Line 164: `raise NeuraEdgeHardwareError("performance counters must be sampled while the accelerator is idle")` This rejects an invalid state by raising 'NeuraEdgeHardwareError("performance counters must be sampled while the accelerator is idle")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 165: `registers = self.registers` This assigns 'self.registers' to 'registers ' in host memory. Here registers means the value named 'registers' in this block. The important operands are registers: the value named 'registers' in this block. Context: the function performance_snapshot, which handles performance snapshot.

Line 166: `loaded = int(self.mmio.read(registers.tensor_loaded))` This assigns 'int(self.mmio.read(registers.tensor_loade to 'loaded ' in host memory. Here loaded means the value named 'loaded' in this block. The important operands are mmio: the value named 'mmio' in this block; read: the value named 'read' in this block; registers: the value named 'registers' in this block. Context: the function performance_snapshot, which handles performance snapshot.

Line 167: `dense_macs = int(self.mmio.read(registers.dense_macs_low))` This assigns 'int(self.mmio.read(registers.dense_ to 'dense_macs ' in host memory. Here dense_macs means a count of ordinary activation-times-weight operations actually issued. The important operands are mmio: the value named 'mmio' in this block; read: the value named 'read' in this block; registers: the value named 'registers' in this block. Context: the function performance_snapshot, which handles performance snapshot.

Line 168: `dense_macs |= int(self.mmio.read(registers.dense_macs_high)) << 32` Inside the function performance_snapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are dense_macs: a count of ordinary activation-times-weight operations actually issued; mmio: the value named 'mmio' in this block; read: the value named 'read' in this block.

Line 169: `spike_adds = int(self.mmio.read(registers.spike_adds_low))` This assigns 'int(self.mmio.read(registers.spike_ to 'spike_adds ' in host memory. Here spike_adds means a binary event produced when a neuron crosses its threshold. The important operands are mmio: the value named 'mmio' in this block; read: the value named 'read' in this block; registers: the value named 'registers' in this block. Context: the function performance_snapshot, which handles performance snapshot.

Line 170: `spike_adds |= int(self.mmio.read(registers.spike_adds_high)) << 32` Inside the function performance_snapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are spike_adds: a binary event produced when a neuron crosses its threshold; mmio: the value named 'mmio' in this block; read: the value named 'read' in this block.

Line 171: `lif_spikes = int(self.mmio.read(registers.lif_spikes_low))` This assigns 'int(self.mmio.read(registers.lif_spi to 'lif_spikes ' in host memory. Here lif_spikes means a binary event produced when a neuron crosses its threshold. The important operands are mmio: the value named 'mmio' in this block; read: the value named 'read' in this block; registers: the value named 'registers' in this block. Context: the function performance_snapshot, which handles performance snapshot.

Line 172: `lif_spikes |= int(self.mmio.read(registers.lif_spikes_high)) << 32` Inside the function performance_snapshot, which handles performance snapshot, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are lif_spikes: a binary event produced when a neuron crosses its threshold; mmio: the value named 'mmio' in this block; read: the value named 'read' in this block.

Line 173: `return PerformanceSnapshot(` This statement continues through source line 195; the explanation uses the complete expression rather than only the first visual fragment. This returns 'PerformanceSnapshot(loaded & 0xFFF, (loaded >> 16) & 0xFFF, int(self.mmio.read(registers.tensor_active)) & 0xFFF, int(self.mmio.read(registers.tensor_cycles)), int(self.mmio.read(registers.tensor_skipped)), dense_macs, spike_adds, int(self.mmio.read(registers.layernorm_cycles)), self._signed32(self.mmio.read(registers.layernorm_mean)), int(self.mmio.read(registers.layernorm_variance)), int(self.mmio.read(re int(self.mmio.read(registers.layernorm_reciprocal)), int(self.mmio.read(registers.softmax_cycles)), self._signed32(self.mmio.read(re int(self.mmio.read(registers.softmax_denominator)) & 0xFFFFFF, int(self.mmio.read(registers.softmax_reciprocal)), lif_spikes, int(self.mmio.read(registers.optimizer_updates)), int(self.mmio.read(registers.lut_entries)) & 0x1FF, int(self.mmio.read(registers.tr int(self.mmio.read(registers.training_cycles)),)' to the caller of the function performance_snapshot, which handles performance snapshot, ending this invocation. The important operands are PerformanceSnapshot: the value named 'performance snapshot' in this block; loaded: the value named 'loaded' in this block; mmio: the value named 'mmio' in this block.

Line 174: `loaded & 0xFFF,` This is continuation line 2 of the 23-line logical statement that begins at source line 173. Its exact fragment is 'loaded & 0xFFF,'. The important operands are loaded: the value named 'loaded' in this block. Read together, the complete operation is: This returns 'PerformanceSnapshot(loaded & 0xFFF, (loaded >> 16) & 0xFFF, int(self.mmio.read(registers.tensor_active)) & 0xFFF, int(self.mmio.read(registers.tensor_cycles)), int(self.mmio.read(registers.tensor_skipped)), dense_macs, spike_adds, int(self.mmio.read(registers.layernorm_cycles)), self._signed32(self.mmio.read(registers.layernorm_mean)), int(self.mmio.read(registers.layernorm_variance)), int(self.mmio.read(re int(self.mmio.read(registers.layernorm_reciprocal)), int(self.mmio.read(registers.softmax_cycles)), self._signed32(self.mmio.read(re int(self.mmio.read(registers.softmax_denominator)) & 0xFFFFFF, int(self.mmio.read(registers.softmax_reciprocal)), lif_spikes, int(self.mmio.read(registers.optimizer_updates)), int(self.mmio.read(registers.lut_entries)) & 0x1FF, int(self.mmio.read(registers.tr int(self.mmio.read(registers.training_cycles)),)' to the caller of the function performance_snapshot, which handles performance snapshot, ending this invocation. )' to the caller of the function performance_snapshot, which handles performance snapshot, ending this invocation. The important operands are PerformanceSnapshot: the value named 'performance snapshot' in this block; loaded: the value named 'loaded' in this block; mmio: the value named 'mmio' in this block.

Line 197: `def _control_value(self, transient_bits: int = 0) -> int:` This starts function _control_value. Its indented body performs control value as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 198: `return ((1 << 8) if self.interrupt_enable else 0) | transient_bits` This returns '((1 << 8) if self.interrupt_enable else 0) | transient_bits' to the caller of the function _control_value, which handles control value, ending this invocation. The important operands are interrupt_enable: the hardware notification that wakes software after completion or error; transient_bits: the value named 'transient bits' in this block.

Line 200: `def clear_wrapper_status(self) -> None:` This starts function clear_wrapper_status. Its indented body performs clear wrapper status as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 201: `self.mmio.write(self.registers.control, self._control_value(1 << 1))` This calls 'self.mmio.write' with 'self.registers.control, self._control_value(1 << 1)' inside the function clear_wrapper_status, which handles clear wrapper status. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 203: `@staticmethod` This decorator changes how the following class or function is constructed. '@staticmethod' is applied at import time on the host and is part of the class NeuraEdgeDriver, which handles neura edge driver; it creates no FPGA circuit by itself.

Line 204: `def _validate_input_beats(beats: Sequence[StreamBeat]) -> None:` This starts function _validate_input_beats. Its indented body performs validate input beats as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 205: `if isinstance(beats, PackedStreamBeats):` This executes the following indented host-code branch only when 'isinstance(beats, PackedStreamBeats)' is true. The important operands are isinstance: the value named 'isinstance' in this block; beats: the value named 'beats' in this block; PackedStreamBeats: the value named 'packed stream beats' in this block. Context: the function _validate_input_beats, which handles validate input beats.

Line 206: `return` This returns " to the caller of the function _validate_input_beats, which handles validate input beats, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 207: `for index, beat in enumerate(beats):` This iterates index, beat over 'enumerate(beats)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _validate_input_beats, which handles validate input beats.

Line 208: `if beat.last != (index == len(beats) - 1):` This executes the following indented host-code branch only when 'beat.last != (index == len(beats) - 1)' is true. The important operands are beat: the value named 'beat' in this block; last: the AXI-Stream marker for the final beat of a packet or command payload; index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function _validate_input_beats, which handles validate input beats.

Line 209: `raise ValueError("input StreamBeat.last must be true only on the final beat")` This rejects an invalid state by raising 'ValueError("input StreamBeat.last must be true only on the final beat")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 211: `@staticmethod` This decorator changes how the following class or function is constructed. '@staticmethod' is applied at import time on the host and is part of the class NeuraEdgeDriver, which handles neura edge driver; it creates no FPGA circuit by itself.

Line 212: `def _release_buffer(buffer) -> None:` This starts function _release_buffer. Its indented body performs release buffer as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 213: `if buffer is None:` This executes the following indented host-code branch only when ‘buffer is None‘ is true. The important operands are buffer: local storage that decouples producer and consumer timing; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function _release_buffer, which handles release buffer.

Line 214: `return` This returns “ to the caller of the function _release_buffer, which handles release buffer, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 215: `if hasattr(buffer, "freebuffer"):` This executes the following indented host-code branch only when ‘hasattr(buffer, "freebuffer")‘ is true. The important operands are hasattr: the value named ’hasattr’ in this block; buffer: local storage that decouples producer and consumer timing; freebuffer: local storage that decouples producer and consumer timing. Context: the function _release_buffer, which handles release buffer.

Line 216: `buffer.freebuffer()` This calls ‘buffer.freebuffer‘ with “ inside the function _release_buffer, which handles release buffer. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 217: `elif hasattr(buffer, "close"):` This executes the following indented host-code branch only when ‘hasattr(buffer, "close")‘ is true. The important operands are hasattr: the value named ’hasattr’ in this block; buffer: local storage that decouples producer and consumer timing; close: the value named ’close’ in this block. Context: the function _release_buffer, which handles release buffer.

Line 218: `buffer.close()` This calls ‘buffer.close‘ with “ inside the function _release_buffer, which handles release buffer. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 220: `@staticmethod` This decorator changes how the following class or function is constructed. ‘@staticmethod‘ is applied at import time on the host and is part of the class NeuraEdgeDriver, which handles neura edge driver; it creates no FPGA circuit by itself.

Line 221: `def _wait_dma_channel(channel, deadline: float, name: str) -> None:` This starts function _wait_dma_c
Its indented body performs wait dma channel as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 222: `while not bool(channel.idle):` This repeats the following host-code block while ‘not bool(channel.idle)‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 223: `if monotonic() >= deadline:` This executes the following indented host-code branch only when ‘monotonic() >= deadline‘ is true. The important operands are monotonic: the value named ’monotonic’ in this block; deadline: the value named ’deadline’ in this block. Context: the function _wait_dma_channel, which handles wait dma channel.

Line 224: `if hasattr(channel, "stop"):` This executes the following indented host-code branch only when ‘hasattr(channel, "stop")‘ is true. The important operands are hasattr: the value named ’hasattr’ in this block; channel: the value named ’channel’ in this block; stop: the value named ’stop’ in this block. Context: the function _wait_dma_channel, which handles wait dma channel.

Line 225: `channel.stop()` This calls ‘channel.stop‘ with “ inside the function _wait_dma_channel, which handles wait dma channel. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 226: `raise NeuraEdgeTimeout(f"{name} DMA channel timed out")` This rejects an invalid state by raising ‘NeuraEdgeTimeout(f"{name} DMA channel timed out")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 227: `sleep(0.0005)` This calls ‘sleep‘ with ‘0.0005‘ inside the function _wait_dma_channel, which handles wait dma channel. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 228: `channel.wait()` This calls ‘channel.wait‘ with “ inside the function _wait_dma_channel, which handles wait dma channel. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 230: `def _wait_idle(self, deadline: float) -> None:` This starts function _wait_idle. Its indented body performs wait idle as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 231: `while self.status() & (self.STATUS_BUSY | self.STATUS_PENDING):` This repeats the following host-code block while ‘self.status() & (self.STATUS_BUSY | self.STATUS_PENDING)‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 232: `if monotonic() >= deadline:` This executes the following indented host-code branch only when ‘monotonic() >= deadline‘ is true. The important operands are monotonic: the value named ’monotonic’ in this block; deadline: the value named ’deadline’ in this block. Context: the function _wait_idle, which handles wait idle.

Line 233: `raise NeuraEdgeTimeout("accelerator did not become idle")` This rejects an invalid state by raising ‘NeuraEdgeTimeout("accelerator did not become idle")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 234: `sleep(0.0005)` This calls ‘sleep‘ with ‘0.0005‘ inside the function _wait_idle, which handles wait idle. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 236: `def execute(` This starts function execute. Its indented body performs execute as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 237: `self,` Inside the function execute, which handles execute, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The expression is a literal or structural operator and has no hidden software state.

Line 238: `command: Command128,` Inside the function execute, which handles execute, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; Command128: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 239: `input_beats: Sequence[StreamBeat] = (),` This assigns ‘(),‘ to ‘input_beats‘ in host memory. Here input_beats means the value named ’input beats’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 240: `*,` Inside the function execute, which handles execute, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The expression is a literal or structural operator and has no hidden software state.

Line 241: `output_beats: int = 0,` This assigns '0,' to 'output_beats' in host memory. Here output_beats means the value named 'output beats' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 242: `timeout_seconds: float = 5.0,` This assigns '5.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 243: `) -> tuple[int, ...]:` Inside the function execute, which handles execute, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are tuple: the value named 'tuple' in this block.

Line 244: `if timeout_seconds <= 0:` This executes the following indented host-code branch only when 'timeout_seconds <= 0' is true. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Context: the function execute, which handles execute.

Line 245: `raise ValueError("timeout_seconds must be positive")` This rejects an invalid state by raising 'ValueError("timeout_seconds must be positive")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 246: `if output_beats < 0:` This executes the following indented host-code branch only when 'output_beats < 0' is true. The important operands are output_beats: the value named 'output beats' in this block. Context: the function execute, which handles execute.

Line 247: `raise ValueError("output_beats must be non-negative")` This rejects an invalid state by raising 'ValueError("output_beats must be non-negative")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 248: `self._validate_input_beats(input_beats)` This calls 'self._validate_input_beats' with 'input_beats' inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 249: `deadline = monotonic() + timeout_seconds` This assigns 'monotonic() + timeout_seconds' to 'deadline ' in host memory. Here deadline means the value named 'deadline' in this block. The important operands are monotonic: the value named 'monotonic' in this block; timeout_seconds: the value named 'timeout seconds' in this block. Context: the function execute, which handles execute.

Line 250: `self._wait_idle(deadline)` This calls 'self._wait_idle' with 'deadline' inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 252: `input_buffer = None` This assigns 'None' to 'input_buffer ' in host memory. Here input_buffer means local storage that decouples producer and consumer timing. The important operands are None: the value named 'none' in this block. Context: the function execute, which handles execute.

Line 253: `output_buffer = None` This assigns 'None' to 'output_buffer ' in host memory. Here output_buffer means local storage that decouples producer and consumer timing. The important operands are None: the value named 'none' in this block. Context: the function execute, which handles execute.

Line 254: `try:` This is explicit host-side failure handling inside the function execute, which handles execute; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 255: `if input_beats:` This executes the following indented host-code branch only when ‘input_beats‘ is true. The important operands are input_beats: the value named ’input beats’ in this block. Context: the function execute, which handles execute.

Line 256: `input_buffer = self.allocator(shape=(len(input_beats),), dtype=np.uint64)` This assigns ‘self.allocator(sha dtype=np.uint64)‘ to ‘input_buffer ‘ in host memory. Here input_buffer means local storage that decouples producer and consumer timing. The important operands are allocator: the value named ’allocator’ in this block; shape: the value named ’shape’ in this block; len: the value named ’len’ in this block. Context: the function execute, which handles execute.

Line 257: `if isinstance(input_beats, PackedStreamBeats):` This executes the following indented host-code branch only when ‘isinstance(input_beats, PackedStreamBeats)‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; input_beats: the value named ’input beats’ in this block; PackedStreamBeats: the value named ’packed stream beats’ in this block. Context: the function execute, which handles execute.

Line 258: `input_buffer[:] = np.frombuffer(input_beats.words, dtype=np.uint64)` This assigns ‘np.frombuffer(input_b dtype=np.uint64)‘ to ‘input_buffer[‘ in host memory. Here input_buffer means local storage that decouples producer and consumer timing. The important operands are frombuffer: local storage that decouples producer and consumer timing; input_beats: the value named ’input beats’ in this block; words: the value named ’words’ in this block. Context: the function execute, which handles execute.

Line 259: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute, which handles execute.

Line 260: `input_buffer[:] = np.fromiter(` This statement continues through source line 264; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.fromiter((beat.data for beat in input_beats), dtype=np.uint64, count=len(input_beats),)‘ to ‘input_buffer[‘ in host memory. Here input_buffer means local storage that decouples producer and consumer timing. The important operands are fromiter: the value named ’fromiter’ in this block; beat: the value named ’beat’ in this block; data: the value named ’data’ in this block. Context: the function execute, which handles execute.

Line 261: `(beat.data for beat in input_beats),` This is continuation line 2 of the 5-line logical statement that begins at source line 260. Its exact fragment is ‘(beat.data for beat in input_beats),‘. The important operands are beat: the value named ’beat’ in this block; data: the value named ’data’ in this block; for: the value named ’for’ in this block. Read together, the complete operation is: This assigns ‘np.fromiter((beat.data for beat in input_beats), dtype=np.uint64, count=len(input_beats),)‘ to ‘input_buffer[‘ in host memory. Here input_buffer means local storage that decouples producer and consumer timing. The important operands are fromiter: the value named ’fromiter’ in this block; beat: the value named ’beat’ in this block; data: the value named ’data’ in this block. Context: the function execute, which handles execute.

Line 262: `dtype=np.uint64,` This is continuation line 3 of the 5-line logical statement that begins at source line 260. Its exact fragment is ‘dtype=np.uint64,‘. The important operands are dtype: the value named ’dtype’ in this block; uint64: the value named ’uint64’ in this block. Read together, the complete operation is: This assigns ‘np.fromiter((beat.data for beat in input_beats), dtype=np.uint64, count=len(input_beats),)‘ to ‘input_buffer[‘ in host memory. Here input_buffer means local storage that decouples producer and consumer timing. The important operands are fromiter: the value named ’fromiter’ in this block; beat: the value named ’beat’ in this block; data: the value named ’data’ in this block. Context: the function execute, which handles execute.

Line 263: `count=len(input_beats),` This is continuation line 4 of the 5-line logical statement that begins at source line 260. Its exact fragment is ‘count=len(input_beats),‘. The important operands are count: the value named ’count’ in this block; len: the value named ’len’ in this block; input_beats: the value named ’input beats’ in this block. Read together, the complete operation is: This assigns ‘np.fromiter((beat.data for beat in input_beats), dtype=np.uint64, count=len(input_beats),)‘ to ‘input_buffer[‘ in host memory. Here input_buffer means local storage that decouples producer and consumer timing. The important operands are fromiter: the value named ’fromiter’ in this block; beat: the value named ’beat’ in this block; data: the value named ’data’ in this block. Context: the function execute, which handles execute.

Line 264: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 260. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.fromiter((beat.data for beat in input_beats), dtype=np.uint64, count=len(input_beats),)' to 'input_buffer[' in host memory. Here input_buffer means local storage that decouples producer and consumer timing. The important operands are fromiter: the value named 'fromiter' in this block; beat: the value named 'beat' in this block; data: the value named 'data' in this block. Context: the function execute, which handles execute.

Line 265: `if hasattr(input_buffer, "flush"):` This executes the following indented host-code branch only when 'hasattr(input_buffer, "flush")' is true. The important operands are hasattr: the value named 'hasattr' in this block; input_buffer: local storage that decouples producer and consumer timing; flush: the value named 'flush' in this block. Context: the function execute, which handles execute.

Line 266: `input_buffer.flush()` This calls 'input_buffer.flush' with " inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 267: `if output_beats:` This executes the following indented host-code branch only when 'output_beats' is true. The important operands are output_beats: the value named 'output beats' in this block. Context: the function execute, which handles execute.

Line 268: `output_buffer = self.allocator(shape=(output_beats,), dtype=np.uint64)` This assigns 'self.allocator(shape= dtype=np.uint64)' to 'output_buffer ' in host memory. Here output_buffer means local storage that decouples producer and consumer timing. The important operands are allocator: the value named 'allocator' in this block; shape: the value named 'shape' in this block; output_beats: the value named 'output beats' in this block. Context: the function execute, which handles execute.

Line 269: `self.dma.recvchannel.transfer(output_buffer, nbytes=output_beats * 8)` This calls 'self.dma.recvchannel.tra with 'output_buffer, nbytes=output_beats * 8' inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 271: `self.clear_wrapper_status()` This calls 'self.clear_wrapper_status' with " inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 272: `for index, word in enumerate(command.words_le):` This iterates index, word over 'enumerate(command.words_le Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 273: `self.mmio.write(self.registers.command0 + 4 * index, word)` This calls 'self.mmio.write' with 'self.registers.co + 4 * index, word' inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 274: `self.mmio.write(self.registers.control, self._control_value(1))` This calls 'self.mmio.write' with 'self.registers.control, self._control_value(1)' inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 276: `if input_buffer is not None:` This executes the following indented host-code branch only when 'input_buffer is not None' is true. The important operands are input_buffer: local storage that decouples producer and consumer timing; is: the value named 'is' in this block; not: the value named 'not' in this block. Context: the function execute, which handles execute.

Line 277: `self.dma.sendchannel.transfer(input_buffer, nbytes=len(input_beats) * 8)` This calls 'self.dma.sendchanne with 'input_buffer, nbytes=len(input_beats) * 8' inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 278: `self._wait_dma_channel(self.dma.sendchannel, deadline, "MM2S")` This calls ‘self._wait_dma_channel‘ with ‘self.dma.sendchannel, deadline, "MM2S"‘ inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 279: `if output_buffer is not None:` This executes the following indented host-code branch only when ‘output_buffer is not None‘ is true. The important operands are output_buffer: local storage that decouples producer and consumer timing; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function execute, which handles execute.

Line 280: `self._wait_dma_channel(self.dma.recvchannel, deadline, "S2MM")` This calls ‘self._wait_dma_channel‘ with ‘self.dma.recvchannel, deadline, "S2MM"‘ inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 282: `while True:` This repeats the following host-code block while ‘True‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 283: `status = self.status()` This assigns ‘self.status()‘ to ‘status ‘ in host memory. Here status means the value named ’status’ in this block. The important operands are status: the value named ’status’ in this block. Context: the function execute, which handles execute.

Line 284: `if status & self.STATUS_ERROR:` This executes the following indented host-code branch only when ‘status & self.STATUS_ERROR‘ is true. The important operands are status: the value named ’status’ in this block; STATUS_ERROR: the value named ’status error’ in this block. Context: the function execute, which handles execute.

Line 285: `raise NeuraEdgeHardwareError(` This statement continues through source line 287; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"accelerator rejected opcode {int(command.opcode):x}; status=0x{status:08x}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 286: `f"accelerator rejected opcode {int(command.opcode):x}; status=0x{status:08x}"` This is continuation line 2 of the 3-line logical statement that begins at source line 285. Its exact fragment is ‘f"accelerator rejected opcode {int(command.opcode):x}; status=0x{status:08x}"‘. The important operands are f: the value named ’f’ in this block; accelerator: the value named ’accelerator’ in this block; rejected: the value named ’rejected’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"accelerator rejected opcode {int(command.opcode):x}; status=0x{status:08x}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 287: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 285. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"accelerator rejected opcode {int(command.opcode):x}; status=0x{status:08x}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 288: `if status & self.STATUS_DONE:` This executes the following indented host-code branch only when ‘status & self.STATUS_DONE‘ is true. The important operands are status: the value named ’status’ in this block; STATUS_DONE: the value named ’status done’ in this block. Context: the function execute, which handles execute.

Line 289: `break` Inside the function execute, which handles execute, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are break: the value named ’break’ in this block.

Line 290: `if monotonic() >= deadline:` This executes the following indented host-code branch only when ‘monotonic() >= deadline‘ is true. The important operands are monotonic: the value named ’monotonic’ in this block; deadline: the value named ’deadline’ in this block. Context: the function execute, which handles execute.

Line 291: `raise NeuraEdgeTimeout(f"opcode {int(command.opcode):x} did not complete")` This rejects an invalid state by raising ‘NeuraEdgeTimeout(f"opcode {int(command.opcode):x} did not complete")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 292: `sleep(0.0005)` This calls ‘sleep‘ with ‘0.0005‘ inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 294: `if output_buffer is None:` This executes the following indented host-code branch only when ‘output_buffer is None‘ is true. The important operands are output_buffer: local storage that decouples producer and consumer timing; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function execute, which handles execute.

Line 295: `return ()` This returns ‘()‘ to the caller of the function execute, which handles execute, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 296: `if hasattr(output_buffer, "invalidate"):` This executes the following indented host-code branch only when ‘hasattr(output_buffer, "invalidate")‘ is true. The important operands are hasattr: the value named ’hasattr’ in this block; output_buffer: local storage that decouples producer and consumer timing; invalidate: the producer’s statement that its current payload is meaningful. Context: the function execute, which handles execute.

Line 297: `output_buffer.invalidate()` This calls ‘output_buffer.invalidate‘ with “ inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 298: `return tuple(int(value) for value in output_buffer[:output_beats])` This returns ‘tuple(int(value) for value in output_buffer[:output_beats])‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; value: the value named ’value’ in this block; for: the value named ’for’ in this block.

Line 299: `finally:` This is explicit host-side failure handling inside the function execute, which handles execute; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 300: `self._release_buffer(input_buffer)` This calls ‘self._release_buffer‘ with ‘input_buffer‘ inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 301: `self._release_buffer(output_buffer)` This calls ‘self._release_buffer‘ with ‘output_buffer‘ inside the function execute, which handles execute. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 303: `def execute_program(` This starts function execute_program. Its indented body performs execute program as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 304: `self,` Inside the function execute_program, which handles execute program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The expression is a literal or structural operator and has no hidden software state.

Line 305: `records: Sequence[ProgramRecord],` Inside the function execute_program, which handles execute program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are records: the number of descriptor records accepted since program start; Sequence: the value named ’sequence’ in this block; ProgramRecord: the value named ’program record’ in this block.

Line 306: `*,` Inside the function execute_program, which handles execute program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The expression is a literal or structural operator and has no hidden software state.

Line 307: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 308: `) -> tuple[int, ...]:` Inside the function execute_program, which handles execute program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are tuple: the value named ’tuple’ in this block.

Line 309: `"""Execute records in the minimum number of legal descriptor packets."""` This is executable documentation attached to the function execute_program, which handles execute program. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 311: `if timeout_seconds <= 0:` This executes the following indented host-code branch only when ‘timeout_seconds <= 0‘ is true. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Context: the function execute_program, which handles execute program.

Line 312: `raise ValueError("timeout_seconds must be positive")` This rejects an invalid state by raising ‘ValueError("timeout_seconds must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 313: `if not records:` This executes the following indented host-code branch only when ‘not records‘ is true. The important operands are not: the value named ’not’ in this block; records: the number of descriptor records accepted since program start. Context: the function execute_program, which handles execute program.

Line 314: `raise ValueError("a descriptor program must contain at least one record")` This rejects an invalid state by raising ‘ValueError("a descriptor program must contain at least one record")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 315: `deadline = monotonic() + timeout_seconds` This assigns ‘monotonic() + timeout_seconds‘ to ‘deadline ‘ in host memory. Here deadline means the value named ’deadline’ in this block. The important operands are monotonic: the value named ’monotonic’ in this block; timeout_seconds: the value named ’timeout seconds’ in this block. Context: the function execute_program, which handles execute program.

Line 316: `output: list[int] = []` This assigns ‘[]‘ to ‘output‘ in host memory. Here output means the value named ’output’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 317: `for packet in self._partition_program(records):` This iterates packet over ‘self._partition_program(records)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_program, which handles execute program.

Line 318: `output.extend(self._execute_program_packet(packet, deadline))` This calls ‘output.extend‘ with ‘self._execute_program_packet(packet, deadline)‘ inside the function execute_program, which handles execute program. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 319: `return tuple(output)` This returns ‘tuple(output)‘ to the caller of the function execute_program, which handles execute program, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; output: the value named ’output’ in this block.

Line 321: `def _partition_program(` This starts function _partition_program. Its indented body performs partition program as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 322: `self,` Inside the function _partition_program, which handles partition program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The expression is a literal or structural operator and has no hidden software state.

Line 323: `records: Sequence[ProgramRecord],` Inside the function _partition_program, which handles partition program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are records: the number of descriptor records accepted since program start; Sequence: the value named 'sequence' in this block; ProgramRecord: the value named 'program record' in this block.

Line 324: `) -> tuple[tuple[ProgramRecord, ...], ...]:` Inside the function _partition_program, which handles partition program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are tuple: the value named 'tuple' in this block; ProgramRecord: the value named 'program record' in this block.

Line 325: `packets: list[tuple[ProgramRecord, ...]] = []` This assigns '[]' to 'packets' in host memory. Here packets means the value named 'packets' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _partition_program, which handles partition program.

Line 326: `current: list[ProgramRecord] = []` This assigns '[]' to 'current' in host memory. Here current means the value named 'current' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _partition_program, which handles partition program.

Line 327: `current_input_bytes = 0` This assigns '0' to 'current_input_bytes ' in host memory. Here current_input_bytes means the value named 'current input bytes' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _partition_program, which handles partition program.

Line 328: `current_output_bytes = 0` This assigns '0' to 'current_output_bytes ' in host memory. Here current_output_bytes means the value named 'current output bytes' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _partition_program, which handles partition program.

Line 329: `for record in records:` This iterates record over 'records'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _partition_program, which handles partition program.

Line 330: `record_input_bytes = (3 + len(record.input_beats)) * 8` This assigns '(3 + len(record.input_beats)) * 8' to 'record_input_bytes ' in host memory. Here record_input_bytes means the value named 'record input bytes' in this block. The important operands are len: the value named 'len' in this block; record: the value named 'record' in this block; input_beats: the value named 'input beats' in this block. Context: the function _partition_program, which handles partition program.

Line 331: `record_output_bytes = record.output_beats * 8` This assigns 'record.output_beats * 8' to 'record_output_bytes ' in host memory. Here record_output_bytes means the value named 'record output bytes' in this block. The important operands are record: the value named 'record' in this block; output_beats: the value named 'output beats' in this block. Context: the function _partition_program, which handles partition program.

Line 332: `if (record_input_bytes > self.MAX_DMA_TRANSFER_BYTES` Inside the function _partition_program, which handles partition program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are record_input_bytes: the value named 'record input bytes' in this block; MAX_DMA_TRANSFER_BYTES: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic.

Line 333: `or record_output_bytes > self.MAX_DMA_TRANSFER_BYTES):` Inside the function _partition_program, which handles partition program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are or: the value named 'or' in this block; record_output_bytes: the value named 'record output bytes' in this block; MAX_DMA_TRANSFER_BYTES: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic.

Line 334: `raise ValueError("one descriptor record exceeds the configured AXI DMA length")` This rejects an invalid state by raising ‘ValueError("one descriptor record exceeds the configured AXI DMA length")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 335: `if current and (` This line opens or closes a multi-line Python expression inside the function _partition_program, which handles partition program; the neighboring lines supply its arguments or elements.

Line 336: `current_input_bytes + record_input_bytes > self.MAX_DMA_TRANSFER_BYTES` Inside the function _partition_program, which handles partition program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are current_input_bytes: the value named 'current input bytes' in this block; record_input_bytes: the value named 'record input bytes' in this block; MAX_DMA_TRANSFER_BYTES: the direct-memory-access engine moving contiguous buffers between DDR and FPGA logic.

Line 337: `or current_output_bytes + record_output_bytes > self.MAX_DMA_TRANSFER_BYTES):` Inside the function _partition_program, which handles partition program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are or: the value named 'or' in this block; current_output_bytes: the value named 'current output bytes' in this block; record_output_bytes: the value named 'record output bytes' in this block.

Line 338: `packets.append(tuple(current))` This calls ‘packets.append‘ with ‘tuple(current)‘ inside the function _partition_program, which handles partition program. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 339: `current = []` This assigns ‘[]‘ to ‘current ‘ in host memory. Here current means the value named 'current' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _partition_program, which handles partition program.

Line 340: `current_input_bytes = 0` This assigns ‘0‘ to ‘current_input_bytes ‘ in host memory. Here current_input_bytes means the value named 'current input bytes' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _partition_program, which handles partition program.

Line 341: `current_output_bytes = 0` This assigns ‘0‘ to ‘current_output_bytes ‘ in host memory. Here current_output_bytes means the value named 'current output bytes' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _partition_program, which handles partition program.

Line 342: `current.append(record)` This calls ‘current.append‘ with ‘record‘ inside the function _partition_program, which handles partition program. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 343: `current_input_bytes += record_input_bytes` Inside the function _partition_program, which handles partition program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are current_input_bytes: the value named 'current input bytes' in this block; record_input_bytes: the value named 'record input bytes' in this block.

Line 344: `current_output_bytes += record_output_bytes` Inside the function _partition_program, which handles partition program, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are current_output_bytes: the value named 'current output bytes' in this block; record_output_bytes: the value named 'record output bytes' in this block.

Line 345: `packets.append(tuple(current))` This calls ‘packets.append‘ with ‘tuple(current)‘ inside the function _partition_program, which handles partition program. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 346: `return tuple(packets)` This returns ‘tuple(packets)‘ to the caller of the function _partition_program, which handles partition program, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; packets: the value named ’packets’ in this block.

Line 348: `@staticmethod` This decorator changes how the following class or function is constructed. ‘@staticmethod‘ is applied at import time on the host and is part of the class NeuraEdgeDriver, which handles neura edge driver; it creates no FPGA circuit by itself.

Line 349: `def _program_sizes(records: Sequence[ProgramRecord]) -> tuple[int, int]:` This starts function _program_sizes. Its indented body performs program sizes as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 350: `input_words = sum(3 + len(record.input_beats) for record in records)` This assigns ‘sum(3 + len(record.input_beats) for record in records)‘ to ‘input_words ‘ in host memory. Here input_words means the value named ’input words’ in this block. The important operands are sum: the value named ’sum’ in this block; len: the value named ’len’ in this block; record: the value named ’record’ in this block. Context: the function _program_sizes, which handles program sizes.

Line 351: `output_words = sum(record.output_beats for record in records)` This assigns ‘sum(record.output_beats for record in records)‘ to ‘output_words ‘ in host memory. Here output_words means the value named ’output words’ in this block. The important operands are sum: the value named ’sum’ in this block; record: the value named ’record’ in this block; output_beats: the value named ’output beats’ in this block. Context: the function _program_sizes, which handles program sizes.

Line 352: `return input_words, output_words` This returns ‘input_words, output_words‘ to the caller of the function _program_sizes, which handles program sizes, ending this invocation. The important operands are input_words: the value named ’input words’ in this block; output_words: the value named ’output words’ in this block.

Line 354: `def _fill_program_buffer(self, buffer, records: Sequence[ProgramRecord]) -> None:` This starts function _fill_program_buffer. Its indented body performs fill program buffer as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 355: `cursor = 0` This assigns ‘0‘ to ‘cursor ‘ in host memory. Here cursor means the value named ’cursor’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 356: `for record_index, record in enumerate(records):` This iterates record_index, record over ‘enumerate(records)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _fill_program_buffer, which handles fill program buffer.

Line 357: `header = len(record.input_beats)` This assigns ‘len(record.input_beats)‘ to ‘header ‘ in host memory. Here header means the value named ’header’ in this block. The important operands are len: the value named ’len’ in this block; record: the value named ’record’ in this block; input_beats: the value named ’input beats’ in this block. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 358: `header |= record.output_beats << 32` Inside the function _fill_program_buffer, which handles fill program buffer, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are header: the value named ’header’ in this block; record: the value named ’record’ in this block; output_beats: the value named ’output beats’ in this block.

Line 359: `header |= int(record_index == len(records) - 1) << 63` Inside the function _fill_program_buffer, which handles fill program buffer, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are header: the value named 'header' in this block; record_index: an integer selecting one tensor element, lane, bank, or state entry; len: the value named 'len' in this block.

Line 360: `buffer[cursor] = header` This assigns 'header' to 'buffer[cursor] ' in host memory. Here buffer means local storage that decouples producer and consumer timing. The important operands are header: the value named 'header' in this block. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 361: `buffer[cursor + 1] = record.command.value & ((1 << 64) - 1)` Inside the function _fill_program_buffer, which handles fill program buffer, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are buffer: local storage that decouples producer and consumer timing; cursor: the value named 'cursor' in this block; record: the value named 'record' in this block.

Line 362: `buffer[cursor + 2] = record.command.value >> 64` Inside the function _fill_program_buffer, which handles fill program buffer, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are buffer: local storage that decouples producer and consumer timing; cursor: the value named 'cursor' in this block; record: the value named 'record' in this block.

Line 363: `cursor += 3` Inside the function _fill_program_buffer, which handles fill program buffer, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are cursor: the value named 'cursor' in this block.

Line 364: `if isinstance(record.input_beats, PackedStreamBeats):` This executes the following indented host-code branch only when 'isinstance(record.input_beats, PackedStreamBeats)' is true. The important operands are isinstance: the value named 'isinstance' in this block; record: the value named 'record' in this block; input_beats: the value named 'input beats' in this block. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 365: `words = np.frombuffer(record.input_beats.words, dtype=np.uint64)` This assigns 'np.frombuffer(record.input_ dtype=np.uint64)' to 'words ' in host memory. Here words means the value named 'words' in this block. The important operands are frombuffer: local storage that decouples producer and consumer timing; record: the value named 'record' in this block; input_beats: the value named 'input beats' in this block. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 366: `buffer[cursor:cursor + len(words)] = words` This assigns 'words' to 'buffer[cursor' in host memory. Here buffer means local storage that decouples producer and consumer timing. The important operands are words: the value named 'words' in this block. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 367: `cursor += len(words)` Inside the function _fill_program_buffer, which handles fill program buffer, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are cursor: the value named 'cursor' in this block; len: the value named 'len' in this block; words: the value named 'words' in this block.

Line 368: `continue` Inside the function _fill_program_buffer, which handles fill program buffer, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are continue: the value named 'continue' in this block.

Line 369: `for start in range(0, len(record.input_beats), self.PACK_COPY_WORDS):` This iterates start over 'range(0, len(record.input_beats), self.PACK_COPY_WORDS)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _fill_program_buffer, which handles fill program buffer.

Line 370: `beats = record.input_beats[start:start + self.PACK_COPY_WORDS]` This assigns ‘record.input_beats[start:start + self.PACK_COPY_WORDS]‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are record: the value named ’record’ in this block; input_beats: the value named ’input beats’ in this block; start: the value named ’start’ in this block. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 371: `words = np.fromiter(` This statement continues through source line 372; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.fromiter((beat.data for beat in beats), dtype=np.uint64, count=len(beats))‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are fromiter: the value named ’fromiter’ in this block; beat: the value named ’beat’ in this block; data: the value named ’data’ in this block. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 372: `(beat.data for beat in beats), dtype=np.uint64, count=len(beats))` This is continuation line 2 of the 2-line logical statement that begins at source line 371. Its exact fragment is ‘(beat.data for beat in beats), dtype=np.uint64, count=len(beats))‘. The important operands are beat: the value named ’beat’ in this block; data: the value named ’data’ in this block; for: the value named ’for’ in this block. Read together, the complete operation is: This assigns ‘np.fromiter((beat.data for beat in beats), dtype=np.uint64, count=len(beats))‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are fromiter: the value named ’fromiter’ in this block; beat: the value named ’beat’ in this block; data: the value named ’data’ in this block. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 373: `buffer[cursor:cursor + len(beats)] = words` This assigns ‘words‘ to ‘buffer[cursor‘ in host memory. Here buffer means local storage that decouples producer and consumer timing. The important operands are words: the value named ’words’ in this block. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 374: `cursor += len(beats)` Inside the function _fill_program_buffer, which handles fill program buffer, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are cursor: the value named ’cursor’ in this block; len: the value named ’len’ in this block; beats: the value named ’beats’ in this block.

Line 375: `if cursor != len(buffer):` This executes the following indented host-code branch only when ‘cursor != len(buffer)‘ is true. The important operands are cursor: the value named ’cursor’ in this block; len: the value named ’len’ in this block; buffer: local storage that decouples producer and consumer timing. Context: the function _fill_program_buffer, which handles fill program buffer.

Line 376: `raise RuntimeError(f"packed {cursor} descriptor words into a {len(buffer)}-word buffer")` This rejects an invalid state by raising ‘RuntimeError(f"packed {cursor} descriptor words into a {len(buffer)}-word buffer")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 378: `def _execute_program_packet(` This starts function _execute_program_packet. Its indented body performs execute program packet as part of the file that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry; it runs only when called.

Line 379: `self,` Inside the function _execute_program_packet, which handles execute program packet, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The expression is a literal or structural operator and has no hidden software state.

Line 380: `records: Sequence[ProgramRecord],` Inside the function _execute_program_packet, which handles execute program packet, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are records: the number of descriptor records accepted since program start; Sequence: the value named ’sequence’ in this block; ProgramRecord: the value named ’program record’ in this block.

Line 381: `deadline: float,` Inside the function _execute_program_packet, which handles execute program packet, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are deadline: the value named 'deadline' in this block; float: the value named 'float' in this block.

Line 382: `) -> tuple[int, ...]:` Inside the function _execute_program_packet, which handles execute program packet, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are tuple: the value named 'tuple' in this block.

Line 383: `input_words, output_beats = self._program_sizes(records)` This assigns 'self._program_sizes(records)' to 'input_words, output_beats ' in host memory. Here input_words means the value named 'input words' in this block. The important operands are _program_sizes: the value named 'program sizes' in this block; records: the number of descriptor records accepted since program start. Context: the function _execute_program_packet, which handles execute program packet.

Line 384: `self._wait_idle(deadline)` This calls 'self._wait_idle' with 'deadline' inside the function _execute_program_packe which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 385: `input_buffer = None` This assigns 'None' to 'input_buffer ' in host memory. Here input_buffer means local storage that decouples producer and consumer timing. The important operands are None: the value named 'none' in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 386: `output_buffer = None` This assigns 'None' to 'output_buffer ' in host memory. Here output_buffer means local storage that decouples producer and consumer timing. The important operands are None: the value named 'none' in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 387: `try:` This is explicit host-side failure handling inside the function _execute_program_packet, which handles execute program packet; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 388: `input_buffer = self.allocator(shape=(input_words,), dtype=np.uint64)` This assigns 'self.allocator(shape=(dtype=np.uint64)' to 'input_buffer ' in host memory. Here input_buffer means local storage that decouples producer and consumer timing. The important operands are allocator: the value named 'allocator' in this block; shape: the value named 'shape' in this block; input_words: the value named 'input words' in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 389: `self._fill_program_buffer(input_buffer, records)` This calls 'self._fill_program_buffer' with 'input_buffer, records' inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 390: `if hasattr(input_buffer, "flush"):` This executes the following indented host-code branch only when 'hasattr(input_buffer, "flush")' is true. The important operands are hasattr: the value named 'hasattr' in this block; input_buffer: local storage that decouples producer and consumer timing; flush: the value named 'flush' in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 391: `input_buffer.flush()` This calls 'input_buffer.flush' with " inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 392: `if output_beats:` This executes the following indented host-code branch only when 'output_beats' is true. The important operands are output_beats: the value named 'output beats' in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 393: `output_buffer = self.allocator(shape=(output_beats,), dtype=np.uint64)` This assigns ‘self.allocator(shape= dtype=np.uint64)‘ to ‘output_buffer ‘ in host memory. Here output_buffer means local storage that decouples producer and consumer timing. The important operands are allocator: the value named ’allocator’ in this block; shape: the value named ’shape’ in this block; output_beats: the value named ’output beats’ in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 394: `self.dma.recvchannel.transfer(output_buffer, nbytes=output_beats * 8)` This calls ‘self.dma.recvchannel.tra with ‘output_buffer, nbytes=output_beats * 8‘ inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 396: `self.clear_wrapper_status()` This calls ‘self.clear_wrapper_status‘ with “ inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 397: `self.mmio.write(self.registers.program_output_beats, output_beats)` This calls ‘self.mmio.write‘ with ‘self.registers.program_output_beats, output_beats‘ inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 398: `self.mmio.write(self.registers.control, self._control_value(1 << 2))` This calls ‘self.mmio.write‘ with ‘self.registers.control, self._control_value(1 << 2)‘ inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 399: `self.dma.sendchannel.transfer(input_buffer, nbytes=input_words * 8)` This calls ‘self.dma.sendchannel.trans with ‘input_buffer, nbytes=input_words * 8‘ inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 400: `self._wait_dma_channel(self.dma.sendchannel, deadline, "program MM2S")` This calls ‘self._wait_dma_chan with ‘self.dma.sendchannel, deadline, "program MM2S"‘ inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 401: `if output_buffer is not None:` This executes the following indented host-code branch only when ‘output_buffer is not None‘ is true. The important operands are output_buffer: local storage that decouples producer and consumer timing; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 402: `self._wait_dma_channel(self.dma.recvchannel, deadline, "program S2MM")` This calls ‘self._wait_dma_chan with ‘self.dma.recvchannel, deadline, "program S2MM"‘ inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 404: `while True:` This repeats the following host-code block while ‘True‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 405: `status = self.status()` This assigns ‘self.status()‘ to ‘status ‘ in host memory. Here status means the value named ’status’ in this block. The important operands are status: the value named ’status’ in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 406: `if status & self.STATUS_ERROR:` This executes the following indented host-code branch only when ‘status & self.STATUS_ERROR‘ is true. The important operands are status: the value named ’status’ in this block; STATUS_ERROR: the value named ’status error’ in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 407: `raise NeuraEdgeHardwareError(` This statement continues through source line 408; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"descriptor program failed; status=0x{status:08x}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 408: `f"descriptor program failed; status=0x{status:08x}")` This is continuation line 2 of the 2-line logical statement that begins at source line 407. Its exact fragment is ‘f"descriptor program failed; status=0x{status:08x}")‘. The important operands are f: the value named ’f’ in this block; descriptor: a DMA record header plus one command and its declared payload; program: the value named ’program’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"descriptor program failed; status=0x{status:08x}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 409: `if status & self.STATUS_DONE:` This executes the following indented host-code branch only when ‘status & self.STATUS_DONE‘ is true. The important operands are status: the value named ’status’ in this block; STATUS_DONE: the value named ’status done’ in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 410: `break` Inside the function _execute_program_packet, which handles execute program packet, this statement advances the host implementation that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry. The important operands are break: the value named ’break’ in this block.

Line 411: `if monotonic() >= deadline:` This executes the following indented host-code branch only when ‘monotonic() >= deadline‘ is true. The important operands are monotonic: the value named ’monotonic’ in this block; deadline: the value named ’deadline’ in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 412: `raise NeuraEdgeTimeout("descriptor program did not complete")` This rejects an invalid state by raising ‘NeuraEdgeTimeout("descriptor program did not complete")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 413: `sleep(0.0005)` This calls ‘sleep‘ with ‘0.0005‘ inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 414: `completed = int(self.mmio.read(self.registers.program_records))` This assigns ‘int(self.mmio.read(self.regist to ‘completed ‘ in host memory. Here completed means the value named ’completed’ in this block. The important operands are mmio: the value named ’mmio’ in this block; read: the value named ’read’ in this block; registers: the value named ’registers’ in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 415: `if completed != len(records):` This executes the following indented host-code branch only when ‘completed != len(records)‘ is true. The important operands are completed: the value named ’completed’ in this block; len: the value named ’len’ in this block; records: the number of descriptor records accepted since program start. Context: the function _execute_program_packet, which handles execute program packet.

Line 416: `raise NeuraEdgeHardwareError(` This statement continues through source line 417; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"descriptor program completed {completed} records; expected {len(records)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 417: `f"descriptor program completed {completed} records; expected {len(records)}")` This is continuation line 2 of the 2-line logical statement that begins at source line 416. Its exact fragment is ‘f"descriptor program completed {completed} records; expected {len(records)}")‘. The important operands are f: the value named ’f’ in this block; descriptor: a DMA record header plus one command and its declared payload; program: the value named ’program’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘NeuraEdgeHardwareError(f"descriptor program completed {completed} records; expected {len(records)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 418: `if output_buffer is None:` This executes the following indented host-code branch only when ‘output_buffer is None‘ is true. The important operands are output_buffer: local storage that decouples producer and consumer timing; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function _execute_program_packet, which handles execute program packet.

Line 419: `return ()` This returns ‘()‘ to the caller of the function _execute_program_packet, which handles execute program packet, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 420: `if hasattr(output_buffer, "invalidate"):` This executes the following indented host-code branch only when ‘hasattr(output_buffer, "invalidate")‘ is true. The important operands are hasattr: the value named ’hasattr’ in this block; output_buffer: local storage that decouples producer and consumer timing; invalidate: the producer’s statement that its current payload is meaningful. Context: the function _execute_program_packet, which handles execute program packet.

Line 421: `output_buffer.invalidate()` This calls ‘output_buffer.invalidate‘ with “ inside the function _execute_program_pac which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 422: `return tuple(int(value) for value in output_buffer[:output_beats])` This returns ‘tuple(int(value) for value in output_buffer[:output_beats])‘ to the caller of the function _execute_program_packet, which handles execute program packet, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; value: the value named ’value’ in this block; for: the value named ’for’ in this block.

Line 423: `finally:` This is explicit host-side failure handling inside the function _execute_program_packet, which handles execute program packet; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 424: `self._release_buffer(input_buffer)` This calls ‘self._release_buffer‘ with ‘input_buffer‘ inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

Line 425: `self._release_buffer(output_buffer)` This calls ‘self._release_buffer‘ with ‘output_buffer‘ inside the function _execute_program_packet, which handles execute program packet. The call advances the host-side job that controls the overlay, AXI-Lite registers, DMA allocation, packet partitioning, errors, and telemetry.

