output features. Streamed activations, signed weights, and output gradients are buffered in four-lane halves; sixteen signed DSP products are accumulated per cycle. The controller first reduces dY times transposed W into dX, then transposed X times dY into dW, retaining 47-bit partial sums across tiled commands when requested. Separate magnitude, rounding-bias, shift, sign, and saturation states preserve the reference round-once result while breaking the long FPGA timing path.",
    "rtl/neuraedge_log_softmax.sv": "The engine buffers logits, finds their maximum, converts bounded negative differences to power-of-two terms, sums the denominator, divides each term into a fixed probability scale, and streams normalized outputs without a floating-point exponential unit.",
    "rtl/neuraedge_mac2_u8.sv": "Two unsigned byte weights are separated by a guard bit and multiplied by one activation in a DSP48E1. Registered correction handles the DSP's signed interpretation, then slices recover two independent exact 16-bit products without cross-field carry.",
    "rtl/neuraedge_pynq_axi_top.sv": "This is the software-visible shell. AXI-Lite writes configure command and descriptor registers, AXI-Stream carries DMA data, registered credit boundaries break READY timing paths, and status/interrupt registers expose completion, errors, and telemetry.",
    "rtl/neuraedge_sgd_optimizer8.sv": "For eight lanes, the engine reads weight, gradient, and momentum velocity, computes the fixed-point momentum update, rounds the learning-rate product symmetrically, saturates the new signed weight, stores new velocity/weight state, and
```

```
        streams the result.",
    "rtl/neuraedge_tensor_tile.sv": "The 8-by-16 tile schedules 64 packed DSP blocks as 128 dense byte MAC lanes, or bypasses multipliers for binary/ternary conditional additions. Per-row active masks, registered sparse popcount, issue/result FIFOs, and deterministic row/column output order make backpressure safe.",
    "rtl/neuraedge_udivider.sv": "A restoring divider shifts one dividend bit into the remainder each cycle, compares/subtracts the divisor, and writes one quotient bit. Divide-by-zero is reported explicitly instead of producing an accidental numeric value.",
    "rtl/neuraedge_universal_core.sv": "This command arbiter gives exactly one engine ownership of the shared streams. It stages LUT loads, LIF input, and other multibeat commands, then captures each engine into a source-local result bank before a registered shared output stage. Completion waits for the final AXI transfer, so stalls cannot acknowledge a command early; local accept signals prevent an inactive engine's counters from entering another engine's timing cone.",
    "rtl/neuraedge_vector_alu.sv": "Eight signed lanes execute residual add, ReLU, requantization, spike conversion, surrogate-gradient gating, maximum, Q15 multiply, or clamp. Wide intermediate products are registered before rounding and saturation so fixed-point behavior is deterministic.",
    "rtl/neuraedge_weight_bank.sv": "Each bank stores sixteen weight bytes for every reduction position. Eight banks feed outer mode rows or adjacent reduction groups, allowing the same memory organization to support matrix tiles and narrow dot-product schedules.",
    "software/neuraedge_compiler.py": "Validated NumPy tensors are tiled into hardware-sized activation and weight loads followed by compute records. The compiler chooses outer or dot8 reuse from traffic, lowers grouped convolution through im2col, packs little-endian stream beats, and rejects dimensions the RTL cannot represent.",
    "software/neuraedge_protocol.py": "This file is the bit-level contract shared with RTL. It packs each 128-bit command field, declares exact payload/result lengths, wraps records in descriptor headers, and decodes signed results so a software integer has the same bit meaning as FPGA wires.",
    "software/neuraedge_pynq.py": "The board driver loads the BIT/HWH overlay, allocates physically contiguous DMA buffers, writes AXI-Lite registers, arms receive before send, waits with timeouts, checks hardware errors, and returns telemetry beside result words.",
    "software/neuraedge_training.py": "The training compiler converts saved forward activations and class loss derivatives into descriptor programs. It emits surrogate-gradient gates for spike nonlinearities, exact tiled linear-backward commands for dX and dW, and Q16 optimizer commands for persistent weight and momentum state. Every payload length, gradient shape, numeric shift, and returned update is checked against the same protocol helpers used by RTL tests.",
    "software/spikingformer_accelerator.py": "The exported model graph calls compiler primitives in checkpoint order: tokenizer convolutions and LIF, four Q/K/V attention and MLP blocks, residuals, reduction, and classifier. Tensor shapes and quantization records, rather than a hard-coded class result, determine every hardware program.",
    "software/export_spikingformer_hardware.py": "Checkpoint weights and BatchNorm statistics are folded into affine projections, calibrated, quantized, aligned to 64-byte sections, and hashed. The JSON manifest records offsets, shapes, dtypes, scales, and section digests consumed by both emulator and board runtime.",
    "software/generate_debug_report.py": "This evidence builder reads immutable result artifacts instead of rerunning or inventing measurements. It parses VCD transitions and Vivado text tables, plots all standard-test predictions and hardware reports, embeds the native block design, and records every plot's source artifact.",
    "software/spikingformer_reference.py": "The source checkpoint is reconstructed with its original timestep and spike behavior. A separate hardware-emulation path applies exported integer coefficients, allowing full-test accuracy and per-logit disagreement to be measured before board execution.",
    "software/spikingformer_training_runtime.py": "Each epoch loads deterministic CIFAR-10 shards, executes the quantized forward graph, forms the supervised loss gradient, and dispatches hardware backward and optimizer descriptor programs. Updated parameter and velocity arrays are checkpointed atomically with epoch, sample cursor, RNG state, hashes, and metrics, so pause or power loss resumes from a committed minibatch boundary instead of replaying an ambiguous update.",
    "software/train_spikingformer_pynq.py": "The command-line entry point validates the overlay, parameter archive, dataset shards, and ABI before constructing the runtime. It translates pause-file and resume options into explicit checkpoint behavior, reports board telemetry and validation accuracy, and exits nonzero when required physical artifacts or numerical checks fail.",