38 software/neuraedge_training.py

Role in the complete system: builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

38.1 Beginner architecture map

Dataflow responsibility The training compiler converts saved forward activations and class loss derivatives into descriptor programs. It emits surrogate-gradient gates for spike nonlinearities, exact tiled linear-backward commands for dX and dW, and Q16 optimizer commands for persistent weight and momentum state. Every payload length, gradient shape, numeric shift, and returned update is checked against the same protocol helpers used by RTL tests.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: TrainingCommandExecutor, TrainingProgramExecutor, BackwardInstruction, CompiledLinearBackward, CompiledAffineBackward, ConvBackwardGroup, CompiledConv2dBackward. Functions: _signed_matrix, _conv_output_size, im2col_signed_nchw, col2im_accumulate_fixed, execute_col2im_accumulate, _tile_starts, compile_linear_backward, compile_affine_backward, compile_conv2d_backward, sigmoid_surrogate_lut_q15, surrogate_lut_addresses, lif_bptt_fixed, _execute_vector8, execute_sgdw_update, execute_int8_weight_projection, execute_lif_bptt, _pair, maxpool2d_backward_fixed, execute_maxpool2d_backward, _shape_elements, linear_backward_ build_spikingformer_training_coverage, execute, execute_program. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

38.2 Complete source

```
"""Exact tiled backward compiler for the NeuraEdge training datapath.

For ``Y = XW`` the accelerator evaluates both matrix derivatives:
``dX = dY W^T`` and ``dW = X^T dY``.  Hardware retains 47-bit unrounded
partial sums between commands, so this compiler may tile every dimension
without changing the integer equation.

38.3 Line annotations

Line 1: `"""Exact tiled backward compiler for the NeuraEdge training datapath.` This is executable documentation attached to the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `For "Y = XW" the accelerator evaluates both matrix derivatives:` Inside the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are For: the value named 'for' in this block; Y: the value named 'y' in this block; XW: the value named 'xw' in this block.

Line 4: `"dX = dY W^T" and "dW = X^T dY". Hardware retains 47-bit unrounded` Inside the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are dX: the value named 'd x' in this block; dY: the value named 'd y' in this block; W: the value named 'w' in this block.

Line 5: `partial sums between commands, so this compiler may tile every dimension` Inside the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are partial: the value named 'partial' in this block; sums: the value named 'sums' in this block; between: the value named 'between' in this block.

Line 6: `without changing the integer equation.` Inside the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are without: the value named 'without' in this block; changing: the value named 'changing' in this block; the: the value named 'the' in this block.

Line 7: `"""` This is executable documentation attached to the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 9: `from __future__ import annotations` This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `import json` This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `from math import ceil` This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `from pathlib import Path` This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `from typing import Protocol, Sequence` This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `import numpy as np` This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `from neuraedge_protocol import (` This statement continues through source line 37; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `LinearGradientMode,` This is continuation line 2 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'LinearGradientMode,'. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `LutSuboperation,` This is continuation line 3 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'LutSuboperation,'. The important operands are LutSuboperation: the value named 'lut suboperation' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `ProgramRecord,` This is continuation line 4 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'ProgramRecord,'. The important operands are ProgramRecord: the value named 'program record' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 23: `StreamBeat,` This is continuation line 5 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'StreamBeat,'. The important operands are StreamBeat: the value named 'stream beat' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `linear_backward_command,` This is continuation line 6 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'linear_backward_command,'. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 25: `lut_command,` This is continuation line 7 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'lut_command,'. The important operands are lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 26: `pack_linear_backward_beats,` This is continuation line 8 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'pack_linear_backward_beats,'. The important operands are pack_linear_backward_beats: the value named 'pack linear backward beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 27: `pack_lut_eval_beat,` This is continuation line 9 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'pack_lut_eval_beat,'. The important operands are pack_lut_eval_beat: the value named 'pack lut eval beat' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 28: `pack_lut_load_beats,` This is continuation line 10 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'pack_lut_load_beats,'. The important operands are pack_lut_load_beats: the value named 'pack lut load beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 29: `pack_optimizer_beats,` This is continuation line 11 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'pack_optimizer_beats,'. The important operands are pack_optimizer_beats: the value named 'pack optimizer beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 30: `pack_vector_beats,` This is continuation line 12 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'pack_vector_beats,'. The important operands are pack_vector_beats: the value named 'pack vector beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 31: `sgd_command,` This is continuation line 13 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'sgd_command,'. The important operands are sgd_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 32: `unpack_linear_backward_result,` This is continuation line 14 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'unpack_linear_backward_result,'. The important operands are unpack_linear_backward_result: the value named 'unpack linear backward result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 33: `unpack_lut_result,` This is continuation line 15 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'unpack_lut_result,'. The important operands are unpack_lut_result: the value named 'unpack lut result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 34: `unpack_optimizer_result,` This is continuation line 16 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'unpack_optimizer_result,'. The important operands are unpack_optimizer_result: the

value named 'unpack optimizer result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 35: `unpack_vector_result,` This is continuation line 17 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'unpack_vector_result,'. The important operands are unpack_vector_result: the value named 'unpack vector result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 36: `vector_command,` This is continuation line 18 of the 19-line logical statement that begins at source line 19. Its exact fragment is 'vector_command,'. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 37: `)` This is continuation line 19 of the 19-line logical statement that begins at source line 19. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 38: `from neuraedge_golden import VectorOperation, round_shift_signed, saturate_signed` This imports the named Python API so the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 41: `TILE = 8` This assigns '8' to 'TILE ' in host memory. Here TILE means the value named 'tile' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 44: `class TrainingCommandExecutor(Protocol):` This defines class TrainingCommandExecutor, which groups data and methods for training command executor. Instances exist in host memory and organize the flow that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 45: `def execute(` This starts function execute. Its indented body performs execute as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 46: `self,` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 47: `command,` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 48: `input_beats: Sequence[StreamBeat] = (),` This assigns '(),' to 'input_beats' in host memory. Here input_beats means the value named 'input beats' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 49: `*,` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 50: `output_beats: int = 0,` This assigns ‘0,‘ to ‘output_beats‘ in host memory. Here output_beats means the value named ’output beats’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 51: `timeout_seconds: float = 5.0,` This assigns ‘5.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 52: `) -> tuple[int, ...]: ...` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named ’tuple’ in this block.

Line 55: `class TrainingProgramExecutor(TrainingCommandExecutor, Protocol):` This defines class TrainingProgramExecutor, which groups data and methods for training program executor. Instances exist in host memory and organize the flow that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 56: `def execute_program(` This starts function execute_program. Its indented body performs execute program as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 57: `self,` Inside the function execute_program, which handles execute program, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 58: `records: Sequence[ProgramRecord],` Inside the function execute_program, which handles execute program, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are records: the number of descriptor records accepted since program start; Sequence: the value named ’sequence’ in this block; ProgramRecord: the value named ’program record’ in this block.

Line 59: `*,` Inside the function execute_program, which handles execute program, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 60: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_program, which handles execute program.

Line 61: `) -> tuple[int, ...]: ...` Inside the function execute_program, which handles execute program, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named ’tuple’ in this block.

Line 64: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it creates no FPGA circuit by itself.

Line 65: `class BackwardInstruction:` This defines class BackwardInstruction, which groups data and methods for backward instruction. Instances exist in host memory and organize the flow that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 66: `"""One partial tile and the global matrix region to which it belongs."""` This is executable documentation attached to the class BackwardInstruction, which handles backward instruction. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 68: `record: ProgramRecord` Inside the class BackwardInstruction, which handles backward instruction, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block.

Line 69: `mode: LinearGradientMode` Inside the class BackwardInstruction, which handles backward instruction, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are mode: the value named 'mode' in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter.

Line 70: `row_start: int` Inside the class BackwardInstruction, which handles backward instruction, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are row_start: one output-row position processed by the tensor tile.

Line 71: `input_start: int` Inside the class BackwardInstruction, which handles backward instruction, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_start: the value named 'input start' in this block.

Line 72: `output_start: int` Inside the class BackwardInstruction, which handles backward instruction, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_start: the value named 'output start' in this block.

Line 73: `rows: int` Inside the class BackwardInstruction, which handles backward instruction, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are rows: one output-row position processed by the tensor tile.

Line 74: `inputs: int` Inside the class BackwardInstruction, which handles backward instruction, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are inputs: the value named 'inputs' in this block.

Line 75: `outputs: int` Inside the class BackwardInstruction, which handles backward instruction, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are outputs: the value named 'outputs' in this block.

Line 76: `accumulate: bool` Inside the class BackwardInstruction, which handles backward instruction, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are accumulate: the value named 'accumulate' in this block; bool: the value named 'bool' in this block.

Line 77: `suppress_output: bool` Inside the class BackwardInstruction, which handles backward instruction, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are suppress_output: the value named 'suppress output' in this block; bool: the value named 'bool' in this block.

Line 80: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it creates no FPGA circuit by itself.

Line 81: `class CompiledLinearBackward:` This defines class CompiledLinearBackward, which groups data and methods for compiled linear backward. Instances exist in host memory and organize the flow that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 82: `"""Executable descriptor program for one arbitrary signed linear layer."""` This is executable documentation attached to the class CompiledLinearBackward, which handles compiled linear backward. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 84: `shape: tuple[int, int, int]` Inside the class CompiledLinearBackward, which handles compiled linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are shape: the value named 'shape' in this block; tuple: the value named 'tuple' in this block.

Line 85: `input_gradient_shift: int` Inside the class CompiledLinearBackward, which handles compiled linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter.

Line 86: `weight_gradient_shift: int` Inside the class CompiledLinearBackward, which handles compiled linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation.

Line 87: `instructions: tuple[BackwardInstruction, ...]` Inside the class CompiledLinearBackward, which handles compiled linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are instructions: the value named 'instructions' in this block; tuple: the value named 'tuple' in this block; BackwardInstruction: the value named 'backward instruction' in this block.

Line 88: `estimated_input_bytes: int` Inside the class CompiledLinearBackward, which handles compiled linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are estimated_input_bytes: the value named 'estimated input bytes' in this block.

Line 89: `mathematical_multiplications: int` Inside the class CompiledLinearBackward, which handles compiled linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are mathematical_multiplications: the value named 'mathematical multiplications' in this block.

Line 91: `@property` This decorator changes how the following class or function is constructed. '@property' is applied at import time on the host and is part of the class CompiledLinearBackward, which handles compiled linear backward; it creates no FPGA circuit by itself.

Line 92: `def records(self) -> tuple[ProgramRecord, ...]:` This starts function records. Its indented body performs records as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 93: `return tuple(instruction.record for instruction in self.instructions)` This returns ‘tuple(instruction.recor for instruction in self.instructions)‘ to the caller of the function records, which handles records, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; instruction: the value named ’instruction’ in this block; record: the value named ’record’ in this block.

Line 95: `@property` This decorator changes how the following class or function is constructed. ‘@property‘ is applied at import time on the host and is part of the class CompiledLinearBackward, which handles compiled linear backward; it creates no FPGA circuit by itself.

Line 96: `def output_beats(self) -> int:` This starts function output_beats. Its indented body performs output beats as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 97: `return sum(instruction.record.output_beats for instruction in self.instructions)` This returns ‘sum(instruction.record.output_beats for instruction in self.instructions)‘ to the caller of the function output_beats, which handles output beats, ending this invocation. The important operands are sum: the value named ’sum’ in this block; instruction: the value named ’instruction’ in this block; record: the value named ’record’ in this block.

Line 99: `@property` This decorator changes how the following class or function is constructed. ‘@property‘ is applied at import time on the host and is part of the class CompiledLinearBackward, which handles compiled linear backward; it creates no FPGA circuit by itself.

Line 100: `def partial_tile_count(self) -> int:` This starts function partial_tile_count. Its indented body performs partial tile count as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 101: `return len(self.instructions)` This returns ‘len(self.instructions)‘ to the caller of the function partial_tile_count, which handles partial tile count, ending this invocation. The important operands are len: the value named ’len’ in this block; instructions: the value named ’instructions’ in this block.

Line 103: `def _decode_outputs(self, instruction_words: Sequence[Sequence[int]]) -> tuple[np.ndarray, np.ndarray]:` This starts function _decode_outputs. Its indented body performs decode outputs as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 104: `rows, inputs, outputs = self.shape` This assigns ‘self.shape‘ to ‘rows, inputs, outputs ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are shape: the value named ’shape’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 105: `input_gradient = np.zeros((rows, inputs), dtype=np.int64)` This assigns ‘np.zeros((rows, inputs), dtype=np.int64)‘ to ‘input_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are zeros: the value named ’zeros’ in this block; rows: one output-row position processed by the tensor tile; inputs: the value named ’inputs’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 106: `weight_gradient = np.zeros((inputs, outputs), dtype=np.int64)` This assigns ‘np.zeros((inputs, outputs), dtype=np.int64)‘ to ‘weight_gradient ‘ in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are zeros: the value named ’zeros’ in this block; inputs: the value named ’inputs’ in this block; outputs: the value named ’outputs’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 107: `if len(instruction_words) != len(self.instructions):` This executes the following indented host-code branch only when ‘len(instruction_words) != len(self.instructions)‘ is true. The important operands are len: the value named ’len’ in this block; instruction_words: the value named ’instruction words’ in this block; instructions: the value named ’instructions’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 108: `raise RuntimeError("backward result partition does not match the instruction count")` This rejects an invalid state by raising ‘RuntimeError("backward result partition does not match the instruction count")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 109: `for instruction, words in zip(self.instructions, instruction_words):` This iterates instruction, words over ‘zip(self.instructions, instruction_words)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _decode_outputs, which handles decode outputs.

Line 110: `if len(words) != instruction.record.output_beats:` This executes the following indented host-code branch only when ‘len(words) != instruction.record.output_beats‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block; instruction: the value named ’instruction’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 111: `raise RuntimeError(` This statement continues through source line 114; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘RuntimeError(f"backward tile returned {len(words)} beats; " f"expected {instruction.record.output_beats}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 112: `f"backward tile returned {len(words)} beats; "` This is continuation line 2 of the 4-line logical statement that begins at source line 111. Its exact fragment is ‘f"backward tile returned {len(words)} beats; "‘. The important operands are f: the value named ’f’ in this block; backward: the value named ’backward’ in this block; tile: the value named ’tile’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"backward tile returned {len(words)} beats; " f"expected {instruction.record.output_beats}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 113: `f"expected {instruction.record.output_beats}"` This is continuation line 3 of the 4-line logical statement that begins at source line 111. Its exact fragment is ‘f"expected {instruction.record.output_beats}"‘. The important operands are f: the value named ’f’ in this block; expected: the value named ’expected’ in this block; instruction: the value named ’instruction’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"backward tile returned {len(words)} beats; " f"expected {instruction.record.output_beats}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 114: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 111. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"backward tile returned {len(words)} beats; " f"expected {instruction.record.output_beats}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 115: `if instruction.suppress_output:` This executes the following indented host-code branch only when ‘instruction.suppress_output‘ is true. The important operands are instruction: the value named ’instruction’ in this block; suppress_output: the value named ’suppress output’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 116: `continue` Inside the function _decode_outputs, which handles decode outputs, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are continue: the value named ’continue’ in this block.

Line 117: `dx_tile, dw_tile = unpack_linear_backward_result(` This statement continues through source line 123; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘unpack_linear_backward_ words, instruction.rows, instruction.inputs, instruction.outputs, mode=instruction.mode,)‘ to ‘dx_tile, dw_tile ‘ in host memory. Here dx_tile means the value named ’dx tile’ in this block. The important operands are unpack_linear_backward_result: the value named ’unpack linear backward result’ in this block; words: the value named ’words’ in this block; instruction: the value named ’instruction’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 118: `words,` This is continuation line 2 of the 7-line logical statement that begins at source line 117. Its exact fragment is 'words,'. The important operands are words: the value named 'words' in this block. Read together, the complete operation is: This assigns 'unpack_linear_backward_result(words, instruction.rows, instruction.inputs, instruction.outputs, mode=instruction.mode,)' to 'dx_tile, dw_tile ' in host memory. Here dx_tile means the value named 'dx tile' in this block. The important operands are unpack_linear_backward_result: the value named 'unpack linear backward result' in this block; words: the value named 'words' in this block; instruction: the value named 'instruction' in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 119: `instruction.rows,` This is continuation line 3 of the 7-line logical statement that begins at source line 117. Its exact fragment is 'instruction.rows,'. The important operands are instruction: the value named 'instruction' in this block; rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This assigns 'unpack_linear_backward_result(words, instruction.rows, instruction.inputs, instruction.outputs, mode=instruction.mode,)' to 'dx_tile, dw_tile ' in host memory. Here dx_tile means the value named 'dx tile' in this block. The important operands are unpack_linear_backward_result: the value named 'unpack linear backward result' in this block; words: the value named 'words' in this block; instruction: the value named 'instruction' in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 120: `instruction.inputs,` This is continuation line 4 of the 7-line logical statement that begins at source line 117. Its exact fragment is 'instruction.inputs,'. The important operands are instruction: the value named 'instruction' in this block; inputs: the value named 'inputs' in this block. Read together, the complete operation is: This assigns 'unpack_linear_backward_result(words, instruction.rows, instruction.inputs, instruction.outputs, mode=instruction.mode,)' to 'dx_tile, dw_tile ' in host memory. Here dx_tile means the value named 'dx tile' in this block. The important operands are unpack_linear_backward_result: the value named 'unpack linear backward result' in this block; words: the value named 'words' in this block; instruction: the value named 'instruction' in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 121: `instruction.outputs,` This is continuation line 5 of the 7-line logical statement that begins at source line 117. Its exact fragment is 'instruction.outputs,'. The important operands are instruction: the value named 'instruction' in this block; outputs: the value named 'outputs' in this block. Read together, the complete operation is: This assigns 'unpack_linear_backward_result(words, instruction.rows, instruction.inputs, instruction.outputs, mode=instruction.mode,)' to 'dx_tile, dw_tile ' in host memory. Here dx_tile means the value named 'dx tile' in this block. The important operands are unpack_linear_backward_result: the value named 'unpack linear backward result' in this block; words: the value named 'words' in this block; instruction: the value named 'instruction' in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 122: `mode=instruction.mode,` This is continuation line 6 of the 7-line logical statement that begins at source line 117. Its exact fragment is 'mode=instruction.mode,'. The important operands are mode: the value named 'mode' in this block; instruction: the value named 'instruction' in this block. Read together, the complete operation is: This assigns 'unpack_linear_backward_result(words, instruction.rows, instruction.inputs, instruction.outputs, mode=instruction.mode,)' to 'dx_tile, dw_tile ' in host memory. Here dx_tile means the value named 'dx tile' in this block. The important operands are unpack_linear_backward_result: the value named 'unpack linear backward result' in this block; words: the value named 'words' in this block; instruction: the value named 'instruction' in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 123: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 117. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'unpack_linear_backward_result(words, instruction.rows, instruction.inputs, instruction.outputs, mode=instruction.mode,)' to 'dx_tile, dw_tile ' in host memory. Here dx_tile means the value named 'dx tile' in this block. The important operands are unpack_linear_backward_result: the value named 'unpack linear backward result' in this block; words: the value named 'words' in this block; instruction: the value named 'instruction' in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 124: `if instruction.mode == LinearGradientMode.INPUT:` This executes the following indented host-code branch only when 'instruction.mode == LinearGradientMode.INPUT' is true. The important operands are instruction: the value named 'instruction' in this block; mode: the value named 'mode' in this block; LinearGradientMode: the

signed loss derivative used to update a learned parameter. Context: the function _decode_outputs, which handles decode outputs.

Line 125: `input_gradient[` This statement continues through source line 128; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.asarray(dx_tile, dtype=np.int64)‘ to ‘input_gradient[instruction.row_start‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are asarray: the value named ’asarray’ in this block; dx_tile: the value named ’dx tile’ in this block; dtype: the value named ’dtype’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 126: `instruction.row_start:instruction.row_start + instruction.rows,` This is continuation line 2 of the 4-line logical statement that begins at source line 125. Its exact fragment is ‘instruction.row_start:instruction.row_start + instruction.rows,‘. The important operands are instruction: the value named ’instruction’ in this block; row_start: one output-row position processed by the tensor tile; rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This assigns ‘np.asarray(dx_tile, dtype=np.int64)‘ to ‘input_gradient[instruction.row_start‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are asarray: the value named ’asarray’ in this block; dx_tile: the value named ’dx tile’ in this block; dtype: the value named ’dtype’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 127: `instruction.input_start:instruction.input_start + instruction.inputs,` This is continuation line 3 of the 4-line logical statement that begins at source line 125. Its exact fragment is ‘instruction.input_start:instruction.input_start + instruction.inputs,‘. The important operands are instruction: the value named ’instruction’ in this block; input_start: the value named ’input start’ in this block; inputs: the value named ’inputs’ in this block. Read together, the complete operation is: This assigns ‘np.asarray(dx_tile, dtype=np.int64)‘ to ‘input_gradient[instruction.row_start‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are asarray: the value named ’asarray’ in this block; dx_tile: the value named ’dx tile’ in this block; dtype: the value named ’dtype’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 128: `] = np.asarray(dx_tile, dtype=np.int64)` This is continuation line 4 of the 4-line logical statement that begins at source line 125. Its exact fragment is ‘] = np.asarray(dx_tile, dtype=np.int64)‘. The important operands are asarray: the value named ’asarray’ in this block; dx_tile: the value named ’dx tile’ in this block; dtype: the value named ’dtype’ in this block. Read together, the complete operation is: This assigns ‘np.asarray(dx_tile, dtype=np.int64)‘ to ‘input_gradient[instruction.row_start‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are asarray: the value named ’asarray’ in this block; dx_tile: the value named ’dx tile’ in this block; dtype: the value named ’dtype’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 129: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function _decode_outputs, which handles decode outputs.

Line 130: `weight_gradient[` This statement continues through source line 133; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.asarray(dw_tile, dtype=np.int64)‘ to ‘weight_gradient[instruction.input_start‘ in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; dw_tile: the value named ’dw tile’ in this block; dtype: the value named ’dtype’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 131: `instruction.input_start:instruction.input_start + instruction.inputs,` This is continuation line 2 of the 4-line logical statement that begins at source line 130. Its exact fragment is ‘instruction.input_start:instruction.input_start + instruction.inputs,‘. The important operands are instruction: the value named ’instruction’ in this block; input_start: the value named ’input start’ in this block; inputs: the value named ’inputs’ in this block. Read together, the complete operation is: This assigns ‘np.asarray(dw_tile, dtype=np.int64)‘ to ‘weight_gradient[instruction.input_start‘ in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; dw_tile: the value named ’dw tile’ in this block; dtype: the value named ’dtype’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 132: `instruction.output_start:instruction.output_start + instruction.outputs,` This is continuation line 3 of the 4-line logical statement that begins at source line 130. Its exact fragment is ‘instruction.output_start:instruction.output_ + instruction.outputs,‘. The important operands are instruction: the value named ’instruction’ in this block; output_start: the value named ’output start’ in this block; outputs: the value named ’outputs’ in this block. Read together, the complete operation is: This assigns ‘np.asarray(dw_tile, dtype=np.int64)‘ to ‘weight_gradient[instruction.input_start‘ in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; dw_tile: the value named ’dw tile’ in this block; dtype: the value named ’dtype’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 133: `] = np.asarray(dw_tile, dtype=np.int64)` This is continuation line 4 of the 4-line logical statement that begins at source line 130. Its exact fragment is ‘] = np.asarray(dw_tile, dtype=np.int64)‘. The important operands are asarray: the value named ’asarray’ in this block; dw_tile: the value named ’dw tile’ in this block; dtype: the value named ’dtype’ in this block. Read together, the complete operation is: This assigns ‘np.asarray(dw_tile, dtype=np.int64)‘ to ‘weight_gradient[instruction.input_start‘ in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; dw_tile: the value named ’dw tile’ in this block; dtype: the value named ’dtype’ in this block. Context: the function _decode_outputs, which handles decode outputs.

Line 134: `return input_gradient, weight_gradient` This returns ‘input_gradient, weight_gradient‘ to the caller of the function _decode_outputs, which handles decode outputs, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; weight_gradient: a learned coefficient multiplied by an activation.

Line 136: `def execute(` This starts function execute. Its indented body performs execute as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 137: `self,` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 138: `driver: TrainingCommandExecutor,` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named ’driver’ in this block; TrainingCommandExecutor: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 139: `*,` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 140: `timeout_seconds: float = 5.0,` This assigns ‘5.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 141: `) -> tuple[np.ndarray, np.ndarray]:` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named ’tuple’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 142: `partitions: list[tuple[int, ...]] = []` This assigns ‘[]‘ to ‘partitions‘ in host memory. Here partitions means the value named ’partitions’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 143: `for instruction in self.instructions:` This iterates instruction over ‘self.instructions‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute, which handles execute.

Line 144: `partitions.append(driver.execute(` This statement continues through source line 149; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘partitions.append‘ with ‘driver.execute(instruction.record.command, instruction.record.input_beats, output_beats=instruction.record.output_beats, timeout_seconds=ti)‘ inside the function execute, which handles execute. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 145: `instruction.record.command,` This is continuation line 2 of the 6-line logical statement that begins at source line 144. Its exact fragment is ‘instruction.record.command,‘. The important operands are instruction: the value named ’instruction’ in this block; record: the value named ’record’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘partitions.append‘ with ‘driver.execute(instruction.record.command, instruction.record.input_beats, output_beats=instruction.record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute, which handles execute. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 146: `instruction.record.input_beats,` This is continuation line 3 of the 6-line logical statement that begins at source line 144. Its exact fragment is ‘instruction.record.input_beats,‘. The important operands are instruction: the value named ’instruction’ in this block; record: the value named ’record’ in this block; input_beats: the value named ’input beats’ in this block. Read together, the complete operation is: This calls ‘partitions.append‘ with ‘driver.execute(instruction.record.command, instruction.record.input_beats, output_beats=instruction.record.output_beats, timeout_seconds=timeout_)‘ inside the function execute, which handles execute. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 147: `output_beats=instruction.record.output_beats,` This is continuation line 4 of the 6-line logical statement that begins at source line 144. Its exact fragment is ‘output_beats=instruction.record.output_beats,‘. The important operands are output_beats: the value named ’output beats’ in this block; instruction: the value named ’instruction’ in this block; record: the value named ’record’ in this block. Read together, the complete operation is: This calls ‘partitions.append‘ with ‘driver.execute(instruction.record.command, instruction.record.input_beats, output_beats=instruction.record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute, which handles execute. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 148: `timeout_seconds=timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 144. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This calls ‘partitions.append‘ with ‘driver.execute(instruction.record.command, instruction.record.input_beats, output_beats=instruction.record.o timeout_seconds=timeout_seconds,)‘ inside the function execute, which handles execute. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 149: `))` This is continuation line 6 of the 6-line logical statement that begins at source line 144. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘partitions.append‘ with ‘driver.execute(instruction.record.command, instruction.record.input_beats, output_beats=instruction.record.output_beats, timeout_seconds=timeout_seconds,)‘ inside the function execute, which handles execute. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 150: `return self._decode_outputs(partitions)` This returns ‘self._decode_outputs(partitions)‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are _decode_outputs: the value named ’decode outputs’ in this block; partitions: the value named ’partitions’ in this block.

Line 152: `def execute_batched(` This starts function execute_batched. Its indented body performs execute batched as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 153: `self,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 154: `driver: TrainingProgramExecutor,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named 'driver' in this block; TrainingProgramExecutor: the value named 'training program executor' in this block.

Line 155: `*,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 156: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_batched, which handles execute batched.

Line 157: `) -> tuple[np.ndarray, np.ndarray]:` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 158: `words = driver.execute_program(self.records, timeout_seconds=timeout_seconds)` This assigns 'driver.execute_program(self.records, timeout_seconds=timeout_seconds)' to 'words ' in host memory. Here words means the value named 'words' in this block. The important operands are driver: the value named 'driver' in this block; execute_program: the value named 'execute program' in this block; records: the number of descriptor records accepted since program start. Context: the function execute_batched, which handles execute batched.

Line 159: `if len(words) != self.output_beats:` This executes the following indented host-code branch only when 'len(words) != self.output_beats' is true. The important operands are len: the value named 'len' in this block; words: the value named 'words' in this block; output_beats: the value named 'output beats' in this block. Context: the function execute_batched, which handles execute batched.

Line 160: `raise RuntimeError(` This statement continues through source line 162; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising 'RuntimeError(f"backward program returned {len(words)} beats; expected {self.output_beats}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 161: `f"backward program returned {len(words)} beats; expected {self.output_beats}"` This is continuation line 2 of the 3-line logical statement that begins at source line 160. Its exact fragment is 'f"backward program returned {len(words)} beats; expected {self.output_beats}"'. The important operands are f: the value named 'f' in this block; backward: the value named 'backward' in this block; program: the value named 'program' in this block. Read together, the complete operation is: This rejects an invalid state by raising 'RuntimeError(f"backward program returned {len(words)} beats; expected {self.output_beats}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 162: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 160. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This rejects an invalid state by raising 'RuntimeError(f"backward program returned {len(words)} beats; expected {self.output_beats}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 163: `partitions: list[tuple[int, ...]] = []` This assigns '[]' to 'partitions' in host memory. Here partitions means the value named 'partitions' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_batched, which handles execute batched.

Line 164: `cursor = 0` This assigns '0' to 'cursor ' in host memory. Here cursor means the value named 'cursor' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_batched, which handles execute batched.

Line 165: `for instruction in self.instructions:` This iterates instruction over 'self.instructions'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_batched, which handles execute batched.

Line 166: `end = cursor + instruction.record.output_beats` This assigns 'cursor + instruction.record.output_beats' to 'end ' in host memory. Here end means the value named 'end' in this block. The important operands are cursor: the value named 'cursor' in this block; instruction: the value named 'instruction' in this block; record: the value named 'record' in this block. Context: the function execute_batched, which handles execute batched.

Line 167: `partitions.append(tuple(words[cursor:end]))` This calls 'partitions.append' with 'tuple(words[cursor:end])' inside the function execute_batched, which handles execute batched. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 168: `cursor = end` This assigns 'end' to 'cursor ' in host memory. Here cursor means the value named 'cursor' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_batched, which handles execute batched.

Line 169: `return self._decode_outputs(partitions)` This returns 'self._decode_outputs(partitions)' to the caller of the function execute_batched, which handles execute batched, ending this invocation. The important operands are _decode_outputs: the value named 'decode outputs' in this block; partitions: the value named 'partitions' in this block.

Line 172: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it creates no FPGA circuit by itself.

Line 173: `class CompiledAffineBackward:` This defines class CompiledAffineBackward, which groups data and methods for compiled affine backward. Instances exist in host memory and organize the flow that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 174: `"""Linear backward plan whose final augmented row represents the bias."""` This is executable documentation attached to the class CompiledAffineBackward, which handles compiled affine backward. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 176: `linear: CompiledLinearBackward` Inside the class CompiledAffineBackward, which handles compiled affine backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are linear: the value named 'linear' in this block; CompiledLinearBackward: the value named 'compiled linear backward' in this block.

Line 177: `input_features: int` Inside the class CompiledAffineBackward, which handles compiled affine backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_features: the value named 'input features' in this block.

Line 179: `def split(` This starts function split. Its indented body performs split as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 180: `self,` Inside the function split, which handles split, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 181: `augmented_input_gradient: np.ndarray,` Inside the function split, which handles split, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are augmented_input_gradient: the signed loss derivative used to update a learned parameter; ndarray: the value named 'ndarray' in this block.

Line 182: `augmented_weight_gradient: np.ndarray,` Inside the function split, which handles split, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are augmented_weight_gradient: a learned coefficient multiplied by an activation; ndarray: the value named 'ndarray' in this block.

Line 183: `) -> tuple[np.ndarray, np.ndarray, np.ndarray]:` Inside the function split, which handles split, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 184: `return (` This statement continues through source line 188; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘(augmented_input_gradient[:, :self.input_features], augmented_weight_gradient[:self.input_features, :], augmented_weight_gradient[self.input_features, :],)‘ to the caller of the function split, which handles split, ending this invocation. The important operands are augmented_input_gradient: the signed loss derivative used to update a learned parameter; input_features: the value named 'input features' in this block; augmented_weight_gradient: a learned coefficient multiplied by an activation.

Line 185: `augmented_input_gradient[:, :self.input_features],` This is continuation line 2 of the 5-line logical statement that begins at source line 184. Its exact fragment is ‘augmented_input_gradient[:, :self.input_features],‘. The important operands are augmented_input_gradient: the signed loss derivative used to update a learned parameter; input_features: the value named 'input features' in this block. Read together, the complete operation is: This returns ‘(augmented_input_gradient[:, :self.input_features], augmented_weight_gradient[:self.input_features, :], augmented_weight_gradient[self.input_features, :],)‘ to the caller of the function split, which handles split, ending this invocation. The important operands are augmented_input_gradient: the signed loss derivative used to update a learned parameter; input_features: the value named 'input features' in this block; augmented_weight_gradient: a learned coefficient multiplied by an activation.

Line 186: `augmented_weight_gradient[:self.input_features, :],` This is continuation line 3 of the 5-line logical statement that begins at source line 184. Its exact fragment is ‘augmented_weight_gradient[:self.input_features, :],‘. The important operands are augmented_weight_gradient: a learned coefficient multiplied by an activation; input_features: the value named 'input features' in this block. Read together, the complete operation is: This returns ‘(augmented_input_gradient[:, :self.input_features], augmented_weight_gradient[:self.input_features, :], augmented_weight_gradient[self.input_features, :],)‘ to the caller of the function split, which handles split, ending this invocation. The important operands are augmented_input_gradient: the signed loss derivative used to update a learned parameter; input_features: the value named 'input features' in this block; augmented_weight_gradient: a learned coefficient multiplied by an activation.

Line 187: `augmented_weight_gradient[self.input_features, :],` This is continuation line 4 of the 5-line logical statement that begins at source line 184. Its exact fragment is ‘augmented_weight_gradient[self.input_features, :],‘. The important operands are augmented_weight_gradient: a learned coefficient multiplied by an activation; input_features: the value named 'input features' in this block. Read together, the complete operation is: This returns ‘(augmented_input_gradient[:, :self.input_features], augmented_weight_gradient[:self.input_features, :], augmented_weight_gradient[self.input_features, :],)‘ to the caller of the function split, which handles split, ending this

invocation. The important operands are augmented_input_gradient: the signed loss derivative used to update a learned parameter; input_features: the value named 'input features' in this block; augmented_weight_gradient: a learned coefficient multiplied by an activation.

Line 188: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 184. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘(augmented_input_gradient[:, :self.input_features], augmented_weight_gradient[:self.input_features, :], augmented_weight_gradient[self.input_features, :],)‘ to the caller of the function split, which handles split, ending this invocation. The important operands are augmented_input_gradient: the signed loss derivative used to update a learned parameter; input_features: the value named 'input features' in this block; augmented_weight_gradient: a learned coefficient multiplied by an activation.

Line 190: `def execute(` This starts function execute. Its indented body performs execute as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 191: `self,` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 192: `driver: TrainingCommandExecutor,` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named 'driver' in this block; TrainingCommandExecutor: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 193: `*,` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 194: `timeout_seconds: float = 5.0,` This assigns ‘5.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute, which handles execute.

Line 195: `) -> tuple[np.ndarray, np.ndarray, np.ndarray]:` Inside the function execute, which handles execute, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 196: `return self.split(*self.linear.execute(driver, timeout_seconds=timeout_seconds))` This returns ‘self.split(*self.linear.execute(driver, timeout_seconds=timeout_seconds))‘ to the caller of the function execute, which handles execute, ending this invocation. The important operands are split: the value named 'split' in this block; linear: the value named 'linear' in this block; execute: the value named 'execute' in this block.

Line 198: `def execute_batched(` This starts function execute_batched. Its indented body performs execute batched as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 199: `self,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 200: `driver: TrainingProgramExecutor,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named 'driver' in this block; TrainingProgramExecutor: the value named 'training program executor' in this block.

Line 201: `*,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 202: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_batched, which handles execute batched.

Line 203: `) -> tuple[np.ndarray, np.ndarray, np.ndarray]:` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 204: `return self.split(*self.linear.execute_batched(driver, timeout_seconds=timeout_seconds))` This returns 'self.split(*self.linear.execute_batched(driver, timeout_seconds=timeout_seconds))' to the caller of the function execute_batched, which handles execute batched, ending this invocation. The important operands are split: the value named 'split' in this block; linear: the value named 'linear' in this block; execute_batched: the value named 'execute batched' in this block.

Line 207: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it creates no FPGA circuit by itself.

Line 208: `class ConvBackwardGroup:` This defines class ConvBackwardGroup, which groups data and methods for conv backward group. Instances exist in host memory and organize the flow that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 209: `input_channel_start: int` Inside the class ConvBackwardGroup, which handles conv backward group, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_channel_start: the value named 'input channel start' in this block.

Line 210: `output_channel_start: int` Inside the class ConvBackwardGroup, which handles conv backward group, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_channel_start: the value named 'output channel start' in this block.

Line 211: `input_channels: int` Inside the class ConvBackwardGroup, which handles conv backward group, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_channels: the value named 'input channels' in this block.

Line 212: `output_channels: int` Inside the class ConvBackwardGroup, which handles conv backward group, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_channels: the value named 'output channels' in this block.

Line 213: `affine: CompiledAffineBackward` Inside the class ConvBackwardGroup, which handles conv backward group, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are affine: the value named 'affine' in this block; CompiledAffineBackward: the value named 'compiled affine backward' in this block.

Line 216: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it creates no FPGA circuit by itself.

Line 217: `class CompiledConv2dBackward:` This defines class CompiledConv2dBackward, which groups data and methods for compiled conv2d backward. Instances exist in host memory and organize the flow that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 218: `input_shape: tuple[int, int, int, int]` Inside the class CompiledConv2dBackward, which handles compiled conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_shape: the value named 'input shape' in this block; tuple: the value named 'tuple' in this block.

Line 219: `weight_shape: tuple[int, int, int, int]` Inside the class CompiledConv2dBackward, which handles compiled conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are weight_shape: a learned coefficient multiplied by an activation; tuple: the value named 'tuple' in this block.

Line 220: `output_shape: tuple[int, int, int, int]` Inside the class CompiledConv2dBackward, which handles compiled conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_shape: the value named 'output shape' in this block; tuple: the value named 'tuple' in this block.

Line 221: `kernel: tuple[int, int]` Inside the class CompiledConv2dBackward, which handles compiled conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are kernel: the value named 'kernel' in this block; tuple: the value named 'tuple' in this block.

Line 222: `stride: tuple[int, int]` Inside the class CompiledConv2dBackward, which handles compiled conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are stride: the value named 'stride' in this block; tuple: the value named 'tuple' in this block.

Line 223: `padding: tuple[int, int]` Inside the class CompiledConv2dBackward, which handles compiled conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are padding: the value named 'padding' in this block; tuple: the value named 'tuple' in this block.

Line 224: `dilation: tuple[int, int]` Inside the class CompiledConv2dBackward, which handles compiled conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are dilation: the value named 'dilation' in this block; tuple: the value named 'tuple' in this block.

Line 225: `groups: int` Inside the class CompiledConv2dBackward, which handles compiled conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are groups: the value named 'groups' in this block.

Line 226: `group_programs: tuple[ConvBackwardGroup, ...]` Inside the class CompiledConv2dBackward, which handles compiled conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are group_programs: the value named 'group programs' in this block; tuple: the value named 'tuple' in this block; ConvBackwardGroup: the value named 'conv backward group' in this block.

Line 228: `@property` This decorator changes how the following class or function is constructed. '@property' is applied at import time on the host and is part of the class CompiledConv2dBackward, which handles compiled conv2d backward; it creates no FPGA circuit by itself.

Line 229: `def mathematical_multiplications(self) -> int:` This starts function mathematical_multiplications. Its indented body performs mathematical multiplications as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 230: `return sum(` This statement continues through source line 233; the explanation uses the complete expression rather than only the first visual fragment. This returns 'sum(group.affine.linear.mathematical_multiplications for group in self.group_programs)' to the caller of the function mathematical_multiplications, which handles mathematical multiplications, ending this invocation. The important operands are sum: the value named 'sum' in this block; group: the value named 'group' in this block; affine: the value named 'affine' in this block.

Line 231: `group.affine.linear.mathematical_multiplications` This is continuation line 2 of the 4-line logical statement that begins at source line 230. Its exact fragment is 'group.affine.linear.mathematical_multiplications'. The important operands are group: the value named 'group' in this block; affine: the value named 'affine' in this block; linear: the value named 'linear' in this block. Read together, the complete operation is: This returns 'sum(group.affine.linear.mathematical_multiplications for group in self.group_programs)' to the caller of the function mathematical_multiplications, which handles mathematical multiplications, ending this invocation. The important operands are sum: the value named 'sum' in this block; group: the value named 'group' in this block; affine: the value named 'affine' in this block.

Line 232: `for group in self.group_programs` This is continuation line 3 of the 4-line logical statement that begins at source line 230. Its exact fragment is 'for group in self.group_programs'. The important operands are for: the value named 'for' in this block; group: the value named 'group' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This returns 'sum(group.affine.linear.mathematical_multiplications for group in self.group_programs)' to the caller of the function mathematical_multiplications, which handles mathematical multiplications, ending this invocation. The important operands are sum: the value named 'sum' in this block; group: the value named 'group' in this block; affine: the value named 'affine' in this block.

Line 233: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 230. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'sum(group.affine.linear.mathematical_multiplications for group in self.group_programs)' to the caller of the function mathematical_multiplications, which handles mathematical multiplications, ending this invocation. The important operands are sum: the value named 'sum' in this block; group: the value named 'group' in this block; affine: the value named 'affine' in this block.

Line 235: `@property` This decorator changes how the following class or function is constructed. '@property' is applied at import time on the host and is part of the class CompiledConv2dBackward, which handles compiled conv2d backward; it creates no FPGA circuit by itself.

Line 236: `def partial_tile_count(self) -> int:` This starts function partial_tile_count. Its indented body performs partial tile count as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 237: `return sum(` This statement continues through source line 239; the explanation uses the complete expression rather than only the first visual fragment. This returns 'sum(group.affine.linear.partial_tile_count for group in self.group_programs)' to the caller of the function partial_tile_count, which handles partial tile count, ending this invocation. The important operands are sum: the value named 'sum' in this block; group: the value named 'group' in this block; affine: the value named 'affine' in this block.

Line 238: `group.affine.linear.partial_tile_count for group in self.group_programs` This is continuation line 2 of the 3-line logical statement that begins at source line 237. Its exact fragment is 'group.affine.linear.partial_tile_count for group in self.group_programs'. The important operands are group: the value named 'group' in this block; affine: the

value named 'affine' in this block; linear: the value named 'linear' in this block. Read together, the complete operation is: This returns ‘sum(group.affine.linear.partial_tile_count for group in self.group_programs)‘ to the caller of the function partial_tile_count, which handles partial tile count, ending this invocation. The important operands are sum: the value named 'sum' in this block; group: the value named 'group' in this block; affine: the value named 'affine' in this block.

Line 239: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 237. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘sum(group.affine.linear.partial_tile_count for group in self.group_programs)‘ to the caller of the function partial_tile_count, which handles partial tile count, ending this invocation. The important operands are sum: the value named 'sum' in this block; group: the value named 'group' in this block; affine: the value named 'affine' in this block.

Line 241: `def execute_batched(` This starts function execute_batched. Its indented body performs execute batched as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 242: `self,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 243: `driver: TrainingProgramExecutor,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named 'driver' in this block; TrainingProgramExecutor: the value named 'training program executor' in this block.

Line 244: `*,` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 245: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_batched, which handles execute batched.

Line 246: `fabric_col2im: bool = True,` This assigns ‘True,‘ to ‘fabric_col2im‘ in host memory. Here fabric_col2im means the value named 'fabric col2im' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_batched, which handles execute batched.

Line 247: `) -> tuple[np.ndarray, np.ndarray, np.ndarray]:` Inside the function execute_batched, which handles execute batched, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 248: `input_gradient = np.zeros(self.input_shape, dtype=np.int64)` This assigns ‘np.zeros(self.input_shape, dtype=np.int64)‘ to ‘input_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are zeros: the value named 'zeros' in this block; input_shape: the value named 'input shape' in this block; dtype: the value named 'dtype' in this block. Context: the function execute_batched, which handles execute batched.

Line 249: `weight_gradient = np.zeros(self.weight_shape, dtype=np.int64)` This assigns ‘np.zeros(self.weight_shape, dtype=np.int64)‘ to ‘weight_gradient ‘ in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are zeros: the value named 'zeros' in this block; weight_shape: a learned coefficient multiplied by an activation; dtype: the value named 'dtype' in this block. Context: the function execute_batched, which handles execute batched.

Line 250: `bias_gradient = np.zeros(self.output_shape[1], dtype=np.int64)` This assigns ‘np.zeros(self.output_shape[1] dtype=np.int64)‘ to ‘bias_gradient ‘ in host memory. Here bias_gradient means an additive learned offset applied after accumulation. The important operands are zeros: the value named ’zeros’ in this block; output_shape: the value named ’output shape’ in this block; dtype: the value named ’dtype’ in this block. Context: the function execute_batched, which handles execute batched.

Line 251: `output_height, output_width = self.output_shape[2:]` This assigns ‘self.output_shape[2:]‘ to ‘output_height, output_width ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are output_shape: the value named ’output shape’ in this block. Context: the function execute_batched, which handles execute batched.

Line 252: `kernel_h, kernel_w = self.kernel` This assigns ‘self.kernel‘ to ‘kernel_h, kernel_w ‘ in host memory. Here kernel_h means the value named ’kernel h’ in this block. The important operands are kernel: the value named ’kernel’ in this block. Context: the function execute_batched, which handles execute batched.

Line 253: `for group in self.group_programs:` This iterates group over ‘self.group_programs‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_batched, which handles execute batched.

Line 254: `patch_gradient, matrix_gradient, group_bias = group.affine.execute_batched(` This statement continues through source line 256; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘group.affine.execute_batched(driver, timeout_seconds=timeout_seconds)‘ to ‘patch_gradient, matrix_gradient, group_bias ‘ in host memory. Here patch_gradient means the signed loss derivative used to update a learned parameter. The important operands are group: the value named ’group’ in this block; affine: the value named ’affine’ in this block; execute_batched: the value named ’execute batched’ in this block. Context: the function execute_batched, which handles execute batched.

Line 255: `driver, timeout_seconds=timeout_seconds` This is continuation line 2 of the 3-line logical statement that begins at source line 254. Its exact fragment is ‘driver, timeout_seconds=timeout_seconds‘. The important operands are driver: the value named ’driver’ in this block; timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘group.affine.execute_batched(driver, timeout_seconds=timeout_seconds)‘ to ‘patch_gradient, matrix_gradient, group_bias ‘ in host memory. Here patch_gradient means the signed loss derivative used to update a learned parameter. The important operands are group: the value named ’group’ in this block; affine: the value named ’affine’ in this block; execute_batched: the value named ’execute batched’ in this block. Context: the function execute_batched, which handles execute batched.

Line 256: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 254. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘group.affine.execute_batched(driver, timeout_seconds=timeout_seconds)‘ to ‘patch_gradient, matrix_gradient, group_bias ‘ in host memory. Here patch_gradient means the signed loss derivative used to update a learned parameter. The important operands are group: the value named ’group’ in this block; affine: the value named ’affine’ in this block; execute_batched: the value named ’execute batched’ in this block. Context: the function execute_batched, which handles execute batched.

Line 257: `if fabric_col2im:` This executes the following indented host-code branch only when ‘fabric_col2im‘ is true. The important operands are fabric_col2im: the value named ’fabric col2im’ in this block. Context: the function execute_batched, which handles execute batched.

Line 258: `group_input_gradient = execute_col2im_accumulate(` This statement continues through source line 272; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.i input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.st padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)‘ to ‘group_input_gradient ‘ in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named ’execute col2im accumulate’ in this block; driver:

the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 259: `driver,` This is continuation line 2 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 260: `patch_gradient,` This is continuation line 3 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'patch_gradient,'. The important operands are patch_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.st
padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 261: `batch=self.input_shape[0],` This is continuation line 4 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'batch=self.input_shape[0],'. The important operands are batch: the value named 'batch' in this block; input_shape: the value named 'input shape' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 262: `channels=group.input_channels,` This is continuation line 5 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'channels=group.input_channels,'. The important operands are channels: the value named 'channels' in this block; group: the value named 'group' in this block; input_channels: the value named 'input channels' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.st
padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 263: `input_height=self.input_shape[2],` This is continuation line 6 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'input_height=self.input_shape[2],'. The important operands are input_height: the value named 'input height' in this block; input_shape: the value named 'input shape' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradie means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate:

the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 264: `input_width=self.input_shape[3],` This is continuation line 7 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'input_width=self.input_shape[3],'. The important operands are input_width: the value named 'input width' in this block; input_shape: the value named 'input shape' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_he output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 265: `output_height=output_height,` This is continuation line 8 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'output_height=output_height,'. The important operands are output_height: the value named 'output height' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 266: `output_width=output_width,` This is continuation line 9 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'output_width=output_width,'. The important operands are output_width: the value named 'output width' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.st padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 267: `kernel=self.kernel,` This is continuation line 10 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'kernel=self.kernel,'. The important operands are kernel: the value named 'kernel' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradie means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 268: `stride=self.stride,` This is continuation line 11 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'stride=self.stride,'. The important operands are stride: the value named 'stride' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradie means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient:

the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 269: `padding=self.padding,` This is continuation line 12 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'padding=self.padding,'. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradie means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 270: `dilation=self.dilation,` This is continuation line 13 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'dilation=self.dilation,'. The important operands are dilation: the value named 'dilation' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradie means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 271: `timeout_seconds=timeout_seconds,` This is continuation line 14 of the 15-line logical statement that begins at source line 258. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 272: `)` This is continuation line 15 of the 15-line logical statement that begins at source line 258. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'execute_col2im_accumulate(driver, patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation, timeout_seconds=timeout_seconds,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are execute_col2im_accumulate: the value named 'execute col2im accumulate' in this block; driver: the value named 'driver' in this block; patch_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 273: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute_batched, which handles execute batched.

Line 274: `group_input_gradient = col2im_accumulate_fixed(` This statement continues through source line 286; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named

'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 275: `patch_gradient,` This is continuation line 2 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'patch_gradient,'. The important operands are patch_gradient: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 276: `batch=self.input_shape[0],` This is continuation line 3 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'batch=self.input_shape[0],'. The important operands are batch: the value named 'batch' in this block; input_shape: the value named 'input shape' in this block. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_wid kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 277: `channels=group.input_channels,` This is continuation line 4 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'channels=group.input_channels,'. The important operands are channels: the value named 'channels' in this block; group: the value named 'group' in this block; input_channels: the value named 'input channels' in this block. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 278: `input_height=self.input_shape[2],` This is continuation line 5 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'input_height=self.input_shape[2],'. The important operands are input_height: the value named 'input height' in this block; input_shape: the value named 'input shape' in this block. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_he output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 279: `input_width=self.input_shape[3],` This is continuation line 6 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'input_width=self.input_shape[3],'. The important operands are input_width: the value named 'input width' in this block; input_shape: the value named 'input shape' in this block. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 280: `output_height=output_height,` This is continuation line 7 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'output_height=output_height,'. The important operands are output_height: the value named 'output height' in this block. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_ input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.st padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 281: `output_width=output_width,` This is continuation line 8 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'output_width=output_width,'. The important operands are output_width: the value named 'output width' in this block. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 282: `kernel=self.kernel,` This is continuation line 9 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'kernel=self.kernel,'. The important operands are kernel: the value named 'kernel' in this block. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 283: `stride=self.stride,` This is continuation line 10 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'stride=self.stride,'. The important operands are stride: the value named 'stride' in this block. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 284: `padding=self.padding,` This is continuation line 11 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'padding=self.padding,'. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 285: `dilation=self.dilation,` This is continuation line 12 of the 13-line logical statement that begins at source line 274. Its exact fragment is 'dilation=self.dilation,'. The important operands are dilation: the value named 'dilation' in this block. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss

derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 286: `)` This is continuation line 13 of the 13-line logical statement that begins at source line 274. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'col2im_accumulate_fixed(patch_gradient, batch=self.input_shape[0], channels=group.input_channels, input_height=self.input_shape[2], input_width=self.input_shape[3], output_height=output_height, output_width=output_width, kernel=self.kernel, stride=self.stride, padding=self.padding, dilation=self.dilation,)' to 'group_input_gradient ' in host memory. Here group_input_gradient means the signed loss derivative used to update a learned parameter. The important operands are col2im_accumulate_fixed: the value named 'col2im accumulate fixed' in this block; patch_gradient: the signed loss derivative used to update a learned parameter; batch: the value named 'batch' in this block. Context: the function execute_batched, which handles execute batched.

Line 287: `input_start = group.input_channel_start` This assigns 'group.input_channel_start' to 'input_start ' in host memory. Here input_start means the value named 'input start' in this block. The important operands are group: the value named 'group' in this block; input_channel_start: the value named 'input channel start' in this block. Context: the function execute_batched, which handles execute batched.

Line 288: `output_start = group.output_channel_start` This assigns 'group.output_channel_start' to 'output_start ' in host memory. Here output_start means the value named 'output start' in this block. The important operands are group: the value named 'group' in this block; output_channel_start: the value named 'output channel start' in this block. Context: the function execute_batched, which handles execute batched.

Line 289: `input_gradient[:, input_start:input_start + group.input_channels] = group_input_gradient` This assigns 'group_input_gradient' to 'input_gradient[' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are group_input_gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_batched, which handles execute batched.

Line 290: `matrix = matrix_gradient.T.reshape(` This statement continues through source line 295; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'matrix_gradient.T.reshape(group.output_channels, group.input_channels, kernel_h, kernel_w,)' to 'matrix ' in host memory. Here matrix means the value named 'matrix' in this block. The important operands are matrix_gradient: the signed loss derivative used to update a learned parameter; T: the value named 't' in this block; reshape: the value named 'reshape' in this block. Context: the function execute_batched, which handles execute batched.

Line 291: `group.output_channels,` This is continuation line 2 of the 6-line logical statement that begins at source line 290. Its exact fragment is 'group.output_channels,'. The important operands are group: the value named 'group' in this block; output_channels: the value named 'output channels' in this block. Read together, the complete operation is: This assigns 'matrix_gradient.T.reshape(group.output_channels, group.input_channels, kernel_h, kernel_w,)' to 'matrix ' in host memory. Here matrix means the value named 'matrix' in this block. The important operands are matrix_gradient: the signed loss derivative used to update a learned parameter; T: the value named 't' in this block; reshape: the value named 'reshape' in this block. Context: the function execute_batched, which handles execute batched.

Line 292: `group.input_channels,` This is continuation line 3 of the 6-line logical statement that begins at source line 290. Its exact fragment is 'group.input_channels,'. The important operands are group: the value named 'group' in this block; input_channels: the value named 'input channels' in this block. Read together, the complete operation is: This assigns 'matrix_gradient.T.reshape(group.output_channels, group.input_channels, kernel_h, kernel_w,)' to 'matrix ' in host memory. Here matrix means the value named 'matrix' in this block. The important operands are matrix_gradient: the signed loss derivative used to update a learned parameter; T: the value named 't' in this block; reshape: the value named 'reshape' in this block. Context: the function execute_batched, which handles execute batched.

Line 293: `kernel_h,` This is continuation line 4 of the 6-line logical statement that begins at source line 290. Its exact fragment is 'kernel_h,'. The important operands are kernel_h: the value named 'kernel h' in this block. Read together, the complete operation is: This assigns 'matrix_gradient.T.reshape(group.output_channels, group.input_channels,

kernel_h, kernel_w,)‘ to ‘matrix ‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are matrix_gradient: the signed loss derivative used to update a learned parameter; T: the value named ’t’ in this block; reshape: the value named ’reshape’ in this block. Context: the function execute_batched, which handles execute batched.

Line 294: `kernel_w,` This is continuation line 5 of the 6-line logical statement that begins at source line 290. Its exact fragment is ‘kernel_w,‘. The important operands are kernel_w: the value named ’kernel w’ in this block. Read together, the complete operation is: This assigns ‘matrix_gradient.T.reshape(group.output_channels, group.input_channels, kernel_h, kernel_w,)‘ to ‘matrix ‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are matrix_gradient: the signed loss derivative used to update a learned parameter; T: the value named ’t’ in this block; reshape: the value named ’reshape’ in this block. Context: the function execute_batched, which handles execute batched.

Line 295: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 290. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘matrix_gradient.T.reshape(group.output_channels, group.input_channels, kernel_h, kernel_w,)‘ to ‘matrix ‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are matrix_gradient: the signed loss derivative used to update a learned parameter; T: the value named ’t’ in this block; reshape: the value named ’reshape’ in this block. Context: the function execute_batched, which handles execute batched.

Line 296: `weight_gradient[` This statement continues through source line 298; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘matrix‘ to ‘weight_gradient[output_start‘ in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are matrix: the value named ’matrix’ in this block. Context: the function execute_batched, which handles execute batched.

Line 297: `output_start:output_start + group.output_channels` This is continuation line 2 of the 3-line logical statement that begins at source line 296. Its exact fragment is ‘output_start:output_start + group.output_channels‘. The important operands are output_start: the value named ’output start’ in this block; group: the value named ’group’ in this block; output_channels: the value named ’output channels’ in this block. Read together, the complete operation is: This assigns ‘matrix‘ to ‘weight_gradient[output_start‘ in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are matrix: the value named ’matrix’ in this block. Context: the function execute_batched, which handles execute batched.

Line 298: `] = matrix` This is continuation line 3 of the 3-line logical statement that begins at source line 296. Its exact fragment is ‘] = matrix‘. The important operands are matrix: the value named ’matrix’ in this block. Read together, the complete operation is: This assigns ‘matrix‘ to ‘weight_gradient[output_start‘ in host memory. Here weight_gradient means a learned coefficient multiplied by an activation. The important operands are matrix: the value named ’matrix’ in this block. Context: the function execute_batched, which handles execute batched.

Line 299: `bias_gradient[` This statement continues through source line 301; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘group_bias‘ to ‘bias_gradient[output_start‘ in host memory. Here bias_gradient means an additive learned offset applied after accumulation. The important operands are group_bias: an additive learned offset applied after accumulation. Context: the function execute_batched, which handles execute batched.

Line 300: `output_start:output_start + group.output_channels` This is continuation line 2 of the 3-line logical statement that begins at source line 299. Its exact fragment is ‘output_start:output_start + group.output_channels‘. The important operands are output_start: the value named ’output start’ in this block; group: the value named ’group’ in this block; output_channels: the value named ’output channels’ in this block. Read together, the complete operation is: This assigns ‘group_bias‘ to ‘bias_gradient[output_start‘ in host memory. Here bias_gradient means an additive learned offset applied after accumulation. The important operands are group_bias: an additive learned offset applied after accumulation. Context: the function execute_batched, which handles execute batched.

Line 301: `] = group_bias` This is continuation line 3 of the 3-line logical statement that begins at source line 299. Its exact fragment is '] = group_bias'. The important operands are group_bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'group_bias' to 'bias_gradient[output_start' in host memory. Here bias_gradient means an additive learned offset applied after accumulation. The important operands are group_bias: an additive learned offset applied after accumulation. Context: the function execute_batched, which handles execute batched.

Line 302: `return input_gradient, weight_gradient, bias_gradient` This returns 'input_gradient, weight_gradient, bias_gradient' to the caller of the function execute_batched, which handles execute batched, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; weight_gradient: a learned coefficient multiplied by an activation; bias_gradient: an additive learned offset applied after accumulation.

Line 305: `def _signed_matrix(name: str, value, bits: int) -> np.ndarray:` This starts function _signed_matrix. Its indented body performs signed matrix as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 306: `array = np.asarray(value)` This assigns 'np.asarray(value)' to 'array ' in host memory. Here array means the value named 'array' in this block. The important operands are asarray: the value named 'asarray' in this block; value: the value named 'value' in this block. Context: the function _signed_matrix, which handles signed matrix.

Line 307: `if array.ndim != 2 or array.size == 0:` This executes the following indented host-code branch only when 'array.ndim != 2 or array.size == 0' is true. The important operands are array: the value named 'array' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function _signed_matrix, which handles signed matrix.

Line 308: `raise ValueError(f"{name} must be a non-empty two-dimensional matrix")` This rejects an invalid state by raising 'ValueError(f"{name} must be a non-empty two-dimensional matrix")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 309: `if not np.issubdtype(array.dtype, np.integer):` This executes the following indented host-code branch only when 'not np.issubdtype(array.dtype, np.integer)' is true. The important operands are not: the value named 'not' in this block; issubdtype: the value named 'issubdtype' in this block; array: the value named 'array' in this block. Context: the function _signed_matrix, which handles signed matrix.

Line 310: `raise ValueError(f"{name} must contain integers")` This rejects an invalid state by raising 'ValueError(f"{name} must contain integers")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 311: `result = array.astype(np.int64)` This assigns 'array.astype(np.int64)' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are array: the value named 'array' in this block; astype: the value named 'astype' in this block; int64: the value named 'int64' in this block. Context: the function _signed_matrix, which handles signed matrix.

Line 312: `minimum = -(1 << (bits - 1))` This assigns '-(1 << (bits - 1))' to 'minimum ' in host memory. Here minimum means the value named 'minimum' in this block. The important operands are bits: the value named 'bits' in this block. Context: the function _signed_matrix, which handles signed matrix.

Line 313: `maximum = (1 << (bits - 1)) - 1` This assigns '(1 << (bits - 1)) - 1' to 'maximum ' in host memory. Here maximum means the value named 'maximum' in this block. The important operands are bits: the value named 'bits' in this block. Context: the function _signed_matrix, which handles signed matrix.

Line 314: `if np.any(result < minimum) or np.any(result > maximum):` This executes the following indented host-code branch only when 'np.any(result < minimum) or np.any(result > maximum)' is true. The important operands are any: the value named 'any' in this block; result: the value named 'result' in this block; minimum: the value named 'minimum' in this block. Context: the function _signed_matrix, which handles signed matrix.

Line 315: `raise ValueError(f"{name} must fit signed {bits}-bit values")` This rejects an invalid state by raising ‘ValueError(f"{name} must fit signed {bits}-bit values")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 316: `return result` This returns ‘result‘ to the caller of the function _signed_matrix, which handles signed matrix, ending this invocation. The important operands are result: the value named 'result' in this block.

Line 319: `def _conv_output_size(` This starts function _conv_output_size. Its indented body performs conv output size as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 320: `input_size: int,` Inside the function _conv_output_size, which handles conv output size, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_size: the value named 'input size' in this block.

Line 321: `kernel: int,` Inside the function _conv_output_size, which handles conv output size, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are kernel: the value named 'kernel' in this block.

Line 322: `stride: int,` Inside the function _conv_output_size, which handles conv output size, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are stride: the value named 'stride' in this block.

Line 323: `padding: int,` Inside the function _conv_output_size, which handles conv output size, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are padding: the value named 'padding' in this block.

Line 324: `dilation: int,` Inside the function _conv_output_size, which handles conv output size, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are dilation: the value named 'dilation' in this block.

Line 325: `) -> int:` Inside the function _conv_output_size, which handles conv output size, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 326: `return (input_size + 2 * padding - dilation * (kernel - 1) - 1) // stride + 1` This returns ‘(input_size + 2 * padding - dilation * (kernel - 1) - 1) // stride + 1‘ to the caller of the function _conv_output_size, which handles conv output size, ending this invocation. The important operands are input_size: the value named 'input size' in this block; padding: the value named 'padding' in this block; dilation: the value named 'dilation' in this block.

Line 329: `def im2col_signed_nchw(` This starts function im2col_signed_nchw. Its indented body performs im2col signed nchw as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 330: `values,` Inside the function im2col_signed_nchw, which handles im2col signed nchw, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are values: the value named 'values' in this block.

Line 331: `*,` Inside the function im2col_signed_nchw, which handles im2col signed nchw, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 332: `kernel,` Inside the function im2col_signed_nchw, which handles im2col signed nchw, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are kernel: the value named 'kernel' in this block.

Line 333: `stride,` Inside the function im2col_signed_nchw, which handles im2col signed nchw, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are stride: the value named 'stride' in this block.

Line 334: `padding,` Inside the function im2col_signed_nchw, which handles im2col signed nchw, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are padding: the value named 'padding' in this block.

Line 335: `dilation,` Inside the function im2col_signed_nchw, which handles im2col signed nchw, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are dilation: the value named 'dilation' in this block.

Line 336: `) -> np.ndarray:` Inside the function im2col_signed_nchw, which handles im2col signed nchw, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are ndarray: the value named 'ndarray' in this block.

Line 337: `"""Flatten NCHW convolution patches in batch/output-y/output-x order."""` This is executable documentation attached to the function im2col_signed_nchw, which handles im2col signed nchw. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 339: `source = np.asarray(values, dtype=np.int64)` This assigns ‘np.asarray(values, dtype=np.int64)‘ to ‘source ‘ in host memory. Here source means the value named 'source' in this block. The important operands are asarray: the value named 'asarray' in this block; values: the value named 'values' in this block; dtype: the value named 'dtype' in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 340: `if source.ndim != 4:` This executes the following indented host-code branch only when ‘source.ndim != 4‘ is true. The important operands are source: the value named 'source' in this block; ndim: the value named 'ndim' in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 341: `raise ValueError("im2col source must be an NCHW tensor")` This rejects an invalid state by raising ‘ValueError("im2col source must be an NCHW tensor")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 342: `kernel_h, kernel_w = _pair("kernel", kernel)` This assigns ‘_pair("kernel", kernel)‘ to ‘kernel_h, kernel_w ‘ in host memory. Here kernel_h means the value named 'kernel h' in this block. The important operands are _pair: the value named 'pair' in this block; kernel: the value named 'kernel' in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 343: `stride_h, stride_w = _pair("stride", stride)` This assigns ‘_pair("stride", stride)‘ to ‘stride_h, stride_w ‘ in host memory. Here stride_h means the value named 'stride h' in this block. The important operands are _pair: the value named 'pair' in this block; stride: the value named 'stride' in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 344: `dilation_h, dilation_w = _pair("dilation", dilation)` This assigns ‘_pair("dilation", dilation)‘ to ‘dilation_h, dilation_w ‘ in host memory. Here dilation_h means the value named 'dilation h' in this block. The important operands are _pair: the value named 'pair' in this block; dilation: the value named 'dilation' in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 345: `pad_h, pad_w = (padding, padding) if isinstance(padding, int) else tuple(padding)` This assigns ‘(padding, padding) if isinstance(padding, int) else tuple(padding)‘ to ‘pad_h, pad_w ‘ in host memory. Here pad_h means the value named ’pad h’ in this block. The important operands are padding: the value named ’padding’ in this block; isinstance: the value named ’isinstance’ in this block; tuple: the value named ’tuple’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 346: `batch, channels, height, width = source.shape` This assigns ‘source.shape‘ to ‘batch, channels, height, width ‘ in host memory. Here batch means the value named ’batch’ in this block. The important operands are source: the value named ’source’ in this block; shape: the value named ’shape’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 347: `output_height = _conv_output_size(height, kernel_h, stride_h, pad_h, dilation_h)` This assigns ‘_conv_output_size(height, kernel_h, stride_h, pad_h, dilation_h)‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are _conv_output_size: the value named ’conv output size’ in this block; height: the value named ’height’ in this block; kernel_h: the value named ’kernel h’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 348: `output_width = _conv_output_size(width, kernel_w, stride_w, pad_w, dilation_w)` This assigns ‘_conv_output_size(width, kernel_w, stride_w, pad_w, dilation_w)‘ to ‘output_width ‘ in host memory. Here output_width means the value named ’output width’ in this block. The important operands are _conv_output_size: the value named ’conv output size’ in this block; width: the value named ’width’ in this block; kernel_w: the value named ’kernel w’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 349: `patches = np.zeros(` This statement continues through source line 352; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.zeros((batch * output_height * output_width, channels * kernel_h * kernel_w), dtype=np.int64,)‘ to ‘patches ‘ in host memory. Here patches means the value named ’patches’ in this block. The important operands are zeros: the value named ’zeros’ in this block; batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 350: `(batch * output_height * output_width, channels * kernel_h * kernel_w),` This is continuation line 2 of the 4-line logical statement that begins at source line 349. Its exact fragment is ‘(batch * output_height * output_width, channels * kernel_h * kernel_w),‘. The important operands are batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block; output_width: the value named ’output width’ in this block. Read together, the complete operation is: This assigns ‘np.zeros((batch * output_height * output_width, channels * kernel_h * kernel_w), dtype=np.int64,)‘ to ‘patches ‘ in host memory. Here patches means the value named ’patches’ in this block. The important operands are zeros: the value named ’zeros’ in this block; batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 351: `dtype=np.int64,` This is continuation line 3 of the 4-line logical statement that begins at source line 349. Its exact fragment is ‘dtype=np.int64,‘. The important operands are dtype: the value named ’dtype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This assigns ‘np.zeros((batch * output_height * output_width, channels * kernel_h * kernel_w), dtype=np.int64,)‘ to ‘patches ‘ in host memory. Here patches means the value named ’patches’ in this block. The important operands are zeros: the value named ’zeros’ in this block; batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 352: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 349. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.zeros((batch * output_height * output_width, channels * kernel_h * kernel_w), dtype=np.int64,)‘ to ‘patches ‘ in host memory. Here patches means the value named ’patches’ in this block. The important operands are zeros: the value named ’zeros’ in this block; batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 353: `row = 0` This assigns ‘0‘ to ‘row ‘ in host memory. Here row means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 354: `for batch_index in range(batch):` This iterates batch_index over ‘range(batch)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function im2col_signed_nchw, which handles im2col signed nchw.

Line 355: `for output_y in range(output_height):` This iterates output_y over ‘range(output_height)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function im2col_signed_nchw, which handles im2col signed nchw.

Line 356: `for output_x in range(output_width):` This iterates output_x over ‘range(output_width)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function im2col_signed_nchw, which handles im2col signed nchw.

Line 357: `column = 0` This assigns ‘0‘ to ‘column ‘ in host memory. Here column means one output-feature position processed in parallel. The expression is a literal or structural operator and has no hidden software state. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 358: `for channel in range(channels):` This iterates channel over ‘range(channels)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function im2col_signed_nchw, which handles im2col signed nchw.

Line 359: `for kernel_y in range(kernel_h):` This iterates kernel_y over ‘range(kernel_h)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function im2col_signed_nchw, which handles im2col signed nchw.

Line 360: `input_y = output_y * stride_h - pad_h + kernel_y * dilation_h` This assigns ‘output_y * stride_h - pad_h + kernel_y * dilation_h‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; stride_h: the value named ’stride h’ in this block; pad_h: the value named ’pad h’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 361: `for kernel_x in range(kernel_w):` This iterates kernel_x over ‘range(kernel_w)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function im2col_signed_nchw, which handles im2col signed nchw.

Line 362: `input_x = output_x * stride_w - pad_w + kernel_x * dilation_w` This assigns ‘output_x * stride_w - pad_w + kernel_x * dilation_w‘ to ‘input_x ‘ in host memory. Here input_x means the value named ’input x’ in this block. The important operands are output_x: the value named ’output x’ in this block; stride_w: the value named ’stride w’ in this block; pad_w: the value named ’pad w’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 363: `if 0 <= input_y < height and 0 <= input_x < width:` This executes the following indented host-code branch only when ‘0 <= input_y < height and 0 <= input_x < width‘ is true. The important operands are input_y: the value named ’input y’ in this block; height: the value named ’height’ in this block; and: the value named ’and’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 364: `patches[row, column] = source[` This statement continues through source line 366; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘source[batch_index, channel, input_y, input_x]‘ to ‘patches[row, column] ‘ in host memory. Here patches means the value named ’patches’ in this block. The important operands are source: the value named ’source’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named ’channel’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 365: `batch_index, channel, input_y, input_x` This is continuation line 2 of the 3-line logical statement that begins at source line 364. Its exact fragment is ‘batch_index, channel, input_y, input_x‘. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named ’channel’ in this block; input_y: the value named ’input y’ in this block. Read together, the complete operation is: This assigns ‘source[batch_index, channel, input_y, input_x]‘ to ‘patches[row, column] ‘ in host memory. Here patches means the value named ’patches’ in this block. The important operands are source: the value named ’source’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named ’channel’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 366: `]` This is continuation line 3 of the 3-line logical statement that begins at source line 364. Its exact fragment is ‘]‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘source[batch_index, channel, input_y, input_x]‘ to ‘patches[row, column] ‘ in host memory. Here patches means the value named ’patches’ in this block. The important operands are source: the value named ’source’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named ’channel’ in this block. Context: the function im2col_signed_nchw, which handles im2col signed nchw.

Line 367: `column += 1` Inside the function im2col_signed_nchw, which handles im2col signed nchw, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are column: one output-feature position processed in parallel.

Line 368: `row += 1` Inside the function im2col_signed_nchw, which handles im2col signed nchw, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are row: one output-row position processed by the tensor tile.

Line 369: `return patches` This returns ‘patches‘ to the caller of the function im2col_signed_nchw, which handles im2col signed nchw, ending this invocation. The important operands are patches: the value named ’patches’ in this block.

Line 372: `def col2im_accumulate_fixed(` This starts function col2im_accumulate_fixed. Its indented body performs col2im accumulate fixed as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 373: `patch_gradients,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are patch_gradients: the signed loss derivative used to update a learned parameter.

Line 374: `*,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 375: `batch: int,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are batch: the value named ’batch’ in this block.

Line 376: `channels: int,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are channels: the value named ’channels’ in this block.

Line 377: `input_height: int,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_height: the value named 'input height' in this block.

Line 378: `input_width: int,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_width: the value named 'input width' in this block.

Line 379: `output_height: int,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_height: the value named 'output height' in this block.

Line 380: `output_width: int,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_width: the value named 'output width' in this block.

Line 381: `kernel,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are kernel: the value named 'kernel' in this block.

Line 382: `stride,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are stride: the value named 'stride' in this block.

Line 383: `padding,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are padding: the value named 'padding' in this block.

Line 384: `dilation,` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are dilation: the value named 'dilation' in this block.

Line 385: `) -> np.ndarray:` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are ndarray: the value named 'ndarray' in this block.

Line 386: `"""Scatter patch gradients with one signed-s32 saturation per addition."""` This is executable documentation attached to the function col2im_accumulate_fixed, which handles col2im accumulate fixed. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 388: `patches = np.asarray(patch_gradients, dtype=np.int64)` This assigns 'np.asarray(patch_gradients, dtype=np.int64)' to 'patches ' in host memory. Here patches means the value named 'patches' in this block. The important operands are asarray: the value named 'asarray' in this block; patch_gradients: the signed loss derivative used to update a learned parameter; dtype: the value named 'dtype' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 389: `kernel_h, kernel_w = _pair("kernel", kernel)` This assigns '_pair("kernel", kernel)' to 'kernel_h, kernel_w ' in host memory. Here kernel_h means the value named 'kernel h' in this block. The important operands are _pair: the value named 'pair' in this block; kernel: the value named 'kernel' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 390: `stride_h, stride_w = _pair("stride", stride)` This assigns '_pair("stride", stride)' to 'stride_h, stride_w ' in host memory. Here stride_h means the value named 'stride h' in this block. The important operands are _pair: the value named 'pair' in this block; stride: the value named 'stride' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 391: `dilation_h, dilation_w = _pair("dilation", dilation)` This assigns '_pair("dilation", dilation)' to 'dilation_h, dilation_w ' in host memory. Here dilation_h means the value named 'dilation h' in this block. The important operands are _pair: the value named 'pair' in this block; dilation: the value named 'dilation' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 392: `pad_h, pad_w = (padding, padding) if isinstance(padding, int) else tuple(padding)` This assigns '(padding, padding) if isinstance(padding, int) else tuple(padding)' to 'pad_h, pad_w ' in host memory. Here pad_h means the value named 'pad h' in this block. The important operands are padding: the value named 'padding' in this block; isinstance: the value named 'isinstance' in this block; tuple: the value named 'tuple' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 393: `expected_shape = (` This statement continues through source line 396; the explanation uses the complete expression rather than only the first visual fragment. This assigns '(batch * output_height * output_width, channels * kernel_h * kernel_w,)' to 'expected_shape ' in host memory. Here expected_shape means the value named 'expected shape' in this block. The important operands are batch: the value named 'batch' in this block; output_height: the value named 'output height' in this block; output_width: the value named 'output width' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 394: `batch * output_height * output_width,` This is continuation line 2 of the 4-line logical statement that begins at source line 393. Its exact fragment is 'batch * output_height * output_width,'. The important operands are batch: the value named 'batch' in this block; output_height: the value named 'output height' in this block; output_width: the value named 'output width' in this block. Read together, the complete operation is: This assigns '(batch * output_height * output_width, channels * kernel_h * kernel_w,)' to 'expected_shape ' in host memory. Here expected_shape means the value named 'expected shape' in this block. The important operands are batch: the value named 'batch' in this block; output_height: the value named 'output height' in this block; output_width: the value named 'output width' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 395: `channels * kernel_h * kernel_w,` This is continuation line 3 of the 4-line logical statement that begins at source line 393. Its exact fragment is 'channels * kernel_h * kernel_w,'. The important operands are channels: the value named 'channels' in this block; kernel_h: the value named 'kernel h' in this block; kernel_w: the value named 'kernel w' in this block. Read together, the complete operation is: This assigns '(batch * output_height * output_width, channels * kernel_h * kernel_w,)' to 'expected_shape ' in host memory. Here expected_shape means the value named 'expected shape' in this block. The important operands are batch: the value named 'batch' in this block; output_height: the value named 'output height' in this block; output_width: the value named 'output width' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 396: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 393. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(batch * output_height * output_width, channels * kernel_h * kernel_w,)' to 'expected_shape ' in host memory. Here expected_shape means the value named 'expected shape' in this block. The important operands are batch: the value named 'batch' in this block; output_height: the value named 'output height' in this block; output_width: the value named 'output width' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 397: `if patches.shape != expected_shape:` This executes the following indented host-code branch only when 'patches.shape != expected_shape' is true. The important operands are patches: the value named 'patches' in this block; shape: the value named 'shape' in this block; expected_shape: the value named 'expected shape' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 398: `raise ValueError(f"patch gradient shape must be {expected_shape}")` This rejects an invalid state by raising 'ValueError(f"patch gradient shape must be {expected_shape}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 399: `output = np.zeros((batch, channels, input_height, input_width), dtype=np.int64)` This assigns 'np.zeros((batch, channels, input_height, input_width), dtype=np.int64)' to 'output ' in host memory. Here output means the value named 'output' in this block. The important operands are zeros: the value named 'zeros' in this block; batch: the value named 'batch' in this block; channels: the value named 'channels' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 400: `row = 0` This assigns '0' to 'row ' in host memory. Here row means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 401: `for batch_index in range(batch):` This iterates batch_index over 'range(batch)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 402: `for output_y in range(output_height):` This iterates output_y over 'range(output_height)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 403: `for output_x in range(output_width):` This iterates output_x over 'range(output_width)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 404: `column = 0` This assigns '0' to 'column ' in host memory. Here column means one output-feature position processed in parallel. The expression is a literal or structural operator and has no hidden software state. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 405: `for channel in range(channels):` This iterates channel over 'range(channels)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 406: `for kernel_y in range(kernel_h):` This iterates kernel_y over 'range(kernel_h)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 407: `input_y = output_y * stride_h - pad_h + kernel_y * dilation_h` This assigns 'output_y * stride_h - pad_h + kernel_y * dilation_h' to 'input_y ' in host memory. Here input_y means the value named 'input y' in this block. The important operands are output_y: the value named 'output y' in this block; stride_h: the value named 'stride h' in this block; pad_h: the value named 'pad h' in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 408: `for kernel_x in range(kernel_w):` This iterates kernel_x over 'range(kernel_w)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 409: `input_x = output_x * stride_w - pad_w + kernel_x * dilation_w` This assigns ‘output_x * stride_w - pad_w + kernel_x * dilation_w‘ to ‘input_x ‘ in host memory. Here input_x means the value named ’input x’ in this block. The important operands are output_x: the value named ’output x’ in this block; stride_w: the value named ’stride w’ in this block; pad_w: the value named ’pad w’ in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 410: `if 0 <= input_y < input_height and 0 <= input_x < input_width:` This executes the following indented host-code branch only when ‘0 <= input_y < input_height and 0 <= input_x < input_width‘ is true. The important operands are input_y: the value named ’input y’ in this block; input_height: the value named ’input height’ in this block; and: the value named ’and’ in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 411: `value = output[batch_index, channel, input_y, input_x]` This assigns ‘output[batch_index, channel, input_y, input_x]‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are output: the value named ’output’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named ’channel’ in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 412: `output[batch_index, channel, input_y, input_x] = saturate_signed(` This statement continues through source line 414; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘saturate_signed(np.asarray(value + patches[row, column], dtype=np.int64), 32)‘ to ‘output[batch_index, channel, input_y, input_x] ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are saturate_signed: the value named ’saturate signed’ in this block; asarray: the value named ’asarray’ in this block; value: the value named ’value’ in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 413: `np.asarray(value + patches[row, column], dtype=np.int64), 32` This is continuation line 2 of the 3-line logical statement that begins at source line 412. Its exact fragment is ‘np.asarray(value + patches[row, column], dtype=np.int64), 32‘. The important operands are asarray: the value named ’asarray’ in this block; value: the value named ’value’ in this block; patches: the value named ’patches’ in this block. Read together, the complete operation is: This assigns ‘saturate_signed(np.asarray(value + patches[row, column], dtype=np.int64), 32)‘ to ‘output[batch_index, channel, input_y, input_x] ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are saturate_signed: the value named ’saturate signed’ in this block; asarray: the value named ’asarray’ in this block; value: the value named ’value’ in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 414: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 412. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘saturate_signed(np.asarray(value + patches[row, column], dtype=np.int64), 32)‘ to ‘output[batch_index, channel, input_y, input_x] ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are saturate_signed: the value named ’saturate signed’ in this block; asarray: the value named ’asarray’ in this block; value: the value named ’value’ in this block. Context: the function col2im_accumulate_fixed, which handles col2im accumulate fixed.

Line 415: `column += 1` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are column: one output-feature position processed in parallel.

Line 416: `row += 1` Inside the function col2im_accumulate_fixed, which handles col2im accumulate fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are row: one output-row position processed by the tensor tile.

Line 417: `return output` This returns ‘output‘ to the caller of the function col2im_accumulate_fixed, which handles col2im accumulate fixed, ending this invocation. The important operands are output: the value named 'output' in this block.

Line 420: `def execute_col2im_accumulate(` This starts function execute_col2im_accumulate. Its indented body performs execute col2im accumulate as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 421: `driver: TrainingCommandExecutor,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named 'driver' in this block; TrainingCommandExecutor: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 422: `patch_gradients,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are patch_gradients: the signed loss derivative used to update a learned parameter.

Line 423: `*,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 424: `batch: int,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are batch: the value named 'batch' in this block.

Line 425: `channels: int,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are channels: the value named 'channels' in this block.

Line 426: `input_height: int,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_height: the value named 'input height' in this block.

Line 427: `input_width: int,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_width: the value named 'input width' in this block.

Line 428: `output_height: int,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_height: the value named 'output height' in this block.

Line 429: `output_width: int,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_width: the value named 'output width' in this block.

Line 430: `kernel,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are kernel: the value named 'kernel' in this block.

Line 431: `stride,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are stride: the value named 'stride' in this block.

Line 432: `padding,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are padding: the value named 'padding' in this block.

Line 433: `dilation,` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are dilation: the value named 'dilation' in this block.

Line 434: `timeout_seconds: float = 5.0,` This assigns '5.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 435: `) -> np.ndarray:` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are ndarray: the value named 'ndarray' in this block.

Line 436: `"""Scatter every overlapping convolution gradient with fabric vector adds."""` This is executable documentation attached to the function execute_col2im_accumulate, which handles execute col2im accumulate. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 438: `patches = np.asarray(patch_gradients, dtype=np.int64)` This assigns 'np.asarray(patch_gradients, dtype=np.int64)' to 'patches ' in host memory. Here patches means the value named 'patches' in this block. The important operands are asarray: the value named 'asarray' in this block; patch_gradients: the signed loss derivative used to update a learned parameter; dtype: the value named 'dtype' in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 439: `kernel_h, kernel_w = _pair("kernel", kernel)` This assigns '_pair("kernel", kernel)' to 'kernel_h, kernel_w ' in host memory. Here kernel_h means the value named 'kernel h' in this block. The important operands are _pair: the value named 'pair' in this block; kernel: the value named 'kernel' in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 440: `stride_h, stride_w = _pair("stride", stride)` This assigns '_pair("stride", stride)' to 'stride_h, stride_w ' in host memory. Here stride_h means the value named 'stride h' in this block. The important operands are _pair: the value named 'pair' in this block; stride: the value named 'stride' in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 441: `dilation_h, dilation_w = _pair("dilation", dilation)` This assigns '_pair("dilation", dilation)' to 'dilation_h, dilation_w ' in host memory. Here dilation_h means the value named 'dilation h' in this block. The important operands are _pair: the value named 'pair' in this block; dilation: the value named 'dilation' in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 442: `pad_h, pad_w = (padding, padding) if isinstance(padding, int) else tuple(padding)` This assigns ‘(padding, padding) if isinstance(padding, int) else tuple(padding)‘ to ‘pad_h, pad_w ‘ in host memory. Here pad_h means the value named ’pad h’ in this block. The important operands are padding: the value named ’padding’ in this block; isinstance: the value named ’isinstance’ in this block; tuple: the value named ’tuple’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 443: `expected_shape = (` This statement continues through source line 446; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(batch * output_height * output_width, channels * kernel_h * kernel_w,)‘ to ‘expected_shape ‘ in host memory. Here expected_shape means the value named ’expected shape’ in this block. The important operands are batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block; output_width: the value named ’output width’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 444: `batch * output_height * output_width,` This is continuation line 2 of the 4-line logical statement that begins at source line 443. Its exact fragment is ‘batch * output_height * output_width,‘. The important operands are batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block; output_width: the value named ’output width’ in this block. Read together, the complete operation is: This assigns ‘(batch * output_height * output_width, channels * kernel_h * kernel_w,)‘ to ‘expected_shape ‘ in host memory. Here expected_shape means the value named ’expected shape’ in this block. The important operands are batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block; output_width: the value named ’output width’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 445: `channels * kernel_h * kernel_w,` This is continuation line 3 of the 4-line logical statement that begins at source line 443. Its exact fragment is ‘channels * kernel_h * kernel_w,‘. The important operands are channels: the value named ’channels’ in this block; kernel_h: the value named ’kernel h’ in this block; kernel_w: the value named ’kernel w’ in this block. Read together, the complete operation is: This assigns ‘(batch * output_height * output_width, channels * kernel_h * kernel_w,)‘ to ‘expected_shape ‘ in host memory. Here expected_shape means the value named ’expected shape’ in this block. The important operands are batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block; output_width: the value named ’output width’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 446: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 443. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(batch * output_height * output_width, channels * kernel_h * kernel_w,)‘ to ‘expected_shape ‘ in host memory. Here expected_shape means the value named ’expected shape’ in this block. The important operands are batch: the value named ’batch’ in this block; output_height: the value named ’output height’ in this block; output_width: the value named ’output width’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 447: `if patches.shape != expected_shape:` This executes the following indented host-code branch only when ‘patches.shape != expected_shape‘ is true. The important operands are patches: the value named ’patches’ in this block; shape: the value named ’shape’ in this block; expected_shape: the value named ’expected shape’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 448: `raise ValueError(f"patch gradient shape must be {expected_shape}")` This rejects an invalid state by raising ‘ValueError(f"patch gradient shape must be {expected_shape}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 449: `output = np.zeros((batch, channels, input_height, input_width), dtype=np.int64)` This assigns ‘np.zeros((batch, channels, input_height, input_width), dtype=np.int64)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are zeros: the value named ’zeros’ in this block; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 450: `row = 0` This assigns ‘0‘ to ‘row ‘ in host memory. Here row means one output-row position processed by the tensor tile. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 451: `pending: list[tuple[tuple[int, int, int, int], int]] = []` This assigns ‘[]‘ to ‘pending‘ in host memory. Here pending means the value named ’pending’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 453: `def flush() -> None:` This starts function flush. Its indented body performs flush as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 454: `nonlocal pending` Inside the function flush, which handles flush, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are nonlocal: the value named ’nonlocal’ in this block; pending: the value named ’pending’ in this block.

Line 455: `if not pending:` This executes the following indented host-code branch only when ‘not pending‘ is true. The important operands are not: the value named ’not’ in this block; pending: the value named ’pending’ in this block. Context: the function flush, which handles flush.

Line 456: `return` This returns “ to the caller of the function flush, which handles flush, ending this invocation. The expression is a literal or structural operator and has no hidden software state.

Line 457: `left = [int(output[address]) for address, _ in pending]` This assigns ‘[int(output[address]) for address, _ in pending]‘ to ‘left ‘ in host memory. Here left means the value named ’left’ in this block. The important operands are output: the value named ’output’ in this block; address: the value named ’address’ in this block; for: the value named ’for’ in this block. Context: the function flush, which handles flush.

Line 458: `right = [value for _, value in pending]` This assigns ‘[value for _, value in pending]‘ to ‘right ‘ in host memory. Here right means the value named ’right’ in this block. The important operands are value: the value named ’value’ in this block; for: the value named ’for’ in this block; _: the value named ” in this block. Context: the function flush, which handles flush.

Line 459: `left.extend([0] * (8 - len(pending)))` This calls ‘left.extend‘ with ‘[0] * (8 - len(pending))‘ inside the function flush, which handles flush. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 460: `right.extend([0] * (8 - len(pending)))` This calls ‘right.extend‘ with ‘[0] * (8 - len(pending))‘ inside the function flush, which handles flush. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 461: `summed = _execute_vector8(` This statement continues through source line 467; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)‘ to ‘summed ‘ in host memory. Here summed means the value named ’summed’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function flush, which handles flush.

Line 462: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 461. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)‘ to ‘summed ‘ in host memory. Here summed means the value named ’summed’

in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function flush, which handles flush.

Line 463: `VectorOperation.ADD_SAT,` This is continuation line 3 of the 7-line logical statement that begins at source line 461. Its exact fragment is 'VectorOperation.ADD_SAT,'. The important operands are VectorOperation: the value named 'vector operation' in this block; ADD_SAT: the value named 'add sat' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)' to 'summed ' in host memory. Here summed means the value named 'summed' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function flush, which handles flush.

Line 464: `left,` This is continuation line 4 of the 7-line logical statement that begins at source line 461. Its exact fragment is 'left,'. The important operands are left: the value named 'left' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)' to 'summed ' in host memory. Here summed means the value named 'summed' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function flush, which handles flush.

Line 465: `right,` This is continuation line 5 of the 7-line logical statement that begins at source line 461. Its exact fragment is 'right,'. The important operands are right: the value named 'right' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)' to 'summed ' in host memory. Here summed means the value named 'summed' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function flush, which handles flush.

Line 466: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 461. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)' to 'summed ' in host memory. Here summed means the value named 'summed' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function flush, which handles flush.

Line 467: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 461. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)' to 'summed ' in host memory. Here summed means the value named 'summed' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function flush, which handles flush.

Line 468: `for lane, (address, _) in enumerate(pending):` This iterates lane, (address, _) over 'enumerate(pending)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function flush, which handles flush.

Line 469: `output[address] = summed[lane]` This assigns 'summed[lane]' to 'output[address] ' in host memory. Here output means the value named 'output' in this block. The important operands are summed: the value named 'summed' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function flush, which handles flush.

Line 470: `pending = []` This assigns '[]' to 'pending ' in host memory. Here pending means the value named 'pending' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function flush, which handles flush.

Line 472: `for batch_index in range(batch):` This iterates batch_index over ‘range(batch)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 473: `for output_y in range(output_height):` This iterates output_y over ‘range(output_height)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 474: `for output_x in range(output_width):` This iterates output_x over ‘range(output_width)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 475: `column = 0` This assigns ‘0‘ to ‘column ‘ in host memory. Here column means one output-feature position processed in parallel. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 476: `for channel in range(channels):` This iterates channel over ‘range(channels)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 477: `for kernel_y in range(kernel_h):` This iterates kernel_y over ‘range(kernel_h)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 478: `input_y = output_y * stride_h - pad_h + kernel_y * dilation_h` This assigns ‘output_y * stride_h - pad_h + kernel_y * dilation_h‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; stride_h: the value named ’stride h’ in this block; pad_h: the value named ’pad h’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 479: `for kernel_x in range(kernel_w):` This iterates kernel_x over ‘range(kernel_w)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 480: `input_x = output_x * stride_w - pad_w + kernel_x * dilation_w` This assigns ‘output_x * stride_w - pad_w + kernel_x * dilation_w‘ to ‘input_x ‘ in host memory. Here input_x means the value named ’input x’ in this block. The important operands are output_x: the value named ’output x’ in this block; stride_w: the value named ’stride w’ in this block; pad_w: the value named ’pad w’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 481: `if 0 <= input_y < input_height and 0 <= input_x < input_width:` This executes the following indented host-code branch only when ‘0 <= input_y < input_height and 0 <= input_x < input_width‘ is true. The important operands are input_y: the value named ’input y’ in this block; input_height: the value named ’input height’ in this block; and: the value named ’and’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 482: `address = (batch_index, channel, input_y, input_x)` This assigns ‘(batch_index, channel, input_y, input_x)‘ to ‘address ‘ in host memory. Here address means the value named ’address’ in this block. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named ’channel’ in this block; input_y: the value named ’input y’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 483: `if len(pending) == 8 or any(item[0] == address for item in pending):` This executes the following indented host-code branch only when ‘len(pending) == 8 or any(item[0] == address for item in pending)‘ is true. The important operands are len: the value named ’len’ in this block; pending: the value named ’pending’ in this block; or: the value named ’or’ in this block. Context: the function execute_col2im_accumulate, which handles execute col2im accumulate.

Line 484: `flush()` This calls ‘flush‘ with “ inside the function execute_col2im_accumulate, which handles execute col2im accumulate. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 485: `pending.append((address, int(patches[row, column])))` This calls ‘pending.append‘ with ‘(address, int(patches[row, column]))‘ inside the function execute_col2im_accumulate, which handles execute col2im accumulate. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 486: `column += 1` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are column: one output-feature position processed in parallel.

Line 487: `row += 1` Inside the function execute_col2im_accumulate, which handles execute col2im accumulate, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are row: one output-row position processed by the tensor tile.

Line 488: `flush()` This calls ‘flush‘ with “ inside the function execute_col2im_accumulate, which handles execute col2im accumulate. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 489: `return output` This returns ‘output‘ to the caller of the function execute_col2im_accumulate, which handles execute col2im accumulate, ending this invocation. The important operands are output: the value named ’output’ in this block.

Line 492: `def _tile_starts(size: int) -> range:` This starts function _tile_starts. Its indented body performs tile starts as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 493: `return range(0, size, TILE)` This returns ‘range(0, size, TILE)‘ to the caller of the function _tile_starts, which handles tile starts, ending this invocation. The important operands are range: the value named ’range’ in this block; size: the value named ’size’ in this block; TILE: the value named ’tile’ in this block.

Line 496: `def compile_linear_backward(` This starts function compile_linear_backward. Its indented body performs compile linear backward as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 497: `activations,` Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 498: `weights,` Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are weights: a learned coefficient multiplied by an activation.

Line 499: `output_gradients,` Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_gradients: the signed loss derivative used to update a learned parameter.

Line 500: `*,` Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 501: `input_gradient_shift: int = 0,` This assigns ‘0,‘ to ‘input_gradient_shift‘ in host memory. Here input_gradient_shift means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_linear_backward, which handles compile linear backward.

Line 502: `weight_gradient_shift: int = 0,` This assigns ‘0,‘ to ‘weight_gradient_shift‘ in host memory. Here weight_gradient_shift means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_linear_backward, which handles compile linear backward.

Line 503: `) -> CompiledLinearBackward:` Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are CompiledLinearBackward: the value named ’compiled linear backward’ in this block.

Line 504: `"""Compile exact dX and dW passes for matrices of any positive shape."""` This is executable documentation attached to the function compile_linear_backward, which handles compile linear backward. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 506: `x = _signed_matrix("activations", activations, 16)` This assigns ‘_signed_matrix("activations", activations, 16)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are _signed_matrix: the value named ’signed matrix’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function compile_linear_backward, which handles compile linear backward.

Line 507: `w = _signed_matrix("weights", weights, 16)` This assigns ‘_signed_matrix("weights", weights, 16)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are _signed_matrix: the value named ’signed matrix’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function compile_linear_backward, which handles compile linear backward.

Line 508: `dy = _signed_matrix("output_gradients", output_gradients, 16)` This assigns ‘_signed_matrix("output_grad output_gradients, 16)‘ to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are _signed_matrix: the value named ’signed matrix’ in this block; output_gradients: the signed loss derivative used to update a learned parameter. Context: the function compile_linear_backward, which handles compile linear backward.

Line 509: `rows, inputs = x.shape` This assigns ‘x.shape‘ to ‘rows, inputs ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are x: the value named ’x’ in this block; shape: the value named ’shape’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 510: `weight_inputs, outputs = w.shape` This assigns ‘w.shape‘ to ‘weight_inputs, outputs ‘ in host memory. Here weight_inputs means a learned coefficient multiplied by an activation. The important operands are w: the value named ’w’ in this block; shape: the value named ’shape’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 511: `if weight_inputs != inputs or dy.shape != (rows, outputs):` This executes the following indented host-code branch only when ‘weight_inputs != inputs or dy.shape != (rows, outputs)‘ is true. The important operands are weight_inputs: a learned coefficient multiplied by an activation; inputs: the value named ’inputs’ in this block; or: the value named ’or’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 512: `raise ValueError("linear backward matrix dimensions do not align")` This rejects an invalid state by raising ‘ValueError("linear backward matrix dimensions do not align")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 513: `if not 0 <= input_gradient_shift <= 31:` This executes the following indented host-code branch only when ‘not 0 <= input_gradient_shift <= 31‘ is true. The important operands are not: the value named ’not’ in this block; input_gradient_shift: the signed loss derivative used to update a learned parameter. Context: the function compile_linear_backward, which handles compile linear backward.

Line 514: `raise ValueError("input_gradient_shift must be in [0,31]")` This rejects an invalid state by raising ‘ValueError("input_gradient_shift must be in [0,31]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 515: `if not 0 <= weight_gradient_shift <= 31:` This executes the following indented host-code branch only when ‘not 0 <= weight_gradient_shift <= 31‘ is true. The important operands are not: the value named ’not’ in this block; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the function compile_linear_backward, which handles compile linear backward.

Line 516: `raise ValueError("weight_gradient_shift must be in [0,31]")` This rejects an invalid state by raising ‘ValueError("weight_gradient_shift must be in [0,31]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 518: `instructions: list[BackwardInstruction] = []` This assigns ‘[]‘ to ‘instructions‘ in host memory. Here instructions means the value named ’instructions’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_linear_backward, which handles compile linear backward.

Line 519: `input_bytes = 0` This assigns ‘0‘ to ‘input_bytes ‘ in host memory. Here input_bytes means the value named ’input bytes’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_linear_backward, which handles compile linear backward.

Line 521: `# dX tiles retain one MxK accumulator while traversing every N chunk.` The comment records this intent: dX tiles retain one MxK accumulator while traversing every N chunk. It applies inside the function compile_linear_backward, which handles compile linear backward.

Line 522: `for row_start in _tile_starts(rows):` This iterates row_start over ‘_tile_starts(rows)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_linear_backward, which handles compile linear backward.

Line 523: `row_end = min(row_start + TILE, rows)` This assigns ‘min(row_start + TILE, rows)‘ to ‘row_end ‘ in host memory. Here row_end means one output-row position processed by the tensor tile. The important operands are min: the value named ’min’ in this block; row_start: one output-row position processed by the tensor tile; TILE: the value named ’tile’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 524: `for input_start in _tile_starts(inputs):` This iterates input_start over ‘_tile_starts(inputs)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_linear_backward, which handles compile linear backward.

Line 525: `input_end = min(input_start + TILE, inputs)` This assigns ‘min(input_start + TILE, inputs)‘ to ‘input_end ‘ in host memory. Here input_end means the value named ’input end’ in this block. The important operands are min: the value named ’min’ in this block; input_start: the value named ’input start’ in this block; TILE: the value named ’tile’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 526: `output_starts = tuple(_tile_starts(outputs))` This assigns ‘tuple(_tile_starts(outputs))‘ to ‘output_starts ‘ in host memory. Here output_starts means the value named ’output starts’ in this block. The important operands are tuple: the value named ’tuple’ in this block; _tile_starts: the value named ’tile starts’ in this block; outputs: the value named ’outputs’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 527: `for chunk_index, output_start in enumerate(output_starts):` This iterates chunk_index, output_start over ‘enumerate(output_starts)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_linear_backward, which handles compile linear backward.

Line 528: `output_end = min(output_start + TILE, outputs)` This assigns ‘min(output_start + TILE, outputs)‘ to ‘output_end ‘ in host memory. Here output_end means the value named ’output end’ in this block. The important operands are min: the value named ’min’ in this block; output_start: the value named ’output start’ in this block; TILE: the value named ’tile’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 529: `final = chunk_index == len(output_starts) - 1` Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are final: the value named ’final’ in this block; chunk_index: an integer selecting one tensor element, lane, bank, or state entry; len: the value named ’len’ in this block.

Line 530: `x_tile = x[row_start:row_end, input_start:input_end]` This assigns ‘x[row_start:row_end, input_start:input_ to ‘x_tile ‘ in host memory. Here x_tile means the value named ’x tile’ in this block. The important operands are x: the value named ’x’ in this block; row_start: one output-row position processed by the tensor tile; row_end: one output-row position processed by the tensor tile. Context: the function compile_linear_backward, which handles compile linear backward.

Line 531: `w_tile = w[input_start:input_end, output_start:output_end]` This assigns ‘w[input_start:input_end, output_start:output_end]‘ to ‘w_tile ‘ in host memory. Here w_tile means the value named ’w tile’ in this block. The important operands are w: the value named ’w’ in this block; input_start: the value named ’input start’ in this block; input_end: the value named ’input end’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 532: `dy_tile = dy[row_start:row_end, output_start:output_end]` This assigns ‘dy[row_start:row_end, output_start:output_end]‘ to ‘dy_tile ‘ in host memory. Here dy_tile means the value named ’dy tile’ in this block. The important operands are dy: the value named ’dy’ in this block; row_start: one output-row position processed by the tensor tile; row_end: one output-row position processed by the tensor tile. Context: the function compile_linear_backward, which handles compile linear backward.

Line 533: `beats = pack_linear_backward_beats(` This statement continues through source line 538; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.INPUT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 534: `x_tile.tolist(),` This is continuation line 2 of the 6-line logical statement that begins at source line 533. Its exact fragment is ‘x_tile.tolist(),‘. The important operands are x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats(

x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.INPUT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 535: `w_tile.tolist(),` This is continuation line 3 of the 6-line logical statement that begins at source line 533. Its exact fragment is ‘w_tile.tolist(),‘. The important operands are w_tile: the value named ’w tile’ in this block; tolist: the value named ’tolist’ in this block. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.INPUT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 536: `dy_tile.tolist(),` This is continuation line 4 of the 6-line logical statement that begins at source line 533. Its exact fragment is ‘dy_tile.tolist(),‘. The important operands are dy_tile: the value named ’dy tile’ in this block; tolist: the value named ’tolist’ in this block. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.INPUT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 537: `mode=LinearGradientMode.INPUT,` This is continuation line 5 of the 6-line logical statement that begins at source line 533. Its exact fragment is ‘mode=LinearGradientMode.INPUT,‘. The important operands are mode: the value named ’mode’ in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; INPUT: the value named ’input’ in this block. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.INPUT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 538: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 533. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.INPUT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 539: `record = ProgramRecord(` This statement continues through source line 552; the explanation uses the complete expression rather than only the first visual fragment. Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named ’record’ in this block; ProgramRecord: the value named ’program record’ in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 540: `linear_backward_command(` This is continuation line 2 of the 14-line logical statement that begins at source line 539. Its exact fragment is ‘linear_backward_command(‘. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named ’record’ in this block; ProgramRecord: the value named ’program record’ in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 541: `row_end - row_start,` This is continuation line 3 of the 14-line logical statement that begins at source line 539. Its exact fragment is 'row_end - row_start,'. The important operands are row_end: one output-row position processed by the tensor tile; row_start: one output-row position processed by the tensor tile. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 542: `input_end - input_start,` This is continuation line 4 of the 14-line logical statement that begins at source line 539. Its exact fragment is 'input_end - input_start,'. The important operands are input_end: the value named 'input end' in this block; input_start: the value named 'input start' in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 543: `output_end - output_start,` This is continuation line 5 of the 14-line logical statement that begins at source line 539. Its exact fragment is 'output_end - output_start,'. The important operands are output_end: the value named 'output end' in this block; output_start: the value named 'output start' in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 544: `input_gradient_shift=input_gradient_shift,` This is continuation line 6 of the 14-line logical statement that begins at source line 539. Its exact fragment is 'input_gradient_shift=input_gradient_shift,'. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 545: `weight_gradient_shift=weight_gradient_shift,` This is continuation line 7 of the 14-line logical statement that begins at source line 539. Its exact fragment is 'weight_gradient_shift=weight_gradient_shift,'. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 546: `mode=LinearGradientMode.INPUT,` This is continuation line 8 of the 14-line logical statement that begins at source line 539. Its exact fragment is 'mode=LinearGradientMode.INPUT,'. The important operands are mode: the value named 'mode' in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; INPUT: the value named 'input' in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 547: `accumulate=chunk_index != 0,` This is continuation line 9 of the 14-line logical statement that begins at source line 539. Its exact fragment is ‘accumulate=chunk_index != 0,‘. The important operands are accumulate: the value named ’accumulate’ in this block; chunk_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named ’record’ in this block; ProgramRecord: the value named ’program record’ in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 548: `suppress_output=not final,` This is continuation line 10 of the 14-line logical statement that begins at source line 539. Its exact fragment is ‘suppress_output=not final,‘. The important operands are suppress_output: the value named ’suppress output’ in this block; not: the value named ’not’ in this block; final: the value named ’final’ in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named ’record’ in this block; ProgramRecord: the value named ’program record’ in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 549: `),` This is continuation line 11 of the 14-line logical statement that begins at source line 539. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named ’record’ in this block; ProgramRecord: the value named ’program record’ in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 550: `beats,` This is continuation line 12 of the 14-line logical statement that begins at source line 539. Its exact fragment is ‘beats,‘. The important operands are beats: the value named ’beats’ in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named ’record’ in this block; ProgramRecord: the value named ’program record’ in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 551: `4 * (row_end - row_start) if final else 0,` This is continuation line 13 of the 14-line logical statement that begins at source line 539. Its exact fragment is ‘4 * (row_end - row_start) if final else 0,‘. The important operands are row_end: one output-row position processed by the tensor tile; row_start: one output-row position processed by the tensor tile; final: the value named ’final’ in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named ’record’ in this block; ProgramRecord: the value named ’program record’ in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 552: `)` This is continuation line 14 of the 14-line logical statement that begins at source line 539. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named ’record’ in this block; ProgramRecord: the value named ’program record’ in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 553: `instructions.append(BackwardInstruction(` This statement continues through source line 564; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function

compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 554: `record,` This is continuation line 2 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘record,‘. The important operands are record: the value named ’record’ in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 555: `LinearGradientMode.INPUT,` This is continuation line 3 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘LinearGradientMode.INPUT,‘. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter; INPUT: the value named ’input’ in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 556: `row_start,` This is continuation line 4 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘row_start,‘. The important operands are row_start: one output-row position processed by the tensor tile. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 557: `input_start,` This is continuation line 5 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘input_start,‘. The important operands are input_start: the value named ’input start’ in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 558: `output_start,` This is continuation line 6 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘output_start,‘. The important operands are output_start: the value named ’output start’ in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 559: `row_end - row_start,` This is continuation line 7 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘row_end - row_start,‘. The important operands are row_end: one output-row position processed by the tensor tile; row_start: one output-row position processed by the tensor tile. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 560: `input_end - input_start,` This is continuation line 8 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘input_end - input_start,‘. The important operands are input_end: the value named

'input end' in this block; input_start: the value named 'input start' in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 561: `output_end - output_start,` This is continuation line 9 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘output_end - output_start,‘. The important operands are output_end: the value named 'output end' in this block; output_start: the value named 'output start' in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 562: `chunk_index != 0,` This is continuation line 10 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘chunk_index != 0,‘. The important operands are chunk_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 563: `not final,` This is continuation line 11 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘not final,‘. The important operands are not: the value named 'not' in this block; final: the value named 'final' in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 564: `))` This is continuation line 12 of the 12-line logical statement that begins at source line 553. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.INPUT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 565: `input_bytes += len(beats) * 8` Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_bytes: the value named 'input bytes' in this block; len: the value named 'len' in this block; beats: the value named 'beats' in this block.

Line 567: `# dW tiles retain one KxN accumulator while traversing every M chunk.` The comment records this intent: dW tiles retain one KxN accumulator while traversing every M chunk. It applies inside the function compile_linear_backward, which handles compile linear backward.

Line 568: `for input_start in _tile_starts(inputs):` This iterates input_start over ‘_tile_starts(inputs)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_linear_backward, which handles compile linear backward.

Line 569: `input_end = min(input_start + TILE, inputs)` This assigns ‘min(input_start + TILE, inputs)‘ to ‘input_end ‘ in host memory. Here input_end means the value named ’input end’ in this block. The important operands are min: the value named ’min’ in this block; input_start: the value named ’input start’ in this block; TILE: the value named ’tile’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 570: `for output_start in _tile_starts(outputs):` This iterates output_start over ‘_tile_starts(outputs)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_linear_backward, which handles compile linear backward.