30.3 Line annotations

Line 1: `"""Generate an auditable, context-aware line-by-line source reference.` This is executable documentation attached to the file whose role is to generates this source-reference volume and its source-integrity manifest. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `The generated TeX contains the complete source text and one explanation for` Inside the file whose role is to generates this source-reference volume and its source-integrity manifest, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are The: the value named 'the' in this block; generated: the value named 'generated' in this block; TeX: the value named 'te x' in this block.

Line 4: `every nonblank line.  Explanations use the enclosing Python function or RTL` Inside the file whose role is to generates this source-reference volume and its source-integrity manifest, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are every: the value named 'every' in this block; nonblank: the value named 'nonblank' in this block; line: the value named 'line' in this block.

Line 5: `process, known accelerator signal meanings, and the exact left/right sides of` Inside the file whose role is to generates this source-reference volume and its source-integrity manifest, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are process: the value named 'process' in this block; known: the value named 'known' in this block; accelerator: the value named 'accelerator' in this block.

Line 6: `assignments.  A JSON manifest records every included file and SHA-256 digest so` Inside the file whose role is to generates this source-reference volume and its source-integrity manifest, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are assignments: the value named 'assignments' in this block; A: the value named 'a' in this block; JSON: the value named 'json' in this block.

Line 7: `the PDF can be checked against the source tree that produced it.` Inside the file whose role is to generates this source-reference volume and its source-integrity manifest, this statement advances the host implementation that generates this source-reference volume and its source-integrity manifest. The important operands are the: the value named 'the' in this block; PDF: the value named 'pdf' in this block; can: the value named 'can' in this block.