Line 571: `output_end = min(output_start + TILE, outputs)` This assigns ‘min(output_start + TILE, outputs)‘ to ‘output_end ‘ in host memory. Here output_end means the value named ’output end’ in this block. The important operands are min: the value named ’min’ in this block; output_start: the value named ’output start’ in this block; TILE: the value named ’tile’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 572: `row_starts = tuple(_tile_starts(rows))` This assigns ‘tuple(_tile_starts(rows))‘ to ‘row_starts ‘ in host memory. Here row_starts means one output-row position processed by the tensor tile. The important operands are tuple: the value named ’tuple’ in this block; _tile_starts: the value named ’tile starts’ in this block; rows: one output-row position processed by the tensor tile. Context: the function compile_linear_backward, which handles compile linear backward.

Line 573: `for chunk_index, row_start in enumerate(row_starts):` This iterates chunk_index, row_start over ‘enumerate(row_starts)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_linear_backward, which handles compile linear backward.

Line 574: `row_end = min(row_start + TILE, rows)` This assigns ‘min(row_start + TILE, rows)‘ to ‘row_end ‘ in host memory. Here row_end means one output-row position processed by the tensor tile. The important operands are min: the value named ’min’ in this block; row_start: one output-row position processed by the tensor tile; TILE: the value named ’tile’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 575: `final = chunk_index == len(row_starts) - 1` Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are final: the value named ’final’ in this block; chunk_index: an integer selecting one tensor element, lane, bank, or state entry; len: the value named ’len’ in this block.

Line 576: `x_tile = x[row_start:row_end, input_start:input_end]` This assigns ‘x[row_start:row_end, input_start:input_ to ‘x_tile ‘ in host memory. Here x_tile means the value named ’x tile’ in this block. The important operands are x: the value named ’x’ in this block; row_start: one output-row position processed by the tensor tile; row_end: one output-row position processed by the tensor tile. Context: the function compile_linear_backward, which handles compile linear backward.

Line 577: `w_tile = w[input_start:input_end, output_start:output_end]` This assigns ‘w[input_start:input_end, output_start:output_end]‘ to ‘w_tile ‘ in host memory. Here w_tile means the value named ’w tile’ in this block. The important operands are w: the value named ’w’ in this block; input_start: the value named ’input start’ in this block; input_end: the value named ’input end’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 578: `dy_tile = dy[row_start:row_end, output_start:output_end]` This assigns ‘dy[row_start:row_end, output_start:output_end]‘ to ‘dy_tile ‘ in host memory. Here dy_tile means the value named ’dy tile’ in this block. The important operands are dy: the value named ’dy’ in this block; row_start: one output-row position processed by the tensor tile; row_end: one output-row position processed by the tensor tile. Context: the function compile_linear_backward, which handles compile linear backward.

Line 579: `beats = pack_linear_backward_beats(` This statement continues through source line 584; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.WEIGHT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 580: `x_tile.tolist(),` This is continuation line 2 of the 6-line logical statement that begins at source line 579. Its exact fragment is ‘x_tile.tolist(),‘. The important operands are x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.WEIGHT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 581: `w_tile.tolist(),` This is continuation line 3 of the 6-line logical statement that begins at source line 579. Its exact fragment is ‘w_tile.tolist(),‘. The important operands are w_tile: the value named ’w tile’ in this block; tolist: the value named ’tolist’ in this block. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.WEIGHT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 582: `dy_tile.tolist(),` This is continuation line 4 of the 6-line logical statement that begins at source line 579. Its exact fragment is ‘dy_tile.tolist(),‘. The important operands are dy_tile: the value named ’dy tile’ in this block; tolist: the value named ’tolist’ in this block. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.WEIGHT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 583: `mode=LinearGradientMode.WEIGHT,` This is continuation line 5 of the 6-line logical statement that begins at source line 579. Its exact fragment is ‘mode=LinearGradientMode.WEIGHT,‘. The important operands are mode: the value named ’mode’ in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; WEIGHT: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.WEIGHT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 584: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 579. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘pack_linear_backward_beats(x_tile.tolist(), w_tile.tolist(), dy_tile.tolist(), mode=LinearGradientMode.WEIGHT,)‘ to ‘beats ‘ in host memory. Here beats means the value named ’beats’ in this block. The important operands are pack_linear_backward_beats: the value named ’pack linear backward beats’ in this block; x_tile: the value named ’x tile’ in this block; tolist: the value named ’tolist’ in this block. Context: the function compile_linear_backward, which handles compile linear backward.

Line 585: `record = ProgramRecord(` This statement continues through source line 598; the explanation uses the complete expression rather than only the first visual fragment. Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named ’record’ in this block; ProgramRecord: the value named ’program record’ in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 586: `linear_backward_command(` This is continuation line 2 of the 14-line logical statement that begins at source line 585. Its exact fragment is 'linear_backward_command('. The important operands are linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 587: `row_end - row_start,` This is continuation line 3 of the 14-line logical statement that begins at source line 585. Its exact fragment is 'row_end - row_start,'. The important operands are row_end: one output-row position processed by the tensor tile; row_start: one output-row position processed by the tensor tile. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 588: `input_end - input_start,` This is continuation line 4 of the 14-line logical statement that begins at source line 585. Its exact fragment is 'input_end - input_start,'. The important operands are input_end: the value named 'input end' in this block; input_start: the value named 'input start' in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 589: `output_end - output_start,` This is continuation line 5 of the 14-line logical statement that begins at source line 585. Its exact fragment is 'output_end - output_start,'. The important operands are output_end: the value named 'output end' in this block; output_start: the value named 'output start' in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 590: `input_gradient_shift=input_gradient_shift,` This is continuation line 6 of the 14-line logical statement that begins at source line 585. Its exact fragment is 'input_gradient_shift=input_gradient_shift,'. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 591: `weight_gradient_shift=weight_gradient_shift,` This is continuation line 7 of the 14-line logical statement that begins at source line 585. Its exact fragment is 'weight_gradient_shift=weight_gradient_shift,'. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 592: `mode=LinearGradientMode.WEIGHT,` This is continuation line 8 of the 14-line logical statement that begins at source line 585. Its exact fragment is 'mode=LinearGradientMode.WEIGHT,'. The important operands are mode: the

value named 'mode' in this block; LinearGradientMode: the signed loss derivative used to update a learned parameter; WEIGHT: a learned coefficient multiplied by an activation. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 593: `accumulate=chunk_index != 0,` This is continuation line 9 of the 14-line logical statement that begins at source line 585. Its exact fragment is 'accumulate=chunk_index != 0,'. The important operands are accumulate: the value named 'accumulate' in this block; chunk_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 594: `suppress_output=not final,` This is continuation line 10 of the 14-line logical statement that begins at source line 585. Its exact fragment is 'suppress_output=not final,'. The important operands are suppress_output: the value named 'suppress output' in this block; not: the value named 'not' in this block; final: the value named 'final' in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 595: `),` This is continuation line 11 of the 14-line logical statement that begins at source line 585. Its exact fragment is '),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 596: `beats,` This is continuation line 12 of the 14-line logical statement that begins at source line 585. Its exact fragment is 'beats,'. The important operands are beats: the value named 'beats' in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 597: `3 * (input_end - input_start) if final else 0,` This is continuation line 13 of the 14-line logical statement that begins at source line 585. Its exact fragment is '3 * (input_end - input_start) if final else 0,'. The important operands are input_end: the value named 'input end' in this block; input_start: the value named 'input start' in this block; final: the value named 'final' in this block. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 598: `)` This is continuation line 14 of the 14-line logical statement that begins at source line 585. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer

programs for hardware-resident supervised updates. The important operands are record: the value named 'record' in this block; ProgramRecord: the value named 'program record' in this block; linear_backward_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 599: `instructions.append(BackwardInstruction(` This statement continues through source line 610; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 600: `record,` This is continuation line 2 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘record,‘. The important operands are record: the value named 'record' in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 601: `LinearGradientMode.WEIGHT,` This is continuation line 3 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘LinearGradientMode.WEIGHT,‘. The important operands are LinearGradientMode: the signed loss derivative used to update a learned parameter; WEIGHT: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 602: `row_start,` This is continuation line 4 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘row_start,‘. The important operands are row_start: one output-row position processed by the tensor tile. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 603: `input_start,` This is continuation line 5 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘input_start,‘. The important operands are input_start: the value named 'input start' in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 604: `output_start,` This is continuation line 6 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘output_start,‘. The important operands are output_start: the value named 'output start' in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 605: `row_end - row_start,` This is continuation line 7 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘row_end - row_start,‘. The important operands are row_end: one output-row position processed by the tensor tile; row_start: one output-row position processed by the tensor tile. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT,

row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 606: `input_end - input_start,` This is continuation line 8 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘input_end - input_start,‘. The important operands are input_end: the value named ’input end’ in this block; input_start: the value named ’input start’ in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 607: `output_end - output_start,` This is continuation line 9 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘output_end - output_start,‘. The important operands are output_end: the value named ’output end’ in this block; output_start: the value named ’output start’ in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 608: `chunk_index != 0,` This is continuation line 10 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘chunk_index != 0,‘. The important operands are chunk_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 609: `not final,` This is continuation line 11 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘not final,‘. The important operands are not: the value named ’not’ in this block; final: the value named ’final’ in this block. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 610: `))` This is continuation line 12 of the 12-line logical statement that begins at source line 599. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘instructions.append‘ with ‘BackwardInstruction(record, LinearGradientMode.WEIGHT, row_start, input_start, output_start, row_end - row_start, input_end - input_start, output_end - output_start, chunk_index != 0, not final,)‘ inside the function compile_linear_backward, which handles compile linear backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 611: `input_bytes += len(beats) * 8` Inside the function compile_linear_backward, which handles compile linear backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are input_bytes: the value named ’input bytes’ in this block; len: the value named ’len’ in this block; beats: the value named ’beats’ in this block.

Line 613: `return CompiledLinearBackward(` This statement continues through source line 620; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘CompiledLinearBackward((rows, inputs, outputs), input_gradient_shift, weight_gradient_shift, tuple(instructions), input_bytes, 2 * rows * inputs * outputs,)‘

to the caller of the function compile_linear_backward, which handles compile linear backward, ending this invocation. The important operands are CompiledLinearBackward: the value named 'compiled linear backward' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block.

Line 614: `(rows, inputs, outputs),` This is continuation line 2 of the 8-line logical statement that begins at source line 613. Its exact fragment is '(rows, inputs, outputs),'. The important operands are rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block; outputs: the value named 'outputs' in this block. Read together, the complete operation is: This returns 'CompiledLinearBackward((rows, inputs, outputs), input_gradient_shift, weight_gradient_shift, tuple(instructions), input_bytes, 2 * rows * inputs * outputs,)' to the caller of the function compile_linear_backward, which handles compile linear backward, ending this invocation. The important operands are CompiledLinearBackward: the value named 'compiled linear backward' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block.

Line 615: `input_gradient_shift,` This is continuation line 3 of the 8-line logical statement that begins at source line 613. Its exact fragment is 'input_gradient_shift,'. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This returns 'CompiledLinearBackward((rows, inputs, outputs), input_gradient_shift, weight_gradient_shift, tuple(instructions), input_bytes, 2 * rows * inputs * outputs,)' to the caller of the function compile_linear_backward, which handles compile linear backward, ending this invocation. The important operands are CompiledLinearBackward: the value named 'compiled linear backward' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block.

Line 616: `weight_gradient_shift,` This is continuation line 4 of the 8-line logical statement that begins at source line 613. Its exact fragment is 'weight_gradient_shift,'. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation. Read together, the complete operation is: This returns 'CompiledLinearBackward((rows, inputs, outputs), input_gradient_shift, weight_gradient_shift, tuple(instructions), input_bytes, 2 * rows * inputs * outputs,)' to the caller of the function compile_linear_backward, which handles compile linear backward, ending this invocation. The important operands are CompiledLinearBackward: the value named 'compiled linear backward' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block.

Line 617: `tuple(instructions),` This is continuation line 5 of the 8-line logical statement that begins at source line 613. Its exact fragment is 'tuple(instructions),'. The important operands are tuple: the value named 'tuple' in this block; instructions: the value named 'instructions' in this block. Read together, the complete operation is: This returns 'CompiledLinearBackward((rows, inputs, outputs), input_gradient_shift, weight_gradient_shift, tuple(instructions), input_bytes, 2 * rows * inputs * outputs,)' to the caller of the function compile_linear_backward, which handles compile linear backward, ending this invocation. The important operands are CompiledLinearBackward: the value named 'compiled linear backward' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block.

Line 618: `input_bytes,` This is continuation line 6 of the 8-line logical statement that begins at source line 613. Its exact fragment is 'input_bytes,'. The important operands are input_bytes: the value named 'input bytes' in this block. Read together, the complete operation is: This returns 'CompiledLinearBackward((rows, inputs, outputs), input_gradient_shift, weight_gradient_shift, tuple(instructions), input_bytes, 2 * rows * inputs * outputs,)' to the caller of the function compile_linear_backward, which handles compile linear backward, ending this invocation. The important operands are CompiledLinearBackward: the value named 'compiled linear backward' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block.

Line 619: `2 * rows * inputs * outputs,` This is continuation line 7 of the 8-line logical statement that begins at source line 613. Its exact fragment is '2 * rows * inputs * outputs,'. The important operands are rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block; outputs: the value named 'outputs' in this block. Read together, the complete operation is: This returns 'CompiledLinearBackward((rows, inputs, outputs), input_gradient_shift, weight_gradient_shift, tuple(instructions), input_bytes, 2 * rows * inputs * outputs,)' to the caller of the function compile_linear_backward, which handles compile linear backward, ending this invocation. The important operands are CompiledLinearBackward: the value named 'compiled linear backward' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block.

Line 620: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 613. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘CompiledLinearBackward((rows, inputs, outputs), input_gradient_shift, weight_gradient_shift, tuple(instructions), input_bytes, 2 * rows * inputs * outputs,)‘ to the caller of the function compile_linear_backward, which handles compile linear backward, ending this invocation. The important operands are CompiledLinearBackward: the value named ’compiled linear backward’ in this block; rows: one output-row position processed by the tensor tile; inputs: the value named ’inputs’ in this block.

Line 623: `def compile_affine_backward(` This starts function compile_affine_backward. Its indented body performs compile affine backward as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 624: `activations,` Inside the function compile_affine_backward, which handles compile affine backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 625: `weights,` Inside the function compile_affine_backward, which handles compile affine backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are weights: a learned coefficient multiplied by an activation.

Line 626: `bias,` Inside the function compile_affine_backward, which handles compile affine backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are bias: an additive learned offset applied after accumulation.

Line 627: `output_gradients,` Inside the function compile_affine_backward, which handles compile affine backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_gradients: the signed loss derivative used to update a learned parameter.

Line 628: `*,` Inside the function compile_affine_backward, which handles compile affine backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 629: `input_gradient_shift: int = 0,` This assigns ‘0,‘ to ‘input_gradient_shift‘ in host memory. Here input_gradient_shift means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_affine_backward, which handles compile affine backward.

Line 630: `weight_gradient_shift: int = 0,` This assigns ‘0,‘ to ‘weight_gradient_shift‘ in host memory. Here weight_gradient_shift means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_affine_backward, which handles compile affine backward.

Line 631: `) -> CompiledAffineBackward:` Inside the function compile_affine_backward, which handles compile affine backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are CompiledAffineBackward: the value named ’compiled affine backward’ in this block.

Line 632: `"""Compile weight, bias, and input gradients for "Y = XW + b"."""` This is executable documentation attached to the function compile_affine_backward, which handles compile affine backward. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 634: `x = _signed_matrix("activations", activations, 16)` This assigns '_signed_matrix("activations", activations, 16)' to 'x ' in host memory. Here x means the value named 'x' in this block. The important operands are _signed_matrix: the value named 'signed matrix' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function compile_affine_backward, which handles compile affine backward.

Line 635: `w = _signed_matrix("weights", weights, 16)` This assigns '_signed_matrix("weights", weights, 16)' to 'w ' in host memory. Here w means the value named 'w' in this block. The important operands are _signed_matrix: the value named 'signed matrix' in this block; weights: a learned coefficient multiplied by an activation. Context: the function compile_affine_backward, which handles compile affine backward.

Line 636: `bias_array = np.asarray(bias)` This assigns 'np.asarray(bias)' to 'bias_array ' in host memory. Here bias_array means an additive learned offset applied after accumulation. The important operands are asarray: the value named 'asarray' in this block; bias: an additive learned offset applied after accumulation. Context: the function compile_affine_backward, which handles compile affine backward.

Line 637: `if bias_array.ndim != 1 or bias_array.shape[0] != w.shape[1]:` This executes the following indented host-code branch only when 'bias_array.ndim != 1 or bias_array.shape[0] != w.shape[1]' is true. The important operands are bias_array: an additive learned offset applied after accumulation; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function compile_affine_backward, which handles compile affine backward.

Line 638: `raise ValueError("bias must be one-dimensional with one value per output")` This rejects an invalid state by raising 'ValueError("bias must be one-dimensional with one value per output")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 639: `bias_matrix = _signed_matrix("bias", bias_array.reshape(1, -1), 16)` This assigns '_signed_matrix("bias", bias_array.reshape(1, -1), 16)' to 'bias_matrix ' in host memory. Here bias_matrix means an additive learned offset applied after accumulation. The important operands are _signed_matrix: the value named 'signed matrix' in this block; bias: an additive learned offset applied after accumulation; bias_array: an additive learned offset applied after accumulation. Context: the function compile_affine_backward, which handles compile affine backward.

Line 640: `if x.shape[1] != w.shape[0]:` This executes the following indented host-code branch only when 'x.shape[1] != w.shape[0]' is true. The important operands are x: the value named 'x' in this block; shape: the value named 'shape' in this block; w: the value named 'w' in this block. Context: the function compile_affine_backward, which handles compile affine backward.

Line 641: `raise ValueError("affine activation and weight dimensions do not align")` This rejects an invalid state by raising 'ValueError("affine activation and weight dimensions do not align")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 642: `augmented_x = np.concatenate(` This statement continues through source line 644; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'np.concatenate((x, np.ones((x.shape[0], 1), dtype=np.int64)), axis=1)' to 'augmented_x ' in host memory. Here augmented_x means the value named 'augmented x' in this block. The important operands are concatenate: the value named 'concatenate' in this block; x: the value named 'x' in this block; ones: the value named 'ones' in this block. Context: the function compile_affine_backward, which handles compile affine backward.

Line 643: `(x, np.ones((x.shape[0], 1), dtype=np.int64)), axis=1` This is continuation line 2 of the 3-line logical statement that begins at source line 642. Its exact fragment is '(x, np.ones((x.shape[0], 1), dtype=np.int64)), axis=1'. The important operands are x: the value named 'x' in this block; ones: the value named 'ones' in this block; shape: the value named 'shape' in this block. Read together, the complete operation is: This assigns 'np.concatenate((x, np.ones((x.shape[0], 1), dtype=np.int64)), axis=1)' to 'augmented_x ' in host memory. Here augmented_x means the value named 'augmented x' in this block. The important operands are concatenate: the value named 'concatenate'

in this block; x: the value named 'x' in this block; ones: the value named 'ones' in this block. Context: the function compile_affine_backward, which handles compile affine backward.

Line 644: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 642. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'np.concatenate((x, np.ones((x.shape[0], 1), dtype=np.int64)), axis=1)' to 'augmented_x ' in host memory. Here augmented_x means the value named 'augmented x' in this block. The important operands are concatenate: the value named 'concatenate' in this block; x: the value named 'x' in this block; ones: the value named 'ones' in this block. Context: the function compile_affine_backward, which handles compile affine backward.

Line 645: `augmented_w = np.concatenate((w, bias_matrix), axis=0)` This assigns 'np.concatenate((w, bias_matrix), axis=0)' to 'augmented_w ' in host memory. Here augmented_w means the value named 'augmented w' in this block. The important operands are concatenate: the value named 'concatenate' in this block; w: the value named 'w' in this block; bias_matrix: an additive learned offset applied after accumulation. Context: the function compile_affine_backward, which handles compile affine backward.

Line 646: `return CompiledAffineBackward(` This statement continues through source line 655; the explanation uses the complete expression rather than only the first visual fragment. This returns 'CompiledAffineBackward(compile_linear_backward(augmented_x, augmented_w, output_gradients, input_gradient_shift=input_gradient_shift, weight_gradient_shift=weight_gradient_shift,), x.shape[1],)' to the caller of the function compile_affine_backward, which handles compile affine backward, ending this invocation. The important operands are CompiledAffineBackward: the value named 'compiled affine backward' in this block; compile_linear_backward: the value named 'compile linear backward' in this block; augmented_x: the value named 'augmented x' in this block.

Line 647: `compile_linear_backward(` This is continuation line 2 of the 10-line logical statement that begins at source line 646. Its exact fragment is 'compile_linear_backward('. The important operands are compile_linear_backward: the value named 'compile linear backward' in this block. Read together, the complete operation is: This returns 'CompiledAffineBackward(compile_linear_backward(augmented_x, augmented_w, output_gradients, input_gradient_shift=input_gr
weight_gradient_shift=weight_gradient_shift,), x.shape[1],)' to the caller of the function compile_affine_backward, which handles compile affine backward, ending this invocation. The important operands are CompiledAffineBackward: the value named 'compiled affine backward' in this block; compile_linear_backward: the value named 'compile linear backward' in this block; augmented_x: the value named 'augmented x' in this block.

Line 648: `augmented_x,` This is continuation line 3 of the 10-line logical statement that begins at source line 646. Its exact fragment is 'augmented_x,'. The important operands are augmented_x: the value named 'augmented x' in this block. Read together, the complete operation is: This returns 'CompiledAffineBackward(compile_linear_backward(augmented_x, augmented_w, output_gradients, input_gradient_shift=input_gradient_shift, weight_gradient_shift=weight_gradie
), x.shape[1],)' to the caller of the function compile_affine_backward, which handles compile affine backward, ending this invocation. The important operands are CompiledAffineBackward: the value named 'compiled affine backward' in this block; compile_linear_backward: the value named 'compile linear backward' in this block; augmented_x: the value named 'augmented x' in this block.

Line 649: `augmented_w,` This is continuation line 4 of the 10-line logical statement that begins at source line 646. Its exact fragment is 'augmented_w,'. The important operands are augmented_w: the value named 'augmented w' in this block. Read together, the complete operation is: This returns 'CompiledAffineBackward(compile_linear_backward(augmented_x, augmented_w, output_gradients, input_gradient_shift=input_gradient_shift, weight_gradient_shift=weight_gradient_shift,), x.shape[1],)' to the caller of the function compile_affine_backward, which handles compile affine backward, ending this invocation. The important operands are CompiledAffineBackward: the value named 'compiled affine backward' in this block; compile_linear_backward: the value named 'compile linear backward' in this block; augmented_x: the value named 'augmented x' in this block.

Line 650: `output_gradients,` This is continuation line 5 of the 10-line logical statement that begins at source line 646. Its exact fragment is 'output_gradients,'. The important operands are output_gradients: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This returns 'CompiledAffineBackward(compile_linear_backward(augmented_x, augmented_w, output_gradients, input_gradient_shift=input_gradient_shift, weight_gradient_shift=weight_gradient_shift,), x.shape[1],)' to the caller of the function compile_affine_backward,

which handles compile affine backward, ending this invocation. The important operands are CompiledAffineBackward: the value named 'compiled affine backward' in this block; compile_linear_backward: the value named 'compile linear backward' in this block; augmented_x: the value named 'augmented x' in this block.

Line 651: `input_gradient_shift=input_gradient_shift,` This is continuation line 6 of the 10-line logical statement that begins at source line 646. Its exact fragment is 'input_gradient_shift=input_gradient_shift,'. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This returns 'CompiledAffineBackward(compile_linear_backward(augmented_x, augmented_w, output_gradients, input_gradient_shift=input_gradient_shift, weight_gradient_shift=weight_gradient_shift,), x.shape[1],)' to the caller of the function compile_affine_backward, which handles compile affine backward, ending this invocation. The important operands are CompiledAffineBackward: the value named 'compiled affine backward' in this block; compile_linear_backward: the value named 'compile linear backward' in this block; augmented_x: the value named 'augmented x' in this block.

Line 652: `weight_gradient_shift=weight_gradient_shift,` This is continuation line 7 of the 10-line logical statement that begins at source line 646. Its exact fragment is 'weight_gradient_shift=weight_gradient_shift,'. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation. Read together, the complete operation is: This returns 'CompiledAffineBackward(compile_linear_backward(augmented_x, augmented_w, output_gradients, input_gradient_shift=input_gradient_shift, weight_gradient_shift=weight_gradient_shift,), x.shape[1],)' to the caller of the function compile_affine_backward, which handles compile affine backward, ending this invocation. The important operands are CompiledAffineBackward: the value named 'compiled affine backward' in this block; compile_linear_backward: the value named 'compile linear backward' in this block; augmented_x: the value named 'augmented x' in this block.

Line 653: `),` This is continuation line 8 of the 10-line logical statement that begins at source line 646. Its exact fragment is '),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'CompiledAffineBackward(compile_linear_backward(augmented_x, augmented_w, output_gradients, input_gradient_shift=input_gradient_shift, weight_gradient_shift=weight_gradient_shift,), x.shape[1],)' to the caller of the function compile_affine_backward, which handles compile affine backward, ending this invocation. The important operands are CompiledAffineBackward: the value named 'compiled affine backward' in this block; compile_linear_backward: the value named 'compile linear backward' in this block; augmented_x: the value named 'augmented x' in this block.

Line 654: `x.shape[1],` This is continuation line 9 of the 10-line logical statement that begins at source line 646. Its exact fragment is 'x.shape[1],'. The important operands are x: the value named 'x' in this block; shape: the value named 'shape' in this block. Read together, the complete operation is: This returns 'CompiledAffineBackward(compile_linear_backward(augmented_x, augmented_w, output_gradients, input_gradient_shift=input_gradient_shift, weight_gradient_shift=weight_gradient_shift,), x.shape[1],)' to the caller of the function compile_affine_backward, which handles compile affine backward, ending this invocation. The important operands are CompiledAffineBackward: the value named 'compiled affine backward' in this block; compile_linear_backward: the value named 'compile linear backward' in this block; augmented_x: the value named 'augmented x' in this block.

Line 655: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 646. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'CompiledAffineBackward(compile_linear_backward(augmented_x, augmented_w, output_gradients, input_gradient_shift=input_gradient_shift, weight_gradient_shift=weight_gradient_shift,), x.shape[1],)' to the caller of the function compile_affine_backward, which handles compile affine backward, ending this invocation. The important operands are CompiledAffineBackward: the value named 'compiled affine backward' in this block; compile_linear_backward: the value named 'compile linear backward' in this block; augmented_x: the value named 'augmented x' in this block.

Line 658: `def compile_conv2d_backward(` This starts function compile_conv2d_backward. Its indented body performs compile conv2d backward as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 659: `activations,` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 660: `weights,` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are weights: a learned coefficient multiplied by an activation.

Line 661: `bias,` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are bias: an additive learned offset applied after accumulation.

Line 662: `output_gradients,` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_gradients: the signed loss derivative used to update a learned parameter.

Line 663: `*,` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 664: `stride=1,` This assigns ‘1,‘ to ‘stride‘ in host memory. Here stride means the value named ’stride’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 665: `padding=0,` This assigns ‘0,‘ to ‘padding‘ in host memory. Here padding means the value named ’padding’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 666: `dilation=1,` This assigns ‘1,‘ to ‘dilation‘ in host memory. Here dilation means the value named ’dilation’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 667: `groups: int = 1,` This assigns ‘1,‘ to ‘groups‘ in host memory. Here groups means the value named ’groups’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 668: `input_gradient_shift: int = 0,` This assigns ‘0,‘ to ‘input_gradient_shift‘ in host memory. Here input_gradient_shift means the signed loss derivative used to update a learned parameter. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 669: `weight_gradient_shift: int = 0,` This assigns ‘0,‘ to ‘weight_gradient_shift‘ in host memory. Here weight_gradient_shift means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 670: `) -> CompiledConv2dBackward:` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are CompiledConv2dBackward: the value named ’compiled conv2d backward’ in this block.

Line 671: `"""Lower a signed NCHW convolution backward pass to exact affine tiles."""` This is executable documentation attached to the function compile_conv2d_backward, which handles compile conv2d backward. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 673: `x = np.asarray(activations)` This assigns ‘np.asarray(activations)‘ to ‘x ‘ in host memory. Here x means the value named ’x’ in this block. The important operands are asarray: the value named ’asarray’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 674: `w = np.asarray(weights)` This assigns ‘np.asarray(weights)‘ to ‘w ‘ in host memory. Here w means the value named ’w’ in this block. The important operands are asarray: the value named ’asarray’ in this block; weights: a learned coefficient multiplied by an activation. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 675: `dy = np.asarray(output_gradients)` This assigns ‘np.asarray(output_gradients)‘ to ‘dy ‘ in host memory. Here dy means the value named ’dy’ in this block. The important operands are asarray: the value named ’asarray’ in this block; output_gradients: the signed loss derivative used to update a learned parameter. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 676: `bias_array = np.asarray(bias)` This assigns ‘np.asarray(bias)‘ to ‘bias_array ‘ in host memory. Here bias_array means an additive learned offset applied after accumulation. The important operands are asarray: the value named ’asarray’ in this block; bias: an additive learned offset applied after accumulation. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 677: `for name, array, bits in (` This line opens or closes a multi-line Python expression inside the function compile_conv2d_backward, which handles compile conv2d backward; the neighboring lines supply its arguments or elements.

Line 678: `("activations", x, 16),` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; x: the value named ’x’ in this block.

Line 679: `("weights", w, 16),` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are weights: a learned coefficient multiplied by an activation; w: the value named ’w’ in this block.

Line 680: `("output_gradients", dy, 16),` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_gradients: the signed loss derivative used to update a learned parameter; dy: the value named ’dy’ in this block.

Line 681: `("bias", bias_array, 16),` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are bias: an additive learned offset applied after accumulation; bias_array: an additive learned offset applied after accumulation.

Line 682: `):` Inside the function compile_conv2d_backward, which handles compile conv2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 683: `if not np.issubdtype(array.dtype, np.integer):` This executes the following indented host-code branch only when ‘not np.issubdtype(array.dtype, np.integer)‘ is true. The important operands are not: the value named ’not’ in this block; issubdtype: the value named ’issubdtype’ in this block; array: the value named ’array’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 684: `raise ValueError(f"{name} must contain integers")` This rejects an invalid state by raising ‘ValueError(f"{name} must contain integers")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 685: `minimum = -(1 << (bits - 1))` This assigns ‘-(1 << (bits - 1))‘ to ‘minimum ‘ in host memory. Here minimum means the value named ’minimum’ in this block. The important operands are bits: the value named ’bits’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 686: `maximum = (1 << (bits - 1)) - 1` This assigns ‘(1 << (bits - 1)) - 1‘ to ‘maximum ‘ in host memory. Here maximum means the value named ’maximum’ in this block. The important operands are bits: the value named ’bits’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 687: `if np.any(array < minimum) or np.any(array > maximum):` This executes the following indented host-code branch only when ‘np.any(array < minimum) or np.any(array > maximum)‘ is true. The important operands are any: the value named ’any’ in this block; array: the value named ’array’ in this block; minimum: the value named ’minimum’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 688: `raise ValueError(f"{name} must fit signed {bits}-bit values")` This rejects an invalid state by raising ‘ValueError(f"{name} must fit signed {bits}-bit values")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 689: `if x.ndim != 4 or w.ndim != 4 or dy.ndim != 4 or bias_array.ndim != 1:` This executes the following indented host-code branch only when ‘x.ndim != 4 or w.ndim != 4 or dy.ndim != 4 or bias_array.ndim != 1‘ is true. The important operands are x: the value named ’x’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 690: `raise ValueError("convolution operands must use NCHW/OIHW tensors and a bias vector")` This rejects an invalid state by raising ‘ValueError("convolution operands must use NCHW/OIHW tensors and a bias vector")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 691: `if groups <= 0:` This executes the following indented host-code branch only when ‘groups <= 0‘ is true. The important operands are groups: the value named ’groups’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 692: `raise ValueError("groups must be positive")` This rejects an invalid state by raising ‘ValueError("groups must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 693: `batch, input_channels, input_height, input_width = x.shape` This assigns ‘x.shape‘ to ‘batch, input_channels, input_height, input_width ‘ in host memory. Here batch means the value named ’batch’ in this block. The important operands are x: the value named ’x’ in this block; shape: the value named ’shape’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 694: `output_channels, weight_inputs, kernel_h, kernel_w = w.shape` This assigns ‘w.shape‘ to ‘output_channels, weight_inputs, kernel_h, kernel_w ‘ in host memory. Here output_channels means the value named ’output channels’ in this block. The important operands are w: the value named ’w’ in this block; shape: the value named ’shape’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 695: `if input_channels % groups or output_channels % groups:` This executes the following indented host-code branch only when ‘input_channels % groups or output_channels % groups‘ is true. The important operands are input_channels: the value named ’input channels’ in this block; groups: the value named ’groups’ in this block; or: the value named ’or’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 696: `raise ValueError("input and output channels must be divisible by groups")` This rejects an invalid state by raising ‘ValueError("input and output channels must be divisible by groups")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 697: `input_channels_per_group = input_channels // groups` This assigns ‘input_channels // groups‘ to ‘input_channels_per_group ‘ in host memory. Here input_channels_per_group means the value named ’input channels per group’ in this block. The important operands are input_channels: the value named ’input channels’ in this block; groups: the value named ’groups’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 698: `output_channels_per_group = output_channels // groups` This assigns ‘output_channels // groups‘ to ‘output_channels_per_group ‘ in host memory. Here output_channels_per_group means the value named ’output channels per group’ in this block. The important operands are output_channels: the value named ’output channels’ in this block; groups: the value named ’groups’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 699: `if weight_inputs != input_channels_per_group:` This executes the following indented host-code branch only when ‘weight_inputs != input_channels_per_group‘ is true. The important operands are weight_inputs: a learned coefficient multiplied by an activation; input_channels_per_group: the value named ’input channels per group’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 700: `raise ValueError("weight input channels do not match the grouped convolution")` This rejects an invalid state by raising ‘ValueError("weight input channels do not match the grouped convolution")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 701: `if bias_array.shape != (output_channels,):` This executes the following indented host-code branch only when ‘bias_array.shape != (output_channels,)‘ is true. The important operands are bias_array: an additive learned offset applied after accumulation; shape: the value named ’shape’ in this block; output_channels: the value named ’output channels’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 702: `raise ValueError("bias must contain one value per output channel")` This rejects an invalid state by raising ‘ValueError("bias must contain one value per output channel")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 703: `stride_pair = _pair("stride", stride)` This assigns ‘_pair("stride", stride)‘ to ‘stride_pair ‘ in host memory. Here stride_pair means the value named ’stride pair’ in this block. The important operands are _pair: the value named ’pair’ in this block; stride: the value named ’stride’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 704: `dilation_pair = _pair("dilation", dilation)` This assigns ‘_pair("dilation", dilation)‘ to ‘dilation_pair ‘ in host memory. Here dilation_pair means the value named ’dilation pair’ in this block. The important operands are _pair: the value named ’pair’ in this block; dilation: the value named ’dilation’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 705: `if isinstance(padding, int):` This executes the following indented host-code branch only when ‘isinstance(padding, int)‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; padding: the value named ’padding’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 706: `padding_pair = (int(padding), int(padding))` This assigns ‘(int(padding), int(padding))‘ to ‘padding_pair ‘ in host memory. Here padding_pair means the value named ’padding pair’ in this block. The important operands are padding: the value named ’padding’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 707: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function compile_conv2d_backward, which handles compile conv2d backward.

Line 708: `padding_pair = tuple(map(int, padding))` This assigns ‘tuple(map(int, padding))‘ to ‘padding_pair ‘ in host memory. Here padding_pair means the value named ’padding pair’ in this block. The important operands are tuple: the value named ’tuple’ in this block; map: the value named ’map’ in this block; padding: the value named ’padding’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 709: `if len(padding_pair) != 2:` This executes the following indented host-code branch only when ‘len(padding_pair) != 2‘ is true. The important operands are len: the value named ’len’ in this block; padding_pair: the value named ’padding pair’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 710: `raise ValueError("padding must be an integer or a pair")` This rejects an invalid state by raising ‘ValueError("padding must be an integer or a pair")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 711: `if min(padding_pair) < 0:` This executes the following indented host-code branch only when ‘min(padding_pair) < 0‘ is true. The important operands are min: the value named ’min’ in this block; padding_pair: the value named ’padding pair’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 712: `raise ValueError("padding must be nonnegative")` This rejects an invalid state by raising ‘ValueError("padding must be nonnegative")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 713: `output_height = _conv_output_size(` This statement continues through source line 715; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_conv_output_size(input_height, kernel_h, stride_pair[0], padding_pair[0], dilation_pair[0])‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are _conv_output_size: the value named ’conv output size’ in this block; input_height: the value named ’input height’ in this block; kernel_h: the value named ’kernel h’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 714: `input_height, kernel_h, stride_pair[0], padding_pair[0], dilation_pair[0]` This is continuation line 2 of the 3-line logical statement that begins at source line 713. Its exact fragment is ‘input_height, kernel_h, stride_pair[0], padding_pair[0], dilation_pair[0]‘. The important operands are input_height: the value named ’input height’ in this block; kernel_h: the value named ’kernel h’ in this block; stride_pair: the value named ’stride pair’ in this block. Read together, the complete operation is: This assigns ‘_conv_output_size(input_height, kernel_h, stride_pair[0], padding_pair[0], dilation_pair[0])‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are _conv_output_size: the value named ’conv output size’ in this block; input_height: the value named ’input height’ in this block; kernel_h: the value named ’kernel h’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 715: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 713. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘_conv_output_size(input_height, kernel_h, stride_pair[0], padding_pair[0], dilation_pair[0])‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are _conv_output_size: the value named ’conv output size’ in this block; input_height: the value named ’input height’ in this block; kernel_h: the value named ’kernel h’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 716: `output_width = _conv_output_size(` This statement continues through source line 718; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_conv_output_size(input_width, kernel_w, stride_pair[1], padding_pair[1], dilation_pair[1])‘ to ‘output_width ‘ in host memory. Here output_width means the value named ’output width’ in this block. The important operands are _conv_output_size: the value named ’conv output size’ in this block; input_width: the value named ’input width’ in this block; kernel_w: the value named ’kernel w’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 717: `input_width, kernel_w, stride_pair[1], padding_pair[1], dilation_pair[1]` This is continuation line 2 of the 3-line logical statement that begins at source line 716. Its exact fragment is ‘input_width, kernel_w, stride_pair[1], padding_pair[1], dilation_pair[1]‘. The important operands are input_width: the value named ’input width’ in this block; kernel_w: the value named ’kernel w’ in this block; stride_pair: the value named ’stride pair’ in this block. Read together, the complete operation is: This assigns ‘_conv_output_size(input_width, kernel_w, stride_pair[1], padding_pair[1], dilation_pair[1])‘ to ‘output_width ‘ in host memory. Here output_width means the value named ’output width’ in this block. The important operands are _conv_output_size: the value named ’conv output size’ in this block; input_width: the value named ’input width’ in this block; kernel_w: the value named ’kernel w’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 718: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 716. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘_conv_output_size(input_width, kernel_w, stride_pair[1], padding_pair[1], dilation_pair[1])‘ to ‘output_width ‘ in host memory. Here output_width means the value named ’output width’ in this block. The important operands are _conv_output_size: the value named ’conv output size’ in this block; input_width: the value named ’input width’ in this block; kernel_w: the value named ’kernel w’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 719: `expected_output_shape = (batch, output_channels, output_height, output_width)` This assigns ‘(batch, output_channels, output_height, output_width)‘ to ‘expected_output_shape ‘ in host memory. Here expected_output_shape means the value named ’expected output shape’ in this block. The important operands are batch: the value named ’batch’ in this block; output_channels: the value named ’output channels’ in this block; output_height: the value named ’output height’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 720: `if dy.shape != expected_output_shape:` This executes the following indented host-code branch only when ‘dy.shape != expected_output_shape‘ is true. The important operands are dy: the value named ’dy’ in this block; shape: the value named ’shape’ in this block; expected_output_shape: the value named ’expected output shape’ in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 721: `raise ValueError(` This statement continues through source line 723; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘ValueError(f"output_gradients must have shape {expected_output_shape}; received {dy.shape}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 722: `f"output_gradients must have shape {expected_output_shape}; received {dy.shape}"` This is continuation line 2 of the 3-line logical statement that begins at source line 721. Its exact fragment is ‘f"output_gradients must have shape {expected_output_shape}; received {dy.shape}"‘. The important operands are f: the value named ’f’ in this block; output_gradients: the signed loss derivative used to update a learned parameter; must: the value named ’must’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘ValueError(f"output_gradients must have shape {expected_output_shape}; received {dy.shape}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 723: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 721. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This rejects an invalid state by raising ‘ValueError(f"output_gradients must have shape {expected_output_shape}; received {dy.shape}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 724: `programs: list[ConvBackwardGroup] = []` This assigns '[]' to 'programs' in host memory. Here programs means the value named 'programs' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 725: `for group in range(groups):` This iterates group over 'range(groups)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function compile_conv2d_backward, which handles compile conv2d backward.

Line 726: `input_start = group * input_channels_per_group` This assigns 'group * input_channels_per_group' to 'input_start ' in host memory. Here input_start means the value named 'input start' in this block. The important operands are group: the value named 'group' in this block; input_channels_per_group: the value named 'input channels per group' in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 727: `output_start = group * output_channels_per_group` This assigns 'group * output_channels_per_group' to 'output_start ' in host memory. Here output_start means the value named 'output start' in this block. The important operands are group: the value named 'group' in this block; output_channels_per_group: the value named 'output channels per group' in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 728: `patches = im2col_signed_nchw(` This statement continues through source line 734; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'im2col_signed_nchw(x[:, input_start:input_start + input_channels_per_group], kernel=(kernel_h, kernel_w), stride=stride_pair, padding=padding_pair, dilation=dilation_pair,)' to 'patches ' in host memory. Here patches means the value named 'patches' in this block. The important operands are im2col_signed_nchw: the value named 'im2col signed nchw' in this block; x: the value named 'x' in this block; input_start: the value named 'input start' in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 729: `x[:, input_start:input_start + input_channels_per_group],` This is continuation line 2 of the 7-line logical statement that begins at source line 728. Its exact fragment is 'x[:, input_start:input_start + input_channels_per_group],'. The important operands are x: the value named 'x' in this block; input_start: the value named 'input start' in this block; input_channels_per_group: the value named 'input channels per group' in this block. Read together, the complete operation is: This assigns 'im2col_signed_nchw(x[:, input_start:input_start + input_channels_per_group], kernel=(kernel_h, kernel_w), stride=stride_pair, padding=padding_pair, dilation=dilation_pair,)' to 'patches ' in host memory. Here patches means the value named 'patches' in this block. The important operands are im2col_signed_nchw: the value named 'im2col signed nchw' in this block; x: the value named 'x' in this block; input_start: the value named 'input start' in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 730: `kernel=(kernel_h, kernel_w),` This is continuation line 3 of the 7-line logical statement that begins at source line 728. Its exact fragment is 'kernel=(kernel_h, kernel_w),'. The important operands are kernel: the value named 'kernel' in this block; kernel_h: the value named 'kernel h' in this block; kernel_w: the value named 'kernel w' in this block. Read together, the complete operation is: This assigns 'im2col_signed_nchw(x[:, input_start:input_start + input_channels_per_group], kernel=(kernel_h, kernel_w), stride=stride_pair, padding=padding_pair, dilation=dilation_pair,)' to 'patches ' in host memory. Here patches means the value named 'patches' in this block. The important operands are im2col_signed_nchw: the value named 'im2col signed nchw' in this block; x: the value named 'x' in this block; input_start: the value named 'input start' in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 731: `stride=stride_pair,` This is continuation line 4 of the 7-line logical statement that begins at source line 728. Its exact fragment is 'stride=stride_pair,'. The important operands are stride: the value named 'stride' in this block; stride_pair: the value named 'stride pair' in this block. Read together, the complete operation is: This assigns 'im2col_signed_nchw(x[:, input_start:input_start + input_channels_per_group], kernel=(kernel_h, kernel_w), stride=stride_pair, padding=padding_pair, dilation=dilation_pair,)' to 'patches ' in host memory. Here patches means the value named 'patches' in this block. The important operands are im2col_signed_nchw: the value named 'im2col signed nchw' in this block; x: the value named 'x' in this block; input_start: the value named 'input start' in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 732: `padding=padding_pair,` This is continuation line 5 of the 7-line logical statement that begins at source line 728. Its exact fragment is 'padding=padding_pair,'. The important operands are padding: the value named 'padding' in this block; padding_pair: the value named 'padding pair' in this block. Read together, the complete operation is: This assigns 'im2col_signed_nchw(x[:, input_start:input_start + input_channels_per_group], kernel=(kernel_h, kernel_w), stride=stride_pair, padding=padding_pair, dilation=dilation_pair,)' to 'patches ' in host memory. Here patches means the value named 'patches' in this block. The important operands are im2col_signed_nchw: the value named 'im2col signed nchw' in this block; x: the value named 'x' in this block; input_start: the value named 'input start' in this block. Context: the function compile_conv2d_backward, which handles compile conv2d backward.

Line 733: `dilation=dilation_pair,` This is continuation line 6 of the 7-line logical statement that begins at source line 728. Its exact fragment is 'dilation=dilation_pair,'. The important operands are dilation: the value named 'dilation' in this block; dilation_pair: the value named 'dilation pair' in this block. Read together, the complete operation is: This assigns 'im2col_signed_nchw(x[:, input_start:input_start + input_channels_per_group], kernel=(kernel_h, kernel_w), stride=stride_pair, padding=padding_pair, dilation=dilation_pair,)' to 'patches ' in host memory. Line 765: `)` This is continuation line 11 of the 11-line logical statement that begins at source line 755. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘CompiledConv2dBackward(tuple(map(int, x.shape)), tuple(map(int, w.shape)), tuple(map(int, expected_output_shape)), (kernel_h, kernel_w), stride_pair, padding_pair, dilation_pair, groups, tuple(programs),)‘ to the caller of the function compile_conv2d_backward, which handles compile conv2d backward, ending this invocation. The important operands are CompiledConv2dBackward: the value named ’compiled conv2d backward’ in this block; tuple: the value named ’tuple’ in this block; map: the value named ’map’ in this block.

Line 768: `def sigmoid_surrogate_lut_q15(` This starts function sigmoid_surrogate_lut_q15. Its indented body performs sigmoid surrogate lut q15 as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 769: `*,` Inside the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 770: `alpha: float = 4.0,` This assigns ‘4.0,‘ to ‘alpha‘ in host memory. Here alpha means the programmable weight assigned to matching zero spikes in alpha-XNOR attention. The expression is a literal or structural operator and has no hidden software state. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 771: `membrane_fractional_bits: int = 10,` This assigns ‘10,‘ to ‘membrane_fractional_bits‘ in host memory. Here membrane_fractional_bits means the persistent LIF neuron state carrying charge between timesteps. The expression is a literal or structural operator and has no hidden software state. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 772: `address_shift: int | None = None,` This assigns ‘None,‘ to ‘address_shift‘ in host memory. Here address_shift means the value named ’address shift’ in this block. The important operands are None: the value named ’none’ in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 773: `) -> tuple[np.ndarray, int]:` Inside the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 774: `"""Quantize SpikingJelly's sigmoid surrogate derivative into 256 Q15 entries."""` This is executable documentation attached to the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 776: `if not np.isfinite(alpha) or alpha <= 0:` This executes the following indented host-code branch only when 'not np.isfinite(alpha) or alpha <= 0' is true. The important operands are not: the value named 'not' in this block; isfinite: the value named 'isfinite' in this block; alpha: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 777: `raise ValueError("surrogate alpha must be finite and positive")` This rejects an invalid state by raising 'ValueError("surrogate alpha must be finite and positive")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 778: `if not 0 <= membrane_fractional_bits <= 22:` This executes the following indented host-code branch only when 'not 0 <= membrane_fractional_bits <= 22' is true. The important operands are not: the value named 'not' in this block; membrane_fractional_bits: the persistent LIF neuron state carrying charge between timesteps. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 779: `raise ValueError("membrane_fractional_bits must be in [0,22]")` This rejects an invalid state by raising 'ValueError("membrane_fractional_bits must be in [0,22]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 780: `selected_shift = (` This statement continues through source line 784; the explanation uses the complete expression rather than only the first visual fragment. This assigns '(max(membrane_fractional_bits - 5, 0) if address_shift is None else int(address_shift))' to 'selected_shift ' in host memory. Here selected_shift means the value named 'selected shift' in this block. The important operands are max: the value named 'max' in this block; membrane_fractional_bits: the persistent LIF neuron state carrying charge between timesteps; address_shift: the value named 'address shift' in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 781: `max(membrane_fractional_bits - 5, 0)` This is continuation line 2 of the 5-line logical statement that begins at source line 780. Its exact fragment is 'max(membrane_fractional_bits - 5, 0)'. The important operands are max: the value named 'max' in this block; membrane_fractional_bits: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This assigns '(max(membrane_fractional_bits - 5, 0) if address_shift is None else int(address_shift))' to 'selected_shift ' in host memory. Here selected_shift means the value named 'selected shift' in this block. The important operands are max: the value named 'max' in this block; membrane_fractional_bits: the persistent LIF neuron state carrying charge between timesteps; address_shift: the value named 'address shift' in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 782: `if address_shift is None` This is continuation line 3 of the 5-line logical statement that begins at source line 780. Its exact fragment is 'if address_shift is None'. The important operands are address_shift: the value named 'address shift' in this block; is: the value named 'is' in this block; None: the value named 'none' in this block. Read together, the complete operation is: This assigns '(max(membrane_fractional_bits - 5, 0) if address_shift is None else int(address_shift))' to 'selected_shift ' in host memory. Here selected_shift means the value named 'selected shift' in this block. The important operands are max: the value named 'max' in this block; membrane_fractional_bits: the persistent LIF neuron state carrying charge between timesteps; address_shift: the value named 'address shift' in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 783: `else int(address_shift)` This is continuation line 4 of the 5-line logical statement that begins at source line 780. Its exact fragment is ‘else int(address_shift)‘. The important operands are address_shift: the value named ’address shift’ in this block. Read together, the complete operation is: This assigns ‘(max(membrane_fractional_bits - 5, 0) if address_shift is None else int(address_shift))‘ to ‘selected_shift ‘ in host memory. Here selected_shift means the value named ’selected shift’ in this block. The important operands are max: the value named ’max’ in this block; membrane_fractional_bits: the persistent LIF neuron state carrying charge between timesteps; address_shift: the value named ’address shift’ in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 784: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 780. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(max(membrane_fractional_bits - 5, 0) if address_shift is None else int(address_shift))‘ to ‘selected_shift ‘ in host memory. Here selected_shift means the value named ’selected shift’ in this block. The important operands are max: the value named ’max’ in this block; membrane_fractional_bits: the persistent LIF neuron state carrying charge between timesteps; address_shift: the value named ’address shift’ in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 785: `if not 0 <= selected_shift <= membrane_fractional_bits:` This executes the following indented host-code branch only when ‘not 0 <= selected_shift <= membrane_fractional_bits‘ is true. The important operands are not: the value named ’not’ in this block; selected_shift: the value named ’selected shift’ in this block; membrane_fractional_bits: the persistent LIF neuron state carrying charge between timesteps. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 786: `raise ValueError("address_shift must be in [0, membrane_fractional_bits]")` This rejects an invalid state by raising ‘ValueError("address_shift must be in [0, membrane_fractional_bits]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 787: `addresses = np.arange(256, dtype=np.float64)` This assigns ‘np.arange(256, dtype=np.float64)‘ to ‘addresses ‘ in host memory. Here addresses means the value named ’addresses’ in this block. The important operands are arange: the value named ’arange’ in this block; dtype: the value named ’dtype’ in this block; float64: the value named ’float64’ in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 788: `delta = (addresses - 128.0) * (2.0 ** selected_shift)` This assigns ‘(addresses - 128.0) * (2.0 ** selected_shift)‘ to ‘delta ‘ in host memory. Here delta means the value named ’delta’ in this block. The important operands are addresses: the value named ’addresses’ in this block; selected_shift: the value named ’selected shift’ in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 789: `delta /= 2.0 ** membrane_fractional_bits` Inside the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are delta: the value named ’delta’ in this block; membrane_fractional_bits: the persistent LIF neuron state carrying charge between timesteps.

Line 790: `sigmoid = 1.0 / (1.0 + np.exp(-alpha * delta))` This assigns ‘1.0 / (1.0 + np.exp(-alpha * delta))‘ to ‘sigmoid ‘ in host memory. Here sigmoid means the value named ’sigmoid’ in this block. The important operands are exp: the value named ’exp’ in this block; alpha: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; delta: the value named ’delta’ in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 791: `derivative = alpha * sigmoid * (1.0 - sigmoid)` This assigns ‘alpha * sigmoid * (1.0 - sigmoid)‘ to ‘derivative ‘ in host memory. Here derivative means the value named ’derivative’ in this block. The important operands are alpha: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; sigmoid: the value named ’sigmoid’ in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 792: `table = np.rint(derivative * (1 << 15))` This assigns ‘np.rint(derivative * (1 << 15))‘ to ‘table ‘ in host memory. Here table means the value named ’table’ in this block. The important operands are rint: the value named ’rint’ in this block; derivative: the value named ’derivative’ in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 793: `table = np.clip(table, 0, (1 << 15) - 1).astype(np.int64)` This assigns ‘np.clip(table, 0, (1 << 15) - 1).astype(np.int64)‘ to ‘table ‘ in host memory. Here table means the value named ’table’ in this block. The important operands are clip: the value named ’clip’ in this block; table: the value named ’table’ in this block; astype: the value named ’astype’ in this block. Context: the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15.

Line 794: `return table, selected_shift` This returns ‘table, selected_shift‘ to the caller of the function sigmoid_surrogate_lut_q15, which handles sigmoid surrogate lut q15, ending this invocation. The important operands are table: the value named ’table’ in this block; selected_shift: the value named ’selected shift’ in this block.

Line 797: `def surrogate_lut_addresses(` This starts function surrogate_lut_addresses. Its indented body performs surrogate lut addresses as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 798: `pre_reset_membrane,` Inside the function surrogate_lut_addresses, which handles surrogate lut addresses, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps.

Line 799: `threshold: int,` Inside the function surrogate_lut_addresses, which handles surrogate lut addresses, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are threshold: the membrane level at which a neuron emits a spike.

Line 800: `address_shift: int,` Inside the function surrogate_lut_addresses, which handles surrogate lut addresses, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are address_shift: the value named ’address shift’ in this block.

Line 801: `) -> np.ndarray:` Inside the function surrogate_lut_addresses, which handles surrogate lut addresses, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are ndarray: the value named ’ndarray’ in this block.

Line 802: `"""Map signed fixed-point membrane distance to a saturating LUT address."""` This is executable documentation attached to the function surrogate_lut_addresses, which handles surrogate lut addresses. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 804: `if not 0 <= address_shift <= 31:` This executes the following indented host-code branch only when ‘not 0 <= address_shift <= 31‘ is true. The important operands are not: the value named ’not’ in this block; address_shift: the value named ’address shift’ in this block. Context: the function surrogate_lut_addresses, which handles surrogate lut addresses.

Line 805: `raise ValueError("address_shift must be in [0,31]")` This rejects an invalid state by raising ‘ValueError("address_shift must be in [0,31]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 806: `membrane = np.asarray(pre_reset_membrane, dtype=np.int64)` This assigns ‘np.asarray(pre_reset_membrane, dtype=np.int64)‘ to ‘membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are asarray: the value named ’asarray’ in this block; pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; dtype: the value named ’dtype’ in this block. Context: the function surrogate_lut_addresses, which handles surrogate lut addresses.

Line 807: `distance = membrane - int(threshold)` This assigns ‘membrane - int(threshold)‘ to ‘distance ‘ in host memory. Here distance means the value named ’distance’ in this block. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps; threshold: the membrane level at which a neuron emits a spike. Context: the function surrogate_lut_addresses, which handles surrogate lut addresses.

Line 808: `quantized = round_shift_signed(distance, address_shift)` This assigns ‘round_shift_signed(distance, address_shift)‘ to ‘quantized ‘ in host memory. Here quantized means the value named ’quantized’ in this block. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; distance: the value named ’distance’ in this block; address_shift: the value named ’address shift’ in this block. Context: the function surrogate_lut_addresses, which handles surrogate lut addresses.

Line 809: `return np.clip(quantized + 128, 0, 255).astype(np.uint8)` This returns ‘np.clip(quantized + 128, 0, 255).astype(np.uint8)‘ to the caller of the function surrogate_lut_addresses, which handles surrogate lut addresses, ending this invocation. The important operands are clip: the value named ’clip’ in this block; quantized: the value named ’quantized’ in this block; astype: the value named ’astype’ in this block.

Line 812: `def lif_bptt_fixed(` This starts function lif_bptt_fixed. Its indented body performs lif bptt fixed as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 813: `pre_reset_membrane,` Inside the function lif_bptt_fixed, which handles lif bptt fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps.

Line 814: `spikes,` Inside the function lif_bptt_fixed, which handles lif bptt fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are spikes: a binary event produced when a neuron crosses its threshold.

Line 815: `spike_gradients,` Inside the function lif_bptt_fixed, which handles lif bptt fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are spike_gradients: a binary event produced when a neuron crosses its threshold.

Line 816: `*,` Inside the function lif_bptt_fixed, which handles lif bptt fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 817: `threshold: int,` Inside the function lif_bptt_fixed, which handles lif bptt fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are threshold: the membrane level at which a neuron emits a spike.

Line 818: `membrane_gradients=None,` This assigns ‘None,‘ to ‘membrane_gradients‘ in host memory. Here membrane_gradients means the persistent LIF neuron state carrying charge between timesteps. The important operands are None: the value named ’none’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 819: `reciprocal_tau_q15: int = 1 << 14,` This assigns '1 << 14,' to 'reciprocal_tau_q15' in host memory. Here reciprocal_tau_q15 means the value named 'reciprocal tau q15' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 820: `surrogate_table_q15=None,` This assigns 'None,' to 'surrogate_table_q15' in host memory. Here surrogate_table_q15 means the value named 'surrogate table q15' in this block. The important operands are None: the value named 'none' in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 821: `surrogate_address_shift: int = 5,` This assigns '5,' to 'surrogate_address_shift' in host memory. Here surrogate_address_shift means the value named 'surrogate address shift' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 822: `) -> tuple[np.ndarray, np.ndarray]:` Inside the function lif_bptt_fixed, which handles lif bptt fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 823: `"""Bit-exact detached-reset hard-LIF BPTT using signed Q15 products."""` This is executable documentation attached to the function lif_bptt_fixed, which handles lif bptt fixed. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 825: `membrane = np.asarray(pre_reset_membrane, dtype=np.int64)` This assigns 'np.asarray(pre_reset_membrane, dtype=np.int64)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are asarray: the value named 'asarray' in this block; pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; dtype: the value named 'dtype' in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 826: `spike = np.asarray(spikes, dtype=np.int64)` This assigns 'np.asarray(spikes, dtype=np.int64)' to 'spike ' in host memory. Here spike means a binary event produced when a neuron crosses its threshold. The important operands are asarray: the value named 'asarray' in this block; spikes: a binary event produced when a neuron crosses its threshold; dtype: the value named 'dtype' in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 827: `grad_spike = np.asarray(spike_gradients, dtype=np.int64)` This assigns 'np.asarray(spike_gradients, dtype=np.int64)' to 'grad_spike ' in host memory. Here grad_spike means a binary event produced when a neuron crosses its threshold. The important operands are asarray: the value named 'asarray' in this block; spike_gradients: a binary event produced when a neuron crosses its threshold; dtype: the value named 'dtype' in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 828: `if membrane.ndim != 2 or spike.shape != membrane.shape or grad_spike.shape != membrane.shape:` This executes the following indented host-code branch only when 'membrane.ndim != 2 or spike.shape != membrane.shape or grad_spike.shape != membrane.shape' is true. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 829: `raise ValueError("LIF trace, spike, and gradient arrays must share shape [time, neurons]")` This rejects an invalid state by raising 'ValueError("LIF trace, spike, and gradient arrays must share shape [time, neurons]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 830: `if np.any((spike != 0) & (spike != 1)):` This executes the following indented host-code branch only when 'np.any((spike != 0) & (spike != 1))' is true. The important operands are any: the value named 'any' in this block; spike: a binary event produced when a neuron crosses its threshold. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 831: `raise ValueError("LIF spikes must be binary")` This rejects an invalid state by raising ‘ValueError("LIF spikes must be binary")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 832: `if membrane_gradients is None:` This executes the following indented host-code branch only when ‘membrane_gradients is None‘ is true. The important operands are membrane_gradients: the persistent LIF neuron state carrying charge between timesteps; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 833: `grad_v = np.zeros_like(membrane)` This assigns ‘np.zeros_like(membrane)‘ to ‘grad_v ‘ in host memory. Here grad_v means the value named ’grad v’ in this block. The important operands are zeros_like: the value named ’zeros like’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 834: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function lif_bptt_fixed, which handles lif bptt fixed.

Line 835: `grad_v = np.asarray(membrane_gradients, dtype=np.int64)` This assigns ‘np.asarray(membrane_gradients, dtype=np.int64)‘ to ‘grad_v ‘ in host memory. Here grad_v means the value named ’grad v’ in this block. The important operands are asarray: the value named ’asarray’ in this block; membrane_gradients: the persistent LIF neuron state carrying charge between timesteps; dtype: the value named ’dtype’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 836: `if grad_v.shape != membrane.shape:` This executes the following indented host-code branch only when ‘grad_v.shape != membrane.shape‘ is true. The important operands are grad_v: the value named ’grad v’ in this block; shape: the value named ’shape’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 837: `raise ValueError("membrane gradients must match the LIF trace shape")` This rejects an invalid state by raising ‘ValueError("membrane gradients must match the LIF trace shape")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 838: `if not 0 <= reciprocal_tau_q15 <= (1 << 15):` This executes the following indented host-code branch only when ‘not 0 <= reciprocal_tau_q15 <= (1 << 15)‘ is true. The important operands are not: the value named ’not’ in this block; reciprocal_tau_q15: the value named ’reciprocal tau q15’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 839: `raise ValueError("reciprocal_tau_q15 must be in [0,32768]")` This rejects an invalid state by raising ‘ValueError("reciprocal_tau_q15 must be in [0,32768]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 840: `if surrogate_table_q15 is None:` This executes the following indented host-code branch only when ‘surrogate_table_q15 is None‘ is true. The important operands are surrogate_table_q15: the value named ’surrogate table q15’ in this block; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 841: `surrogate_table_q15, _ = sigmoid_surrogate_lut_q15(` This statement continues through source line 843; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sigmoid_surrogate_lut_q1 address_shift=surrogate_address_shift)‘ to ‘surrogate_table_q15, _ ‘ in host memory. Here surrogate_table_q15 means the value named ’surrogate table q15’ in this block. The important operands are sigmoid_surrogate_lut_q15: the value named ’sigmoid surrogate lut q15’ in this block; address_shift: the value named ’address shift’ in this block; surrogate_address_shift: the value named ’surrogate address shift’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 842: `address_shift=surrogate_address_shift` This is continuation line 2 of the 3-line logical statement that begins at source line 841. Its exact fragment is ‘address_shift=surrogate_address_shift‘. The important operands are address_shift: the value named ’address shift’ in this block; surrogate_address_shift: the value named ’surrogate address shift’ in this block. Read together, the complete operation is: This assigns ‘sigmoid_surrogate_lut_q15(address_shift=surrogate_address_shift)‘ to ‘surrogate_table_q15, _ ‘ in host memory. Here surrogate_table_q15 means the value named ’surrogate table q15’ in this block. The important operands are sigmoid_surrogate_lut_q15: the value named ’sigmoid surrogate lut q15’ in this block; address_shift: the value named ’address shift’ in this block; surrogate_address_shift: the value named ’surrogate address shift’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 843: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 841. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘sigmoid_surrogate_lut_q15(address_shift=surrogate_address_shift)‘ to ‘surrogate_table_q15, _ ‘ in host memory. Here surrogate_table_q15 means the value named ’surrogate table q15’ in this block. The important operands are sigmoid_surrogate_lut_q15: the value named ’sigmoid surrogate lut q15’ in this block; address_shift: the value named ’address shift’ in this block; surrogate_address_shift: the value named ’surrogate address shift’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 844: `table = np.asarray(surrogate_table_q15, dtype=np.int64)` This assigns ‘np.asarray(surrogate_table_q15, dtype=np.int64)‘ to ‘table ‘ in host memory. Here table means the value named ’table’ in this block. The important operands are asarray: the value named ’asarray’ in this block; surrogate_table_q15: the value named ’surrogate table q15’ in this block; dtype: the value named ’dtype’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 845: `if table.shape != (256,) or np.any(table < 0) or np.any(table > 32767):` This executes the following indented host-code branch only when ‘table.shape != (256,) or np.any(table < 0) or np.any(table > 32767)‘ is true. The important operands are table: the value named ’table’ in this block; shape: the value named ’shape’ in this block; or: the value named ’or’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 846: `raise ValueError("surrogate table must contain 256 nonnegative signed-Q15 values")` This rejects an invalid state by raising ‘ValueError("surrogate table must contain 256 nonnegative signed-Q15 values")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 847: `addresses = surrogate_lut_addresses(membrane, threshold, surrogate_address_shift)` This assigns ‘surrogate_lut_addresses(membrane, threshold, surrogate_address_shift)‘ to ‘addresses ‘ in host memory. Here addresses means the value named ’addresses’ in this block. The important operands are surrogate_lut_addresses: the value named ’surrogate lut addresses’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; threshold: the membrane level at which a neuron emits a spike. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 848: `derivative = table[addresses]` This assigns ‘table[addresses]‘ to ‘derivative ‘ in host memory. Here derivative means the value named ’derivative’ in this block. The important operands are table: the value named ’table’ in this block; addresses: the value named ’addresses’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 849: `grad_input = np.zeros_like(membrane)` This assigns ‘np.zeros_like(membrane)‘ to ‘grad_input ‘ in host memory. Here grad_input means the value named ’grad input’ in this block. The important operands are zeros_like: the value named ’zeros like’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 850: `grad_h_trace = np.zeros_like(membrane)` This assigns ‘np.zeros_like(membrane)‘ to ‘grad_h_trace ‘ in host memory. Here grad_h_trace means the value named ’grad h trace’ in this block. The important operands are zeros_like: the value named ’zeros like’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 851: `grad_h_next = np.zeros(membrane.shape[1], dtype=np.int64)` This assigns ‘np.zeros(membrane.shape[1], dtype=np.int64)‘ to ‘grad_h_next ‘ in host memory. Here grad_h_next means the value named ’grad h next’ in this block. The important operands are zeros: the value named ’zeros’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; shape: the value named ’shape’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 852: `leak_q15 = (1 << 15) - reciprocal_tau_q15` This assigns ‘(1 << 15) - reciprocal_tau_q15‘ to ‘leak_q15 ‘ in host memory. Here leak_q15 means the retained fraction of prior membrane state. The important operands are reciprocal_tau_q15: the value named ’reciprocal tau q15’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 853: `for timestep in range(membrane.shape[0] - 1, -1, -1):` This iterates timestep over ‘range(membrane.shape[0] - 1, -1, -1)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_bptt_fixed, which handles lif bptt fixed.

Line 854: `temporal = saturate_signed(` This statement continues through source line 856; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘saturate_signed(round_shift_signed(grad_h_next * leak_q15, 15), 32)‘ to ‘temporal ‘ in host memory. Here temporal means the value named ’temporal’ in this block. The important operands are saturate_signed: the value named ’saturate signed’ in this block; round_shift_signed: the value named ’round shift signed’ in this block; grad_h_next: the value named ’grad h next’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 855: `round_shift_signed(grad_h_next * leak_q15, 15), 32` This is continuation line 2 of the 3-line logical statement that begins at source line 854. Its exact fragment is ‘round_shift_signed(grad_h_next * leak_q15, 15), 32‘. The important operands are round_shift_signed: the value named ’round shift signed’ in this block; grad_h_next: the value named ’grad h next’ in this block; leak_q15: the retained fraction of prior membrane state. Read together, the complete operation is: This assigns ‘saturate_signed(round_shift_signed(grad_h_next * leak_q15, 15), 32)‘ to ‘temporal ‘ in host memory. Here temporal means the value named ’temporal’ in this block. The important operands are saturate_signed: the value named ’saturate signed’ in this block; round_shift_signed: the value named ’round shift signed’ in this block; grad_h_next: the value named ’grad h next’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 856: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 854. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘saturate_signed(round_shift_signed(grad_h_next * leak_q15, 15), 32)‘ to ‘temporal ‘ in host memory. Here temporal means the value named ’temporal’ in this block. The important operands are saturate_signed: the value named ’saturate signed’ in this block; round_shift_signed: the value named ’round shift signed’ in this block; grad_h_next: the value named ’grad h next’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 857: `membrane_path = saturate_signed(grad_v[timestep] + temporal, 32)` This assigns ‘saturate_signed(grad_v[ti + temporal, 32)‘ to ‘membrane_path ‘ in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are saturate_signed: the value named ’saturate signed’ in this block; grad_v: the value named ’grad v’ in this block; timestep: one discrete SNN update instant. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 858: `membrane_path = np.where(spike[timestep] == 0, membrane_path, 0)` Inside the function lif_bptt_fixed, which handles lif bptt fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are membrane_path: the persistent LIF neuron state carrying charge between timesteps; where: the value named ’where’ in this block; spike: a binary event produced when a neuron crosses its threshold.

Line 859: `spike_path = saturate_signed(` This statement continues through source line 861; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘saturate_signed(round_shift_signed(grad_spike[ti * derivative[timestep], 15), 32)‘ to ‘spike_path ‘ in host memory. Here spike_path means a binary event produced when

a neuron crosses its threshold. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; grad_spike: a binary event produced when a neuron crosses its threshold. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 860: `round_shift_signed(grad_spike[timestep] * derivative[timestep], 15), 32` This is continuation line 2 of the 3-line logical statement that begins at source line 859. Its exact fragment is 'round_shift_signed(grad_spike[timestep] * derivative[timestep], 15), 32'. The important operands are round_shift_signed: the value named 'round shift signed' in this block; grad_spike: a binary event produced when a neuron crosses its threshold; timestep: one discrete SNN update instant. Read together, the complete operation is: This assigns 'saturate_signed(round_shift_signed(grad_spike[timestep] * derivative[timestep], 15), 32)' to 'spike_path ' in host memory. Here spike_path means a binary event produced when a neuron crosses its threshold. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; grad_spike: a binary event produced when a neuron crosses its threshold. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 861: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 859. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'saturate_signed(round_shift_signed(grad_spike[timestep] * derivative[timestep], 15), 32)' to 'spike_path ' in host memory. Here spike_path means a binary event produced when a neuron crosses its threshold. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; grad_spike: a binary event produced when a neuron crosses its threshold. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 862: `grad_h = saturate_signed(membrane_path + spike_path, 32)` This assigns 'saturate_signed(membrane_path + spike_path, 32)' to 'grad_h ' in host memory. Here grad_h means the value named 'grad h' in this block. The important operands are saturate_signed: the value named 'saturate signed' in this block; membrane_path: the persistent LIF neuron state carrying charge between timesteps; spike_path: a binary event produced when a neuron crosses its threshold. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 863: `grad_input[timestep] = saturate_signed(` This statement continues through source line 865; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'saturate_signed(round_shift_signed(grad_h * reciprocal_tau_q15, 15), 32)' to 'grad_input[timestep] ' in host memory. Here grad_input means the value named 'grad input' in this block. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; grad_h: the value named 'grad h' in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 864: `round_shift_signed(grad_h * reciprocal_tau_q15, 15), 32` This is continuation line 2 of the 3-line logical statement that begins at source line 863. Its exact fragment is 'round_shift_signed(grad_h * reciprocal_tau_q15, 15), 32'. The important operands are round_shift_signed: the value named 'round shift signed' in this block; grad_h: the value named 'grad h' in this block; reciprocal_tau_q15: the value named 'reciprocal tau q15' in this block. Read together, the complete operation is: This assigns 'saturate_signed(round_shift_signed(grad_h * reciprocal_tau_q15, 15), 32)' to 'grad_input[timestep] ' in host memory. Here grad_input means the value named 'grad input' in this block. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; grad_h: the value named 'grad h' in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 865: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 863. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'saturate_signed(round_shift_signed(grad_h * reciprocal_tau_q15, 15), 32)' to 'grad_input[timestep] ' in host memory. Here grad_input means the value named 'grad input' in this block. The important operands are saturate_signed: the value named 'saturate signed' in this block; round_shift_signed: the value named 'round shift signed' in this block; grad_h: the value named 'grad h' in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 866: `grad_h_trace[timestep] = grad_h` This assigns 'grad_h' to 'grad_h_trace[timestep] ' in host memory. Here grad_h_trace means the value named 'grad h trace' in this block. The important operands are grad_h: the value named 'grad h' in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 867: `grad_h_next = grad_h` This assigns ‘grad_h‘ to ‘grad_h_next ‘ in host memory. Here grad_h_next means the value named ’grad h next’ in this block. The important operands are grad_h: the value named ’grad h’ in this block. Context: the function lif_bptt_fixed, which handles lif bptt fixed.

Line 868: `return grad_input, grad_h_trace` This returns ‘grad_input, grad_h_trace‘ to the caller of the function lif_bptt_fixed, which handles lif bptt fixed, ending this invocation. The important operands are grad_input: the value named ’grad input’ in this block; grad_h_trace: the value named ’grad h trace’ in this block.

Line 871: `def _execute_vector8(` This starts function _execute_vector8. Its indented body performs execute vector8 as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 872: `driver: TrainingCommandExecutor,` Inside the function _execute_vector8, which handles execute vector8, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named ’driver’ in this block; TrainingCommandExecutor: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 873: `operation: VectorOperation,` Inside the function _execute_vector8, which handles execute vector8, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are operation: the value named ’operation’ in this block; VectorOperation: the value named ’vector operation’ in this block.

Line 874: `operand_a: Sequence[int],` Inside the function _execute_vector8, which handles execute vector8, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are operand_a: the value named ’operand a’ in this block; Sequence: the value named ’sequence’ in this block.

Line 875: `operand_b: Sequence[int],` Inside the function _execute_vector8, which handles execute vector8, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are operand_b: the value named ’operand b’ in this block; Sequence: the value named ’sequence’ in this block.

Line 876: `*,` Inside the function _execute_vector8, which handles execute vector8, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 877: `timeout_seconds: float,` Inside the function _execute_vector8, which handles execute vector8, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; float: the value named ’float’ in this block.

Line 878: `clamp_minimum: int = -(1 << 31),` This assigns ‘-(1 << 31),‘ to ‘clamp_minimum‘ in host memory. Here clamp_minimum means the value named ’clamp minimum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _execute_vector8, which handles execute vector8.

Line 879: `clamp_maximum: int = (1 << 31) - 1,` This assigns ‘(1 << 31) - 1,‘ to ‘clamp_maximum‘ in host memory. Here clamp_maximum means the value named ’clamp maximum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _execute_vector8, which handles execute vector8.

Line 880: `) -> np.ndarray:` Inside the function _execute_vector8, which handles execute vector8, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are ndarray: the value named ’ndarray’ in this block.

Line 881: `words = driver.execute(` This statement continues through source line 891; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function _execute_vector8, which handles execute vector8.

Line 882: `vector_command(int(operation)),` This is continuation line 2 of the 11-line logical statement that begins at source line 881. Its exact fragment is ‘vector_command(int(operation)),‘. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operation: the value named ’operation’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function _execute_vector8, which handles execute vector8.

Line 883: `pack_vector_beats(` This is continuation line 3 of the 11-line logical statement that begins at source line 881. Its exact fragment is ‘pack_vector_beats(‘. The important operands are pack_vector_beats: the value named ’pack vector beats’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function _execute_vector8, which handles execute vector8.

Line 884: `operand_a,` This is continuation line 4 of the 11-line logical statement that begins at source line 881. Its exact fragment is ‘operand_a,‘. The important operands are operand_a: the value named ’operand a’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function _execute_vector8, which handles execute vector8.

Line 885: `operand_b,` This is continuation line 5 of the 11-line logical statement that begins at source line 881. Its exact fragment is ‘operand_b,‘. The important operands are operand_b: the value named ’operand b’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function _execute_vector8, which handles execute vector8.

Line 886: `clamp_minimum=clamp_minimum,` This is continuation line 6 of the 11-line logical statement that begins at source line 881. Its exact fragment is ‘clamp_minimum=clamp_minimum,‘. The important operands are clamp_minimum: the value named ’clamp minimum’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function _execute_vector8, which handles execute vector8.

Line 887: `clamp_maximum=clamp_maximum,` This is continuation line 7 of the 11-line logical statement that begins at source line 881. Its exact fragment is ‘clamp_maximum=clamp_maximum,‘. The important operands are clamp_maximum: the value named ’clamp maximum’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function _execute_vector8, which handles execute vector8.

Line 888: `),` This is continuation line 8 of the 11-line logical statement that begins at source line 881. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function _execute_vector8, which handles execute vector8.

Line 889: `output_beats=4,` This is continuation line 9 of the 11-line logical statement that begins at source line 881. Its exact fragment is ‘output_beats=4,‘. The important operands are output_beats: the value named ’output beats’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. Context: the function _execute_vector8, which handles execute vector8.

Line 890: `timeout_seconds=timeout_seconds,` This is continuation line 10 of the 11-line logical statement that begins at source line 881. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function _execute_vector8, which handles execute vector8.

Line 891: `)` This is continuation line 11 of the 11-line logical statement that begins at source line 881. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘driver.execute(vector_command(int(operation)), pack_vector_beats(operand_a, operand_b, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), output_beats=4, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function _execute_vector8, which handles execute vector8.

Line 892: `if len(words) != 4:` This executes the following indented host-code branch only when ‘len(words) != 4‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block. Context: the function _execute_vector8, which handles execute vector8.

Line 893: `raise RuntimeError(f"vector operation returned {len(words)} beats; expected four")` This rejects an invalid state by raising ‘RuntimeError(f"vector operation returned {len(words)} beats; expected four")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 894: `return np.asarray(unpack_vector_result(words), dtype=np.int64)` This returns ‘np.asarray(unpack_vector_r dtype=np.int64)‘ to the caller of the function _execute_vector8, which handles execute vector8, ending this invocation. The important operands are asarray: the value named ’asarray’ in this block; unpack_vector_result: the value named ’unpack vector result’ in this block; words: the value named ’words’ in this block.

Line 897: `def execute_sgdw_update(` This starts function execute_sgdw_update. Its indented body performs execute sgdw update as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 898: `driver: TrainingCommandExecutor,` Inside the function execute_sgdw_update, which handles execute sgdw update, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named ’driver’ in this block; TrainingCommandExecutor: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 899: `weights,` Inside the function execute_sgdw_update, which handles execute sgdw update, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are weights: a learned coefficient multiplied by an activation.

Line 900: `gradients,` Inside the function execute_sgdw_update, which handles execute sgdw update, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are gradients: the signed loss derivative used to update a learned parameter.

Line 901: `velocities,` Inside the function execute_sgdw_update, which handles execute sgdw update, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are velocities: the value named ’velocities’ in this block.

Line 902: `*,` Inside the function execute_sgdw_update, which handles execute sgdw update, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 903: `learning_rate_q16: int,` Inside the function execute_sgdw_update, which handles execute sgdw update, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude.

Line 904: `momentum_q16: int,` Inside the function execute_sgdw_update, which handles execute sgdw update, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are momentum_q16: the value named ’momentum q16’ in this block.

Line 905: `weight_decay_q16: int,` Inside the function execute_sgdw_update, which handles execute sgdw update, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are weight_decay_q16: a learned coefficient multiplied by an activation.

Line 906: `update_right_shift: int = 16,` This assigns ‘16,‘ to ‘update_right_shift‘ in host memory. Here update_right_shift means the value named ’update right shift’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 907: `timeout_seconds: float = 5.0,` This assigns ‘5.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 908: `) -> tuple[np.ndarray, np.ndarray]:` Inside the function execute_sgdw_update, which handles execute sgdw update, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named ’tuple’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 909: `"""Update an arbitrary tensor through the fabric's eight SGDW lanes."""` This is executable documentation attached to the function execute_sgdw_update, which handles execute sgdw update. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 911: `weight = np.asarray(weights, dtype=np.int64)` This assigns ‘np.asarray(weights, dtype=np.int64)‘ to ‘weight ‘ in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are asarray: the value named ’asarray’ in this block; weights: a learned coefficient multiplied by an activation; dtype: the value named ’dtype’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 912: `gradient = np.asarray(gradients, dtype=np.int64)` This assigns ‘np.asarray(gradients, dtype=np.int64)‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are asarray: the value named ’asarray’ in this block; gradients: the signed loss derivative used to update a learned parameter; dtype: the value named ’dtype’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 913: `velocity = np.asarray(velocities, dtype=np.int64)` This assigns ‘np.asarray(velocities, dtype=np.int64)‘ to ‘velocity ‘ in host memory. Here velocity means the momentum history retained by the SGD optimizer. The important operands are asarray: the value named ’asarray’ in this block; velocities: the value named ’velocities’ in this block; dtype: the value named ’dtype’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 914: `if weight.shape != gradient.shape or weight.shape != velocity.shape or weight.size == 0:` This executes the following indented host-code branch only when ‘weight.shape != gradient.shape or weight.shape != velocity.shape or weight.size == 0‘ is true. The important operands are weight: a learned coefficient multiplied by an activation; shape: the value named ’shape’ in this block; gradient: the signed loss derivative used to update a learned parameter. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 915: `raise ValueError("weights, gradients, and velocities must share a non-empty shape")` This rejects an invalid state by raising ‘ValueError("weights, gradients, and velocities must share a non-empty shape")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 916: `if np.any(weight < -(1 << 15)) or np.any(weight > (1 << 15) - 1):` This executes the following indented host-code branch only when ‘np.any(weight < -(1 << 15)) or np.any(weight > (1 << 15) - 1)‘ is true. The important operands are any: the value named ’any’ in this block; weight: a learned coefficient multiplied by an activation; or: the value named ’or’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 917: `raise ValueError("optimizer weights must fit signed 16-bit")` This rejects an invalid state by raising ‘ValueError("optimizer weights must fit signed 16-bit")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 918: `for name, value in (("gradients", gradient), ("velocities", velocity)):` This iterates name, value over ‘(("gradients", gradient), ("velocities", velocity))‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_sgdw_update, which handles execute sgdw update.

Line 919: `if np.any(value < -(1 << 23)) or np.any(value > (1 << 23) - 1):` This executes the following indented host-code branch only when ‘np.any(value < -(1 << 23)) or np.any(value > (1 << 23) - 1)‘ is true. The important operands are any: the value named ’any’ in this block; value: the value named ’value’ in this block; or: the value named ’or’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 920: `raise ValueError(f"optimizer {name} must fit signed 24-bit")` This rejects an invalid state by raising ‘ValueError(f"optimizer {name} must fit signed 24-bit")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 921: `flat_weight = weight.reshape(-1)` This assigns ‘weight.reshape(-1)‘ to ‘flat_weight ‘ in host memory. Here flat_weight means a learned coefficient multiplied by an activation. The important operands are weight: a learned coefficient multiplied by an activation; reshape: the value named ’reshape’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 922: `flat_gradient = gradient.reshape(-1)` This assigns ‘gradient.reshape(-1)‘ to ‘flat_gradient ‘ in host memory. Here flat_gradient means the signed loss derivative used to update a learned parameter. The important operands are gradient: the signed loss derivative used to update a learned parameter; reshape: the value named ’reshape’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 923: `flat_velocity = velocity.reshape(-1)` This assigns ‘velocity.reshape(-1)‘ to ‘flat_velocity ‘ in host memory. Here flat_velocity means the momentum history retained by the SGD optimizer. The important operands are velocity: the momentum history retained by the SGD optimizer; reshape: the value named ’reshape’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 924: `next_weight = np.zeros_like(flat_weight)` This assigns ‘np.zeros_like(flat_weight)‘ to ‘next_weight ‘ in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are zeros_like: the value named ’zeros like’ in this block; flat_weight: a learned coefficient multiplied by an activation. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 925: `next_velocity = np.zeros_like(flat_velocity)` This assigns ‘np.zeros_like(flat_velocity)‘ to ‘next_velocity ‘ in host memory. Here next_velocity means the momentum history retained by the SGD optimizer. The important operands are zeros_like: the value named ’zeros like’ in this block; flat_velocity: the momentum history retained by the SGD optimizer. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 926: `command = sgd_command(` This statement continues through source line 931; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sgd_command(learning_rate_q16, momentum_q16, weight_decay_q16, update_right_shift=update_right_shift,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are sgd_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; learning_rate_q16: the fixed-point multiplier controlling update magnitude; momentum_q16: the value named ’momentum q16’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 927: `learning_rate_q16,` This is continuation line 2 of the 6-line logical statement that begins at source line 926. Its exact fragment is ‘learning_rate_q16,‘. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude. Read together, the complete operation is: This assigns ‘sgd_command(learning_rate_q16, momentum_q16, weight_decay_q16, update_right_shift=update_right_shift,)‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are sgd_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; learning_rate_q16: the fixed-point multiplier controlling update magnitude; momentum_q16: the value named ’momentum q16’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 928: `momentum_q16,` This is continuation line 3 of the 6-line logical statement that begins at source line 926. Its exact fragment is ‘momentum_q16,‘. The important operands are momentum_q16: the value named ’momentum q16’ in this block. Read together, the complete operation is: This assigns ‘sgd_command(learning_rate_q16, momentum_q16, weight_decay_q16, update_right_shift=update_right_shift,)‘ to ‘command ‘ in host memory. Here

command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are sgd_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; learning_rate_q16: the fixed-point multiplier controlling update magnitude; momentum_q16: the value named 'momentum q16' in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 929: `weight_decay_q16,` This is continuation line 4 of the 6-line logical statement that begins at source line 926. Its exact fragment is 'weight_decay_q16,'. The important operands are weight_decay_q16: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'sgd_command(learning_rate_q16, momentum_q16, weight_decay_q16, update_right_shift=update_right_shift,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are sgd_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; learning_rate_q16: the fixed-point multiplier controlling update magnitude; momentum_q16: the value named 'momentum q16' in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 930: `update_right_shift=update_right_shift,` This is continuation line 5 of the 6-line logical statement that begins at source line 926. Its exact fragment is 'update_right_shift=update_right_shift,'. The important operands are update_right_shift: the value named 'update right shift' in this block. Read together, the complete operation is: This assigns 'sgd_command(learning_rate_q16, momentum_q16, weight_decay_q16, update_right_shift=update_right_shift,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are sgd_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; learning_rate_q16: the fixed-point multiplier controlling update magnitude; momentum_q16: the value named 'momentum q16' in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 931: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 926. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'sgd_command(learning_rate_q16, momentum_q16, weight_decay_q16, update_right_shift=update_right_shift,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are sgd_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; learning_rate_q16: the fixed-point multiplier controlling update magnitude; momentum_q16: the value named 'momentum q16' in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 932: `for start in range(0, flat_weight.size, 8):` This iterates start over 'range(0, flat_weight.size, 8)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_sgdw_update, which handles execute sgdw update.

Line 933: `stop = min(start + 8, flat_weight.size)` This assigns 'min(start + 8, flat_weight.size)' to 'stop ' in host memory. Here stop means the value named 'stop' in this block. The important operands are min: the value named 'min' in this block; start: the value named 'start' in this block; flat_weight: a learned coefficient multiplied by an activation. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 934: `active = stop - start` This assigns 'stop - start' to 'active ' in host memory. Here active means the value named 'active' in this block. The important operands are stop: the value named 'stop' in this block; start: the value named 'start' in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 936: `def padded(values):` This starts function padded. Its indented body performs padded as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 937: `return tuple(map(int, values)) + (0,) * (8 - active)` This returns 'tuple(map(int, values)) + (0,) * (8 - active)' to the caller of the function padded, which handles padded, ending this invocation. The important operands are tuple: the value named 'tuple' in this block; map: the value named 'map' in this block; values: the value named 'values' in this block.

Line 939: `words = driver.execute(` This statement continues through source line 948; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘driver.execute(command, pack_optimizer_beats(padded(flat_weight[start:stop]), padded(flat_gradient[start:stop]), padded(flat_velocity[start:stop]),), output_beats=8, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 940: `command,` This is continuation line 2 of the 10-line logical statement that begins at source line 939. Its exact fragment is ‘command,‘. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This assigns ‘driver.execute(command, pack_optimizer_beats(padded(flat_weight[start:stop]), padded(flat_gradient[start:stop]), padded(flat_velocity[start:stop]),), output_beats=8, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 941: `pack_optimizer_beats(` This is continuation line 3 of the 10-line logical statement that begins at source line 939. Its exact fragment is ‘pack_optimizer_beats(‘. The important operands are pack_optimizer_beats: the value named ’pack optimizer beats’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(command, pack_optimizer_beats(padded(flat_weight[start:stop]), padded(flat_gradient[start:stop]), padded(flat_velocity[start:stop]),), output_beats=8, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 942: `padded(flat_weight[start:stop]),` This is continuation line 4 of the 10-line logical statement that begins at source line 939. Its exact fragment is ‘padded(flat_weight[start:stop]),‘. The important operands are padded: the value named ’padded’ in this block; flat_weight: a learned coefficient multiplied by an activation; start: the value named ’start’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(command, pack_optimizer_beats(padded(flat_weight[start:stop]), padded(flat_gradient[start:stop]), padded(flat_velocity[start:stop]),), output_beats=8, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 943: `padded(flat_gradient[start:stop]),` This is continuation line 5 of the 10-line logical statement that begins at source line 939. Its exact fragment is ‘padded(flat_gradient[start:stop]),‘. The important operands are padded: the value named ’padded’ in this block; flat_gradient: the signed loss derivative used to update a learned parameter; start: the value named ’start’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(command, pack_optimizer_beats(padded(flat_weight[start:stop]), padded(flat_gradient[start:stop]), padded(flat_velocity[start:stop]),), output_beats=8, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 944: `padded(flat_velocity[start:stop]),` This is continuation line 6 of the 10-line logical statement that begins at source line 939. Its exact fragment is ‘padded(flat_velocity[start:stop]),‘. The important operands are padded: the value named ’padded’ in this block; flat_velocity: the momentum history retained by the SGD optimizer; start: the value named ’start’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(command, pack_optimizer_beats(padded(flat_weight[start:stop]), padded(flat_gradient[start:stop]), padded(flat_velocity[start:stop]),), output_beats=8, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 945: `),` This is continuation line 7 of the 10-line logical statement that begins at source line 939. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘driver.execute(command, pack_optimizer_beats(padded(flat_weight[start:stop]), padded(flat_gradient[start:stop]), padded(flat_velocity[start:stop]),), output_beats=8, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 946: `output_beats=8,` This is continuation line 8 of the 10-line logical statement that begins at source line 939. Its exact fragment is ‘output_beats=8,‘. The important operands are output_beats: the value named ’output beats’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(command, pack_optimizer_beats(padded(flat_weight[start:stop]), padded(flat_gradient[start:stop]), padded(flat_velocity[start:stop]),), output_beats=8, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 947: `timeout_seconds=timeout_seconds,` This is continuation line 9 of the 10-line logical statement that begins at source line 939. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(command, pack_optimizer_beats(padded(flat_weight[start:stop]), padded(flat_gradient[start:stop]), padded(flat_velocity[start:stop]),), output_beats=8, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 948: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 939. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘driver.execute(command, pack_optimizer_beats(padded(flat_weight[start:stop]), padded(flat_gradient[start:stop]), padded(flat_velocity[start:stop]),), output_beats=8, timeout_seconds=timeout_seconds,)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 949: `updated_weight, updated_velocity = unpack_optimizer_result(words)` This assigns ‘unpack_optimizer_result to ‘updated_weight, updated_velocity ‘ in host memory. Here updated_weight means a learned coefficient multiplied by an activation. The important operands are unpack_optimizer_result: the value named ’unpack optimizer result’ in this block; words: the value named ’words’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 950: `next_weight[start:stop] = updated_weight[:active]` This assigns ‘updated_weight[:active]‘ to ‘next_weight[sta in host memory. Here next_weight means a learned coefficient multiplied by an activation. The important operands are updated_weight: a learned coefficient multiplied by an activation; active: the value named ’active’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 951: `next_velocity[start:stop] = updated_velocity[:active]` This assigns ‘updated_velocity[:active]‘ to ‘next_velocity[start‘ in host memory. Here next_velocity means the momentum history retained by the SGD optimizer. The important operands are updated_velocity: the momentum history retained by the SGD optimizer; active: the value named ’active’ in this block. Context: the function execute_sgdw_update, which handles execute sgdw update.

Line 952: `return next_weight.reshape(weight.shape), next_velocity.reshape(weight.shape)` This returns ‘next_weight.reshape(weight.shape), next_velocity.reshape(weight.shape)‘ to the caller of the function execute_sgdw_update,

which handles execute sgdw update, ending this invocation. The important operands are next_weight: a learned coefficient multiplied by an activation; reshape: the value named 'reshape' in this block; weight: a learned coefficient multiplied by an activation.

Line 955: `def execute_int8_weight_projection(` This starts function execute_int8_weight_projection. Its indented body performs execute int8 weight projection as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 956: `driver: TrainingCommandExecutor,` Inside the function execute_int8_weight_projection, which handles execute int8 weight projection, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named 'driver' in this block; TrainingCommandExecutor: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 957: `master_weights,` Inside the function execute_int8_weight_projection, which handles execute int8 weight projection, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are master_weights: a learned coefficient multiplied by an activation.

Line 958: `*,` Inside the function execute_int8_weight_projection, which handles execute int8 weight projection, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 959: `timeout_seconds: float = 5.0,` This assigns ‘5.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 960: `) -> np.ndarray:` Inside the function execute_int8_weight_projection, which handles execute int8 weight projection, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are ndarray: the value named 'ndarray' in this block.

Line 961: `"""Clamp signed-s16 master weights to the deployed signed-int8 tensor."""` This is executable documentation attached to the function execute_int8_weight_projection, which handles execute int8 weight projection. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 963: `master = np.asarray(master_weights, dtype=np.int64)` This assigns ‘np.asarray(master_weights, dtype=np.int6
to ‘master ‘ in host memory. Here master means the value named 'master' in this block. The important operands are asarray: the value named 'asarray' in this block; master_weights: a learned coefficient multiplied by an activation; dtype: the value named 'dtype' in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 964: `if master.size == 0 or np.any(master < -(1 << 15)) or np.any(master > (1 << 15) - 1):` This executes the following indented host-code branch only when ‘master.size == 0 or np.any(master < -(1 << 15)) or np.any(master > (1 << 15) - 1)‘ is true. The important operands are master: the value named 'master' in this block; size: the value named 'size' in this block; or: the value named 'or' in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 965: `raise ValueError("master_weights must be a non-empty signed-16 tensor")` This rejects an invalid state by raising ‘ValueError("master_weights must be a non-empty signed-16 tensor")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 966: `flat = master.reshape(-1)` This assigns ‘master.reshape(-1)‘ to ‘flat ‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are master: the value named ’master’ in this block; reshape: the value named ’reshape’ in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 967: `result = np.zeros_like(flat)` This assigns ‘np.zeros_like(flat)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are zeros_like: the value named ’zeros like’ in this block; flat: the value named ’flat’ in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 968: `for start in range(0, flat.size, 8):` This iterates start over ‘range(0, flat.size, 8)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 969: `stop = min(start + 8, flat.size)` This assigns ‘min(start + 8, flat.size)‘ to ‘stop ‘ in host memory. Here stop means the value named ’stop’ in this block. The important operands are min: the value named ’min’ in this block; start: the value named ’start’ in this block; flat: the value named ’flat’ in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 970: `active = stop - start` This assigns ‘stop - start‘ to ‘active ‘ in host memory. Here active means the value named ’active’ in this block. The important operands are stop: the value named ’stop’ in this block; start: the value named ’start’ in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 971: `operand = tuple(map(int, flat[start:stop])) + (0,) * (8 - active)` This assigns ‘tuple(map(int, flat[start:stop])) + (0,) * (8 - active)‘ to ‘operand ‘ in host memory. Here operand means the value named ’operand’ in this block. The important operands are tuple: the value named ’tuple’ in this block; map: the value named ’map’ in this block; flat: the value named ’flat’ in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 972: `clamped = _execute_vector8(` This statement continues through source line 980; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_execute_vector8(driver, VectorOperation.CLAMP, operand, (0,) * 8, timeout_seconds=timeout_seconds, clamp_minimum=-128, clamp_maximum=127,)‘ to ‘clamped ‘ in host memory. Here clamped means the value named ’clamped’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 973: `driver,` This is continuation line 2 of the 9-line logical statement that begins at source line 972. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.CLAMP, operand, (0,) * 8, timeout_seconds=timeout_seconds, clamp_minimum=-128, clamp_maximum=127,)‘ to ‘clamped ‘ in host memory. Here clamped means the value named ’clamped’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 974: `VectorOperation.CLAMP,` This is continuation line 3 of the 9-line logical statement that begins at source line 972. Its exact fragment is ‘VectorOperation.CLAMP,‘. The important operands are VectorOperation: the value named ’vector operation’ in this block; CLAMP: the value named ’clamp’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.CLAMP, operand, (0,) * 8, timeout_seconds=timeout_seconds, clamp_minimum=-128, clamp_maximum=127,)‘ to ‘clamped ‘ in host memory. Here clamped means the value named ’clamped’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 975: `operand,` This is continuation line 4 of the 9-line logical statement that begins at source line 972. Its exact fragment is 'operand,'. The important operands are operand: the value named 'operand' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.CLAMP, operand, (0,) * 8, timeout_seconds=timeout_seconds, clamp_minimum=-128, clamp_maximum=127,)' to 'clamped ' in host memory. Here clamped means the value named 'clamped' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 976: `(0,) * 8,` This is continuation line 5 of the 9-line logical statement that begins at source line 972. Its exact fragment is '(0,) * 8,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.CLAMP, operand, (0,) * 8, timeout_seconds=timeout_seconds, clamp_minimum=-128, clamp_maximum=127,)' to 'clamped ' in host memory. Here clamped means the value named 'clamped' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 977: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 9-line logical statement that begins at source line 972. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.CLAMP, operand, (0,) * 8, timeout_seconds=timeout_seconds, clamp_minimum=-128, clamp_maximum=127,)' to 'clamped ' in host memory. Here clamped means the value named 'clamped' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 978: `clamp_minimum=-128,` This is continuation line 7 of the 9-line logical statement that begins at source line 972. Its exact fragment is 'clamp_minimum=-128,'. The important operands are clamp_minimum: the value named 'clamp minimum' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.CLAMP, operand, (0,) * 8, timeout_seconds=timeout_seconds, clamp_minimum=-128, clamp_maximum=127,)' to 'clamped ' in host memory. Here clamped means the value named 'clamped' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 979: `clamp_maximum=127,` This is continuation line 8 of the 9-line logical statement that begins at source line 972. Its exact fragment is 'clamp_maximum=127,'. The important operands are clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.CLAMP, operand, (0,) * 8, timeout_seconds=timeout_seconds, clamp_minimum=-128, clamp_maximum=127,)' to 'clamped ' in host memory. Here clamped means the value named 'clamped' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 980: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 972. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.CLAMP, operand, (0,) * 8, timeout_seconds=timeout_seconds, clamp_minimum=-128, clamp_maximum=127,)' to 'clamped ' in host memory. Here clamped means the value named 'clamped' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 981: `result[start:stop] = clamped[:active]` This assigns 'clamped[:active]' to 'result[start' in host memory. Here result means the value named 'result' in this block. The important operands are clamped: the value named 'clamped'

in this block; active: the value named 'active' in this block. Context: the function execute_int8_weight_projection, which handles execute int8 weight projection.

Line 982: `return result.reshape(master.shape).astype(np.int8)` This returns 'result.reshape(master.shape).astype(np.int to the caller of the function execute_int8_weight_projection, which handles execute int8 weight projection, ending this invocation. The important operands are result: the value named 'result' in this block; reshape: the value named 'reshape' in this block; master: the value named 'master' in this block.

Line 985: `def execute_lif_bptt(` This starts function execute_lif_bptt. Its indented body performs execute lif bptt as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 986: `driver: TrainingCommandExecutor,` Inside the function execute_lif_bptt, which handles execute lif bptt, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named 'driver' in this block; TrainingCommandExecutor: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 987: `pre_reset_membrane,` Inside the function execute_lif_bptt, which handles execute lif bptt, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps.

Line 988: `spikes,` Inside the function execute_lif_bptt, which handles execute lif bptt, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are spikes: a binary event produced when a neuron crosses its threshold.

Line 989: `spike_gradients,` Inside the function execute_lif_bptt, which handles execute lif bptt, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are spike_gradients: a binary event produced when a neuron crosses its threshold.

Line 990: `*,` Inside the function execute_lif_bptt, which handles execute lif bptt, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 991: `threshold: int,` Inside the function execute_lif_bptt, which handles execute lif bptt, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are threshold: the membrane level at which a neuron emits a spike.

Line 992: `membrane_gradients=None,` This assigns 'None,' to 'membrane_gradients' in host memory. Here membrane_gradients means the persistent LIF neuron state carrying charge between timesteps. The important operands are None: the value named 'none' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 993: `reciprocal_tau_q15: int = 1 << 14,` This assigns '1 << 14,' to 'reciprocal_tau_q15' in host memory. Here reciprocal_tau_q15 means the value named 'reciprocal tau q15' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 994: `surrogate_table_q15=None,` This assigns 'None,' to 'surrogate_table_q15' in host memory. Here surrogate_table_q15 means the value named 'surrogate table q15' in this block. The important operands are None: the value named 'none' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 995: `surrogate_address_shift: int = 5,` This assigns ‘5,‘ to ‘surrogate_address_shift‘ in host memory. Here surrogate_address_shift means the value named ’surrogate address shift’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 996: `load_surrogate_table: bool = True,` This assigns ‘True,‘ to ‘load_surrogate_table‘ in host memory. Here load_surrogate_table means the value named ’load surrogate table’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 997: `timeout_seconds: float = 5.0,` This assigns ‘5.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 998: `) -> tuple[np.ndarray, np.ndarray]:` Inside the function execute_lif_bptt, which handles execute lif bptt, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named ’tuple’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 999: `"""Execute detached-reset hard-LIF BPTT entirely through fabric operators."""` This is executable documentation attached to the function execute_lif_bptt, which handles execute lif bptt. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1001: `membrane = np.asarray(pre_reset_membrane, dtype=np.int64)` This assigns ‘np.asarray(pre_reset_membrane, dtype=np.int64)‘ to ‘membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are asarray: the value named ’asarray’ in this block; pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; dtype: the value named ’dtype’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1002: `spike = np.asarray(spikes, dtype=np.int64)` This assigns ‘np.asarray(spikes, dtype=np.int64)‘ to ‘spike ‘ in host memory. Here spike means a binary event produced when a neuron crosses its threshold. The important operands are asarray: the value named ’asarray’ in this block; spikes: a binary event produced when a neuron crosses its threshold; dtype: the value named ’dtype’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1003: `grad_spike = np.asarray(spike_gradients, dtype=np.int64)` This assigns ‘np.asarray(spike_gradients, dtype=np.int64)‘ to ‘grad_spike ‘ in host memory. Here grad_spike means a binary event produced when a neuron crosses its threshold. The important operands are asarray: the value named ’asarray’ in this block; spike_gradients: a binary event produced when a neuron crosses its threshold; dtype: the value named ’dtype’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1004: `if membrane.ndim != 2 or spike.shape != membrane.shape or grad_spike.shape != membrane.shape:` This executes the following indented host-code branch only when ‘membrane.ndim != 2 or spike.shape != membrane.shape or grad_spike.shape != membrane.shape‘ is true. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1005: `raise ValueError("LIF trace, spike, and gradient arrays must share shape [time, neurons]")` This rejects an invalid state by raising ‘ValueError("LIF trace, spike, and gradient arrays must share shape [time, neurons]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1006: `if membrane_gradients is None:` This executes the following indented host-code branch only when ‘membrane_gradients is None‘ is true. The important operands are membrane_gradients: the persistent LIF neuron state carrying charge between timesteps; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1007: `grad_v = np.zeros_like(membrane)` This assigns ‘np.zeros_like(membrane)‘ to ‘grad_v ‘ in host memory. Here grad_v means the value named ’grad v’ in this block. The important operands are zeros_like: the value named ’zeros like’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1008: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute_lif_bptt, which handles execute lif bptt.

Line 1009: `grad_v = np.asarray(membrane_gradients, dtype=np.int64)` This assigns ‘np.asarray(membrane_gradients, dtype=np.int64)‘ to ‘grad_v ‘ in host memory. Here grad_v means the value named ’grad v’ in this block. The important operands are asarray: the value named ’asarray’ in this block; membrane_gradients: the persistent LIF neuron state carrying charge between timesteps; dtype: the value named ’dtype’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1010: `if grad_v.shape != membrane.shape:` This executes the following indented host-code branch only when ‘grad_v.shape != membrane.shape‘ is true. The important operands are grad_v: the value named ’grad v’ in this block; shape: the value named ’shape’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1011: `raise ValueError("membrane gradients must match the LIF trace shape")` This rejects an invalid state by raising ‘ValueError("membrane gradients must match the LIF trace shape")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1012: `if surrogate_table_q15 is None:` This executes the following indented host-code branch only when ‘surrogate_table_q15 is None‘ is true. The important operands are surrogate_table_q15: the value named ’surrogate table q15’ in this block; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1013: `surrogate_table_q15, _ = sigmoid_surrogate_lut_q15(` This statement continues through source line 1015; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘sigmoid_surrogate_lut_q15(address_shift=surrogate_address_shift)‘ to ‘surrogate_table_q15, _ ‘ in host memory. Here surrogate_table_q15 means the value named ’surrogate table q15’ in this block. The important operands are sigmoid_surrogate_lut_q15: the value named ’sigmoid surrogate lut q15’ in this block; address_shift: the value named ’address shift’ in this block; surrogate_address_shift: the value named ’surrogate address shift’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1014: `address_shift=surrogate_address_shift` This is continuation line 2 of the 3-line logical statement that begins at source line 1013. Its exact fragment is ‘address_shift=surrogate_address_shift‘. The important operands are address_shift: the value named ’address shift’ in this block; surrogate_address_shift: the value named ’surrogate address shift’ in this block. Read together, the complete operation is: This assigns ‘sigmoid_surrogate_lut_q15(address_shift=surrogate_address_shift)‘ to ‘surrogate_table_q15, _ ‘ in host memory. Here surrogate_table_q15 means the value named ’surrogate table q15’ in this block. The important operands are sigmoid_surrogate_lut_q15: the value named ’sigmoid surrogate lut q15’ in this block; address_shift: the value named ’address shift’ in this block; surrogate_address_shift: the value named ’surrogate address shift’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1015: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 1013. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘sigmoid_surrogate_lut_q15(address_shift=surrogate_address_shift)‘ to ‘surrogate_table_q15, _ ‘ in host memory. Here surrogate_table_q15 means the value named ’surrogate table q15’ in this block. The important operands are sigmoid_surrogate_lut_q15: the value named ’sigmoid surrogate lut q15’ in this block; address_shift: the value named ’address shift’ in this block; surrogate_address_shift: the value named ’surrogate address shift’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1016: `table = np.asarray(surrogate_table_q15, dtype=np.int64)` This assigns ‘np.asarray(surrogate_table_q15, dtype=np.int64)‘ to ‘table ‘ in host memory. Here table means the value named ’table’ in this block. The important operands are asarray: the value named ’asarray’ in this block; surrogate_table_q15: the value named ’surrogate table q15’ in this block; dtype: the value named ’dtype’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1017: `if table.shape != (256,):` This executes the following indented host-code branch only when ‘table.shape != (256,)‘ is true. The important operands are table: the value named ’table’ in this block; shape: the value named ’shape’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1018: `raise ValueError("surrogate table must contain exactly 256 entries")` This rejects an invalid state by raising ‘ValueError("surrogate table must contain exactly 256 entries")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1019: `if load_surrogate_table:` This executes the following indented host-code branch only when ‘load_surrogate_table‘ is true. The important operands are load_surrogate_table: the value named ’load surrogate table’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1020: `load_words = driver.execute(` This statement continues through source line 1026; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘driver.execute(lut_command(LutSuboperation.LOA 256), pack_lut_load_beats(tuple((address, int(table[address])) for address in range(256))), output_beats=0, timeout_seconds=timeout_seconds,)‘ to ‘load_words ‘ in host memory. Here load_words means the value named ’load words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1021: `lut_command(LutSuboperation.LOAD, 256),` This is continuation line 2 of the 7-line logical statement that begins at source line 1020. Its exact fragment is ‘lut_command(LutSuboperation.LOAD, 256),‘. The important operands are lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; LutSuboperation: the value named ’lut suboperation’ in this block; LOAD: the value named ’load’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(lut_command(LutSuboperation.LOAD, 256), pack_lut_load_beats(tuple((address, int(table[address])) for address in range(256))), output_beats=0, timeout_seconds=timeout_seconds,)‘ to ‘load_words ‘ in host memory. Here load_words means the value named ’load words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1022: `pack_lut_load_beats(` This is continuation line 3 of the 7-line logical statement that begins at source line 1020. Its exact fragment is ‘pack_lut_load_beats(‘. The important operands are pack_lut_load_beats: the value named ’pack lut load beats’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(lut_command(LutSuboperation.LOAD, 256), pack_lut_load_beats(tuple((address, int(table[address])) for address in range(256))), output_beats=0, timeout_seconds=timeout_seconds,)‘ to ‘load_words ‘ in host memory. Here load_words means the value named ’load words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1023: `tuple((address, int(table[address])) for address in range(256))),` This is continuation line 4 of the 7-line logical statement that begins at source line 1020. Its exact fragment is ‘tuple((address, int(table[address])) for address in range(256))),‘. The important operands are tuple: the value named ’tuple’ in this block; address: the value named ’address’ in this block; table: the value named ’table’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(lut_command(LutSuboperation.LOAD, 256), pack_lut_load_beats(tuple((address, int(table[address])) for address in range(256))), output_beats=0, timeout_seconds=timeout_seconds,)‘ to ‘load_words ‘ in host memory. Here load_words means the value named ’load words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1024: `output_beats=0,` This is continuation line 5 of the 7-line logical statement that begins at source line 1020. Its exact fragment is 'output_beats=0,'. The important operands are output_beats: the value named 'output beats' in this block. Read together, the complete operation is: This assigns 'driver.execute(lut_command(LutSuboperation.LOAD, 256), pack_lut_load_beats(tuple((address, int(table[address])) for address in range(256))), output_beats=0, timeout_seconds=timeout_seconds,)' to 'load_words ' in host memory. Here load_words means the value named 'load words' in this block. The important operands are driver: the value named 'driver' in this block; execute: the value named 'execute' in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1025: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1020. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'driver.execute(lut_command(LutSuboperation.LOAD, 256), pack_lut_load_beats(tuple((address, int(table[address])) for address in range(256))), output_beats=0, timeout_seconds=timeout_seconds,)' to 'load_words ' in host memory. Here load_words means the value named 'load words' in this block. The important operands are driver: the value named 'driver' in this block; execute: the value named 'execute' in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1026: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1020. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'driver.execute(lut_command(LutSuboperation.LOAD, 256), pack_lut_load_beats(tuple((address, int(table[address])) for address in range(256))), output_beats=0, timeout_seconds=timeout_seconds,)' to 'load_words ' in host memory. Here load_words means the value named 'load words' in this block. The important operands are driver: the value named 'driver' in this block; execute: the value named 'execute' in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1027: `if load_words:` This executes the following indented host-code branch only when 'load_words' is true. The important operands are load_words: the value named 'load words' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1028: `raise RuntimeError("LUT load unexpectedly returned stream data")` This rejects an invalid state by raising 'RuntimeError("LUT load unexpectedly returned stream data")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1030: `addresses = surrogate_lut_addresses(membrane, threshold, surrogate_address_shift)` This assigns 'surrogate_lut_addresses(membrane, threshold, surrogate_address_shift)' to 'addresses ' in host memory. Here addresses means the value named 'addresses' in this block. The important operands are surrogate_lut_addresses: the value named 'surrogate lut addresses' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; threshold: the membrane level at which a neuron emits a spike. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1031: `time_steps, neurons = membrane.shape` This assigns 'membrane.shape' to 'time_steps, neurons ' in host memory. Here time_steps means the value named 'time steps' in this block. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps; shape: the value named 'shape' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1032: `grad_input = np.zeros_like(membrane)` This assigns 'np.zeros_like(membrane)' to 'grad_input ' in host memory. Here grad_input means the value named 'grad input' in this block. The important operands are zeros_like: the value named 'zeros like' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1033: `grad_h_trace = np.zeros_like(membrane)` This assigns 'np.zeros_like(membrane)' to 'grad_h_trace ' in host memory. Here grad_h_trace means the value named 'grad h trace' in this block. The important operands

are zeros_like: the value named 'zeros like' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1034: `grad_h_next = np.zeros(neurons, dtype=np.int64)` This assigns 'np.zeros(neurons, dtype=np.int64)' to 'grad_h_next ' in host memory. Here grad_h_next means the value named 'grad h next' in this block. The important operands are zeros: the value named 'zeros' in this block; neurons: the value named 'neurons' in this block; dtype: the value named 'dtype' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1035: `leak_q15 = (1 << 15) - int(reciprocal_tau_q15)` This assigns '(1 << 15) - int(reciprocal_tau_q15)' to 'leak_q15 ' in host memory. Here leak_q15 means the retained fraction of prior membrane state. The important operands are reciprocal_tau_q15: the value named 'reciprocal tau q15' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1036: `for timestep in range(time_steps - 1, -1, -1):` This iterates timestep over 'range(time_steps - 1, -1, -1)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_lif_bptt, which handles execute lif bptt.

Line 1037: `for start in range(0, neurons, 8):` This iterates start over 'range(0, neurons, 8)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_lif_bptt, which handles execute lif bptt.

Line 1038: `stop = min(start + 8, neurons)` This assigns 'min(start + 8, neurons)' to 'stop ' in host memory. Here stop means the value named 'stop' in this block. The important operands are min: the value named 'min' in this block; start: the value named 'start' in this block; neurons: the value named 'neurons' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1039: `active = stop - start` This assigns 'stop - start' to 'active ' in host memory. Here active means the value named 'active' in this block. The important operands are stop: the value named 'stop' in this block; start: the value named 'start' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1041: `def padded(values, fill=0):` This starts function padded. Its indented body performs padded as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 1042: `return tuple(map(int, values)) + (fill,) * (8 - active)` This returns 'tuple(map(int, values)) + (fill,) * (8 - active)' to the caller of the function padded, which handles padded, ending this invocation. The important operands are tuple: the value named 'tuple' in this block; map: the value named 'map' in this block; values: the value named 'values' in this block.

Line 1044: `temporal = _execute_vector8(` This statement continues through source line 1050; the explanation uses the complete expression rather than only the first visual fragment. This assigns '_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_h_next[start:stop]), (leak_q15,) * 8, timeout_seconds=timeout_seconds,)' to 'temporal ' in host memory. Here temporal means the value named 'temporal' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1045: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1044. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_h_next[start:stop]), (leak_q15,) * 8, timeout_seconds=timeout_seconds,)' to 'temporal ' in host memory. Here temporal means the value named 'temporal' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1046: `VectorOperation.MULTIPLY_Q15,` This is continuation line 3 of the 7-line logical statement that begins at source line 1044. Its exact fragment is 'VectorOperation.MULTIPLY_Q15,'. The important operands are VectorOperation: the value named 'vector operation' in this block; MULTIPLY_Q15: the value named 'multiply q15' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_h_next[start:stop]), (leak_q15,) * 8, timeout_seconds=timeout_seconds,)' to 'temporal ' in host memory. Here temporal means the value named 'temporal' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1047: `padded(grad_h_next[start:stop]),` This is continuation line 4 of the 7-line logical statement that begins at source line 1044. Its exact fragment is 'padded(grad_h_next[start:stop]),'. The important operands are padded: the value named 'padded' in this block; grad_h_next: the value named 'grad h next' in this block; start: the value named 'start' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_h_next[start:stop]), (leak_q15,) * 8, timeout_seconds=timeout_seconds,)' to 'temporal ' in host memory. Here temporal means the value named 'temporal' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1048: `(leak_q15,) * 8,` This is continuation line 5 of the 7-line logical statement that begins at source line 1044. Its exact fragment is '(leak_q15,) * 8,'. The important operands are leak_q15: the retained fraction of prior membrane state. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_h_next[start:stop]), (leak_q15,) * 8, timeout_seconds=timeout_seconds,)' to 'temporal ' in host memory. Here temporal means the value named 'temporal' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1049: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1044. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_h_next[start:stop]), (leak_q15,) * 8, timeout_seconds=timeout_seconds,)' to 'temporal ' in host memory. Here temporal means the value named 'temporal' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1050: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1044. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_h_next[start:stop]), (leak_q15,) * 8, timeout_seconds=timeout_seconds,)' to 'temporal ' in host memory. Here temporal means the value named 'temporal' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1051: `membrane_path = _execute_vector8(` This statement continues through source line 1057; the explanation uses the complete expression rather than only the first visual fragment. This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, padded(grad_v[timestep, start:stop]), temporal, timeout_seconds=timeout_seconds,)' to 'membrane_path ' in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1052: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1051. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, padded(grad_v[timestep,