Line 8: `"""` This is executable documentation attached to the file whose role is to generates this source-reference volume and its source-integrity manifest. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 10: `from __future__ import annotations` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `import argparse` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `import ast` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `import hashlib` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `import json` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `import os` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `import re` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `import subprocess` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `from pathlib import Path` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `from typing import Iterable` This imports the named Python API so the file whose role is to generates this source-reference volume and its source-integrity manifest can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 95: `"software/neuraedge_training.py": "The training compiler converts saved forward activations and class loss ...` This is continuation line 24 of the 31-line logical statement that begins at source line 72. Its exact fragment is ‘"software/neuraedge_training.py": "The training compiler converts saved forward activations and class loss derivatives into descriptor programs. It emits surrogate-gradient gates for spike nonlinearities, exact tiled linear-backward commands for dX and dW, and Q16 optimizer commands for persistent weight and momentum state. Every payload length, gradient shape, numeric shift, and returned update is checked against the same protocol helpers used by RTL tests.",‘. The important operands are software: the value named 'software' in this block; neuraedge_training: the value named 'neuraedge training' in this block; py: the value named 'py' in this block. Read together, the complete operation is: This assigns ‘{ "rtl/neuraedge_activation_buffer.sv": "A load command writes activation bytes into addressed entries. During compute, the scheduler presents reduction indices and this memory returns one activation vector per selected row; keeping the tile local avoids rereading DDR for every output column.", "rtl/neuraedge_activation_lut8.sv": "Software first streams address/value pairs into the 256-entry table. A later execute command reads eight addresses in parallel, returns eight programmed nonlinear values, and counts only newly initialized addresses so duplicate writes cannot falsely report a complete table.", "rtl/neuraedge_active_index_buffer.sv": "While activations load, the tensor core tests whether a reduction position is all zero across active rows. Only nonzero positions are written here; compute later walks this compact list, so sparse positions remove issue cycles rather than performing useless zero arithmetic.", "rtl/neuraedge_alpha_xnor.sv": "The input stream supplies packed query and key spike masks. The block counts matching one bits and matching zero bits, weights zero matches by programmable alpha, accumulates across chunks, and emits one fixed-point attention score under valid/ready backpressure.", "rtl/neuraedge_buffered_tensor_core.sv": "This is the tile-level controller around memories and the physical array. Commands are predecoded, validated, and then routed through activation load, weight load, sparse-index formation, issue FIFO, accumulation, and ordered result output states. A two-entry skid FIFO reserves one beat for registered READY latency, decouples the tile's 128-entry result store from parent backpressure, and delays command completion until the buffered final result is actually transferred.", "rtl/neuraedge_descriptor_sequencer.sv": "A DMA record header declares one command's payload and result lengths. The sequencer captures both halves of the 128-bit command, forwards exactly the declared payload, counts accepted results, regenerates final TLAST, and drains malformed packets so the next descriptor starts aligned.", "rtl/neuraedge_integer_layernorm.sv": "The block first stores a vector while accumulating its sum and squared sum. It derives integer mean and variance, invokes the iterative square-root and divider, applies per-element gamma and beta, saturates the result, and preserves output data whenever downstream ready is low.", "rtl/neuraedge_isqrt64.sv": "One iteration examines the next two radicand bits, shifts the partial remainder, conditionally subtracts the trial divisor, and appends one root bit. After 32 iterations the 32-bit result is exactly floor(sqrt(radicand)); a widened subtraction bit makes borrow detection explicit.", "rtl/neuraedge_lif_bank.sv": "Each of 32 lanes reads persistent membrane state, applies the leak shift, adds signed input current, compares against threshold, emits a spike, and writes either reset or integrated membrane back. Segmented counters avoid a long telemetry carry chain on the 200 MHz datapath.", "rtl/neuraedge_linear_backward8.sv": "A command declares up to eight rows, input features, and output features. Streamed activations, signed weights, and output gradients are buffered in four-lane halves; sixteen signed DSP products are accumulated per cycle. The controller first reduces dY times transposed W into dX, then transposed X times dY into dW, retaining 47-bit partial sums across tiled commands when requested. Separate magnitude, rounding-bias, shift, sign, and saturation states preserve the reference round-once result while breaking the long FPGA timing path.", "rtl/neuraedge_log_softmax.sv": "The engine buffers logits, finds their maximum, converts bounded negative differences to power-of-two terms, sums the denominator, divides each term into a fixed probability scale, and streams normalized outputs without a floating-point exponential unit.", "rtl/neuraedge_mac2_u8.sv": "Two unsigned byte weights are separated by a guard bit and multiplied by one activation in a DSP48E1. Registered correction handles the DSP's signed interpretation, then slices recover two independent exact 16-bit products without cross-field carry.", "rtl/neuraedge_pynq_axi_top.sv": "This is the software-visible shell. AXI-Lite writes configure command and descriptor registers, AXI-Stream carries DMA data, registered credit boundaries break READY timing paths, and status/interrupt registers expose completion, errors, and telemetry.", "rtl/neuraedge_sgd_optimizer8.sv": "For eight lanes, the engine reads weight, gradient, and momentum