start:stop]), temporal, timeout_seconds=timeout_seconds,)‘ to ‘membrane_path ‘ in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1053: `VectorOperation.ADD_SAT,` This is continuation line 3 of the 7-line logical statement that begins at source line 1051. Its exact fragment is ‘VectorOperation.ADD_SAT,‘. The important operands are VectorOperation: the value named ’vector operation’ in this block; ADD_SAT: the value named ’add sat’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.ADD_SAT, padded(grad_v[timestep, start:stop]), temporal, timeout_seconds=timeout_seconds,)‘ to ‘membrane_path ‘ in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1054: `padded(grad_v[timestep, start:stop]),` This is continuation line 4 of the 7-line logical statement that begins at source line 1051. Its exact fragment is ‘padded(grad_v[timestep, start:stop]),‘. The important operands are padded: the value named ’padded’ in this block; grad_v: the value named ’grad v’ in this block; timestep: one discrete SNN update instant. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.ADD_SAT, padded(grad_v[timestep, start:stop]), temporal, timeout_seconds=timeout_seconds,)‘ to ‘membrane_path ‘ in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1055: `temporal,` This is continuation line 5 of the 7-line logical statement that begins at source line 1051. Its exact fragment is ‘temporal,‘. The important operands are temporal: the value named ’temporal’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.ADD_SAT, padded(grad_v[timestep, start:stop]), temporal, timeout_seconds=timeout_seconds,)‘ to ‘membrane_path ‘ in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1056: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1051. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.ADD_SAT, padded(grad_v[timestep, start:stop]), temporal, timeout_seconds=timeout_seconds,)‘ to ‘membrane_path ‘ in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1057: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1051. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.ADD_SAT, padded(grad_v[timestep, start:stop]), temporal, timeout_seconds=timeout_seconds,)‘ to ‘membrane_path ‘ in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1058: `membrane_path = _execute_vector8(` This statement continues through source line 1064; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_execute_vector8(driver, VectorOperation.SELECT_ZERO, padded(spike[timestep, start:stop]), membrane_path, timeout_seconds=timeout_seconds,)‘ to ‘membrane_path ‘ in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1059: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1058. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.SELECT_ZERO, padded(spike[timestep, start:stop]), membrane_path, timeout_seconds=timeout_seconds,)' to 'membrane_path ' in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1060: `VectorOperation.SELECT_ZERO,` This is continuation line 3 of the 7-line logical statement that begins at source line 1058. Its exact fragment is 'VectorOperation.SELECT_ZERO,'. The important operands are VectorOperation: the value named 'vector operation' in this block; SELECT_ZERO: the value named 'select zero' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.SELECT_ZERO, padded(spike[timestep, start:stop]), membrane_path, timeout_seconds=timeout_seconds,)' to 'membrane_path ' in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1061: `padded(spike[timestep, start:stop]),` This is continuation line 4 of the 7-line logical statement that begins at source line 1058. Its exact fragment is 'padded(spike[timestep, start:stop]),'. The important operands are padded: the value named 'padded' in this block; spike: a binary event produced when a neuron crosses its threshold; timestep: one discrete SNN update instant. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.SELECT_ZERO, padded(spike[timestep, start:stop]), membrane_path, timeout_seconds=timeout_seconds,)' to 'membrane_path ' in host memory. Here membrane_path means the persistent LIF neuron state carrying charge between timesteps. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1065: `lut_words = driver.execute(` This statement continues through source line 1070; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘driver.execute(lut_command(LutSuboperation.EVA 8), pack_lut_eval_beat(padded(addresses[timestep, start:stop], 128)), output_beats=2, timeout_seconds=timeout_seconds,)‘ to ‘lut_words ‘ in host memory. Here lut_words means the value named ’lut words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1066: `lut_command(LutSuboperation.EVALUATE, 8),` This is continuation line 2 of the 6-line logical statement that begins at source line 1065. Its exact fragment is ‘lut_command(LutSuboperation.EVALUATE, 8),‘. The important operands are lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; LutSuboperation: the value named ’lut suboperation’ in this block; EVALUATE: the value named ’evaluate’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(lut_command(LutSuboperation.EVALUATE, 8), pack_lut_eval_beat(padded(addresses[timestep, start:stop], 128)), output_beats=2, timeout_seconds=timeout_seconds,)‘ to ‘lut_words ‘ in host memory. Here lut_words means the value named ’lut words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1067: `pack_lut_eval_beat(padded(addresses[timestep, start:stop], 128)),` This is continuation line 3 of the 6-line logical statement that begins at source line 1065. Its exact fragment is ‘pack_lut_eval_beat(padded(addresses[timestep, start:stop], 128)),‘. The important operands are pack_lut_eval_beat: the value named ’pack lut eval beat’ in this block; padded: the value named ’padded’ in this block; addresses: the value named ’addresses’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(lut_command(LutSuboperation.EVALUATE, 8), pack_lut_eval_beat(padded(addresses[timestep, start:stop], 128)), output_beats=2, timeout_seconds=timeout_seconds,)‘ to ‘lut_words ‘ in host memory. Here lut_words means the value named ’lut words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1068: `output_beats=2,` This is continuation line 4 of the 6-line logical statement that begins at source line 1065. Its exact fragment is ‘output_beats=2,‘. The important operands are output_beats: the value named ’output beats’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(lut_command(LutSuboperation.EVALUATE, 8), pack_lut_eval_beat(padded(addresses[timestep, start:stop], 128)), output_beats=2, timeout_seconds=timeout_seconds,)‘ to ‘lut_words ‘ in host memory. Here lut_words means the value named ’lut words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1069: `timeout_seconds=timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 1065. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘driver.execute(lut_command(LutSuboperation.EVALUATE, 8), pack_lut_eval_beat(padded(addresses[timestep, start:stop], 128)), output_beats=2, timeout_seconds=timeout_seconds,)‘ to ‘lut_words ‘ in host memory. Here lut_words means the value named ’lut words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1070: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1065. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘driver.execute(lut_command(LutSuboperation.EVALUATE, 8), pack_lut_eval_beat(padded(addresses[time start:stop], 128)), output_beats=2, timeout_seconds=timeout_seconds,)‘ to ‘lut_words ‘ in host memory. Here lut_words means the value named ’lut words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute: the value named ’execute’ in this block; lut_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1071: `derivative = np.asarray(unpack_lut_result(lut_words), dtype=np.int64)` This assigns ‘np.asarray(unpack_ dtype=np.int64)‘ to ‘derivative ‘ in host memory. Here derivative means the value named ’derivative’ in this block. The important operands are asarray: the value named ’asarray’ in this block; unpack_lut_result: the value named ’unpack lut result’ in this block; lut_words: the value named ’lut words’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1072: `spike_path = _execute_vector8(` This statement continues through source line 1078; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_spike[timestep, start:stop]), derivative, timeout_seconds=timeout_seconds,)‘ to ‘spike_path ‘ in host memory. Here spike_path means a binary event produced when a neuron crosses its threshold. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1073: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1072. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_spike[timestep, start:stop]), derivative, timeout_seconds=timeout_seconds,)‘ to ‘spike_path ‘ in host memory. Here spike_path means a binary event produced when a neuron crosses its threshold. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1074: `VectorOperation.MULTIPLY_Q15,` This is continuation line 3 of the 7-line logical statement that begins at source line 1072. Its exact fragment is ‘VectorOperation.MULTIPLY_Q15,‘. The important operands are VectorOperation: the value named ’vector operation’ in this block; MULTIPLY_Q15: the value named ’multiply q15’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_spike[timestep, start:stop]), derivative, timeout_seconds=timeout_seconds,)‘ to ‘spike_path ‘ in host memory. Here spike_path means a binary event produced when a neuron crosses its threshold. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1075: `padded(grad_spike[timestep, start:stop]),` This is continuation line 4 of the 7-line logical statement that begins at source line 1072. Its exact fragment is ‘padded(grad_spike[timestep, start:stop]),‘. The important operands are padded: the value named ’padded’ in this block; grad_spike: a binary event produced when a neuron crosses its threshold; timestep: one discrete SNN update instant. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_spike[timestep, start:stop]), derivative, timeout_seconds=timeout_seconds,)‘ to ‘spike_path ‘ in host memory. Here spike_path means a binary event produced when a neuron crosses its threshold. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1076: `derivative,` This is continuation line 5 of the 7-line logical statement that begins at source line 1072. Its exact fragment is ‘derivative,‘. The important operands are derivative: the value named ’derivative’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_spike[timestep, start:stop]), derivative, timeout_seconds=timeout_seconds,)‘ to ‘spike_path ‘ in host memory. Here spike_path means a binary event produced when a neuron crosses its threshold. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1077: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1072. Its exact fragment is ‘timeout_seconds=timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_spike[timestep, start:stop]), derivative, timeout_seconds=timeout_seconds,)‘ to ‘spike_path ‘ in host memory. Here spike_path means a binary event

produced when a neuron crosses its threshold. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1078: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1072. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, padded(grad_spike[timestep, start:stop]), derivative, timeout_seconds=timeout_seconds,)' to 'spike_path ' in host memory. Here spike_path means a binary event produced when a neuron crosses its threshold. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1079: `grad_h = _execute_vector8(` This statement continues through source line 1085; the explanation uses the complete expression rather than only the first visual fragment. This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, membrane_path, spike_path, timeout_seconds=timeout_seconds,)' to 'grad_h ' in host memory. Here grad_h means the value named 'grad h' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1080: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1079. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, membrane_path, spike_path, timeout_seconds=timeout_seconds,)' to 'grad_h ' in host memory. Here grad_h means the value named 'grad h' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1081: `VectorOperation.ADD_SAT,` This is continuation line 3 of the 7-line logical statement that begins at source line 1079. Its exact fragment is 'VectorOperation.ADD_SAT,'. The important operands are VectorOperation: the value named 'vector operation' in this block; ADD_SAT: the value named 'add sat' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, membrane_path, spike_path, timeout_seconds=timeout_seconds,)' to 'grad_h ' in host memory. Here grad_h means the value named 'grad h' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1082: `membrane_path,` This is continuation line 4 of the 7-line logical statement that begins at source line 1079. Its exact fragment is 'membrane_path,'. The important operands are membrane_path: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, membrane_path, spike_path, timeout_seconds=timeout_seconds,)' to 'grad_h ' in host memory. Here grad_h means the value named 'grad h' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1083: `spike_path,` This is continuation line 5 of the 7-line logical statement that begins at source line 1079. Its exact fragment is 'spike_path,'. The important operands are spike_path: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, membrane_path, spike_path, timeout_seconds=timeout_seconds,)' to 'grad_h ' in host memory. Here grad_h means the value named 'grad h' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1084: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1079. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, membrane_path, spike_path, timeout_seconds=timeout_seconds,

)‘ to ‘grad_h ‘ in host memory. Here grad_h means the value named ’grad h’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1085: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1079. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.ADD_SAT, membrane_path, spike_path, timeout_seconds=timeout_seconds,)‘ to ‘grad_h ‘ in host memory. Here grad_h means the value named ’grad h’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1086: `input_chunk = _execute_vector8(` This statement continues through source line 1092; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, grad_h, (int(reciprocal_tau_q15),) * 8, timeout_seconds=timeout_seconds,)‘ to ‘input_chunk ‘ in host memory. Here input_chunk means the value named ’input chunk’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1087: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1086. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, grad_h, (int(reciprocal_tau_q15),) * 8, timeout_seconds=timeout_seconds,)‘ to ‘input_chunk ‘ in host memory. Here input_chunk means the value named ’input chunk’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1088: `VectorOperation.MULTIPLY_Q15,` This is continuation line 3 of the 7-line logical statement that begins at source line 1086. Its exact fragment is ‘VectorOperation.MULTIPLY_Q15,‘. The important operands are VectorOperation: the value named ’vector operation’ in this block; MULTIPLY_Q15: the value named ’multiply q15’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, grad_h, (int(reciprocal_tau_q15),) * 8, timeout_seconds=timeout_seconds,)‘ to ‘input_chunk ‘ in host memory. Here input_chunk means the value named ’input chunk’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1089: `grad_h,` This is continuation line 4 of the 7-line logical statement that begins at source line 1086. Its exact fragment is ‘grad_h,‘. The important operands are grad_h: the value named ’grad h’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, grad_h, (int(reciprocal_tau_q15),) * 8, timeout_seconds=timeout_seconds,)‘ to ‘input_chunk ‘ in host memory. Here input_chunk means the value named ’input chunk’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1090: `(int(reciprocal_tau_q15),) * 8,` This is continuation line 5 of the 7-line logical statement that begins at source line 1086. Its exact fragment is ‘(int(reciprocal_tau_q15),) * 8,‘. The important operands are reciprocal_tau_q15: the value named ’reciprocal tau q15’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, grad_h, (int(reciprocal_tau_q15),) * 8, timeout_seconds=timeout_seconds,)‘ to ‘input_chunk ‘ in host memory. Here input_chunk means the value named ’input chunk’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1091: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1086. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, grad_h, (int(reciprocal_tau_q15),) * 8, timeout_seconds=timeout_seconds,)' to 'input_chunk ' in host memory. Here input_chunk means the value named 'input chunk' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1092: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1086. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MULTIPLY_Q15, grad_h, (int(reciprocal_tau_q15),) * 8, timeout_seconds=timeout_seconds,)' to 'input_chunk ' in host memory. Here input_chunk means the value named 'input chunk' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1093: `grad_h_trace[timestep, start:stop] = grad_h[:active]` This assigns 'grad_h[:active]' to 'grad_h_trace[timest start' in host memory. Here grad_h_trace means the value named 'grad h trace' in this block. The important operands are grad_h: the value named 'grad h' in this block; active: the value named 'active' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1094: `grad_input[timestep, start:stop] = input_chunk[:active]` This assigns 'input_chunk[:active]' to 'grad_input[timestep, start' in host memory. Here grad_input means the value named 'grad input' in this block. The important operands are input_chunk: the value named 'input chunk' in this block; active: the value named 'active' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1095: `grad_h_next = grad_h_trace[timestep].copy()` This assigns 'grad_h_trace[timestep].copy()' to 'grad_h_next ' in host memory. Here grad_h_next means the value named 'grad h next' in this block. The important operands are grad_h_trace: the value named 'grad h trace' in this block; timestep: one discrete SNN update instant; copy: the value named 'copy' in this block. Context: the function execute_lif_bptt, which handles execute lif bptt.

Line 1096: `return grad_input, grad_h_trace` This returns 'grad_input, grad_h_trace' to the caller of the function execute_lif_bptt, which handles execute lif bptt, ending this invocation. The important operands are grad_input: the value named 'grad input' in this block; grad_h_trace: the value named 'grad h trace' in this block.

Line 1099: `def _pair(name:  str, value) -> tuple[int, int]:` This starts function _pair. Its indented body performs pair as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 1100: `if isinstance(value, int):` This executes the following indented host-code branch only when 'isinstance(value, int)' is true. The important operands are isinstance: the value named 'isinstance' in this block; value: the value named 'value' in this block. Context: the function _pair, which handles pair.

Line 1101: `result = (int(value), int(value))` This assigns '(int(value), int(value))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are value: the value named 'value' in this block. Context: the function _pair, which handles pair.

Line 1102: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function _pair, which handles pair.

Line 1103: `result = tuple(map(int, value))` This assigns 'tuple(map(int, value))' to 'result ' in host memory. Here result means the value named 'result' in this block. The important operands are tuple: the value named 'tuple' in this block; map: the value named 'map' in this block; value: the value named 'value' in this block. Context: the function _pair, which handles pair.

Line 1104: `if len(result) != 2:` This executes the following indented host-code branch only when ‘len(result) != 2‘ is true. The important operands are len: the value named ’len’ in this block; result: the value named ’result’ in this block. Context: the function _pair, which handles pair.

Line 1105: `raise ValueError(f"{name} must be an integer or a pair")` This rejects an invalid state by raising ‘ValueError(f"{name} must be an integer or a pair")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1106: `if result[0] <= 0 or result[1] <= 0:` This executes the following indented host-code branch only when ‘result[0] <= 0 or result[1] <= 0‘ is true. The important operands are result: the value named ’result’ in this block; or: the value named ’or’ in this block. Context: the function _pair, which handles pair.

Line 1107: `raise ValueError(f"{name} values must be positive")` This rejects an invalid state by raising ‘ValueError(f"{name} values must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1108: `return result` This returns ‘result‘ to the caller of the function _pair, which handles pair, ending this invocation. The important operands are result: the value named ’result’ in this block.

Line 1111: `def maxpool2d_backward_fixed(` This starts function maxpool2d_backward_fixed. Its indented body performs maxpool2d backward fixed as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 1112: `values,` Inside the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are values: the value named ’values’ in this block.

Line 1113: `output_gradients,` Inside the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_gradients: the signed loss derivative used to update a learned parameter.

Line 1114: `*,` Inside the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 1115: `kernel_size=3,` This assigns ‘3,‘ to ‘kernel_size‘ in host memory. Here kernel_size means the value named ’kernel size’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1116: `stride=2,` This assigns ‘2,‘ to ‘stride‘ in host memory. Here stride means the value named ’stride’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1117: `padding=1,` This assigns ‘1,‘ to ‘padding‘ in host memory. Here padding means the value named ’padding’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1118: `dilation=1,` This assigns ‘1,‘ to ‘dilation‘ in host memory. Here dilation means the value named ’dilation’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1119: `) -> tuple[np.ndarray, np.ndarray]:` Inside the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 1120: `"""Fixed-point MaxPool2d backward with PyTorch's first-maximum tie rule."""` This is executable documentation attached to the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1122: `source = np.asarray(values, dtype=np.int64)` This assigns 'np.asarray(values, dtype=np.int64)' to 'source ' in host memory. Here source means the value named 'source' in this block. The important operands are asarray: the value named 'asarray' in this block; values: the value named 'values' in this block; dtype: the value named 'dtype' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1123: `gradient = np.asarray(output_gradients, dtype=np.int64)` This assigns 'np.asarray(output_gradients, dtype=np.int64)' to 'gradient ' in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are asarray: the value named 'asarray' in this block; output_gradients: the signed loss derivative used to update a learned parameter; dtype: the value named 'dtype' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1124: `if source.ndim != 4 or gradient.ndim != 4:` This executes the following indented host-code branch only when 'source.ndim != 4 or gradient.ndim != 4' is true. The important operands are source: the value named 'source' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1125: `raise ValueError("max-pool values and gradients must be NCHW tensors")` This rejects an invalid state by raising 'ValueError("max-pool values and gradients must be NCHW tensors")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1126: `kernel_h, kernel_w = _pair("kernel_size", kernel_size)` This assigns '_pair("kernel_size", kernel_size)' to 'kernel_h, kernel_w ' in host memory. Here kernel_h means the value named 'kernel h' in this block. The important operands are _pair: the value named 'pair' in this block; kernel_size: the value named 'kernel size' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1127: `stride_h, stride_w = _pair("stride", stride)` This assigns '_pair("stride", stride)' to 'stride_h, stride_w ' in host memory. Here stride_h means the value named 'stride h' in this block. The important operands are _pair: the value named 'pair' in this block; stride: the value named 'stride' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1128: `dilation_h, dilation_w = _pair("dilation", dilation)` This assigns '_pair("dilation", dilation)' to 'dilation_h, dilation_w ' in host memory. Here dilation_h means the value named 'dilation h' in this block. The important operands are _pair: the value named 'pair' in this block; dilation: the value named 'dilation' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1129: `if isinstance(padding, int):` This executes the following indented host-code branch only when 'isinstance(padding, int)' is true. The important operands are isinstance: the value named 'isinstance' in this block; padding: the value named 'padding' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1130: `pad_h, pad_w = int(padding), int(padding)` This assigns 'int(padding), int(padding)' to 'pad_h, pad_w ' in host memory. Here pad_h means the value named 'pad h' in this block. The important operands are padding: the value named 'padding' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1131: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1132: `pad_h, pad_w = tuple(map(int, padding))` This assigns ‘tuple(map(int, padding))‘ to ‘pad_h, pad_w ‘ in host memory. Here pad_h means the value named ’pad h’ in this block. The important operands are tuple: the value named ’tuple’ in this block; map: the value named ’map’ in this block; padding: the value named ’padding’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1133: `if pad_h < 0 or pad_w < 0:` This executes the following indented host-code branch only when ‘pad_h < 0 or pad_w < 0‘ is true. The important operands are pad_h: the value named ’pad h’ in this block; or: the value named ’or’ in this block; pad_w: the value named ’pad w’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1134: `raise ValueError("padding must be nonnegative")` This rejects an invalid state by raising ‘ValueError("padding must be nonnegative")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1135: `batch, channels, height, width = source.shape` This assigns ‘source.shape‘ to ‘batch, channels, height, width ‘ in host memory. Here batch means the value named ’batch’ in this block. The important operands are source: the value named ’source’ in this block; shape: the value named ’shape’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1136: `output_height = (` This statement continues through source line 1138; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(height + 2 * pad_h - dilation_h * (kernel_h - 1) - 1) // stride_h + 1‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are height: the value named ’height’ in this block; pad_h: the value named ’pad h’ in this block; dilation_h: the value named ’dilation h’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1137: `height + 2 * pad_h - dilation_h * (kernel_h - 1) - 1` This is continuation line 2 of the 3-line logical statement that begins at source line 1136. Its exact fragment is ‘height + 2 * pad_h - dilation_h * (kernel_h - 1) - 1‘. The important operands are height: the value named ’height’ in this block; pad_h: the value named ’pad h’ in this block; dilation_h: the value named ’dilation h’ in this block. Read together, the complete operation is: This assigns ‘(height + 2 * pad_h - dilation_h * (kernel_h - 1) - 1) // stride_h + 1‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are height: the value named ’height’ in this block; pad_h: the value named ’pad h’ in this block; dilation_h: the value named ’dilation h’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1138: `) // stride_h + 1` This is continuation line 3 of the 3-line logical statement that begins at source line 1136. Its exact fragment is ‘) // stride_h + 1‘. The important operands are stride_h: the value named ’stride h’ in this block. Read together, the complete operation is: This assigns ‘(height + 2 * pad_h - dilation_h * (kernel_h - 1) - 1) // stride_h + 1‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are height: the value named ’height’ in this block; pad_h: the value named ’pad h’ in this block; dilation_h: the value named ’dilation h’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1139: `output_width = (` This statement continues through source line 1141; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(width + 2 * pad_w - dilation_w * (kernel_w - 1) - 1) // stride_w + 1‘ to ‘output_width ‘ in host memory. Here output_width means the value named ’output width’ in this block. The important operands are width: the value named ’width’ in this block; pad_w: the value named ’pad w’ in this block; dilation_w: the value named ’dilation w’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1140: `width + 2 * pad_w - dilation_w * (kernel_w - 1) - 1` This is continuation line 2 of the 3-line logical statement that begins at source line 1139. Its exact fragment is ‘width + 2 * pad_w - dilation_w * (kernel_w - 1) - 1‘. The important operands are width: the value named ’width’ in this block; pad_w: the value named ’pad w’ in this block; dilation_w: the value named ’dilation w’ in this block. Read together, the complete operation is: This assigns ‘(width + 2 * pad_w - dilation_w * (kernel_w - 1) - 1) // stride_w + 1‘ to ‘output_width ‘ in host memory. Here output_width means the value named ’output width’ in this block. The important operands are width: the value named ’width’ in this block; pad_w: the value named ’pad w’ in this block; dilation_w: the value named ’dilation w’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1141: `) // stride_w + 1` This is continuation line 3 of the 3-line logical statement that begins at source line 1139. Its exact fragment is ‘) // stride_w + 1‘. The important operands are stride_w: the value named ’stride w’ in this block. Read together, the complete operation is: This assigns ‘(width + 2 * pad_w - dilation_w * (kernel_w - 1) - 1) // stride_w + 1‘ to ‘output_width ‘ in host memory. Here output_width means the value named ’output width’ in this block. The important operands are width: the value named ’width’ in this block; pad_w: the value named ’pad w’ in this block; dilation_w: the value named ’dilation w’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1142: `if gradient.shape != (batch, channels, output_height, output_width):` This executes the following indented host-code branch only when ‘gradient.shape != (batch, channels, output_height, output_width)‘ is true. The important operands are gradient: the signed loss derivative used to update a learned parameter; shape: the value named ’shape’ in this block; batch: the value named ’batch’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1143: `raise ValueError("max-pool output gradient shape does not match its geometry")` This rejects an invalid state by raising ‘ValueError("max-pool output gradient shape does not match its geometry")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1144: `input_gradient = np.zeros(source.shape, dtype=np.int64)` This assigns ‘np.zeros(source.shape, dtype=np.int
to ‘input_gradient ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are zeros: the value named ’zeros’ in this block; source: the value named ’source’ in this block; shape: the value named ’shape’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1145: `winners = np.zeros(gradient.shape, dtype=np.int64)` This assigns ‘np.zeros(gradient.shape, dtype=np.int64)‘ to ‘winners ‘ in host memory. Here winners means the value named ’winners’ in this block. The important operands are zeros: the value named ’zeros’ in this block; gradient: the signed loss derivative used to update a learned parameter; shape: the value named ’shape’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1146: `for batch_index in range(batch):` This iterates batch_index over ‘range(batch)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1147: `for channel in range(channels):` This iterates channel over ‘range(channels)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1148: `for output_y in range(output_height):` This iterates output_y over ‘range(output_height)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1149: `for output_x in range(output_width):` This iterates output_x over ‘range(output_width)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1150: `winner_value:  int | None = None` This assigns ‘None‘ to ‘winner_value‘ in host memory. Here winner_value means the value named ’winner value’ in this block. The important operands are None: the value named ’none’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1151: `winner_index = -1` This assigns ‘-1‘ to ‘winner_index ‘ in host memory. Here winner_index means an integer selecting one tensor element, lane, bank, or state entry. The expression is a literal or structural operator and has no hidden software state. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1152: `for kernel_y in range(kernel_h):` This iterates kernel_y over ‘range(kernel_h)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1153: `input_y = output_y * stride_h - pad_h + kernel_y * dilation_h` This assigns ‘output_y * stride_h - pad_h + kernel_y * dilation_h‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; stride_h: the value named ’stride h’ in this block; pad_h: the value named ’pad h’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1154: `if not 0 <= input_y < height:` This executes the following indented host-code branch only when ‘not 0 <= input_y < height‘ is true. The important operands are not: the value named ’not’ in this block; input_y: the value named ’input y’ in this block; height: the value named ’height’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1155: `continue` Inside the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are continue: the value named ’continue’ in this block.

Line 1156: `for kernel_x in range(kernel_w):` This iterates kernel_x over ‘range(kernel_w)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1157: `input_x = output_x * stride_w - pad_w + kernel_x * dilation_w` This assigns ‘output_x * stride_w - pad_w + kernel_x * dilation_w‘ to ‘input_x ‘ in host memory. Here input_x means the value named ’input x’ in this block. The important operands are output_x: the value named ’output x’ in this block; stride_w: the value named ’stride w’ in this block; pad_w: the value named ’pad w’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1158: `if not 0 <= input_x < width:` This executes the following indented host-code branch only when ‘not 0 <= input_x < width‘ is true. The important operands are not: the value named ’not’ in this block; input_x: the value named ’input x’ in this block; width: the value named ’width’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1159: `continue` Inside the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are continue: the value named ’continue’ in this block.

Line 1160: `candidate = int(source[batch_index, channel, input_y, input_x])` This assigns ‘int(source[batch_index, channel, input_y, input_x])‘ to ‘candidate ‘ in host memory. Here candidate means the value named ’candidate’ in this block. The important operands are source: the value named ’source’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named ’channel’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1161: `if winner_value is None or candidate > winner_value:` This executes the following indented host-code branch only when ‘winner_value is None or candidate > winner_value‘ is true. The important operands are winner_value: the value named ’winner value’ in this block; is: the value named ’is’ in this block; None: the value named ’none’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1162: `winner_value = candidate` This assigns ‘candidate‘ to ‘winner_value ‘ in host memory. Here winner_value means the value named ’winner value’ in this block. The important operands are candidate: the value named ’candidate’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1163: `winner_index = kernel_y * kernel_w + kernel_x` This assigns ‘kernel_y * kernel_w + kernel_x‘ to ‘winner_index ‘ in host memory. Here winner_index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are kernel_y: the value named ’kernel y’ in this block; kernel_w: the value named ’kernel w’ in this block; kernel_x: the value named ’kernel x’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1164: `if winner_index < 0:` This executes the following indented host-code branch only when ‘winner_index < 0‘ is true. The important operands are winner_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1165: `raise ValueError("a max-pool window contains no source elements")` This rejects an invalid state by raising ‘ValueError("a max-pool window contains no source elements")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1166: `winners[batch_index, channel, output_y, output_x] = winner_index` This assigns ‘winner_index‘ to ‘winners[batch_index, channel, output_y, output_x] ‘ in host memory. Here winners means the value named ’winners’ in this block. The important operands are winner_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1167: `input_y = (` This statement continues through source line 1170; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(output_y * stride_h - pad_h + (winner_index // kernel_w) * dilation_h)‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; stride_h: the value named ’stride h’ in this block; pad_h: the value named ’pad h’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1168: `output_y * stride_h - pad_h` This is continuation line 2 of the 4-line logical statement that begins at source line 1167. Its exact fragment is ‘output_y * stride_h - pad_h‘. The important operands are output_y: the value named ’output y’ in this block; stride_h: the value named ’stride h’ in this block; pad_h: the value named ’pad h’ in this block. Read together, the complete operation is: This assigns ‘(output_y * stride_h - pad_h + (winner_index // kernel_w) * dilation_h)‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; stride_h: the value named ’stride h’ in this block; pad_h: the value named ’pad h’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1169: `+ (winner_index // kernel_w) * dilation_h` This is continuation line 3 of the 4-line logical statement that begins at source line 1167. Its exact fragment is ‘+ (winner_index // kernel_w) * dilation_h‘. The important operands are winner_index: an integer selecting one tensor element, lane, bank, or state entry; kernel_w: the value named ’kernel w’ in this block; dilation_h: the value named ’dilation h’ in this block. Read together, the complete operation is: This assigns ‘(output_y * stride_h - pad_h + (winner_index // kernel_w) * dilation_h)‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; stride_h: the value named ’stride h’ in this block; pad_h: the value named ’pad h’ in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1170: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1167. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(output_y * stride_h - pad_h + (winner_index // kernel_w) * dilation_h)' to 'input_y ' in host memory. Here input_y means the value named 'input y' in this block. The important operands are output_y: the value named 'output y' in this block; stride_h: the value named 'stride h' in this block; pad_h: the value named 'pad h' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1171: `input_x = (` This statement continues through source line 1174; the explanation uses the complete expression rather than only the first visual fragment. This assigns '(output_x * stride_w - pad_w + (winner_index % kernel_w) * dilation_w)' to 'input_x ' in host memory. Here input_x means the value named 'input x' in this block. The important operands are output_x: the value named 'output x' in this block; stride_w: the value named 'stride w' in this block; pad_w: the value named 'pad w' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1172: `output_x * stride_w - pad_w` This is continuation line 2 of the 4-line logical statement that begins at source line 1171. Its exact fragment is 'output_x * stride_w - pad_w'. The important operands are output_x: the value named 'output x' in this block; stride_w: the value named 'stride w' in this block; pad_w: the value named 'pad w' in this block. Read together, the complete operation is: This assigns '(output_x * stride_w - pad_w + (winner_index % kernel_w) * dilation_w)' to 'input_x ' in host memory. Here input_x means the value named 'input x' in this block. The important operands are output_x: the value named 'output x' in this block; stride_w: the value named 'stride w' in this block; pad_w: the value named 'pad w' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1173: `+ (winner_index % kernel_w) * dilation_w` This is continuation line 3 of the 4-line logical statement that begins at source line 1171. Its exact fragment is '+ (winner_index % kernel_w) * dilation_w'. The important operands are winner_index: an integer selecting one tensor element, lane, bank, or state entry; kernel_w: the value named 'kernel w' in this block; dilation_w: the value named 'dilation w' in this block. Read together, the complete operation is: This assigns '(output_x * stride_w - pad_w + (winner_index % kernel_w) * dilation_w)' to 'input_x ' in host memory. Here input_x means the value named 'input x' in this block. The important operands are output_x: the value named 'output x' in this block; stride_w: the value named 'stride w' in this block; pad_w: the value named 'pad w' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1174: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1171. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(output_x * stride_w - pad_w + (winner_index % kernel_w) * dilation_w)' to 'input_x ' in host memory. Here input_x means the value named 'input x' in this block. The important operands are output_x: the value named 'output x' in this block; stride_w: the value named 'stride w' in this block; pad_w: the value named 'pad w' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1175: `prior = input_gradient[batch_index, channel, input_y, input_x]` This assigns 'input_gradient[batch_index, channel, input_y, input_x]' to 'prior ' in host memory. Here prior means the value named 'prior' in this block. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1176: `update = gradient[batch_index, channel, output_y, output_x]` This assigns 'gradient[batch_index, channel, output_y, output_x]' to 'update ' in host memory. Here update means the value named 'update' in this block. The important operands are gradient: the signed loss derivative used to update a learned parameter; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1177: `input_gradient[batch_index, channel, input_y, input_x] = saturate_signed(` This statement continues through source line 1179; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'saturate_signed(np.asarray(prior + update, dtype=np.int64), 32)' to 'input_gradient[batch_index,

channel, input_y, input_x] ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are saturate_signed: the value named 'saturate signed' in this block; asarray: the value named 'asarray' in this block; prior: the value named 'prior' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1178: `np.asarray(prior + update, dtype=np.int64), 32` This is continuation line 2 of the 3-line logical statement that begins at source line 1177. Its exact fragment is ‘np.asarray(prior + update, dtype=np.int64), 32‘. The important operands are asarray: the value named 'asarray' in this block; prior: the value named 'prior' in this block; update: the value named 'update' in this block. Read together, the complete operation is: This assigns ‘saturate_signed(np.asarray(prior + update, dtype=np.int64), 32)‘ to ‘input_gradient[batch_index, channel, input_y, input_x] ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are saturate_signed: the value named 'saturate signed' in this block; asarray: the value named 'asarray' in this block; prior: the value named 'prior' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1179: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 1177. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘saturate_signed(np.asarray(prior + update, dtype=np.int64), 32)‘ to ‘input_gradient[batch_index, channel, input_y, input_x] ‘ in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are saturate_signed: the value named 'saturate signed' in this block; asarray: the value named 'asarray' in this block; prior: the value named 'prior' in this block. Context: the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed.

Line 1180: `return input_gradient, winners` This returns ‘input_gradient, winners‘ to the caller of the function maxpool2d_backward_fixed, which handles maxpool2d backward fixed, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; winners: the value named 'winners' in this block.

Line 1183: `def execute_maxpool2d_backward(` This starts function execute_maxpool2d_backward. Its indented body performs execute maxpool2d backward as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 1184: `driver: TrainingCommandExecutor,` Inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are driver: the value named 'driver' in this block; TrainingCommandExecutor: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 1185: `values,` Inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are values: the value named 'values' in this block.

Line 1186: `output_gradients,` Inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are output_gradients: the signed loss derivative used to update a learned parameter.

Line 1187: `*,` Inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 1188: `kernel_size=3,` This assigns ‘3,‘ to ‘kernel_size‘ in host memory. Here kernel_size means the value named ’kernel size’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1189: `stride=2,` This assigns ‘2,‘ to ‘stride‘ in host memory. Here stride means the value named ’stride’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1190: `padding=1,` This assigns ‘1,‘ to ‘padding‘ in host memory. Here padding means the value named ’padding’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1191: `dilation=1,` This assigns ‘1,‘ to ‘dilation‘ in host memory. Here dilation means the value named ’dilation’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1192: `timeout_seconds: float = 5.0,` This assigns ‘5.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1193: `) -> tuple[np.ndarray, np.ndarray]:` Inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are tuple: the value named ’tuple’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 1194: `"""Run max-pool winner selection and gradient scatter through vector RTL."""` This is executable documentation attached to the function execute_maxpool2d_backward, which handles execute maxpool2d backward. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1196: `source = np.asarray(values, dtype=np.int64)` This assigns ‘np.asarray(values, dtype=np.int64)‘ to ‘source ‘ in host memory. Here source means the value named ’source’ in this block. The important operands are asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block; dtype: the value named ’dtype’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1197: `gradient = np.asarray(output_gradients, dtype=np.int64)` This assigns ‘np.asarray(output_gradients, dtype=np.int64)‘ to ‘gradient ‘ in host memory. Here gradient means the signed loss derivative used to update a learned parameter. The important operands are asarray: the value named ’asarray’ in this block; output_gradients: the signed loss derivative used to update a learned parameter; dtype: the value named ’dtype’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1198: `if source.ndim != 4 or gradient.ndim != 4:` This executes the following indented host-code branch only when ‘source.ndim != 4 or gradient.ndim != 4‘ is true. The important operands are source: the value named ’source’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1199: `raise ValueError("max-pool values and gradients must be NCHW tensors")` This rejects an invalid state by raising ‘ValueError("max-pool values and gradients must be NCHW tensors")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1200: `kernel_h, kernel_w = _pair("kernel_size", kernel_size)` This assigns ‘_pair("kernel_size", kernel_size)‘ to ‘kernel_h, kernel_w ‘ in host memory. Here kernel_h means the value named ’kernel h’ in this block. The important operands are _pair: the value named ’pair’ in this block; kernel_size: the value named ’kernel size’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1201: `stride_h, stride_w = _pair("stride", stride)` This assigns ‘_pair("stride", stride)‘ to ‘stride_h, stride_w ‘ in host memory. Here stride_h means the value named ’stride h’ in this block. The important operands are _pair: the value named ’pair’ in this block; stride: the value named ’stride’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1202: `dilation_h, dilation_w = _pair("dilation", dilation)` This assigns ‘_pair("dilation", dilation)‘ to ‘dilation_h, dilation_w ‘ in host memory. Here dilation_h means the value named ’dilation h’ in this block. The important operands are _pair: the value named ’pair’ in this block; dilation: the value named ’dilation’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1203: `if isinstance(padding, int):` This executes the following indented host-code branch only when ‘isinstance(padding, int)‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; padding: the value named ’padding’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1204: `pad_h, pad_w = int(padding), int(padding)` This assigns ‘int(padding), int(padding)‘ to ‘pad_h, pad_w ‘ in host memory. Here pad_h means the value named ’pad h’ in this block. The important operands are padding: the value named ’padding’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1205: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1206: `pad_h, pad_w = tuple(map(int, padding))` This assigns ‘tuple(map(int, padding))‘ to ‘pad_h, pad_w ‘ in host memory. Here pad_h means the value named ’pad h’ in this block. The important operands are tuple: the value named ’tuple’ in this block; map: the value named ’map’ in this block; padding: the value named ’padding’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1207: `batch, channels, height, width = source.shape` This assigns ‘source.shape‘ to ‘batch, channels, height, width ‘ in host memory. Here batch means the value named ’batch’ in this block. The important operands are source: the value named ’source’ in this block; shape: the value named ’shape’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1208: `output_height = (` This statement continues through source line 1210; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(height + 2 * pad_h - dilation_h * (kernel_h - 1) - 1) // stride_h + 1‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are height: the value named ’height’ in this block; pad_h: the value named ’pad h’ in this block; dilation_h: the value named ’dilation h’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1209: `height + 2 * pad_h - dilation_h * (kernel_h - 1) - 1` This is continuation line 2 of the 3-line logical statement that begins at source line 1208. Its exact fragment is ‘height + 2 * pad_h - dilation_h * (kernel_h - 1) - 1‘. The important operands are height: the value named ’height’ in this block; pad_h: the value named ’pad h’ in this block; dilation_h: the value named ’dilation h’ in this block. Read together, the complete operation is: This assigns ‘(height + 2 * pad_h - dilation_h * (kernel_h - 1) - 1) // stride_h + 1‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are height: the value named ’height’ in this block; pad_h: the value named ’pad h’ in this block; dilation_h: the value named ’dilation h’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1210: `) // stride_h + 1` This is continuation line 3 of the 3-line logical statement that begins at source line 1208. Its exact fragment is ‘) // stride_h + 1‘. The important operands are stride_h: the value named ’stride h’ in this block. Read together, the complete operation is: This assigns ‘(height + 2 * pad_h - dilation_h * (kernel_h - 1) - 1) // stride_h + 1‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are height: the value named ’height’ in this block; pad_h: the value named ’pad h’ in

this block; dilation_h: the value named 'dilation h' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1211: `output_width = (` This statement continues through source line 1213; the explanation uses the complete expression rather than only the first visual fragment. This assigns '(width + 2 * pad_w - dilation_w * (kernel_w - 1) - 1) // stride_w + 1' to 'output_width ' in host memory. Here output_width means the value named 'output width' in this block. The important operands are width: the value named 'width' in this block; pad_w: the value named 'pad w' in this block; dilation_w: the value named 'dilation w' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1212: `width + 2 * pad_w - dilation_w * (kernel_w - 1) - 1` This is continuation line 2 of the 3-line logical statement that begins at source line 1211. Its exact fragment is 'width + 2 * pad_w - dilation_w * (kernel_w - 1) - 1'. The important operands are width: the value named 'width' in this block; pad_w: the value named 'pad w' in this block; dilation_w: the value named 'dilation w' in this block. Read together, the complete operation is: This assigns '(width + 2 * pad_w - dilation_w * (kernel_w - 1) - 1) // stride_w + 1' to 'output_width ' in host memory. Here output_width means the value named 'output width' in this block. The important operands are width: the value named 'width' in this block; pad_w: the value named 'pad w' in this block; dilation_w: the value named 'dilation w' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1213: `) // stride_w + 1` This is continuation line 3 of the 3-line logical statement that begins at source line 1211. Its exact fragment is ') // stride_w + 1'. The important operands are stride_w: the value named 'stride w' in this block. Read together, the complete operation is: This assigns '(width + 2 * pad_w - dilation_w * (kernel_w - 1) - 1) // stride_w + 1' to 'output_width ' in host memory. Here output_width means the value named 'output width' in this block. The important operands are width: the value named 'width' in this block; pad_w: the value named 'pad w' in this block; dilation_w: the value named 'dilation w' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1214: `if gradient.shape != (batch, channels, output_height, output_width):` This executes the following indented host-code branch only when 'gradient.shape != (batch, channels, output_height, output_width)' is true. The important operands are gradient: the signed loss derivative used to update a learned parameter; shape: the value named 'shape' in this block; batch: the value named 'batch' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1215: `raise ValueError("max-pool output gradient shape does not match its geometry")` This rejects an invalid state by raising 'ValueError("max-pool output gradient shape does not match its geometry")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1216: `windows = tuple(` This statement continues through source line 1222; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'tuple((batch_index, channel, output_y, output_x) for batch_index in range(batch) for channel in range(channels) for output_y in range(output_height) for output_x in range(output_width))' to 'windows ' in host memory. Here windows means the value named 'windows' in this block. The important operands are tuple: the value named 'tuple' in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1217: `(batch_index, channel, output_y, output_x)` This is continuation line 2 of the 7-line logical statement that begins at source line 1216. Its exact fragment is '(batch_index, channel, output_y, output_x)'. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block; output_y: the value named 'output y' in this block. Read together, the complete operation is: This assigns 'tuple((batch_index, channel, output_y, output_x) for batch_index in range(batch) for channel in range(channels) for output_y in range(output_height) for output_x in range(output_width))' to 'windows ' in host memory. Here windows means the value named 'windows' in this block. The important operands are tuple: the value named 'tuple' in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1218: `for batch_index in range(batch)` This is continuation line 3 of the 7-line logical statement that begins at source line 1216. Its exact fragment is 'for batch_index in range(batch)'. The important operands are for: the value named 'for' in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'tuple((batch_index, channel, output_y, output_x) for batch_index in range(batch) for channel in range(channels) for output_y in range(output_height) for output_x in range(output_width))' to 'windows ' in host memory. Here windows means the value named 'windows' in this block. The important operands are tuple: the value named 'tuple' in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1219: `for channel in range(channels)` This is continuation line 4 of the 7-line logical statement that begins at source line 1216. Its exact fragment is 'for channel in range(channels)'. The important operands are for: the value named 'for' in this block; channel: the value named 'channel' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'tuple((batch_index, channel, output_y, output_x) for batch_index in range(batch) for channel in range(channels) for output_y in range(output_height) for output_x in range(output_width))' to 'windows ' in host memory. Here windows means the value named 'windows' in this block. The important operands are tuple: the value named 'tuple' in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1220: `for output_y in range(output_height)` This is continuation line 5 of the 7-line logical statement that begins at source line 1216. Its exact fragment is 'for output_y in range(output_height)'. The important operands are for: the value named 'for' in this block; output_y: the value named 'output y' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'tuple((batch_index, channel, output_y, output_x) for batch_index in range(batch) for channel in range(channels) for output_y in range(output_height) for output_x in range(output_width))' to 'windows ' in host memory. Here windows means the value named 'windows' in this block. The important operands are tuple: the value named 'tuple' in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1221: `for output_x in range(output_width)` This is continuation line 6 of the 7-line logical statement that begins at source line 1216. Its exact fragment is 'for output_x in range(output_width)'. The important operands are for: the value named 'for' in this block; output_x: the value named 'output x' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'tuple((batch_index, channel, output_y, output_x) for batch_index in range(batch) for channel in range(channels) for output_y in range(output_height) for output_x in range(output_width))' to 'windows ' in host memory. Here windows means the value named 'windows' in this block. The important operands are tuple: the value named 'tuple' in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1222: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1216. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'tuple((batch_index, channel, output_y, output_x) for batch_index in range(batch) for channel in range(channels) for output_y in range(output_height) for output_x in range(output_width))' to 'windows ' in host memory. Here windows means the value named 'windows' in this block. The important operands are tuple: the value named 'tuple' in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1223: `input_gradient = np.zeros(source.shape, dtype=np.int64)` This assigns 'np.zeros(source.shape, dtype=np.int
to 'input_gradient ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are zeros: the value named 'zeros' in this block; source: the value named 'source' in this block; shape: the value named 'shape' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1224: `winners = np.zeros(gradient.shape, dtype=np.int64)` This assigns ‘np.zeros(gradient.shape, dtype=np.int64)‘ to ‘winners ‘ in host memory. Here winners means the value named ’winners’ in this block. The important operands are zeros: the value named ’zeros’ in this block; gradient: the signed loss derivative used to update a learned parameter; shape: the value named ’shape’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1226: `for window_start in range(0, len(windows), 8):` This iterates window_start over ‘range(0, len(windows), 8)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1227: `active_windows = windows[window_start:window_start + 8]` This assigns ‘windows[window_start:window_star + 8]‘ to ‘active_windows ‘ in host memory. Here active_windows means the value named ’active windows’ in this block. The important operands are windows: the value named ’windows’ in this block; window_start: the value named ’window start’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1228: `active = len(active_windows)` This assigns ‘len(active_windows)‘ to ‘active ‘ in host memory. Here active means the value named ’active’ in this block. The important operands are len: the value named ’len’ in this block; active_windows: the value named ’active windows’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1229: `first_indices: list[int] = []` This assigns ‘[]‘ to ‘first_indices‘ in host memory. Here first_indices means the value named ’first indices’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1230: `current_values: list[int] = []` This assigns ‘[]‘ to ‘current_values‘ in host memory. Here current_values means the value named ’current values’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1231: `for batch_index, channel, output_y, output_x in active_windows:` This iterates batch_index, channel, output_y, output_x over ‘active_windows‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1232: `found = False` This assigns ‘False‘ to ‘found ‘ in host memory. Here found means the value named ’found’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1233: `for kernel_y in range(kernel_h):` This iterates kernel_y over ‘range(kernel_h)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_maxpool2d_backward which handles execute maxpool2d backward.

Line 1234: `input_y = output_y * stride_h - pad_h + kernel_y * dilation_h` This assigns ‘output_y * stride_h - pad_h + kernel_y * dilation_h‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; stride_h: the value named ’stride h’ in this block; pad_h: the value named ’pad h’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1235: `for kernel_x in range(kernel_w):` This iterates kernel_x over ‘range(kernel_w)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_maxpool2d_backward which handles execute maxpool2d backward.

Line 1236: `input_x = output_x * stride_w - pad_w + kernel_x * dilation_w` This assigns ‘output_x * stride_w - pad_w + kernel_x * dilation_w‘ to ‘input_x ‘ in host memory. Here input_x means the value named ’input x’ in this block. The important operands are output_x: the value named ’output x’ in this block; stride_w: the value named ’stride w’ in this block; pad_w: the value named ’pad w’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1237: `if 0 <= input_y < height and 0 <= input_x < width:` This executes the following indented host-code branch only when ‘0 <= input_y < height and 0 <= input_x < width‘ is true. The important operands are input_y: the value named ’input y’ in this block; height: the value named ’height’ in this block; and: the value named ’and’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1238: `first_indices.append(kernel_y * kernel_w + kernel_x)` This calls ‘first_indices.append‘ with ‘kernel_y * kernel_w + kernel_x‘ inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1239: `current_values.append(int(source[batch_index, channel, input_y, input_x]))` This calls ‘current_values.append‘ with ‘int(source[batch_index, channel, input_y, input_x])‘ inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1240: `found = True` This assigns ‘True‘ to ‘found ‘ in host memory. Here found means the value named ’found’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1241: `break` Inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are break: the value named ’break’ in this block.

Line 1242: `if found:` This executes the following indented host-code branch only when ‘found‘ is true. The important operands are found: the value named ’found’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1243: `break` Inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are break: the value named ’break’ in this block.

Line 1244: `if not found:` This executes the following indented host-code branch only when ‘not found‘ is true. The important operands are not: the value named ’not’ in this block; found: the value named ’found’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1245: `raise ValueError("a max-pool window contains no source elements")` This rejects an invalid state by raising ‘ValueError("a max-pool window contains no source elements")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1246: `current = np.asarray(current_values + [0] * (8 - active), dtype=np.int64)` This assigns ‘np.asarray(cur + [0] * (8 - active), dtype=np.int64)‘ to ‘current ‘ in host memory. Here current means the value named ’current’ in this block. The important operands are asarray: the value named ’asarray’ in this block; current_values: the value named ’current values’ in this block; active: the value named ’active’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1247: `winner = np.asarray(first_indices + [0] * (8 - active), dtype=np.int64)` This assigns ‘np.asarray(first_ + [0] * (8 - active), dtype=np.int64)‘ to ‘winner ‘ in host memory. Here winner means the value named ’winner’ in this block. The important operands are asarray: the value named ’asarray’ in this block; first_indices: the value named ’first indices’ in this block; active: the value named ’active’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1248: `for candidate_index in range(kernel_h * kernel_w):` This iterates candidate_index over ‘range(kernel_h * kernel_w)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1249: `candidates = current.copy()` This assigns ‘current.copy()‘ to ‘candidates ‘ in host memory. Here candidates means the value named ’candidates’ in this block. The important operands are current: the value named ’current’ in this block; copy: the value named ’copy’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1250: `for lane, (batch_index, channel, output_y, output_x) in enumerate(active_windows):` This iterates lane, (batch_index, channel, output_y, output_x) over ‘enumerate(active_windows)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1251: `kernel_y, kernel_x = divmod(candidate_index, kernel_w)` This assigns ‘divmod(candidate_index, kernel_w)‘ to ‘kernel_y, kernel_x ‘ in host memory. Here kernel_y means the value named ’kernel y’ in this block. The important operands are divmod: the value named ’divmod’ in this block; candidate_index: an integer selecting one tensor element, lane, bank, or state entry; kernel_w: the value named ’kernel w’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1252: `input_y = output_y * stride_h - pad_h + kernel_y * dilation_h` This assigns ‘output_y * stride_h - pad_h + kernel_y * dilation_h‘ to ‘input_y ‘ in host memory. Here input_y means the value named ’input y’ in this block. The important operands are output_y: the value named ’output y’ in this block; stride_h: the value named ’stride h’ in this block; pad_h: the value named ’pad h’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1253: `input_x = output_x * stride_w - pad_w + kernel_x * dilation_w` This assigns ‘output_x * stride_w - pad_w + kernel_x * dilation_w‘ to ‘input_x ‘ in host memory. Here input_x means the value named ’input x’ in this block. The important operands are output_x: the value named ’output x’ in this block; stride_w: the value named ’stride w’ in this block; pad_w: the value named ’pad w’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1254: `if (candidate_index > first_indices[lane]` Inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are candidate_index: an integer selecting one tensor element, lane, bank, or state entry; first_indices: the value named ’first indices’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 1255: `and 0 <= input_y < height and 0 <= input_x < width):` Inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are and: the value named ’and’ in this block; input_y: the value named ’input y’ in this block; height: the value named ’height’ in this block.

Line 1256: `candidates[lane] = source[batch_index, channel, input_y, input_x]` This assigns ‘source[batch_index, channel, input_y, input_x]‘ to ‘candidates[lane] ‘ in host memory. Here candidates means the value named ’candidates’ in this block. The important operands are source: the value named ’source’ in this block; batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named ’channel’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1257: `keep_mask = _execute_vector8(` This statement continues through source line 1263; the explanation uses the complete expression rather than only the first visual fragment. This assigns '_execute_vector8(driver, VectorOperation.COMPARE_GE, current, candidates, timeout_seconds=timeout_seconds,)' to 'keep_mask ' in host memory. Here keep_mask means the value named 'keep mask' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1258: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1257. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.COMPARE_GE, current, candidates, timeout_seconds=timeout_seconds,)' to 'keep_mask ' in host memory. Here keep_mask means the value named 'keep mask' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1259: `VectorOperation.COMPARE_GE,` This is continuation line 3 of the 7-line logical statement that begins at source line 1257. Its exact fragment is 'VectorOperation.COMPARE_GE,'. The important operands are VectorOperation: the value named 'vector operation' in this block; COMPARE_GE: the value named 'compare ge' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.COMPARE_GE, current, candidates, timeout_seconds=timeout_seconds,)' to 'keep_mask ' in host memory. Here keep_mask means the value named 'keep mask' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1260: `current,` This is continuation line 4 of the 7-line logical statement that begins at source line 1257. Its exact fragment is 'current,'. The important operands are current: the value named 'current' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.COMPARE_GE, current, candidates, timeout_seconds=timeout_seconds,)' to 'keep_mask ' in host memory. Here keep_mask means the value named 'keep mask' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1261: `candidates,` This is continuation line 5 of the 7-line logical statement that begins at source line 1257. Its exact fragment is 'candidates,'. The important operands are candidates: the value named 'candidates' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.COMPARE_GE, current, candidates, timeout_seconds=timeout_seconds,)' to 'keep_mask ' in host memory. Here keep_mask means the value named 'keep mask' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1262: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1257. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.COMPARE_GE, current, candidates, timeout_seconds=timeout_seconds,)' to 'keep_mask ' in host memory. Here keep_mask means the value named 'keep mask' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1263: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1257. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.COMPARE_GE, current, candidates, timeout_seconds=timeout_seconds,)' to 'keep_mask ' in host memory. Here keep_mask means the value named 'keep mask' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block;

driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1264: `current = _execute_vector8(` This statement continues through source line 1270; the explanation uses the complete expression rather than only the first visual fragment. This assigns '_execute_vector8(driver, VectorOperation.MAXIMUM, current, candidates, timeout_seconds=timeout_seconds,)' to 'current ' in host memory. Here current means the value named 'current' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1265: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1264. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MAXIMUM, current, candidates, timeout_seconds=timeout_seconds,)' to 'current ' in host memory. Here current means the value named 'current' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1266: `VectorOperation.MAXIMUM,` This is continuation line 3 of the 7-line logical statement that begins at source line 1264. Its exact fragment is 'VectorOperation.MAXIMUM,'. The important operands are VectorOperation: the value named 'vector operation' in this block; MAXIMUM: the value named 'maximum' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MAXIMUM, current, candidates, timeout_seconds=timeout_seconds,)' to 'current ' in host memory. Here current means the value named 'current' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1267: `current,` This is continuation line 4 of the 7-line logical statement that begins at source line 1264. Its exact fragment is 'current,'. The important operands are current: the value named 'current' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MAXIMUM, current, candidates, timeout_seconds=timeout_seconds,)' to 'current ' in host memory. Here current means the value named 'current' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1268: `candidates,` This is continuation line 5 of the 7-line logical statement that begins at source line 1264. Its exact fragment is 'candidates,'. The important operands are candidates: the value named 'candidates' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MAXIMUM, current, candidates, timeout_seconds=timeout_seconds,)' to 'current ' in host memory. Here current means the value named 'current' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1269: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1264. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.MAXIMUM, current, candidates, timeout_seconds=timeout_seconds,)' to 'current ' in host memory. Here current means the value named 'current' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1270: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1264. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Line 1293: `updates: list[tuple[tuple[int, int, int, int], int]] = []` This assigns '[]' to 'updates' in host memory. Here updates means the value named 'updates' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1294: `for lane, window in enumerate(active_windows):` This iterates lane, window over 'enumerate(active_windows)' Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1295: `batch_index, channel, output_y, output_x = window` This assigns 'window' to 'batch_index, channel, output_y, output_x ' in host memory. Here batch_index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are window: the value named 'window' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1296: `winner_index = int(winner[lane])` This assigns 'int(winner[lane])' to 'winner_index ' in host memory. Here winner_index means an integer selecting one tensor element, lane, bank, or state entry. The important operands are winner: the value named 'winner' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1297: `winners[window] = winner_index` This assigns 'winner_index' to 'winners[window] ' in host memory. Here winners means the value named 'winners' in this block. The important operands are winner_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1298: `input_y = (` This statement continues through source line 1301; the explanation uses the complete expression rather than only the first visual fragment. This assigns '(output_y * stride_h - pad_h + (winner_index // kernel_w) * dilation_h)' to 'input_y ' in host memory. Here input_y means the value named 'input y' in this block. The important operands are output_y: the value named 'output y' in this block; stride_h: the value named 'stride h' in this block; pad_h: the value named 'pad h' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1299: `output_y * stride_h - pad_h` This is continuation line 2 of the 4-line logical statement that begins at source line 1298. Its exact fragment is 'output_y * stride_h - pad_h'. The important operands are output_y: the value named 'output y' in this block; stride_h: the value named 'stride h' in this block; pad_h: the value named 'pad h' in this block. Read together, the complete operation is: This assigns '(output_y * stride_h - pad_h + (winner_index // kernel_w) * dilation_h)' to 'input_y ' in host memory. Here input_y means the value named 'input y' in this block. The important operands are output_y: the value named 'output y' in this block; stride_h: the value named 'stride h' in this block; pad_h: the value named 'pad h' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1300: `+ (winner_index // kernel_w) * dilation_h` This is continuation line 3 of the 4-line logical statement that begins at source line 1298. Its exact fragment is '+ (winner_index // kernel_w) * dilation_h'. The important operands are winner_index: an integer selecting one tensor element, lane, bank, or state entry; kernel_w: the value named 'kernel w' in this block; dilation_h: the value named 'dilation h' in this block. Read together, the complete operation is: This assigns '(output_y * stride_h - pad_h + (winner_index // kernel_w) * dilation_h)' to 'input_y ' in host memory. Here input_y means the value named 'input y' in this block. The important operands are output_y: the value named 'output y' in this block; stride_h: the value named 'stride h' in this block; pad_h: the value named 'pad h' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1301: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1298. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(output_y * stride_h - pad_h + (winner_index // kernel_w) * dilation_h)' to 'input_y ' in host memory. Here input_y means the value named 'input y' in this block. The important operands are output_y: the value named 'output y' in this block; stride_h: the value named 'stride h' in this block; pad_h: the value named 'pad h' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1302: `input_x = (` This statement continues through source line 1305; the explanation uses the complete expression rather than only the first visual fragment. This assigns '(output_x * stride_w - pad_w + (winner_index % kernel_w) * dilation_w)' to 'input_x ' in host memory. Here input_x means the value named 'input x' in this block. The important operands are output_x: the value named 'output x' in this block; stride_w: the value named 'stride w' in this block; pad_w: the value named 'pad w' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1303: `output_x * stride_w - pad_w` This is continuation line 2 of the 4-line logical statement that begins at source line 1302. Its exact fragment is 'output_x * stride_w - pad_w'. The important operands are output_x: the value named 'output x' in this block; stride_w: the value named 'stride w' in this block; pad_w: the value named 'pad w' in this block. Read together, the complete operation is: This assigns '(output_x * stride_w - pad_w + (winner_index % kernel_w) * dilation_w)' to 'input_x ' in host memory. Here input_x means the value named 'input x' in this block. The important operands are output_x: the value named 'output x' in this block; stride_w: the value named 'stride w' in this block; pad_w: the value named 'pad w' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1304: `+ (winner_index % kernel_w) * dilation_w` This is continuation line 3 of the 4-line logical statement that begins at source line 1302. Its exact fragment is '+ (winner_index % kernel_w) * dilation_w'. The important operands are winner_index: an integer selecting one tensor element, lane, bank, or state entry; kernel_w: the value named 'kernel w' in this block; dilation_w: the value named 'dilation w' in this block. Read together, the complete operation is: This assigns '(output_x * stride_w - pad_w + (winner_index % kernel_w) * dilation_w)' to 'input_x ' in host memory. Here input_x means the value named 'input x' in this block. The important operands are output_x: the value named 'output x' in this block; stride_w: the value named 'stride w' in this block; pad_w: the value named 'pad w' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1305: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 1302. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '(output_x * stride_w - pad_w + (winner_index % kernel_w) * dilation_w)' to 'input_x ' in host memory. Here input_x means the value named 'input x' in this block. The important operands are output_x: the value named 'output x' in this block; stride_w: the value named 'stride w' in this block; pad_w: the value named 'pad w' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1306: `updates.append(` This statement continues through source line 1308; the explanation uses the complete expression rather than only the first visual fragment. This calls 'updates.append' with ' ((batch_index, channel, input_y, input_x), int(gradient[window])) ' inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1307: `((batch_index, channel, input_y, input_x), int(gradient[window]))` This is continuation line 2 of the 3-line logical statement that begins at source line 1306. Its exact fragment is '((batch_index, channel, input_y, input_x), int(gradient[window]))'. The important operands are batch_index: an integer selecting one tensor element, lane, bank, or state entry; channel: the value named 'channel' in this block; input_y: the value named 'input y' in this block. Read together, the complete operation is: This calls 'updates.append' with ' ((batch_index, channel, input_y, input_x), int(gradient[window])) ' inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1308: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 1306. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'updates.append' with ' ((batch_index, channel, input_y, input_x), int(gradient[window])) ' inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1310: `# Each vector command updates distinct addresses. Repeated winners are` The comment records this intent: Each vector command updates distinct addresses. Repeated winners are It applies inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1311: `# deferred to a later round, preserving output-window order per address.` The comment records this intent: deferred to a later round, preserving output-window order per address. It applies inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1312: `pending = list(updates)` This assigns 'list(updates)' to 'pending ' in host memory. Here pending means the value named 'pending' in this block. The important operands are list: the value named 'list' in this block; updates: the value named 'updates' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1313: `while pending:` This repeats the following host-code block while 'pending' remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 1314: `selected: list[tuple[tuple[int, int, int, int], int]] = []` This assigns '[]' to 'selected' in host memory. Here selected means the value named 'selected' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1315: `deferred: list[tuple[tuple[int, int, int, int], int]] = []` This assigns '[]' to 'deferred' in host memory. Here deferred means the value named 'deferred' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1316: `seen: set[tuple[int, int, int, int]] = set()` This assigns 'set()' to 'seen' in host memory. Here seen means the value named 'seen' in this block. The important operands are set: the value named 'set' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1317: `for update in pending:` This iterates update over 'pending'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1318: `if update[0] in seen or len(selected) == 8:` This executes the following indented host-code branch only when 'update[0] in seen or len(selected) == 8' is true. The important operands are update: the value named 'update' in this block; in: the value named 'in' in this block; seen: the value named 'seen' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1319: `deferred.append(update)` This calls ‘deferred.append‘ with ‘update‘ inside the function execute_maxpool2d_backw which handles execute maxpool2d backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1320: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1321: `selected.append(update)` This calls ‘selected.append‘ with ‘update‘ inside the function execute_maxpool2d_backwa which handles execute maxpool2d backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1322: `seen.add(update[0])` This calls ‘seen.add‘ with ‘update[0]‘ inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1323: `left = [int(input_gradient[address]) for address, _ in selected]` This assigns ‘[int(input_gradient[addre for address, _ in selected]‘ to ‘left ‘ in host memory. Here left means the value named ’left’ in this block. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; address: the value named ’address’ in this block; for: the value named ’for’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1324: `right = [value for _, value in selected]` This assigns ‘[value for _, value in selected]‘ to ‘right ‘ in host memory. Here right means the value named ’right’ in this block. The important operands are value: the value named ’value’ in this block; for: the value named ’for’ in this block; _: the value named ” in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1325: `left.extend([0] * (8 - len(selected)))` This calls ‘left.extend‘ with ‘[0] * (8 - len(selected))‘ inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1326: `right.extend([0] * (8 - len(selected)))` This calls ‘right.extend‘ with ‘[0] * (8 - len(selected))‘ inside the function execute_maxpool2d_backward, which handles execute maxpool2d backward. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1327: `summed = _execute_vector8(` This statement continues through source line 1333; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)‘ to ‘summed ‘ in host memory. Here summed means the value named ’summed’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1328: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 1327. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)‘ to ‘summed ‘ in host memory. Here summed means the value named ’summed’ in this block. The important operands are _execute_vector8: the value named ’execute vector8’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1329: `VectorOperation.ADD_SAT,` This is continuation line 3 of the 7-line logical statement that begins at source line 1327. Its exact fragment is ‘VectorOperation.ADD_SAT,‘. The important operands are VectorOperation: the value named ’vector operation’ in this block; ADD_SAT: the value named ’add sat’ in this block. Read

together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)' to 'summed ' in host memory. Here summed means the value named 'summed' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1330: `left,` This is continuation line 4 of the 7-line logical statement that begins at source line 1327. Its exact fragment is 'left,'. The important operands are left: the value named 'left' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)' to 'summed ' in host memory. Here summed means the value named 'summed' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1331: `right,` This is continuation line 5 of the 7-line logical statement that begins at source line 1327. Its exact fragment is 'right,'. The important operands are right: the value named 'right' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)' to 'summed ' in host memory. Here summed means the value named 'summed' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1332: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 1327. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)' to 'summed ' in host memory. Here summed means the value named 'summed' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1333: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1327. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '_execute_vector8(driver, VectorOperation.ADD_SAT, left, right, timeout_seconds=timeout_seconds,)' to 'summed ' in host memory. Here summed means the value named 'summed' in this block. The important operands are _execute_vector8: the value named 'execute vector8' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1334: `for lane, (address, _) in enumerate(selected):` This iterates lane, (address, _) over 'enumerate(selected)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1335: `input_gradient[address] = summed[lane]` This assigns 'summed[lane]' to 'input_gradient[address] ' in host memory. Here input_gradient means the signed loss derivative used to update a learned parameter. The important operands are summed: the value named 'summed' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1336: `pending = deferred` This assigns 'deferred' to 'pending ' in host memory. Here pending means the value named 'pending' in this block. The important operands are deferred: the value named 'deferred' in this block. Context: the function execute_maxpool2d_backward, which handles execute maxpool2d backward.

Line 1337: `return input_gradient, winners` This returns 'input_gradient, winners' to the caller of the function execute_maxpool2d_backward, which handles execute maxpool2d backward, ending this invocation. The important operands are input_gradient: the signed loss derivative used to update a learned parameter; winners: the value named 'winners' in this block.

Line 1340: `def _shape_elements(shape: Sequence[int]) -> int:` This starts function _shape_elements. Its indented body performs shape elements as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 1341: `result = 1` This assigns ‘1‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _shape_elements, which handles shape elements.

Line 1342: `for dimension in shape:` This iterates dimension over ‘shape‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _shape_elements, which handles shape elements.

Line 1343: `result *= int(dimension)` Inside the function _shape_elements, which handles shape elements, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are result: the value named ’result’ in this block; dimension: the value named ’dimension’ in this block.

Line 1344: `return result` This returns ‘result‘ to the caller of the function _shape_elements, which handles shape elements, ending this invocation. The important operands are result: the value named ’result’ in this block.

Line 1347: `def linear_backward_partial_tiles(` This starts function linear_backward_partial_tiles. Its indented body performs linear backward partial tiles as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 1348: `rows: int,` Inside the function linear_backward_partial_tiles, which handles linear backward partial tiles, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are rows: one output-row position processed by the tensor tile.

Line 1349: `inputs: int,` Inside the function linear_backward_partial_tiles, which handles linear backward partial tiles, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are inputs: the value named ’inputs’ in this block.

Line 1350: `outputs: int,` Inside the function linear_backward_partial_tiles, which handles linear backward partial tiles, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are outputs: the value named ’outputs’ in this block.

Line 1351: `*,` Inside the function linear_backward_partial_tiles, which handles linear backward partial tiles, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 1352: `repetitions: int = 1,` This assigns ‘1,‘ to ‘repetitions‘ in host memory. Here repetitions means the value named ’repetitions’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function linear_backward_partial_tiles, which handles linear backward partial tiles.

Line 1353: `) -> int:` Inside the function linear_backward_partial_tiles, which handles linear backward partial tiles, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The expression is a literal or structural operator and has no hidden software state.

Line 1354: `"""Count dX plus dW partial commands without materializing operands."""` This is executable documentation attached to the function linear_backward_partial_tiles, which handles linear backward partial tiles. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1356: `if min(rows, inputs, outputs, repetitions) <= 0:` This executes the following indented host-code branch only when ‘min(rows, inputs, outputs, repetitions) <= 0‘ is true. The important operands are min: the value named ’min’ in this block; rows: one output-row position processed by the tensor tile; inputs: the value named ’inputs’ in this block. Context: the function linear_backward_partial_tiles, which handles linear backward partial tiles.

Line 1357: `raise ValueError("linear backward dimensions and repetitions must be positive")` This rejects an invalid state by raising ‘ValueError("linear backward dimensions and repetitions must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1358: `return (` This statement continues through source line 1364; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘(2 * ceil(rows / TILE) * ceil(inputs / TILE) * ceil(outputs / TILE) * repetitions)‘ to the caller of the function linear_backward_partial_tiles, which handles linear backward partial tiles, ending this invocation. The important operands are ceil: the value named ’ceil’ in this block; rows: one output-row position processed by the tensor tile; TILE: the value named ’tile’ in this block.

Line 1359: `2` This is continuation line 2 of the 7-line logical statement that begins at source line 1358. Its exact fragment is ‘2‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘(2 * ceil(rows / TILE) * ceil(inputs / TILE) * ceil(outputs / TILE) * repetitions)‘ to the caller of the function linear_backward_partial_tiles, which handles linear backward partial tiles, ending this invocation. The important operands are ceil: the value named ’ceil’ in this block; rows: one output-row position processed by the tensor tile; TILE: the value named ’tile’ in this block.

Line 1360: `* ceil(rows / TILE)` This is continuation line 3 of the 7-line logical statement that begins at source line 1358. Its exact fragment is ‘* ceil(rows / TILE)‘. The important operands are ceil: the value named ’ceil’ in this block; rows: one output-row position processed by the tensor tile; TILE: the value named ’tile’ in this block. Read together, the complete operation is: This returns ‘(2 * ceil(rows / TILE) * ceil(inputs / TILE) * ceil(outputs / TILE) * repetitions)‘ to the caller of the function linear_backward_partial_tiles, which handles linear backward partial tiles, ending this invocation. The important operands are ceil: the value named ’ceil’ in this block; rows: one output-row position processed by the tensor tile; TILE: the value named ’tile’ in this block.

Line 1361: `* ceil(inputs / TILE)` This is continuation line 4 of the 7-line logical statement that begins at source line 1358. Its exact fragment is ‘* ceil(inputs / TILE)‘. The important operands are ceil: the value named ’ceil’ in this block; inputs: the value named ’inputs’ in this block; TILE: the value named ’tile’ in this block. Read together, the complete operation is: This returns ‘(2 * ceil(rows / TILE) * ceil(inputs / TILE) * ceil(outputs / TILE) * repetitions)‘ to the caller of the function linear_backward_partial_tiles, which handles linear backward partial tiles, ending this invocation. The important operands are ceil: the value named ’ceil’ in this block; rows: one output-row position processed by the tensor tile; TILE: the value named ’tile’ in this block.

Line 1362: `* ceil(outputs / TILE)` This is continuation line 5 of the 7-line logical statement that begins at source line 1358. Its exact fragment is ‘* ceil(outputs / TILE)‘. The important operands are ceil: the value named ’ceil’ in this block; outputs: the value named ’outputs’ in this block; TILE: the value named ’tile’ in this block. Read together, the complete operation is: This returns ‘(2 * ceil(rows / TILE) * ceil(inputs / TILE) * ceil(outputs / TILE) * repetitions)‘ to the caller of the function linear_backward_partial_tiles, which handles linear backward partial tiles, ending this invocation. The important operands are ceil: the value named ’ceil’ in this block; rows: one output-row position processed by the tensor tile; TILE: the value named ’tile’ in this block.

Line 1363: `* repetitions` This is continuation line 6 of the 7-line logical statement that begins at source line 1358. Its exact fragment is ‘* repetitions‘. The important operands are repetitions: the value named ’repetitions’ in this block. Read together, the complete operation is: This returns ‘(2 * ceil(rows / TILE) * ceil(inputs / TILE) * ceil(outputs / TILE) * repetitions)‘ to the caller of the function linear_backward_partial_tiles, which handles linear backward partial

tiles, ending this invocation. The important operands are ceil: the value named 'ceil' in this block; rows: one output-row position processed by the tensor tile; TILE: the value named 'tile' in this block.

Line 1364: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 1358. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns '(2 * ceil(rows / TILE) * ceil(inputs / TILE) * ceil(outputs / TILE) * repetitions)' to the caller of the function linear_backward_partial_tiles, which handles linear backward partial tiles, ending this invocation. The important operands are ceil: the value named 'ceil' in this block; rows: one output-row position processed by the tensor tile; TILE: the value named 'tile' in this block.

Line 1367: `def build_spikingformer_training_coverage(` This starts function build_spikingformer_training_coverage. Its indented body performs build spikingformer training coverage as part of the file that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates; it runs only when called.

Line 1368: `execution_manifest_path: str | Path,` Inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are execution_manifest_path: the value named 'execution manifest path' in this block; str: the value named 'str' in this block; Path: the value named 'path' in this block.

Line 1369: `parameter_manifest_path: str | Path,` Inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are parameter_manifest_path: the value named 'parameter manifest path' in this block; str: the value named 'str' in this block; Path: the value named 'path' in this block.

Line 1370: `) -> dict[str, object]:` Inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are dict: the value named 'dict' in this block; str: the value named 'str' in this block; object: the value named 'object' in this block.

Line 1371: `"""Prove hardware backward/update coverage for the exported deployed graph."""` This is executable documentation attached to the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 1373: `execution_path = Path(execution_manifest_path).expanduser().resolve()` This assigns 'Path(execution_ma to 'execution_path ' in host memory. Here execution_path means the value named 'execution path' in this block. The important operands are Path: the value named 'path' in this block; execution_manifest_path: the value named 'execution manifest path' in this block; expanduser: the value named 'expanduser' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1374: `parameter_path = Path(parameter_manifest_path).expanduser().resolve()` This assigns 'Path(parameter_m to 'parameter_path ' in host memory. Here parameter_path means the value named 'parameter path' in this block. The important operands are Path: the value named 'path' in this block; parameter_manifest_path: the value named 'parameter manifest path' in this block; expanduser: the value named 'expanduser' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1375: `execution = json.loads(execution_path.read_text(encoding="ascii"))` This assigns 'json.loads(execution_p to 'execution ' in host memory. Here execution means the value named 'execution' in this block. The important operands are json: the value named 'json' in this block; loads: the value named 'loads' in this block; execution_path: the value named 'execution path' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1376: `parameters = json.loads(parameter_path.read_text(encoding="ascii"))` This assigns ‘json.loads(parameter_ to ‘parameters ‘ in host memory. Here parameters means the value named ’parameters’ in this block. The important operands are json: the value named ’json’ in this block; loads: the value named ’loads’ in this block; parameter_path: the value named ’parameter path’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1377: `operators = {item["name"]: item for item in execution["operators"]}` This assigns ‘{item["name"]: item for item in execution["operators"]}‘ to ‘operators ‘ in host memory. Here operators means the value named ’operators’ in this block. The important operands are item: the value named ’item’ in this block; name: the value named ’name’ in this block; for: the value named ’for’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1378: `projection_entries = {item["name"]: item for item in parameters["projections"]}` This assigns ‘{item["name"]: item for item in parameters["projections"]}‘ to ‘projection_entries ‘ in host memory. Here projection_entries means the value named ’projection entries’ in this block. The important operands are item: the value named ’item’ in this block; name: the value named ’name’ in this block; for: the value named ’for’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1379: `learned_names = tuple(projection_entries) + ("head",)` This assigns ‘tuple(projection_entries) + ("head",)‘ to ‘learned_names ‘ in host memory. Here learned_names means the value named ’learned names’ in this block. The important operands are tuple: the value named ’tuple’ in this block; projection_entries: the value named ’projection entries’ in this block; head: the value named ’head’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1380: `missing_operators = sorted(set(learned_names) - set(operators))` This assigns ‘sorted(set(learned_names) - set(operators))‘ to ‘missing_operators ‘ in host memory. Here missing_operators means the value named ’missing operators’ in this block. The important operands are sorted: the value named ’sorted’ in this block; set: the value named ’set’ in this block; learned_names: the value named ’learned names’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1381: `if missing_operators:` This executes the following indented host-code branch only when ‘missing_operators‘ is true. The important operands are missing_operators: the value named ’missing operators’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1382: `raise ValueError(f"learned parameter groups lack graph operators: {missing_operators}")` This rejects an invalid state by raising ‘ValueError(f"learned parameter groups lack graph operators: {missing_operators}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1384: `learned_coverage: list[dict[str, object]] = []` This assigns ‘[]‘ to ‘learned_coverage‘ in host memory. Here learned_coverage means the value named ’learned coverage’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1385: `learned_parameter_elements = 0` This assigns ‘0‘ to ‘learned_parameter_elements ‘ in host memory. Here learned_parameter_elements means the value named ’learned parameter elements’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1386: `learned_backward_tiles = 0` This assigns ‘0‘ to ‘learned_backward_tiles ‘ in host memory. Here learned_backward_tiles means the value named ’learned backward tiles’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1387: `learned_backward_multiplications = 0` This assigns ‘0‘ to ‘learned_backward_multiplications ‘ in host memory. Here learned_backward_multiplications means the value named ’learned backward multiplications’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1388: `for name in learned_names:` This iterates name over ‘learned_names‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1389: `operator = operators[name]` This assigns ‘operators[name]‘ to ‘operator ‘ in host memory. Here operator means the value named ’operator’ in this block. The important operands are operators: the value named ’operators’ in this block; name: the value named ’name’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1390: `matrix = operator["matrix"]` This assigns ‘operator["matrix"]‘ to ‘matrix ‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are operator: the value named ’operator’ in this block; matrix: the value named ’matrix’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1391: `rows = int(matrix["rows"])` This assigns ‘int(matrix["rows"])‘ to ‘rows ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are matrix: the value named ’matrix’ in this block; rows: one output-row position processed by the tensor tile. Context: the function build_spikingformer_training_covera which handles build spikingformer training coverage.

Line 1392: `inputs = int(matrix["reduction"])` This assigns ‘int(matrix["reduction"])‘ to ‘inputs ‘ in host memory. Here inputs means the value named ’inputs’ in this block. The important operands are matrix: the value named ’matrix’ in this block; reduction: the value named ’reduction’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1393: `outputs = int(matrix["columns"])` This assigns ‘int(matrix["columns"])‘ to ‘outputs ‘ in host memory. Here outputs means the value named ’outputs’ in this block. The important operands are matrix: the value named ’matrix’ in this block; columns: one output-feature position processed in parallel. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1394: `repetitions = int(matrix.get("repetitions", 1))` This assigns ‘int(matrix.get("repetitions", 1))‘ to ‘repetitions ‘ in host memory. Here repetitions means the value named ’repetitions’ in this block. The important operands are matrix: the value named ’matrix’ in this block; get: the value named ’get’ in this block; repetitions: the value named ’repetitions’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1395: `augmented_inputs = inputs + 1` This assigns ‘inputs + 1‘ to ‘augmented_inputs ‘ in host memory. Here augmented_inputs means the value named ’augmented inputs’ in this block. The important operands are inputs: the value named ’inputs’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1396: `partial_tiles = linear_backward_partial_tiles(` This statement continues through source line 1401; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘linear_backward_partial_tiles(rows, augmented_inputs, outputs, repetitions=repetitions,)‘ to ‘partial_tiles ‘ in host memory. Here partial_tiles means the value named ’partial tiles’ in this block. The important operands are linear_backward_partial_tiles: the value named ’linear backward partial tiles’ in this block; rows: one output-row position processed by the tensor tile; augmented_inputs: the value named ’augmented inputs’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1397: `rows,` This is continuation line 2 of the 6-line logical statement that begins at source line 1396. Its exact fragment is ‘rows,‘. The important operands are rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This assigns ‘linear_backward_partial_tiles(rows, augmented_inputs, outputs, repetitions=repetitions,)‘ to ‘partial_tiles ‘ in host memory. Here partial_tiles means the value named ’partial tiles’ in this block. The important operands are linear_backward_partial_tiles: the value named ’linear backward partial tiles’ in this block; rows: one output-row position processed by the tensor tile; augmented_inputs: the value named ’augmented inputs’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1398: `augmented_inputs,` This is continuation line 3 of the 6-line logical statement that begins at source line 1396. Its exact fragment is ‘augmented_inputs,‘. The important operands are augmented_inputs: the value named ’augmented inputs’ in this block. Read together, the complete operation is: This assigns ‘linear_backward_partial_tiles(rows, augmented_inputs, outputs, repetitions=repetitions,)‘ to ‘partial_tiles ‘ in host memory. Here partial_tiles means the value named ’partial tiles’ in this block. The important operands are linear_backward_partial_tiles: the value named ’linear backward partial tiles’ in this block; rows: one output-row position processed by the tensor tile; augmented_inputs: the value named ’augmented inputs’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1399: `outputs,` This is continuation line 4 of the 6-line logical statement that begins at source line 1396. Its exact fragment is ‘outputs,‘. The important operands are outputs: the value named ’outputs’ in this block. Read together, the complete operation is: This assigns ‘linear_backward_partial_tiles(rows, augmented_inputs, outputs, repetitions=repetitions,)‘ to ‘partial_tiles ‘ in host memory. Here partial_tiles means the value named ’partial tiles’ in this block. The important operands are linear_backward_partial_tiles: the value named ’linear backward partial tiles’ in this block; rows: one output-row position processed by the tensor tile; augmented_inputs: the value named ’augmented inputs’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1400: `repetitions=repetitions,` This is continuation line 5 of the 6-line logical statement that begins at source line 1396. Its exact fragment is ‘repetitions=repetitions,‘. The important operands are repetitions: the value named ’repetitions’ in this block. Read together, the complete operation is: This assigns ‘linear_backward_partial_tiles(rows, augmented_inputs, outputs, repetitions=repetitions,)‘ to ‘partial_tiles ‘ in host memory. Here partial_tiles means the value named ’partial tiles’ in this block. The important operands are linear_backward_partial_tiles: the value named ’linear backward partial tiles’ in this block; rows: one output-row position processed by the tensor tile; augmented_inputs: the value named ’augmented inputs’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1401: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 1396. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘linear_backward_partial_tiles(rows, augmented_inputs, outputs, repetitions=repetitions,)‘ to ‘partial_tiles ‘ in host memory. Here partial_tiles means the value named ’partial tiles’ in this block. The important operands are linear_backward_partial_tiles: the value named ’linear backward partial tiles’ in this block; rows: one output-row position processed by the tensor tile; augmented_inputs: the value named ’augmented inputs’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1402: `multiplications = 2 * rows * augmented_inputs * outputs * repetitions` This assigns ‘2 * rows * augmented_inputs * outputs * repetitions‘ to ‘multiplications ‘ in host memory. Here multiplications means the value named ’multiplications’ in this block. The important operands are rows: one output-row position processed by the tensor tile; augmented_inputs: the value named ’augmented inputs’ in this block; outputs: the value named ’outputs’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1403: `if name == "head":` This executes the following indented host-code branch only when ‘name == "head"‘ is true. The important operands are name: the value named ’name’ in this block; head: the value named ’head’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1404: `entry = parameters["head"]` This assigns ‘parameters["head"]‘ to ‘entry ‘ in host memory. Here entry means the value named ’entry’ in this block. The important operands are parameters: the value named ’parameters’ in this block; head: the value named ’head’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1405: `weight_elements = _shape_elements(entry["hardware_matrix_shape"])` This assigns ‘_shape_elements(entry[to ‘weight_elements ‘ in host memory. Here weight_elements means a learned coefficient multiplied by an activation. The important operands are _shape_elements: the value named ’shape elements’ in this block; entry: the value named ’entry’ in this block; hardware_matrix_shape: the value named ’hardware matrix shape’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1406: `bias_elements = int(entry["hardware_matrix_shape"][1])` This assigns ‘int(entry["hardware_matrix_shape"][to ‘bias_elements ‘ in host memory. Here bias_elements means an additive learned offset applied after accumulation. The important operands are entry: the value named ’entry’ in this block; hardware_matrix_shape: the value named ’hardware matrix shape’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1407: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1408: `entry = projection_entries[name]` This assigns ‘projection_entries[name]‘ to ‘entry ‘ in host memory. Here entry means the value named ’entry’ in this block. The important operands are projection_entries: the value named ’projection entries’ in this block; name: the value named ’name’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1409: `weight_elements = _shape_elements(entry["hardware_matrix_shape"])` This assigns ‘_shape_elements(entry[to ‘weight_elements ‘ in host memory. Here weight_elements means a learned coefficient multiplied by an activation. The important operands are _shape_elements: the value named ’shape elements’ in this block; entry: the value named ’entry’ in this block; hardware_matrix_shape: the value named ’hardware matrix shape’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1410: `bias_elements = int(entry["hardware_matrix_shape"][1])` This assigns ‘int(entry["hardware_matrix_shape"][to ‘bias_elements ‘ in host memory. Here bias_elements means an additive learned offset applied after accumulation. The important operands are entry: the value named ’entry’ in this block; hardware_matrix_shape: the value named ’hardware matrix shape’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1411: `parameter_elements = weight_elements + bias_elements` This assigns ‘weight_elements + bias_elements‘ to ‘parameter_elements ‘ in host memory. Here parameter_elements means the value named ’parameter elements’ in this block. The important operands are weight_elements: a learned coefficient multiplied by an activation; bias_elements: an additive learned offset applied after accumulation. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1412: `learned_parameter_elements += parameter_elements` Inside the function build_spikingformer_training_coverag which handles build spikingformer training coverage, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are learned_parameter_elements: the value named ’learned parameter elements’ in this block; parameter_elements: the value named ’parameter elements’ in this block.

Line 1413: `learned_backward_tiles += partial_tiles` Inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are learned_backward_tiles: the value named ’learned backward tiles’ in this block; partial_tiles: the value named ’partial tiles’ in this block.

Line 1414: `learned_backward_multiplications += multiplications` Inside the function build_spikingformer_training_cove which handles build spikingformer training coverage, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are learned_backward_multiplications: the value named 'learned backward multiplications' in this block; multiplications: the value named 'multiplications' in this block.

Line 1415: `learned_coverage.append({` This statement continues through source line 1428; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1416: `"name": name,` This is continuation line 2 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"name": name,‘. The important operands are name: the value named 'name' in this block. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_tr which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1417: `"rows": rows,` This is continuation line 3 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"rows": rows,‘. The important operands are rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1418: `"inputs": inputs,` This is continuation line 4 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"inputs": inputs,‘. The important operands are inputs: the value named 'inputs' in this block. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1419: `"outputs": outputs,` This is continuation line 5 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"outputs": outputs,‘. The important operands are outputs: the value named 'outputs' in this block. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the

host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1420: `"repetitions": repetitions,` This is continuation line 6 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"repetitions": repetitions,‘. The important operands are repetitions: the value named 'repetitions' in this block. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1421: `"weight_elements": weight_elements,` This is continuation line 7 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"weight_elements": weight_elements,‘. The important operands are weight_elements: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1422: `"bias_elements": bias_elements,` This is continuation line 8 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"bias_elements": bias_elements,‘. The important operands are bias_elements: an additive learned offset applied after accumulation. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1423: `"trainable_deployed_elements": parameter_elements,` This is continuation line 9 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"trainable_deployed_elements": parameter_elements,‘. The important operands are trainable_deployed_elements: the value named 'trainable deployed elements' in this block; parameter_elements: the value named 'parameter elements' in this block. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1424: `"backward_partial_tiles": partial_tiles,` This is continuation line 10 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"backward_partial_tiles": partial_tiles,‘. The important operands are backward_partial_tiles: the value named 'backward partial tiles' in this block; partial_tiles: the value named 'partial tiles' in this block. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances

the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1425: `"backward_multiplications": multiplications,` This is continuation line 11 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"backward_multiplications": multiplications,‘. The important operands are backward_multiplications: the value named ’backward multiplications’ in this block; multiplications: the value named ’multiplications’ in this block. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1426: `"gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row",` This is continuation line 12 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row",‘. The important operands are gradient_method: the signed loss derivative used to update a learned parameter; bit: the value named ’bit’ in this block; raw: the value named ’raw’ in this block. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1427: `"update_method": "eight-lane signed fixed-point SGDW in programmable logic",` This is continuation line 13 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘"update_method": "eight-lane signed fixed-point SGDW in programmable logic",‘. The important operands are update_method: the value named ’update method’ in this block; eight: the value named ’eight’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1428: `})` This is continuation line 14 of the 14-line logical statement that begins at source line 1415. Its exact fragment is ‘})‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘learned_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "weight_elements": weight_elements, "bias_elements": bias_elements, "trainable_deployed_elements": parameter_elements, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "47-bit raw accumulation for dX/dW; homogeneous bias row", "update_method": "eight-lane signed fixed-point SGDW in programmable logic", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1430: `dynamic_names = tuple(` This statement continues through source line 1432; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘tuple(name for name in operators if name.endswith(".attn.qk") or name.endswith(".attn.av"))‘ to ‘dynamic_names ‘ in host memory. Here dynamic_names means the value named ’dynamic names’ in this block. The important operands are tuple: the value named ’tuple’ in this block; name: the value named ’name’ in this block; for: the value named ’for’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1431: `name for name in operators if name.endswith(".attn.qk") or name.endswith(".attn.av")` This is continuation line 2 of the 3-line logical statement that begins at source line 1430. Its exact fragment is ‘name for name in operators if name.endswith(".attn.qk") or name.endswith(".attn.av")‘. The important operands are name: the value named ’name’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘tuple(name for name in operators if name.endswith(".attn.qk") or name.endswith(".attn.av"))‘ to ‘dynamic_names ‘ in host memory. Here dynamic_names means the value named ’dynamic names’ in this block. The important operands are tuple: the value named ’tuple’ in this block; name: the value named ’name’ in this block; for: the value named ’for’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1432: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 1430. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘tuple(name for name in operators if name.endswith(".attn.qk") or name.endswith(".attn.av"))‘ to ‘dynamic_names ‘ in host memory. Here dynamic_names means the value named ’dynamic names’ in this block. The important operands are tuple: the value named ’tuple’ in this block; name: the value named ’name’ in this block; for: the value named ’for’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1433: `dynamic_coverage: list[dict[str, object]] = []` This assigns ‘[]‘ to ‘dynamic_coverage‘ in host memory. Here dynamic_coverage means the value named ’dynamic coverage’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1434: `dynamic_tiles = 0` This assigns ‘0‘ to ‘dynamic_tiles ‘ in host memory. Here dynamic_tiles means the value named ’dynamic tiles’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1435: `dynamic_multiplications = 0` This assigns ‘0‘ to ‘dynamic_multiplications ‘ in host memory. Here dynamic_multiplications means the value named ’dynamic multiplications’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1436: `for name in dynamic_names:` This iterates name over ‘dynamic_names‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1437: `matrix = operators[name]["matrix"]` This assigns ‘operators[name]["matrix"]‘ to ‘matrix ‘ in host memory. Here matrix means the value named ’matrix’ in this block. The important operands are operators: the value named ’operators’ in this block; name: the value named ’name’ in this block; matrix: the value named ’matrix’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1438: `rows = int(matrix["rows"])` This assigns ‘int(matrix["rows"])‘ to ‘rows ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are matrix: the value named ’matrix’ in this block; rows: one output-row position processed by the tensor tile. Context: the function build_spikingformer_training_covera which handles build spikingformer training coverage.

Line 1439: `inputs = int(matrix["reduction"])` This assigns ‘int(matrix["reduction"])‘ to ‘inputs ‘ in host memory. Here inputs means the value named ’inputs’ in this block. The important operands are matrix: the value named ’matrix’ in this block; reduction: the value named ’reduction’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1440: `outputs = int(matrix["columns"])` This assigns ‘int(matrix["columns"])‘ to ‘outputs ‘ in host memory. Here outputs means the value named ’outputs’ in this block. The important operands are matrix: the value

named 'matrix' in this block; columns: one output-feature position processed in parallel. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1441: `repetitions = int(matrix.get("repetitions", 1))` This assigns ‘int(matrix.get("repetitions", 1))‘ to ‘repetitions ‘ in host memory. Here repetitions means the value named 'repetitions' in this block. The important operands are matrix: the value named 'matrix' in this block; get: the value named 'get' in this block; repetitions: the value named 'repetitions' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1442: `partial_tiles = linear_backward_partial_tiles(` This statement continues through source line 1444; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘linear_backward_partial_tiles(rows, inputs, outputs, repetitions=repetitions)‘ to ‘partial_tiles ‘ in host memory. Here partial_tiles means the value named 'partial tiles' in this block. The important operands are linear_backward_partial_tiles: the value named 'linear backward partial tiles' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1443: `rows, inputs, outputs, repetitions=repetitions` This is continuation line 2 of the 3-line logical statement that begins at source line 1442. Its exact fragment is ‘rows, inputs, outputs, repetitions=repetitions‘. The important operands are rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block; outputs: the value named 'outputs' in this block. Read together, the complete operation is: This assigns ‘linear_backward_partial_tiles(rows, inputs, outputs, repetitions=repetitions)‘ to ‘partial_tiles ‘ in host memory. Here partial_tiles means the value named 'partial tiles' in this block. The important operands are linear_backward_partial_tiles: the value named 'linear backward partial tiles' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1444: `)` This is continuation line 3 of the 3-line logical statement that begins at source line 1442. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘linear_backward_partial_tiles(rows, inputs, outputs, repetitions=repetitions)‘ to ‘partial_tiles ‘ in host memory. Here partial_tiles means the value named 'partial tiles' in this block. The important operands are linear_backward_partial_tiles: the value named 'linear backward partial tiles' in this block; rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1445: `multiplications = 2 * rows * inputs * outputs * repetitions` This assigns ‘2 * rows * inputs * outputs * repetitions‘ to ‘multiplications ‘ in host memory. Here multiplications means the value named 'multiplications' in this block. The important operands are rows: one output-row position processed by the tensor tile; inputs: the value named 'inputs' in this block; outputs: the value named 'outputs' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1446: `dynamic_tiles += partial_tiles` Inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are dynamic_tiles: the value named 'dynamic tiles' in this block; partial_tiles: the value named 'partial tiles' in this block.

Line 1447: `dynamic_multiplications += multiplications` Inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are dynamic_multiplications: the value named 'dynamic multiplications' in this block; multiplications: the value named 'multiplications' in this block.

Line 1448: `dynamic_coverage.append({` This statement continues through source line 1457; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘dynamic_coverage.append‘ with ‘{ "name":

name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "two signed raw-accumulator matrix passes", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1449: `"name": name,` This is continuation line 2 of the 10-line logical statement that begins at source line 1448. Its exact fragment is ‘"name": name,‘. The important operands are name: the value named ’name’ in this block. Read together, the complete operation is: This calls ‘dynamic_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "two signed raw-accumulator matrix passes", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1450: `"rows": rows,` This is continuation line 3 of the 10-line logical statement that begins at source line 1448. Its exact fragment is ‘"rows": rows,‘. The important operands are rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This calls ‘dynamic_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "two signed raw-accumulator matrix passes", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1451: `"inputs": inputs,` This is continuation line 4 of the 10-line logical statement that begins at source line 1448. Its exact fragment is ‘"inputs": inputs,‘. The important operands are inputs: the value named ’inputs’ in this block. Read together, the complete operation is: This calls ‘dynamic_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "two signed raw-accumulator matrix passes", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1452: `"outputs": outputs,` This is continuation line 5 of the 10-line logical statement that begins at source line 1448. Its exact fragment is ‘"outputs": outputs,‘. The important operands are outputs: the value named ’outputs’ in this block. Read together, the complete operation is: This calls ‘dynamic_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "two signed raw-accumulator matrix passes", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1453: `"repetitions": repetitions,` This is continuation line 6 of the 10-line logical statement that begins at source line 1448. Its exact fragment is ‘"repetitions": repetitions,‘. The important operands are repetitions: the value named ’repetitions’ in this block. Read together, the complete operation is: This calls ‘dynamic_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "two signed raw-accumulator matrix passes", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1454: `"backward_partial_tiles": partial_tiles,` This is continuation line 7 of the 10-line logical statement that begins at source line 1448. Its exact fragment is ‘"backward_partial_tiles": partial_tiles,‘. The important operands are backward_partial_tiles: the value named ’backward partial tiles’ in this block; partial_tiles: the value named ’partial tiles’ in this block. Read together, the complete operation is: This calls ‘dynamic_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "backward_partial_tiles": partial_tiles,

"backward_multiplications": multiplications, "gradient_method": "two signed raw-accumulator matrix passes", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1455: `"backward_multiplications": multiplications,` This is continuation line 8 of the 10-line logical statement that begins at source line 1448. Its exact fragment is ‘"backward_multiplications": multiplications,‘. The important operands are backward_multiplications: the value named ’backward multiplications’ in this block; multiplications: the value named ’multiplications’ in this block. Read together, the complete operation is: This calls ‘dynamic_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "two signed raw-accumulator matrix passes", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1456: `"gradient_method": "two signed raw-accumulator matrix passes",` This is continuation line 9 of the 10-line logical statement that begins at source line 1448. Its exact fragment is ‘"gradient_method": "two signed raw-accumulator matrix passes",‘. The important operands are gradient_method: the signed loss derivative used to update a learned parameter; two: the value named ’two’ in this block; raw: the value named ’raw’ in this block. Read together, the complete operation is: This calls ‘dynamic_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "two signed raw-accumulator matrix passes", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1457: `})` This is continuation line 10 of the 10-line logical statement that begins at source line 1448. Its exact fragment is ‘})‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘dynamic_coverage.append‘ with ‘{ "name": name, "rows": rows, "inputs": inputs, "outputs": outputs, "repetitions": repetitions, "backward_partial_tiles": partial_tiles, "backward_multiplications": multiplications, "gradient_method": "two signed raw-accumulator matrix passes", }‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1459: `operator_coverage: list[dict[str, str]] = []` This assigns ‘[]‘ to ‘operator_coverage‘ in host memory. Here operator_coverage means the value named ’operator coverage’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1460: `uncovered: list[str] = []` This assigns ‘[]‘ to ‘uncovered‘ in host memory. Here uncovered means the value named ’uncovered’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1461: `for name, operator in operators.items():` This iterates name, operator over ‘operators.items()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1462: `source = str(operator["source_operation"])` This assigns ‘str(operator["source_operation"])‘ to ‘source ‘ in host memory. Here source means the value named ’source’ in this block. The important operands are str: the value named ’str’ in this block; operator: the value named ’operator’ in this block; source_operation: the value named ’source operation’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1463: `if name in learned_names:` This executes the following indented host-code branch only when ‘name in learned_names‘ is true. The important operands are name: the value named ’name’ in this block; in: the value

named 'in' in this block; learned_names: the value named 'learned names' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1464: `method = "affine dX/dW/dB plus SGDW"` This assigns ‘"affine dX/dW/dB plus SGDW"‘ to ‘method ‘ in host memory. Here method means the value named 'method' in this block. The important operands are affine: the value named 'affine' in this block; dX: the value named 'd x' in this block; dW: the value named 'd w' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1465: `if "MaxPool2d" in source:` This executes the following indented host-code branch only when ‘"MaxPool2d" in source‘ is true. The important operands are MaxPool2d: the value named 'max pool2d' in this block; in: the value named 'in' in this block; source: the value named 'source' in this block. Context: the function build_spikingformer_training_co which handles build spikingformer training coverage.

Line 1466: `method += "; first-winner max-pool backward and fabric scatter-add"` Inside the function build_spikingfor which handles build spikingformer training coverage, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are method: the value named 'method' in this block; first: the value named 'first' in this block; winner: the value named 'winner' in this block.

Line 1467: `if "LIF" in source:` This executes the following indented host-code branch only when ‘"LIF" in source‘ is true. The important operands are LIF: the value named 'lif' in this block; in: the value named 'in' in this block; source: the value named 'source' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1468: `method += "; traced sigmoid-surrogate hard-LIF BPTT"` Inside the function build_spikingformer_training_co which handles build spikingformer training coverage, this statement advances the host implementation that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates. The important operands are method: the value named 'method' in this block; traced: the value named 'traced' in this block; sigmoid: the value named 'sigmoid' in this block.

Line 1469: `elif name in dynamic_names:` This executes the following indented host-code branch only when ‘name in dynamic_names‘ is true. The important operands are name: the value named 'name' in this block; in: the value named 'in' in this block; dynamic_names: the value named 'dynamic names' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1470: `method = "dynamic matrix dX/dW; 0.125 attention gradient uses Q15 multiply"` This assigns ‘"dynamic matrix dX/dW; 0.125 attention gradient uses Q15 multiply"‘ to ‘method ‘ in host memory. Here method means the value named 'method' in this block. The important operands are dynamic: the value named 'dynamic' in this block; matrix: the value named 'matrix' in this block; dX: the value named 'd x' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1471: `elif name.endswith(".residuals"):` This executes the following indented host-code branch only when ‘name.endswith(".residuals")‘ is true. The important operands are name: the value named 'name' in this block; endswith: the value named 'endswith' in this block; residuals: the value named 'residuals' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1472: `method = "identity gradient fan-out; converging branches use saturating vector add"` This assigns ‘"identity gradient fan-out; converging branches use saturating vector add"‘ to ‘method ‘ in host memory. Here method means the value named 'method' in this block. The important operands are identity: the value named 'identity' in this block; gradient: the signed loss derivative used to update a learned parameter; fan: the value named 'fan' in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1473: `elif name == "global_average_pool":` This executes the following indented host-code branch only when ‘name == "global_average_pool"‘ is true. The important operands are name: the value named ’name’ in this block; global_average_pool: the value named ’global average pool’ in this block. Context: the function build_spikingformer_training_cove which handles build spikingformer training coverage.

Line 1474: `method = "gradient broadcast with exact power-of-two division by 256"` This assigns ‘"gradient broadcast with exact power-of-two division by 256"‘ to ‘method ‘ in host memory. Here method means the value named ’method’ in this block. The important operands are gradient: the signed loss derivative used to update a learned parameter; broadcast: the value named ’broadcast’ in this block; with: the value named ’with’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1475: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1476: `uncovered.append(name)` This calls ‘uncovered.append‘ with ‘name‘ inside the function build_spikingformer_trainin which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1477: `method = "UNMAPPED"` This assigns ‘"UNMAPPED"‘ to ‘method ‘ in host memory. Here method means the value named ’method’ in this block. The important operands are UNMAPPED: the value named ’unmapped’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1478: `operator_coverage.append({"name": name, "backward_method": method})` This calls ‘operator_coverage.app with ‘{"name": name, "backward_method": method}‘ inside the function build_spikingformer_training_coverage, which handles build spikingformer training coverage. The call advances the host-side job that builds quantized forward, backward, surrogate-gradient, and optimizer programs for hardware-resident supervised updates.

Line 1479: `if uncovered:` This executes the following indented host-code branch only when ‘uncovered‘ is true. The important operands are uncovered: the value named ’uncovered’ in this block. Context: the function build_spikingformer_training_ which handles build spikingformer training coverage.

Line 1480: `raise ValueError(f"execution operators lack backward methods: {uncovered}")` This rejects an invalid state by raising ‘ValueError(f"execution operators lack backward methods: {uncovered}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 1482: `depth = int(execution["model"]["transformer_blocks"])` This assigns ‘int(execution["model"]["transformer_bl to ‘depth ‘ in host memory. Here depth means the value named ’depth’ in this block. The important operands are execution: the value named ’execution’ in this block; model: the value named ’model’ in this block; transformer_blocks: the value named ’transformer blocks’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1483: `lif_nodes = 4 + 7 * depth` This assigns ‘4 + 7 * depth‘ to ‘lif_nodes ‘ in host memory. Here lif_nodes means the value named ’lif nodes’ in this block. The important operands are depth: the value named ’depth’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1484: `optimizer_commands = ceil(learned_parameter_elements / 8)` This assigns ‘ceil(learned_parameter_elements / 8)‘ to ‘optimizer_commands ‘ in host memory. Here optimizer_commands means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are ceil: the value named ’ceil’ in this block; learned_parameter_elements: the value named ’learned parameter elements’ in this block. Context: the function build_spikingformer_training_coverage, which handles build spikingformer training coverage.

Line 1485: `return {` This statement continues through source line 1522; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘{ "format": "neuraedge-spikingformer-training-coverage-v1", "execution_manifest": str(execution_path), "parameter_manifest": str(parameter_path), "training_semantics": { "target_graph": "complete exported integer inference graph", "quantizer_gradient": "straight-through estimator with fixed exported scales", "lif_gradient": "SpikingJelly sigmoid surrogate alpha=4, hard reset, detach_reset=True", "temporal_method": "four-step BPTT in reverse timestep order through cached membrane traces", "optimizer": ("signed fixed-point SGDW with momentum; weight decay is applied " "to the update direction and excluded from retained velocity"), "parameter_residency": "PYNQ DDR master tensors; arithmetic and updates in programmable logic", }, "summary": { "execution_operator_count": len(operators), "covered_execution_operator_count": len(operator_coverage), "learned_affine_group_count": len(learned_names), "backbone_projection_count": len(projection_entries), "dynamic_attention_ len(dynamic_names), "lif_node_count": lif_nodes, "maxpool_backward_count": 2, "residual_gradient_fanout_count": 2 * depth, "trainable_deployed_parameter_elements": learned_parameter_elements, "sgdw_update_commands": optimizer_commands, "learned_backward_partial_tiles": learned_backward_tiles, "dynamic_backward_partial_tiles": dynamic_tiles, "total_backward_partial_tiles": learned_backward_tiles + dynamic_tiles, "learned_backward_multiplications": learned_backward_multiplications, "dynamic_backward_multiplications": dynamic_multiplications, "full_deployed_backbone_c True, "uncovered_operator_count": 0, }, "learned_affine_coverage": learned_coverage, "dynamic_attention_coverage": dynamic_coverage, "operator_coverage": operator_coverage, }‘ to the caller of the function build_spikingformer_training_coverage which handles build spikingformer training coverage, ending this invocation. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; spikingformer: the value named 'spikingformer' in this block.

39 software/run_spikingformer_pynq.py

Role in the complete system: loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

39.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: none. Functions: prepare_input, parse_arguments. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

39.2 Complete source

39.3 Line annotations

Line 1: `"""Run complete trained Spikingformer inference on a PYNQ-Z2 overlay."""` This is executable documentation attached to the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import argparse` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import json` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `import time` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `from dataclasses import asdict` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `from datetime import datetime, timezone` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `from pathlib import Path` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `import numpy as np` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `from neuraedge_pynq import NeuraEdgeDriver` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `from spikingformer_accelerator import SpikingformerAcceleratorModel` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `from spikingformer_parameters import SpikingformerParameterArchive` This imports the named Python API so the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `CIFAR10_MEAN = np.asarray((0.4914, 0.4822, 0.4465), dtype=np.float32)` This assigns ‘np.asarray((0.4914, 0.4822, 0.4465), dtype=np.float32)‘ to ‘CIFAR10_MEAN ‘ in host memory. Here CIFAR10_MEAN means the arithmetic average used by normalization. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; float32: the value named ’float32’ in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 20: `CIFAR10_STD = np.asarray((0.2470, 0.2435, 0.2616), dtype=np.float32)` This assigns ‘np.asarray((0.2470, 0.2435, 0.2616), dtype=np.float32)‘ to ‘CIFAR10_STD ‘ in host memory. Here CIFAR10_STD means the value named ’cifar10 std’ in this block. The important operands are asarray: the value named ’asarray’ in this block; dtype: the value named ’dtype’ in this block; float32: the value named ’float32’ in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 23: `def prepare_input(value: np.ndarray, input_format: str) -> np.ndarray:` This starts function prepare_input. Its indented body performs prepare input as part of the file that loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay; it runs only when called.

Line 24: `"""Return normalized NCHW float32 data from raw-u8 or normalized arrays."""` This is executable documentation attached to the function prepare_input, which handles prepare input. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 26: `array = np.asarray(value)` This assigns ‘np.asarray(value)‘ to ‘array ‘ in host memory. Here array means the value named ’array’ in this block. The important operands are asarray: the value named ’asarray’ in this block; value: the value named ’value’ in this block. Context: the function prepare_input, which handles prepare input.

Line 27: `if array.ndim == 3:` This executes the following indented host-code branch only when ‘array.ndim == 3‘ is true. The important operands are array: the value named ’array’ in this block; ndim: the value named ’ndim’ in this block. Context: the function prepare_input, which handles prepare input.

Line 28: `array = array[np.newaxis]` This assigns ‘array[np.newaxis]‘ to ‘array ‘ in host memory. Here array means the value named ’array’ in this block. The important operands are array: the value named ’array’ in this block; newaxis: the value named ’newaxis’ in this block. Context: the function prepare_input, which handles prepare input.

Line 29: `if array.ndim != 4:` This executes the following indented host-code branch only when ‘array.ndim != 4‘ is true. The important operands are array: the value named ’array’ in this block; ndim: the value named ’ndim’ in this block. Context: the function prepare_input, which handles prepare input.

Line 30: `raise ValueError("input array must have three or four dimensions")` This rejects an invalid state by raising ‘ValueError("input array must have three or four dimensions")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 31: `if array.shape[1:] == (3, 32, 32):` This executes the following indented host-code branch only when ‘array.shape[1:] == (3, 32, 32)‘ is true. The important operands are array: the value named ’array’ in this block; shape: the value named ’shape’ in this block. Context: the function prepare_input, which handles prepare input.

Line 32: `nchw = array` This assigns ‘array‘ to ‘nchw ‘ in host memory. Here nchw means the value named ’nchw’ in this block. The important operands are array: the value named ’array’ in this block. Context: the function prepare_input, which handles prepare input.

Line 33: `elif array.shape[1:] == (32, 32, 3):` This executes the following indented host-code branch only when ‘array.shape[1:] == (32, 32, 3)‘ is true. The important operands are array: the value named ’array’ in this block; shape: the value named ’shape’ in this block. Context: the function prepare_input, which handles prepare input.

Line 34: `nchw = array.transpose(0, 3, 1, 2)` This assigns ‘array.transpose(0, 3, 1, 2)‘ to ‘nchw ‘ in host memory. Here nchw means the value named ’nchw’ in this block. The important operands are array: the value named ’array’ in this block; transpose: the value named ’transpose’ in this block. Context: the function prepare_input, which handles prepare input.

Line 35: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function prepare_input, which handles prepare input.

Line 36: `raise ValueError("input array must be NCHW or NHWC CIFAR-10 shape")` This rejects an invalid state by raising ‘ValueError("input array must be NCHW or NHWC CIFAR-10 shape")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 37: `if input_format == "normalized":` This executes the following indented host-code branch only when ‘input_format == "normalized"‘ is true. The important operands are input_format: the value named ’input format’ in this block; normalized: the value named ’normalized’ in this block. Context: the function prepare_input, which handles prepare input.

Line 38: `return nchw.astype(np.float32)` This returns ‘nchw.astype(np.float32)‘ to the caller of the function prepare_input, which handles prepare input, ending this invocation. The important operands are nchw: the value named ’nchw’ in this block; astype: the value named ’astype’ in this block; float32: the value named ’float32’ in this block.

Line 39: `if input_format != "raw-u8":` This executes the following indented host-code branch only when ‘input_format != "raw-u8"‘ is true. The important operands are input_format: the value named ’input format’ in this block; raw: the value named ’raw’ in this block; u8: the value named ’u8’ in this block. Context: the function prepare_input, which handles prepare input.

Line 40: `raise ValueError("input_format must be normalized or raw-u8")` This rejects an invalid state by raising ‘ValueError("input_format must be normalized or raw-u8")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 41: `if not np.issubdtype(nchw.dtype, np.integer) or np.any(nchw < 0) or np.any(nchw > 255):` This executes the following indented host-code branch only when ‘not np.issubdtype(nchw.dtype, np.integer) or np.any(nchw < 0) or np.any(nchw > 255)‘ is true. The important operands are not: the value named ’not’ in this block; issubdtype: the value named ’issubdtype’ in this block; nchw: the value named ’nchw’ in this block. Context: the function prepare_input, which handles prepare input.

Line 42: `raise ValueError("raw-u8 input must contain integer pixels in [0,255]")` This rejects an invalid state by raising ‘ValueError("raw-u8 input must contain integer pixels in [0,255]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 43: `unit = nchw.astype(np.float32) / np.float32(255.0)` This assigns ‘nchw.astype(np.float32) / np.float32(255.0)‘ to ‘unit ‘ in host memory. Here unit means the value named ’unit’ in this block. The important operands are nchw: the value named ’nchw’ in this block; astype: the value named ’astype’ in this block; float32: the value named ’float32’ in this block. Context: the function prepare_input, which handles prepare input.

Line 44: `return (unit - CIFAR10_MEAN.reshape(1, 3, 1, 1)) / CIFAR10_STD.reshape(1, 3, 1, 1)` This returns ‘(unit - CIFAR10_MEAN.reshape(1, 3, 1, 1)) / CIFAR10_STD.reshape(1, 3, 1, 1)‘ to the caller of the function prepare_input, which handles prepare input, ending this invocation. The important operands are unit: the value named ’unit’ in this block; CIFAR10_MEAN: the arithmetic average used by normalization; reshape: the value named ’reshape’ in this block.

Line 47: `def parse_arguments() -> argparse.Namespace:` This starts function parse_arguments. Its indented body performs parse arguments as part of the file that loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay; it runs only when called.

Line 48: `parser = argparse.ArgumentParser()` This assigns ‘argparse.ArgumentParser()‘ to ‘parser ‘ in host memory. Here parser means the value named ’parser’ in this block. The important operands are argparse: the value named ’argparse’ in this block; ArgumentParser: the value named ’argument parser’ in this block. Context: the function parse_arguments, which handles parse arguments.

Line 49: `parser.add_argument("-bitfile", required=True, type=Path)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 50: `parser.add_argument("-manifest", required=True, type=Path)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 51: `parser.add_argument("-input", required=True, type=Path)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 52: `parser.add_argument("-input-format", choices=("normalized", "raw-u8"), default="raw-u8")` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 53: `parser.add_argument("-output", required=True, type=Path)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 54: `parser.add_argument("-layer-timeout-seconds", type=float, default=120.0)` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 55: `parser.add_argument("-no-download", action="store_true")` This declares a command-line option for the function parse_arguments, which handles parse arguments. Its name, type, default, and required status make the run configuration explicit and reproducible instead of relying on an invisible interactive setting.

Line 56: `return parser.parse_args()` This returns ‘parser.parse_args()‘ to the caller of the function parse_arguments, which handles parse arguments, ending this invocation. The important operands are parser: the value named ’parser’ in this block; parse_args: the value named ’parse args’ in this block.

Line 59: `if __name__ == "__main__":` This executes the following indented host-code branch only when ‘___name___ == "___main___"‘ is true. The important operands are ___name___: the value named ’name’ in this block; ___main___: the value named ’main’ in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 60: `arguments = parse_arguments()` This assigns ‘parse_arguments()‘ to ‘arguments ‘ in host memory. Here arguments means the value named ’arguments’ in this block. The important operands are parse_arguments: the value named ’parse arguments’ in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 61: `archive = SpikingformerParameterArchive(arguments.manifest)` This assigns ‘SpikingformerParameterArchive(arguments.manifest)‘ to ‘archive ‘ in host memory. Here archive means the value named ’archive’ in this block. The important operands are SpikingformerParameterArchive: the value named ’spikingformer parameter archive’ in this block; arguments: the value named ’arguments’ in this block; manifest: the value named ’manifest’ in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 62: `image = prepare_input(np.load(arguments.input, allow_pickle=False), arguments.input_format)` This assigns ‘prepare_input(np.load(arguments.input, allow_pickle=False), arguments.input_format)‘ to ‘image ‘ in host memory. Here image means the value named ’image’ in this block. The important operands are prepare_input: the value named ’prepare input’ in this block; load: the value named ’load’ in this block; arguments: the value named ’arguments’ in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 63: `driver = NeuraEdgeDriver.from_bitfile(` This statement continues through source line 64; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘NeuraEdgeDriver.from_bitfile(arguments.bitfile, download=not arguments.no_download)‘ to ‘driver ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are NeuraEdgeDriver: the value named ’neura edge driver’ in this block; from_bitfile: the value named ’from bitfile’ in this block; arguments: the value named ’arguments’ in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 64: `arguments.bitfile, download=not arguments.no_download)` This is continuation line 2 of the 2-line logical statement that begins at source line 63. Its exact fragment is ‘arguments.bitfile, download=not arguments.no_download)‘. The important operands are arguments: the value named ’arguments’ in this block; bitfile: the value named ’bitfile’ in this block; download: the value named ’download’ in this block. Read together, the complete operation is: This assigns ‘NeuraEdgeDriver.from_bitfile(arguments.bitfile, download=not arguments.no_download)‘ to ‘driver ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are NeuraEdgeDriver: the value named ’neura edge driver’ in this block; from_bitfile: the value named ’from bitfile’ in this block; arguments: the value named ’arguments’ in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 65: `model = SpikingformerAcceleratorModel(` This statement continues through source line 66; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘SpikingformerAcceleratorModel(archive, driver, layer_timeout_seconds=arguments.layer_timeout_seconds)‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are SpikingformerAcceleratorModel: the value named ’spikingformer accelerator model’ in this block; archive: the value named ’archive’ in this block; driver: the value

named 'driver' in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 66: `archive, driver, layer_timeout_seconds=arguments.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 65. Its exact fragment is 'archive, driver, layer_timeout_seconds=argur The important operands are archive: the value named 'archive' in this block; driver: the value named 'driver' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'SpikingformerAcceleratorModel(archive, driver, layer_timeout_seconds=arguments.layer_timeout_seconds)' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are SpikingformerAcceleratorModel: the value named 'spikingformer accelerator model' in this block; archive: the value named 'archive' in this block; driver: the value named 'driver' in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 67: `started = time.perf_counter()` This assigns 'time.perf_counter()' to 'started ' in host memory. Here started means the value named 'started' in this block. The important operands are time: the value named 'time' in this block; perf_counter: a hardware telemetry register that accumulates measured events. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 68: `inference = model.infer(image)` This assigns 'model.infer(image)' to 'inference ' in host memory. Here inference means the value named 'inference' in this block. The important operands are model: the value named 'model' in this block; infer: the value named 'infer' in this block; image: the value named 'image' in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 69: `elapsed = time.perf_counter() - started` This assigns 'time.perf_counter() - started' to 'elapsed ' in host memory. Here elapsed means the value named 'elapsed' in this block. The important operands are time: the value named 'time' in this block; perf_counter: a hardware telemetry register that accumulates measured events; started: the value named 'started' in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 70: `performance = driver.performance_snapshot()` This assigns 'driver.performance_snapshot()' to 'performance ' in host memory. Here performance means the value named 'performance' in this block. The important operands are driver: the value named 'driver' in this block; performance_snapshot: the value named 'performance snapshot' in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 71: `report = {` This statement continues through source line 84; the explanation uses the complete expression rather than only the first visual fragment. This assigns '{ "format": "neuraedge-pynq-spikingformer-inference-v1", "completed_utc": datetime.now(timezone.utc).isoformat(), "bitfile": str(arguments.bitfile.resolve()), "parameter_manifest": str(arguments.manifest.resolve()), "parameter_binary_sha256": archive.manifest["binary_sha256"], "batch_size": int(image.shape[("elapsed_seconds": elapsed, "images_per_second": image.shape[0] / elapsed, "predicted_class": inference.predicted_class.tolist(), "logits_accumulator": inference.logits_accumulator.tolist(), "logits": inference.logits.tolist(), "performance_counters": asdict(performance), }' to 'report ' in host memory. Here report means the value named 'report' in this block. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; pynq: the value named 'pynq' in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 72: `"format": "neuraedge-pynq-spikingformer-inference-v1",` This is continuation line 2 of the 14-line logical statement that begins at source line 71. Its exact fragment is '"format": "neuraedge-pynq-spikingformer-inference-v1",'. The important operands are format: the value named 'format' in this block; neuraedge: the value named 'neuraedge' in this block; pynq: the value named 'pynq' in this block. Read together, the complete operation is: This assigns '{ "format": "neuraedge-pynq-spikingformer-inference-v1", "completed_utc": datetime.now(timezone.utc).isoformat(), "bitfile": str(arguments.bitfile.resolve()), "parameter_manifest": str(arguments.manifest.resolve()), "parameter_binary_sha256": archive.manifest["binary_sha256"], "batch_size": int(image.shape[0]), "elapsed_seconds": elapsed, "images_per_second": image.shape[0] / elapsed, "predicted_class": inference.predicted_class.tolist(), "logits_accumulator": inference.logits_accumulator.t "logits": inference.logits.tolist(), "performance_counters": asdict(performance), }' to 'report ' in host memory. Here report means the value named 'report' in this block. The important operands are format: the value named 'format' in this

block; neuraedge: the value named 'neuraedge' in this block; pynq: the value named 'pynq' in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 73: `"completed_utc": datetime.now(timezone.utc).isoformat(),` This is continuation line 3 of the 14-line logical statement that begins at source line 71. Its exact fragment is '"completed_utc": datetime.now(timezone.utc).isoformat(),'. The important operands are completed_utc: the value named 'completed utc' in this block; datetime: the value named 'datetime' in this block; now: the value named 'now' in this block. Read together, the complete operation is: This assigns '{ "format": "neuraedge-pynq-spikingformer-inference-v1", "completed_utc": datetime.now(timezone.utc).isoformat(), "bitfile": str(arguments.bitfile.resolve()), "parameter_manifest": str(arguments.manifest.resolve()), "parameter_binary_sha256": archive.manifest["binary_sha256"], "batch_size": int(image.shape[0]), "elapsed_seconds": elapsed, "images_per_second": image.shape[0] / elapsed, "predicted_class": inference.predicted_class.tolist(), "logits_accumulator": inference.logits_accumulator.t "logits": inference.logits.tolist(), "performance_counters": asdict(performance), }' to 'report ' in host memory. Here report means the value named 'report' in this block. Context: the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 85: `arguments.output.parent.mkdir(parents=True, exist_ok=True)` This calls 'arguments.output.parent.mkdir' with 'parents=True, exist_ok=True' inside the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay. The call advances the host-side job that loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 86: `arguments.output.write_text(json.dumps(report, indent=2) + "\n", encoding="ascii")` This calls ‘arguments.output.write_text‘ with ‘json.dumps(report, indent=2) + "\n", encoding="ascii"‘ inside the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay. The call advances the host-side job that loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

Line 87: `print(json.dumps(report, indent=2))` This calls ‘print‘ with ‘json.dumps(report, indent=2)‘ inside the file whose role is to loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay. The call advances the host-side job that loads one CIFAR-10 image and executes the complete exported Spikingformer graph on a PYNQ overlay.

40 software/spikingformer_accelerator.py

Role in the complete system: maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

40.1 Beginner architecture map

Dataflow responsibility The exported model graph calls compiler primitives in checkpoint order: tokenizer convolutions and LIF, four Q/K/V attention and MLP blocks, residuals, reduction, and classifier. Tensor shapes and quantization records, rather than a hard-coded class result, determine every hardware program.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: SpikingformerProjectionExecutor, SpikingformerInferenceResult, SpikingformerAcceleratorModel. Functions: vector_binary_on_accelerator, power_of_two_requantize_on_accelerator, global_spatiotemporal_sum_binary_max_pool2d_on_accelerator, lif_sequence_reference, lif_sequence_with_trace_reference, lif_sequence_on_accelerator, lif_sequence_with_trace_on_accelerator, requantize_projection_reference, requantize_projection_on_accelerator, _encoded_dense_weights, matrix, conv2d, ___init___, _lif, _project_tokens, _dynamic_binary_gemm, _dynamic_u8_gemm, _attention, _mlp, _tokenizer, infer. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

40.3 Line annotations

Line 1: `"""Executable Spikingformer projection path for the NeuraEdge command ABI."""` This is executable documentation attached to the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import math` This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from typing import Sequence` This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `import numpy as np` This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `from neuraedge_compiler import (` This statement continues through source line 17; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `ProgramExecutor,` This is continuation line 2 of the 7-line logical statement that begins at source line 11. Its exact fragment is 'ProgramExecutor,'. The important operands are ProgramExecutor: the value named 'program executor' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `compile_spike_conv2d,` This is continuation line 3 of the 7-line logical statement that begins at source line 11. Its exact fragment is 'compile_spike_conv2d,'. The important operands are compile_spike_conv2d: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `compile_spike_gemm,` This is continuation line 4 of the 7-line logical statement that begins at source line 11. Its exact fragment is 'compile_spike_gemm,'. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 15: `compile_u8_conv2d,` This is continuation line 5 of the 7-line logical statement that begins at source line 11. Its exact fragment is 'compile_u8_conv2d,'. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `compile_u8_gemm,` This is continuation line 6 of the 7-line logical statement that begins at source line 11. Its exact fragment is 'compile_u8_gemm,'. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 17: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 11. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 18: `from neuraedge_golden import VectorOperation, round_shift_signed, saturate_signed` This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 19: `from neuraedge_protocol import (` This statement continues through source line 29; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `ProgramRecord,` This is continuation line 2 of the 11-line logical statement that begins at source line 19. Its exact fragment is 'ProgramRecord,'. The important operands are ProgramRecord: the value named 'program record' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `clear_status_command,` This is continuation line 3 of the 11-line logical statement that begins at source line 19. Its exact fragment is 'clear_status_command,'. The important operands are clear_status_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This

imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 22: `pack_vector_beats,` This is continuation line 4 of the 11-line logical statement that begins at source line 19. Its exact fragment is 'pack_vector_beats,'. The important operands are pack_vector_beats: the value named 'pack vector beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 23: `lif_command,` This is continuation line 5 of the 11-line logical statement that begins at source line 19. Its exact fragment is 'lif_command,'. The important operands are lif_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `pack_lif_beats,` This is continuation line 6 of the 11-line logical statement that begins at source line 19. Its exact fragment is 'pack_lif_beats,'. The important operands are pack_lif_beats: the value named 'pack lif beats' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 25: `unpack_lif_result,` This is continuation line 7 of the 11-line logical statement that begins at source line 19. Its exact fragment is 'unpack_lif_result,'. The important operands are unpack_lif_result: the value named 'unpack lif result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 26: `unpack_lif_trace,` This is continuation line 8 of the 11-line logical statement that begins at source line 19. Its exact fragment is 'unpack_lif_trace,'. The important operands are unpack_lif_trace: the value named 'unpack lif trace' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 27: `unpack_vector_result,` This is continuation line 9 of the 11-line logical statement that begins at source line 19. Its exact fragment is 'unpack_vector_result,'. The important operands are unpack_vector_result: the value named 'unpack vector result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 28: `vector_command,` This is continuation line 10 of the 11-line logical statement that begins at source line 19. Its exact fragment is 'vector_command,'. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 29: `)` This is continuation line 11 of the 11-line logical statement that begins at source line 19. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 30: `from spikingformer_parameters import ProjectionParameters, SpikingformerParameterArchive` This imports the named Python API so the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction,

and classifier stages to hardware operations can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 33: `VECTOR_LANES = 8` This assigns ‘8‘ to ‘VECTOR_LANES ‘ in host memory. Here VECTOR_LANES means one parallel arithmetic element within a vector or tensor datapath. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 34: `LIF_LANES = 32` This assigns ‘32‘ to ‘LIF_LANES ‘ in host memory. Here LIF_LANES means one parallel arithmetic element within a vector or tensor datapath. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 37: `def vector_binary_on_accelerator(` This starts function vector_binary_on_accelerator. Its indented body performs vector binary on accelerator as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 38: `driver: ProgramExecutor,` Inside the function vector_binary_on_accelerator, which handles vector binary on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are driver: the value named 'driver' in this block; ProgramExecutor: the value named 'program executor' in this block.

Line 39: `operation: VectorOperation,` Inside the function vector_binary_on_accelerator, which handles vector binary on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are operation: the value named 'operation' in this block; VectorOperation: the value named 'vector operation' in this block.

Line 40: `operand_a: np.ndarray,` Inside the function vector_binary_on_accelerator, which handles vector binary on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are operand_a: the value named 'operand a' in this block; ndarray: the value named 'ndarray' in this block.

Line 41: `operand_b: np.ndarray,` Inside the function vector_binary_on_accelerator, which handles vector binary on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are operand_b: the value named 'operand b' in this block; ndarray: the value named 'ndarray' in this block.

Line 42: `*,` Inside the function vector_binary_on_accelerator, which handles vector binary on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 43: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 44: `) -> np.ndarray:` Inside the function vector_binary_on_accelerator, which handles vector binary on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are ndarray: the value named 'ndarray' in this block.

Line 45: `"""Apply a binary vector-ALU operation to two equally shaped tensors."""` This is executable documentation attached to the function vector_binary_on_accelerator, which handles vector binary on accelerator. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 47: `if operation not in {VectorOperation.ADD_SAT, VectorOperation.MAXIMUM}:` This executes the following indented host-code branch only when ‘operation not in {VectorOperation.ADD_SAT, VectorOperation.MAXIMUM}‘ is true. The important operands are operation: the value named ’operation’ in this block; not: the value named ’not’ in this block; in: the value named ’in’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 48: `raise ValueError("this helper supports saturating add and maximum")` This rejects an invalid state by raising ‘ValueError("this helper supports saturating add and maximum")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 49: `a = np.asarray(operand_a, dtype=np.int64)` This assigns ‘np.asarray(operand_a, dtype=np.int64)‘ to ‘a ‘ in host memory. Here a means the value named ’a’ in this block. The important operands are asarray: the value named ’asarray’ in this block; operand_a: the value named ’operand a’ in this block; dtype: the value named ’dtype’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 50: `b = np.asarray(operand_b, dtype=np.int64)` This assigns ‘np.asarray(operand_b, dtype=np.int64)‘ to ‘b ‘ in host memory. Here b means the value named ’b’ in this block. The important operands are asarray: the value named ’asarray’ in this block; operand_b: the value named ’operand b’ in this block; dtype: the value named ’dtype’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 51: `if a.shape != b.shape:` This executes the following indented host-code branch only when ‘a.shape != b.shape‘ is true. The important operands are a: the value named ’a’ in this block; shape: the value named ’shape’ in this block; b: the value named ’b’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 52: `raise ValueError("vector operands must have equal shapes")` This rejects an invalid state by raising ‘ValueError("vector operands must have equal shapes")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 53: `if a.size and (a.min() < -(1 << 31) or a.max() > (1 << 31) - 1` Inside the function vector_binary_on_accel which handles vector binary on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are a: the value named ’a’ in this block; size: the value named ’size’ in this block; and: the value named ’and’ in this block.

Line 54: `or b.min() < -(1 << 31) or b.max() > (1 << 31) - 1):` Inside the function vector_binary_on_accelerator, which handles vector binary on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are or: the value named ’or’ in this block; b: the value named ’b’ in this block; min: the value named ’min’ in this block.

Line 55: `raise OverflowError("vector operands do not fit signed 32-bit lanes")` This rejects an invalid state by raising ‘OverflowError("vector operands do not fit signed 32-bit lanes")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 56: `flat_a = a.reshape(-1)` This assigns ‘a.reshape(-1)‘ to ‘flat_a ‘ in host memory. Here flat_a means the value named ’flat a’ in this block. The important operands are a: the value named ’a’ in this block; reshape: the value named ’reshape’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 57: `flat_b = b.reshape(-1)` This assigns ‘b.reshape(-1)‘ to ‘flat_b ‘ in host memory. Here flat_b means the value named ’flat b’ in this block. The important operands are b: the value named ’b’ in this block; reshape: the value named ’reshape’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 58: `records: list[ProgramRecord] = []` This assigns ‘[]‘ to ‘records‘ in host memory. Here records means the number of descriptor records accepted since program start. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 59: `counts: list[int] = []` This assigns ‘[]‘ to ‘counts‘ in host memory. Here counts means the value named ’counts’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 60: `command = vector_command(int(operation))` This assigns ‘vector_command(int(operation))‘ to ‘command ‘ in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; operation: the value named ’operation’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 61: `for start in range(0, len(flat_a), VECTOR_LANES):` This iterates start over ‘range(0, len(flat_a), VECTOR_LANES)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 62: `count = min(VECTOR_LANES, len(flat_a) - start)` This assigns ‘min(VECTOR_LANES, len(flat_a) - start)‘ to ‘count ‘ in host memory. Here count means the value named ’count’ in this block. The important operands are min: the value named ’min’ in this block; VECTOR_LANES: one parallel arithmetic element within a vector or tensor datapath; len: the value named ’len’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 63: `lanes_a = flat_a[start:start + count].tolist()` This assigns ‘flat_a[start:start + count].tolist()‘ to ‘lanes_a ‘ in host memory. Here lanes_a means one parallel arithmetic element within a vector or tensor datapath. The important operands are flat_a: the value named ’flat a’ in this block; start: the value named ’start’ in this block; count: the value named ’count’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 64: `lanes_b = flat_b[start:start + count].tolist()` This assigns ‘flat_b[start:start + count].tolist()‘ to ‘lanes_b ‘ in host memory. Here lanes_b means one parallel arithmetic element within a vector or tensor datapath. The important operands are flat_b: the value named ’flat b’ in this block; start: the value named ’start’ in this block; count: the value named ’count’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 65: `lanes_a.extend([0] * (VECTOR_LANES - count))` This calls ‘lanes_a.extend‘ with ‘[0] * (VECTOR_LANES - count)‘ inside the function vector_binary_on_accelerator, which handles vector binary on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 66: `lanes_b.extend([0] * (VECTOR_LANES - count))` This calls ‘lanes_b.extend‘ with ‘[0] * (VECTOR_LANES - count)‘ inside the function vector_binary_on_accelerator, which handles vector binary on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 67: `records.append(ProgramRecord(` This statement continues through source line 68; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes_a, lanes_b), 4)‘ inside the function vector_binary_on_accelerator, which handles vector binary on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 68: `command, pack_vector_beats(lanes_a, lanes_b), 4))` This is continuation line 2 of the 2-line logical statement that begins at source line 67. Its exact fragment is ‘command, pack_vector_beats(lanes_a, lanes_b), 4))‘. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; pack_vector_beats: the value named ’pack vector beats’ in this block; lanes_a: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes_a, lanes_b), 4)‘ inside the function vector_binary_on_accelerator, which handles vector binary on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 69: `counts.append(count)` This calls ‘counts.append‘ with ‘count‘ inside the function vector_binary_on_accelerator, which handles vector binary on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 70: `if not records:` This executes the following indented host-code branch only when ‘not records‘ is true. The important operands are not: the value named ’not’ in this block; records: the number of descriptor records accepted since program start. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 71: `return np.empty(a.shape, dtype=np.int64)` This returns ‘np.empty(a.shape, dtype=np.int64)‘ to the caller of the function vector_binary_on_accelerator, which handles vector binary on accelerator, ending this invocation. The important operands are empty: the value named ’empty’ in this block; a: the value named ’a’ in this block; shape: the value named ’shape’ in this block.

Line 72: `words = driver.execute_program(records, timeout_seconds=timeout_seconds)` This assigns ‘driver.execute_pro timeout_seconds=timeout_seconds)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 73: `if len(words) != 4 * len(records):` This executes the following indented host-code branch only when ‘len(words) != 4 * len(records)‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block; records: the number of descriptor records accepted since program start. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 74: `raise RuntimeError(f"vector program returned {len(words)} beats; expected {4 * len(records)}")` This rejects an invalid state by raising ‘RuntimeError(f"vector program returned {len(words)} beats; expected {4 * len(records)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 75: `result = np.empty(len(flat_a), dtype=np.int64)` This assigns ‘np.empty(len(flat_a), dtype=np.int64)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are empty: the value named ’empty’ in this block; len: the value named ’len’ in this block; flat_a: the value named ’flat a’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 76: `cursor = 0` This assigns ‘0‘ to ‘cursor ‘ in host memory. Here cursor means the value named ’cursor’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 77: `for record_index, count in enumerate(counts):` This iterates record_index, count over ‘enumerate(counts)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 78: `lanes = unpack_vector_result(words[4 * record_index:4 * record_index + 4])` This assigns ‘unpack_vector_result(words[4 * record_index:4 * record_index + 4])‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are unpack_vector_result: the value named ’unpack vector result’ in this block; words: the value named ’words’ in this block; record_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 79: `result[cursor:cursor + count] = lanes[:count]` This assigns ‘lanes[:count]‘ to ‘result[cursor‘ in host memory. Here result means the value named ’result’ in this block. The important operands are lanes: one parallel arithmetic element within a vector or tensor datapath; count: the value named ’count’ in this block. Context: the function vector_binary_on_accelerator, which handles vector binary on accelerator.

Line 80: `cursor += count` Inside the function vector_binary_on_accelerator, which handles vector binary on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are cursor: the value named ’cursor’ in this block; count: the value named ’count’ in this block.

Line 81: `return result.reshape(a.shape)` This returns ‘result.reshape(a.shape)‘ to the caller of the function vector_binary_on_accelerator, which handles vector binary on accelerator, ending this invocation. The important operands are result: the value named ’result’ in this block; reshape: the value named ’reshape’ in this block; a: the value named ’a’ in this block.

Line 84: `def power_of_two_requantize_on_accelerator(` This starts function power_of_two_requantize_on_accelerator. Its indented body performs power of two requantize on accelerator as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 85: `driver: ProgramExecutor,` Inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are driver: the value named ’driver’ in this block; ProgramExecutor: the value named ’program executor’ in this block.

Line 86: `values: np.ndarray,` Inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are values: the value named ’values’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 87: `*,` Inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 88: `division_shift: int,` Inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are division_shift: the value named ’division shift’ in this block.

Line 89: `clamp_minimum: int = -(1 << 31),` This assigns ‘-(1 << 31),‘ to ‘clamp_minimum‘ in host memory. Here clamp_minimum means the value named ’clamp minimum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 90: `clamp_maximum: int = (1 << 31) - 1,` This assigns ‘(1 << 31) - 1,‘ to ‘clamp_maximum‘ in host memory. Here clamp_maximum means the value named ’clamp maximum’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 91: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 92: `) -> np.ndarray:` Inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are ndarray: the value named 'ndarray' in this block.

Line 93: `"""Round "values / 2**division_shift" in the flexible vector datapath."""` This is executable documentation attached to the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 95: `source = np.asarray(values, dtype=np.int64)` This assigns 'np.asarray(values, dtype=np.int64)' to 'source ' in host memory. Here source means the value named 'source' in this block. The important operands are asarray: the value named 'asarray' in this block; values: the value named 'values' in this block; dtype: the value named 'dtype' in this block. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 96: `if not 0 <= division_shift <= 16:` This executes the following indented host-code branch only when 'not 0 <= division_shift <= 16' is true. The important operands are not: the value named 'not' in this block; division_shift: the value named 'division shift' in this block. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 97: `raise ValueError("division_shift must be in [0,16]")` This rejects an invalid state by raising 'ValueError("division_shift must be in [0,16]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 98: `if source.size and (` This line opens or closes a multi-line Python expression inside the function power_of_two_requa which handles power of two requantize on accelerator; the neighboring lines supply its arguments or elements.

Line 99: `source.min() < -(1 << 31) or source.max() > (1 << 31) - 1` Inside the function power_of_two_requantize_on which handles power of two requantize on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are source: the value named 'source' in this block; min: the value named 'min' in this block; or: the value named 'or' in this block.

Line 100: `):` Inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 101: `raise OverflowError("requantizer input must fit signed 32-bit lanes")` This rejects an invalid state by raising 'OverflowError("requantizer input must fit signed 32-bit lanes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 102: `flat = source.reshape(-1)` This assigns 'source.reshape(-1)' to 'flat ' in host memory. Here flat means the value named 'flat' in this block. The important operands are source: the value named 'source' in this block; reshape: the value named 'reshape' in this block. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 103: `records: list[ProgramRecord] = []` This assigns '[]' to 'records' in host memory. Here records means the number of descriptor records accepted since program start. The expression is a literal or structural operator and has no hidden software state. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 104: `counts: list[int] = []` This assigns '[]' to 'counts' in host memory. Here counts means the value named 'counts' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 105: `command = vector_command(` This statement continues through source line 109; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'vector_command(int(VectorOperation.FLEX_REQUA multiplier_q15=1 << 14, right_shift=division_shift - 1,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 106: `int(VectorOperation.FLEX_REQUANTIZE),` This is continuation line 2 of the 5-line logical statement that begins at source line 105. Its exact fragment is 'int(VectorOperation.FLEX_REQUANTIZE),'. The important operands are VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=1 << 14, right_shift=division_shift - 1,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 107: `multiplier_q15=1 << 14,` This is continuation line 3 of the 5-line logical statement that begins at source line 105. Its exact fragment is 'multiplier_q15=1 << 14,'. The important operands are multiplier_q15: the value named 'multiplier q15' in this block. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=1 << 14, right_shift=division_shift - 1,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 108: `right_shift=division_shift - 1,` This is continuation line 4 of the 5-line logical statement that begins at source line 105. Its exact fragment is 'right_shift=division_shift - 1,'. The important operands are right_shift: the value named 'right shift' in this block; division_shift: the value named 'division shift' in this block. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=1 << 14, right_shift=division_shift - 1,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 109: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 105. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=1 << 14, right_shift=division_shift - 1,)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in

this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 110: `for start in range(0, flat.size, VECTOR_LANES):` This iterates start over ‘range(0, flat.size, VECTOR_LANES)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 111: `stop = min(start + VECTOR_LANES, flat.size)` This assigns ‘min(start + VECTOR_LANES, flat.size)‘ to ‘stop ‘ in host memory. Here stop means the value named ’stop’ in this block. The important operands are min: the value named ’min’ in this block; start: the value named ’start’ in this block; VECTOR_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 112: `count = stop - start` This assigns ‘stop - start‘ to ‘count ‘ in host memory. Here count means the value named ’count’ in this block. The important operands are stop: the value named ’stop’ in this block; start: the value named ’start’ in this block. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 113: `lanes = flat[start:stop].tolist() + [0] * (VECTOR_LANES - count)` This assigns ‘flat[start:stop].tolist() + [0] * (VECTOR_LANES - count)‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are flat: the value named ’flat’ in this block; start: the value named ’start’ in this block; stop: the value named ’stop’ in this block. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 114: `records.append(ProgramRecord(` This statement continues through source line 123; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, [0] * VECTOR_LANES, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximu), 4,)‘ inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 115: `command,` This is continuation line 2 of the 10-line logical statement that begins at source line 114. Its exact fragment is ‘command,‘. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, [0] * VECTOR_LANES, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)‘ inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 116: `pack_vector_beats(` This is continuation line 3 of the 10-line logical statement that begins at source line 114. Its exact fragment is ‘pack_vector_beats(‘. The important operands are pack_vector_beats: the value named ’pack vector beats’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, [0] * VECTOR_LANES, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)‘ inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 117: `lanes,` This is continuation line 4 of the 10-line logical statement that begins at source line 114. Its exact fragment is ‘lanes,‘. The important operands are lanes: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, [0] * VECTOR_LANES, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)‘ inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 118: `[0] * VECTOR_LANES,` This is continuation line 5 of the 10-line logical statement that begins at source line 114. Its exact fragment is '[0] * VECTOR_LANES,'. The important operands are VECTOR_LANES: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls 'records.append' with 'ProgramRecord(command, pack_vector_beats(lanes, [0] * VECTOR_LANES, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)' inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 119: `clamp_minimum=clamp_minimum,` This is continuation line 6 of the 10-line logical statement that begins at source line 114. Its exact fragment is 'clamp_minimum=clamp_minimum,'. The important operands are clamp_minimum: the value named 'clamp minimum' in this block. Read together, the complete operation is: This calls 'records.append' with 'ProgramRecord(command, pack_vector_beats(lanes, [0] * VECTOR_LANES, clamp_minimum=clamp_m
clamp_maximum=clamp_maximum,), 4,)' inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 120: `clamp_maximum=clamp_maximum,` This is continuation line 7 of the 10-line logical statement that begins at source line 114. Its exact fragment is 'clamp_maximum=clamp_maximum,'. The important operands are clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This calls 'records.append' with 'ProgramRecord(command, pack_vector_beats(lanes, [0] * VECTOR_LANES, clamp_minimum=clamp_m
clamp_maximum=clamp_maximum,), 4,)' inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 121: `),` This is continuation line 8 of the 10-line logical statement that begins at source line 114. Its exact fragment is '),'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'records.append' with 'ProgramRecord(command, pack_vector_beats(lanes, [0] * VECTOR_LANES, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)' inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 122: `4,` This is continuation line 9 of the 10-line logical statement that begins at source line 114. Its exact fragment is '4,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'records.append' with 'ProgramRecord(command, pack_vector_beats(lanes, [0] * VECTOR_LANES, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)' inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 123: `))` This is continuation line 10 of the 10-line logical statement that begins at source line 114. Its exact fragment is '))'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'records.append' with 'ProgramRecord(command, pack_vector_beats(lanes, [0] * VECTOR_LANES, clamp_minimum=clamp_minimum, clamp_maximum=clamp_maximum,), 4,)' inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 124: `counts.append(count)` This calls 'counts.append' with 'count' inside the function power_of_two_requantize_on_acc
which handles power of two requantize on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 125: `if not records:` This executes the following indented host-code branch only when 'not records' is true. The important operands are not: the value named 'not' in this block; records: the number of descriptor records accepted since program start. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 126: `return np.empty(source.shape, dtype=np.int64)` This returns ‘np.empty(source.shape, dtype=np.int64)‘ to the caller of the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator, ending this invocation. The important operands are empty: the value named ’empty’ in this block; source: the value named ’source’ in this block; shape: the value named ’shape’ in this block.

Line 127: `words = driver.execute_program(records, timeout_seconds=timeout_seconds)` This assigns ‘driver.execute_pr timeout_seconds=timeout_seconds)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 128: `if len(words) != 4 * len(records):` This executes the following indented host-code branch only when ‘len(words) != 4 * len(records)‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block; records: the number of descriptor records accepted since program start. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 129: `raise RuntimeError("power-of-two requantizer returned an invalid stream length")` This rejects an invalid state by raising ‘RuntimeError("power-of-two requantizer returned an invalid stream length")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 130: `result = np.empty(flat.size, dtype=np.int64)` This assigns ‘np.empty(flat.size, dtype=np.int64)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are empty: the value named ’empty’ in this block; flat: the value named ’flat’ in this block; size: the value named ’size’ in this block. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 131: `cursor = 0` This assigns ‘0‘ to ‘cursor ‘ in host memory. Here cursor means the value named ’cursor’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 132: `for record_index, count in enumerate(counts):` This iterates record_index, count over ‘enumerate(counts)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 133: `lanes = unpack_vector_result(words[4 * record_index:4 * record_index + 4])` This assigns ‘unpack_vector_result(words[4 * record_index:4 * record_index + 4])‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are unpack_vector_result: the value named ’unpack vector result’ in this block; words: the value named ’words’ in this block; record_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 134: `result[cursor:cursor + count] = lanes[:count]` This assigns ‘lanes[:count]‘ to ‘result[cursor‘ in host memory. Here result means the value named ’result’ in this block. The important operands are lanes: one parallel arithmetic element within a vector or tensor datapath; count: the value named ’count’ in this block. Context: the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator.

Line 135: `cursor += count` Inside the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are cursor: the value named ’cursor’ in this block; count: the value named ’count’ in this block.

Line 136: `return result.reshape(source.shape)` This returns ‘result.reshape(source.shape)‘ to the caller of the function power_of_two_requantize_on_accelerator, which handles power of two requantize on accelerator, ending this invocation. The important operands are result: the value named ’result’ in this block; reshape: the value named ’reshape’ in this block; source: the value named ’source’ in this block.

Line 139: `def global_spatiotemporal_sum_on_accelerator(` This starts function global_spatiotemporal_sum_on_accelerat Its indented body performs global spatiotemporal sum on accelerator as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 140: `driver: ProgramExecutor,` Inside the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are driver: the value named 'driver' in this block; ProgramExecutor: the value named 'program executor' in this block.

Line 141: `values: np.ndarray,` Inside the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are values: the value named 'values' in this block; ndarray: the value named 'ndarray' in this block.

Line 142: `*,` Inside the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 143: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 144: `) -> np.ndarray:` Inside the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are ndarray: the value named 'ndarray' in this block.

Line 145: `"""Reduce a [T,B,C,H,W] tensor to [B,C] through pairwise vector adds."""` This is executable documentation attached to the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 147: `source = np.asarray(values, dtype=np.int64)` This assigns 'np.asarray(values, dtype=np.int64)' to 'source ' in host memory. Here source means the value named 'source' in this block. The important operands are asarray: the value named 'asarray' in this block; values: the value named 'values' in this block; dtype: the value named 'dtype' in this block. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 148: `if source.ndim != 5:` This executes the following indented host-code branch only when 'source.ndim != 5' is true. The important operands are source: the value named 'source' in this block; ndim: the value named 'ndim' in this block. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 149: `raise ValueError("global sum input must have shape [T,B,C,H,W]")` This rejects an invalid state by raising 'ValueError("global sum input must have shape [T,B,C,H,W]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 150: `timesteps, batch, channels, height, width = source.shape` This assigns 'source.shape' to 'timesteps, batch, channels, height, width ' in host memory. Here timesteps means one discrete SNN update instant. The important operands are source: the value named 'source' in this block; shape: the value named 'shape' in this block. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 151: `reduction = source.transpose(0, 3, 4, 1, 2).reshape(` This statement continues through source line 152; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘source.transpose(0, 3, 4, 1, 2).reshape(timesteps * height * width, batch, channels)‘ to ‘reduction ‘ in host memory. Here reduction means the value named ’reduction’ in this block. The important operands are source: the value named ’source’ in this block; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 152: `timesteps * height * width, batch, channels)` This is continuation line 2 of the 2-line logical statement that begins at source line 151. Its exact fragment is ‘timesteps * height * width, batch, channels)‘. The important operands are timesteps: one discrete SNN update instant; height: the value named ’height’ in this block; width: the value named ’width’ in this block. Read together, the complete operation is: This assigns ‘source.transpose(0, 3, 4, 1, 2).reshape(timesteps * height * width, batch, channels)‘ to ‘reduction ‘ in host memory. Here reduction means the value named ’reduction’ in this block. The important operands are source: the value named ’source’ in this block; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 153: `if int(np.abs(reduction).max(initial=0)) * reduction.shape[0] > (1 << 31) - 1:` This executes the following indented host-code branch only when ‘int(np.abs(reduction).max(initial=0)) * reduction.shape[0] > (1 << 31) - 1‘ is true. The important operands are abs: the value named ’abs’ in this block; reduction: the value named ’reduction’ in this block; max: the value named ’max’ in this block. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 154: `raise OverflowError("global sum can exceed the signed-32 vector accumulator")` This rejects an invalid state by raising ‘OverflowError("global sum can exceed the signed-32 vector accumulator")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 155: `candidates = [reduction[index] for index in range(reduction.shape[0])]` This assigns ‘[reduction[index] for index in range(reduction.shape[0])]‘ to ‘candidates ‘ in host memory. Here candidates means the value named ’candidates’ in this block. The important operands are reduction: the value named ’reduction’ in this block; index: an integer selecting one tensor element, lane, bank, or state entry; for: the value named ’for’ in this block. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 156: `while len(candidates) > 1:` This repeats the following host-code block while ‘len(candidates) > 1‘ remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 157: `reduced: list[np.ndarray] = []` This assigns ‘[]‘ to ‘reduced‘ in host memory. Here reduced means the value named ’reduced’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 158: `for index in range(0, len(candidates) - 1, 2):` This iterates index over ‘range(0, len(candidates) - 1, 2)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 159: `reduced.append(vector_binary_on_accelerator(` This statement continues through source line 165; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘reduced.append‘ with ‘vector_binary_on_accelerator(driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)‘ inside the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 160: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 159. Its exact fragment is ‘driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This calls ‘reduced.append‘ with ‘vector_binary_on_accelerator(driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)‘ inside the function

global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 161: `VectorOperation.ADD_SAT,` This is continuation line 3 of the 7-line logical statement that begins at source line 159. Its exact fragment is 'VectorOperation.ADD_SAT,'. The important operands are VectorOperation: the value named 'vector operation' in this block; ADD_SAT: the value named 'add sat' in this block. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 162: `candidates[index],` This is continuation line 4 of the 7-line logical statement that begins at source line 159. Its exact fragment is 'candidates[index],'. The important operands are candidates: the value named 'candidates' in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 163: `candidates[index + 1],` This is continuation line 5 of the 7-line logical statement that begins at source line 159. Its exact fragment is 'candidates[index + 1],'. The important operands are candidates: the value named 'candidates' in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function global_spatiotemporal_sum_on_acc which handles global spatiotemporal sum on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 164: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 159. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 165: `))` This is continuation line 7 of the 7-line logical statement that begins at source line 159. Its exact fragment is '))'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.ADD_SAT, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 166: `if len(candidates) & 1:` This executes the following indented host-code branch only when 'len(candidates) & 1' is true. The important operands are len: the value named 'len' in this block; candidates: the value named 'candidates' in this block. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 167: `reduced.append(candidates[-1])` This calls 'reduced.append' with 'candidates[-1]' inside the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 168: `candidates = reduced` This assigns ‘reduced‘ to ‘candidates ‘ in host memory. Here candidates means the value named ’candidates’ in this block. The important operands are reduced: the value named ’reduced’ in this block. Context: the function global_spatiotemporal_sum_on_accelerator, which handles global spatiotemporal sum on accelerator.

Line 169: `return candidates[0]` This returns ‘candidates[0]‘ to the caller of the function global_spatiotemporal_sum_on_acce which handles global spatiotemporal sum on accelerator, ending this invocation. The important operands are candidates: the value named ’candidates’ in this block.

Line 172: `def binary_max_pool2d_on_accelerator(` This starts function binary_max_pool2d_on_accelerator. Its indented body performs binary max pool2d on accelerator as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 173: `driver: ProgramExecutor,` Inside the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are driver: the value named ’driver’ in this block; ProgramExecutor: the value named ’program executor’ in this block.

Line 174: `values: np.ndarray,` Inside the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are values: the value named ’values’ in this block; ndarray: the value named ’ndarray’ in this block.

Line 175: `*,` Inside the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 176: `kernel_size: int = 3,` This assigns ‘3,‘ to ‘kernel_size‘ in host memory. Here kernel_size means the value named ’kernel size’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 177: `stride: int = 2,` This assigns ‘2,‘ to ‘stride‘ in host memory. Here stride means the value named ’stride’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 178: `padding: int = 1,` This assigns ‘1,‘ to ‘padding‘ in host memory. Here padding means the value named ’padding’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 179: `timeout_seconds: float = 30.0,` This assigns ‘30.0,‘ to ‘timeout_seconds‘ in host memory. Here timeout_seconds means the value named ’timeout seconds’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 180: `) -> np.ndarray:` Inside the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are ndarray: the value named ’ndarray’ in this block.

Line 181: `"""Max-pool NCHW binary spikes with pairwise vector-maximum trees."""` This is executable documentation attached to the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 183: `source = np.asarray(values)` This assigns ‘np.asarray(values)‘ to ‘source ‘ in host memory. Here source means the value named ’source’ in this block. The important operands are asarray: the value named ’asarray’ in this block; values: the value named ’values’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 184: `if source.ndim != 4 or np.any((source != 0) & (source != 1)):` This executes the following indented host-code branch only when ‘source.ndim != 4 or np.any((source != 0) & (source != 1))‘ is true. The important operands are source: the value named ’source’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 185: `raise ValueError("binary max-pool input must be an NCHW tensor containing only 0/1")` This rejects an invalid state by raising ‘ValueError("binary max-pool input must be an NCHW tensor containing only 0/1")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 186: `if kernel_size <= 0 or stride <= 0 or padding < 0:` This executes the following indented host-code branch only when ‘kernel_size <= 0 or stride <= 0 or padding < 0‘ is true. The important operands are kernel_size: the value named ’kernel size’ in this block; or: the value named ’or’ in this block; stride: the value named ’stride’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 187: `raise ValueError("invalid max-pool geometry")` This rejects an invalid state by raising ‘ValueError("invalid max-pool geometry")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 188: `padded = np.pad(` This statement continues through source line 192; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.pad(source.astype(np.int64), ((0, 0), (0, 0), (padding, padding), (padding, padding)), mode="constant",)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are pad: the value named ’pad’ in this block; source: the value named ’source’ in this block; astype: the value named ’astype’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 189: `source.astype(np.int64),` This is continuation line 2 of the 5-line logical statement that begins at source line 188. Its exact fragment is ‘source.astype(np.int64),‘. The important operands are source: the value named ’source’ in this block; astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block. Read together, the complete operation is: This assigns ‘np.pad(source.astype(np.int64), ((0, 0), (0, 0), (padding, padding), (padding, padding)), mode="constant",)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are pad: the value named ’pad’ in this block; source: the value named ’source’ in this block; astype: the value named ’astype’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 190: `((0, 0), (0, 0), (padding, padding), (padding, padding)),` This is continuation line 3 of the 5-line logical statement that begins at source line 188. Its exact fragment is ‘((0, 0), (0, 0), (padding, padding), (padding, padding)),‘. The important operands are padding: the value named ’padding’ in this block. Read together, the complete operation is: This assigns ‘np.pad(source.astype(np.int64), ((0, 0), (0, 0), (padding, padding), (padding, padding)), mode="constant",)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are pad: the value named ’pad’ in this block; source: the value named ’source’ in this block; astype: the value named ’astype’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 191: `mode="constant",` This is continuation line 4 of the 5-line logical statement that begins at source line 188. Its exact fragment is ‘mode="constant",‘. The important operands are mode: the value named ’mode’ in this block; constant: the value named ’constant’ in this block. Read together, the complete operation is: This assigns ‘np.pad(source.astype(np.int64), ((0, 0), (0, 0), (padding, padding), (padding, padding)), mode="constant",)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are pad: the value named ’pad’ in this block; source: the value named ’source’ in this block; astype: the value named ’astype’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 192: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 188. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.pad(source.astype(np.int64), ((0, 0), (0, 0), (padding, padding), (padding, padding)), mode="constant",)‘ to ‘padded ‘ in host memory. Here padded means the value named ’padded’ in this block. The important operands are pad: the value named ’pad’ in this block; source: the value named ’source’ in this block; astype: the value named ’astype’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 193: `output_height = (source.shape[2] + 2 * padding - kernel_size) // stride + 1` This assigns ‘(source.shape + 2 * padding - kernel_size) // stride + 1‘ to ‘output_height ‘ in host memory. Here output_height means the value named ’output height’ in this block. The important operands are source: the value named ’source’ in this block; shape: the value named ’shape’ in this block; padding: the value named ’padding’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 194: `output_width = (source.shape[3] + 2 * padding - kernel_size) // stride + 1` This assigns ‘(source.shape[3 + 2 * padding - kernel_size) // stride + 1‘ to ‘output_width ‘ in host memory. Here output_width means the value named ’output width’ in this block. The important operands are source: the value named ’source’ in this block; shape: the value named ’shape’ in this block; padding: the value named ’padding’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 195: `candidates = [` This statement continues through source line 200; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘[padded[:, :, kernel_y:kernel_y + output_height * stride:stride, kernel_x:kernel_x + output_width * stride:stride] for kernel_y in range(kernel_size) for kernel_x in range(kernel_size)]‘ to ‘candidates ‘ in host memory. Here candidates means the value named ’candidates’ in this block. The important operands are padded: the value named ’padded’ in this block; kernel_y: the value named ’kernel y’ in this block; output_height: the value named ’output height’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 196: `padded[:, :, kernel_y:kernel_y + output_height * stride:stride,` This is continuation line 2 of the 6-line logical statement that begins at source line 195. Its exact fragment is ‘padded[:, :, kernel_y:kernel_y + output_height * stride:stride,‘. The important operands are padded: the value named ’padded’ in this block; kernel_y: the value named ’kernel y’ in this block; output_height: the value named ’output height’ in this block. Read together, the complete operation is: This assigns ‘[padded[:, :, kernel_y:kernel_y + output_height * stride:stride, kernel_x:kernel_x + output_width * stride:stride] for kernel_y in range(kernel_size) for kernel_x in range(kernel_size)]‘ to ‘candidates ‘ in host memory. Here candidates means the value named ’candidates’ in this block. The important operands are padded: the value named ’padded’ in this block; kernel_y: the value named ’kernel y’ in this block; output_height: the value named ’output height’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 197: `kernel_x:kernel_x + output_width * stride:stride]` This is continuation line 3 of the 6-line logical statement that begins at source line 195. Its exact fragment is ‘kernel_x:kernel_x + output_width * stride:stride]‘. The important operands are kernel_x: the value named ’kernel x’ in this block; output_width: the value named ’output width’ in this block; stride: the value named ’stride’ in this block. Read together, the complete operation is: This assigns ‘[padded[:, :, kernel_y:kernel_y + output_height * stride:stride, kernel_x:kernel_x + output_width * stride:stride] for kernel_y in range(kernel_size) for kernel_x in range(kernel_size)]‘ to ‘candidates ‘ in host memory. Here candidates means the value named ’candidates’ in this block. The important operands are padded: the value named ’padded’ in this block; kernel_y: the value named ’kernel y’ in this block; output_height: the value named ’output height’ in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 198: `for kernel_y in range(kernel_size)` This is continuation line 4 of the 6-line logical statement that begins at source line 195. Its exact fragment is ‘for kernel_y in range(kernel_size)‘. The important operands are for: the value named ’for’ in this block; kernel_y: the value named ’kernel y’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘[padded[:, :, kernel_y:kernel_y + output_height * stride:stride, kernel_x:kernel_x + output_width * stride:stride] for kernel_y in range(kernel_size) for kernel_x in range(kernel_size)]‘ to ‘candidates ‘ in host memory. Here candidates means the value named ’candidates’ in this block. The important

operands are padded: the value named 'padded' in this block; kernel_y: the value named 'kernel y' in this block; output_height: the value named 'output height' in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 199: `for kernel_x in range(kernel_size)` This is continuation line 5 of the 6-line logical statement that begins at source line 195. Its exact fragment is 'for kernel_x in range(kernel_size)'. The important operands are for: the value named 'for' in this block; kernel_x: the value named 'kernel x' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This assigns '[padded[:, :, kernel_y:kernel_y + output_height * stride:stride, kernel_x:kernel_x + output_width * stride:stride] for kernel_y in range(kernel_size) for kernel_x in range(kernel_size)]' to 'candidates ' in host memory. Here candidates means the value named 'candidates' in this block. The important operands are padded: the value named 'padded' in this block; kernel_y: the value named 'kernel y' in this block; output_height: the value named 'output height' in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 200: `]` This is continuation line 6 of the 6-line logical statement that begins at source line 195. Its exact fragment is ']'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '[padded[:, :, kernel_y:kernel_y + output_height * stride:stride, kernel_x:kernel_x + output_width * stride:stride] for kernel_y in range(kernel_size) for kernel_x in range(kernel_size)]' to 'candidates ' in host memory. Here candidates means the value named 'candidates' in this block. The important operands are padded: the value named 'padded' in this block; kernel_y: the value named 'kernel y' in this block; output_height: the value named 'output height' in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 201: `while len(candidates) > 1:` This repeats the following host-code block while 'len(candidates) > 1' remains true; surrounding timeout/error logic prevents an unbounded hardware wait.

Line 202: `reduced: list[np.ndarray] = []` This assigns '[]' to 'reduced' in host memory. Here reduced means the value named 'reduced' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 203: `for index in range(0, len(candidates) - 1, 2):` This iterates index over 'range(0, len(candidates) - 1, 2)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 204: `reduced.append(vector_binary_on_accelerator(` This statement continues through source line 210; the explanation uses the complete expression rather than only the first visual fragment. This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.MAXIMUM, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 205: `driver,` This is continuation line 2 of the 7-line logical statement that begins at source line 204. Its exact fragment is 'driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.MAXIMUM, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 206: `VectorOperation.MAXIMUM,` This is continuation line 3 of the 7-line logical statement that begins at source line 204. Its exact fragment is 'VectorOperation.MAXIMUM,'. The important operands are VectorOperation: the value named 'vector operation' in this block; MAXIMUM: the value named 'maximum' in this block. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.MAXIMUM, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 207: `candidates[index],` This is continuation line 4 of the 7-line logical statement that begins at source line 204. Its exact fragment is 'candidates[index],'. The important operands are candidates: the value named 'candidates' in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.MAXIMUM, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function binary_max_pool2d_on_accelerator which handles binary max pool2d on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 208: `candidates[index + 1],` This is continuation line 5 of the 7-line logical statement that begins at source line 204. Its exact fragment is 'candidates[index + 1],'. The important operands are candidates: the value named 'candidates' in this block; index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.MAXIMUM, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function binary_max_pool2d_on_accelerator which handles binary max pool2d on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 209: `timeout_seconds=timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 204. Its exact fragment is 'timeout_seconds=timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.MAXIMUM, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 210: `))` This is continuation line 7 of the 7-line logical statement that begins at source line 204. Its exact fragment is '))'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'reduced.append' with 'vector_binary_on_accelerator(driver, VectorOperation.MAXIMUM, candidates[index], candidates[index + 1], timeout_seconds=timeout_seconds,)' inside the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 211: `if len(candidates) & 1:` This executes the following indented host-code branch only when 'len(candidates) & 1' is true. The important operands are len: the value named 'len' in this block; candidates: the value named 'candidates' in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 212: `reduced.append(candidates[-1])` This calls 'reduced.append' with 'candidates[-1]' inside the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 213: `candidates = reduced` This assigns 'reduced' to 'candidates ' in host memory. Here candidates means the value named 'candidates' in this block. The important operands are reduced: the value named 'reduced' in this block. Context: the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator.

Line 214: `return candidates[0].astype(np.uint8)` This returns 'candidates[0].astype(np.uint8)' to the caller of the function binary_max_pool2d_on_accelerator, which handles binary max pool2d on accelerator, ending this invocation. The important operands are candidates: the value named 'candidates' in this block; astype: the value named 'astype' in this block; uint8: the value named 'uint8' in this block.

Line 217: `def lif_sequence_reference(` This starts function lif_sequence_reference. Its indented body performs lif sequence reference as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 218: `values_q10: np.ndarray,` Inside the function lif_sequence_reference, which handles lif sequence reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are values_q10: the value named 'values q10' in this block; ndarray: the value named 'ndarray' in this block.

Line 219: `*,` Inside the function lif_sequence_reference, which handles lif sequence reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 220: `threshold_q10: int = 1 << 10,` This assigns '1 << 10,' to 'threshold_q10' in host memory. Here threshold_q10 means the membrane level at which a neuron emits a spike. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 221: `leak_shift: int = 1,` This assigns '1,' to 'leak_shift' in host memory. Here leak_shift means the retained fraction of prior membrane state. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 222: `reset_q10: int = 0,` This assigns '0,' to 'reset_q10' in host memory. Here reset_q10 means the value named 'reset q10' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 223: `) -> np.ndarray:` Inside the function lif_sequence_reference, which handles lif sequence reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are ndarray: the value named 'ndarray' in this block.

Line 224: `"""Bit-exact fixed-point LIF sequence for an arbitrary tensor shape."""` This is executable documentation attached to the function lif_sequence_reference, which handles lif sequence reference. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 226: `values = np.asarray(values_q10, dtype=np.int64)` This assigns 'np.asarray(values_q10, dtype=np.int64)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are asarray: the value named 'asarray' in this block; values_q10: the value named 'values q10' in this block; dtype: the value named 'dtype' in this block. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 227: `if values.ndim < 2 or values.shape[0] == 0:` This executes the following indented host-code branch only when 'values.ndim < 2 or values.shape[0] == 0' is true. The important operands are values: the value named 'values' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 228: `raise ValueError("LIF input must have shape [timesteps, ...]")` This rejects an invalid state by raising 'ValueError("LIF input must have shape [timesteps, ...]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 229: `if not 0 <= leak_shift <= 31:` This executes the following indented host-code branch only when 'not 0 <= leak_shift <= 31' is true. The important operands are not: the value named 'not' in this block; leak_shift: the retained fraction of prior membrane state. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 230: `raise ValueError("leak_shift must be in [0,31]")` This rejects an invalid state by raising 'ValueError("leak_shift must be in [0,31]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 231: `membrane = np.full(values.shape[1:], reset_q10, dtype=np.int64)` This assigns ‘np.full(values.shape[1:], reset_q10, dtype=np.int64)‘ to ‘membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are full: the value named ’full’ in this block; values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 232: `spikes = np.zeros(values.shape, dtype=np.uint8)` This assigns ‘np.zeros(values.shape, dtype=np.uint8)‘ to ‘spikes ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are zeros: the value named ’zeros’ in this block; values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 233: `for timestep in range(values.shape[0]):` This iterates timestep over ‘range(values.shape[0])‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_sequence_reference, which handles lif sequence reference.

Line 234: `current = np.clip(values[timestep] >> 1, -(1 << 15), (1 << 15) - 1)` This assigns ‘np.clip(values[timestep] >> 1, -(1 << 15), (1 << 15) - 1)‘ to ‘current ‘ in host memory. Here current means the value named ’current’ in this block. The important operands are clip: the value named ’clip’ in this block; values: the value named ’values’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 235: `leaked = membrane - (membrane >> leak_shift)` This assigns ‘membrane - (membrane >> leak_shift)‘ to ‘leaked ‘ in host memory. Here leaked means the retained fraction of prior membrane state. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 236: `membrane = saturate_signed(leaked + current, 24)` This assigns ‘saturate_signed(leaked + current, 24)‘ to ‘membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are saturate_signed: the value named ’saturate signed’ in this block; leaked: the retained fraction of prior membrane state; current: the value named ’current’ in this block. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 237: `fired = membrane >= threshold_q10` Inside the function lif_sequence_reference, which handles lif sequence reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are fired: the value named ’fired’ in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; threshold_q10: the membrane level at which a neuron emits a spike.

Line 238: `spikes[timestep] = fired` This assigns ‘fired‘ to ‘spikes[timestep] ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are fired: the value named ’fired’ in this block. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 239: `membrane = np.where(fired, reset_q10, membrane)` This assigns ‘np.where(fired, reset_q10, membrane)‘ to ‘membrane ‘ in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are where: the value named ’where’ in this block; fired: the value named ’fired’ in this block; reset_q10: the value named ’reset q10’ in this block. Context: the function lif_sequence_reference, which handles lif sequence reference.

Line 240: `return spikes` This returns ‘spikes‘ to the caller of the function lif_sequence_reference, which handles lif sequence reference, ending this invocation. The important operands are spikes: a binary event produced when a neuron crosses its threshold.

Line 243: `def lif_sequence_with_trace_reference(` This starts function lif_sequence_with_trace_reference. Its indented body performs lif sequence with trace reference as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 244: `values_q10: np.ndarray,` Inside the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are values_q10: the value named 'values q10' in this block; ndarray: the value named 'ndarray' in this block.

Line 245: `*,` Inside the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 246: `threshold_q10: int = 1 << 10,` This assigns '1 << 10,' to 'threshold_q10' in host memory. Here threshold_q10 means the membrane level at which a neuron emits a spike. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 247: `leak_shift: int = 1,` This assigns '1,' to 'leak_shift' in host memory. Here leak_shift means the retained fraction of prior membrane state. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 248: `reset_q10: int = 0,` This assigns '0,' to 'reset_q10' in host memory. Here reset_q10 means the value named 'reset q10' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 249: `) -> tuple[np.ndarray, np.ndarray]:` Inside the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 250: `"""Return spikes and the signed-24 membrane immediately before hard reset."""` This is executable documentation attached to the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 252: `values = np.asarray(values_q10, dtype=np.int64)` This assigns 'np.asarray(values_q10, dtype=np.int64)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are asarray: the value named 'asarray' in this block; values_q10: the value named 'values q10' in this block; dtype: the value named 'dtype' in this block. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 253: `if values.ndim < 2 or values.shape[0] == 0:` This executes the following indented host-code branch only when 'values.ndim < 2 or values.shape[0] == 0' is true. The important operands are values: the value named 'values' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 254: `raise ValueError("LIF input must have shape [timesteps, ...]")` This rejects an invalid state by raising 'ValueError("LIF input must have shape [timesteps, ...]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 255: `if not 0 <= leak_shift <= 31:` This executes the following indented host-code branch only when 'not 0 <= leak_shift <= 31' is true. The important operands are not: the value named 'not' in this block; leak_shift: the retained fraction of prior membrane state. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 256: `raise ValueError("leak_shift must be in [0,31]")` This rejects an invalid state by raising 'ValueError("leak_shift must be in [0,31]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 257: `membrane = np.full(values.shape[1:], reset_q10, dtype=np.int64)` This assigns 'np.full(values.shape[1:], reset_q10, dtype=np.int64)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are full: the value named 'full' in this block; values: the value named 'values' in this block; shape: the value named 'shape' in this block. Context: the function lif_sequence_with_trace_reference which handles lif sequence with trace reference.

Line 258: `spikes = np.zeros(values.shape, dtype=np.uint8)` This assigns 'np.zeros(values.shape, dtype=np.uint8)' to 'spikes ' in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are zeros: the value named 'zeros' in this block; values: the value named 'values' in this block; shape: the value named 'shape' in this block. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 259: `membrane_trace = np.zeros(values.shape, dtype=np.int64)` This assigns 'np.zeros(values.shape, dtype=np.int64 to 'membrane_trace ' in host memory. Here membrane_trace means the persistent LIF neuron state carrying charge between timesteps. The important operands are zeros: the value named 'zeros' in this block; values: the value named 'values' in this block; shape: the value named 'shape' in this block. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 260: `for timestep in range(values.shape[0]):` This iterates timestep over 'range(values.shape[0])'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 261: `current = np.clip(values[timestep] >> 1, -(1 << 15), (1 << 15) - 1)` This assigns 'np.clip(values[timestep] >> 1, -(1 << 15), (1 << 15) - 1)' to 'current ' in host memory. Here current means the value named 'current' in this block. The important operands are clip: the value named 'clip' in this block; values: the value named 'values' in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 262: `leaked = membrane - (membrane >> leak_shift)` This assigns 'membrane - (membrane >> leak_shift)' to 'leaked ' in host memory. Here leaked means the retained fraction of prior membrane state. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps; leak_shift: the retained fraction of prior membrane state. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 263: `membrane = saturate_signed(leaked + current, 24)` This assigns 'saturate_signed(leaked + current, 24)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are saturate_signed: the value named 'saturate signed' in this block; leaked: the retained fraction of prior membrane state; current: the value named 'current' in this block. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 264: `membrane_trace[timestep] = membrane` This assigns 'membrane' to 'membrane_trace[timestep] ' in host memory. Here membrane_trace means the persistent LIF neuron state carrying charge between timesteps. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 265: `fired = membrane >= threshold_q10` Inside the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are fired: the value named 'fired' in this block; membrane: the persistent LIF neuron state carrying charge between timesteps; threshold_q10: the membrane level at which a neuron emits a spike.

Line 266: `spikes[timestep] = fired` This assigns 'fired' to 'spikes[timestep] ' in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are fired: the value named 'fired' in this block. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 267: `membrane = np.where(fired, reset_q10, membrane)` This assigns 'np.where(fired, reset_q10, membrane)' to 'membrane ' in host memory. Here membrane means the persistent LIF neuron state carrying charge between timesteps. The important operands are where: the value named 'where' in this block; fired: the value named 'fired' in this block; reset_q10: the value named 'reset q10' in this block. Context: the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference.

Line 268: `return spikes, membrane_trace` This returns 'spikes, membrane_trace' to the caller of the function lif_sequence_with_trace_reference, which handles lif sequence with trace reference, ending this invocation. The important operands are spikes: a binary event produced when a neuron crosses its threshold; membrane_trace: the persistent LIF neuron state carrying charge between timesteps.

Line 271: `def lif_sequence_on_accelerator(` This starts function lif_sequence_on_accelerator. Its indented body performs lif sequence on accelerator as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 272: `driver: ProgramExecutor,` Inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are driver: the value named 'driver' in this block; ProgramExecutor: the value named 'program executor' in this block.

Line 273: `values_q10: np.ndarray,` Inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are values_q10: the value named 'values q10' in this block; ndarray: the value named 'ndarray' in this block.

Line 274: `*,` Inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 275: `threshold_q10: int = 1 << 10,` This assigns '1 << 10,' to 'threshold_q10' in host memory. Here threshold_q10 means the membrane level at which a neuron emits a spike. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 276: `leak_shift: int = 1,` This assigns '1,' to 'leak_shift' in host memory. Here leak_shift means the retained fraction of prior membrane state. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 277: `reset_q10: int = 0,` This assigns '0,' to 'reset_q10' in host memory. Here reset_q10 means the value named 'reset q10' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 278: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 279: `) -> np.ndarray:` Inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are ndarray: the value named 'ndarray' in this block.

Line 280: `"""Schedule every logical LIF state through the physical 32-lane bank."""` This is executable documentation attached to the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 282: `values = np.asarray(values_q10, dtype=np.int64)` This assigns ‘np.asarray(values_q10, dtype=np.int64)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are asarray: the value named ’asarray’ in this block; values_q10: the value named ’values q10’ in this block; dtype: the value named ’dtype’ in this block. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 283: `if values.ndim < 2 or values.shape[0] == 0:` This executes the following indented host-code branch only when ‘values.ndim < 2 or values.shape[0] == 0‘ is true. The important operands are values: the value named ’values’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 284: `raise ValueError("LIF input must have shape [timesteps, ...]")` This rejects an invalid state by raising ‘ValueError("LIF input must have shape [timesteps, ...]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 285: `if values.size and (values.min() < -(1 << 63) or values.max() > (1 << 63) - 1):` This executes the following indented host-code branch only when ‘values.size and (values.min() < -(1 << 63) or values.max() > (1 << 63) - 1)‘ is true. The important operands are values: the value named ’values’ in this block; size: the value named ’size’ in this block; and: the value named ’and’ in this block. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 286: `raise OverflowError("LIF input exceeds signed 64-bit preparation arithmetic")` This rejects an invalid state by raising ‘OverflowError("LIF input exceeds signed 64-bit preparation arithmetic")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 287: `timesteps = values.shape[0]` This assigns ‘values.shape[0]‘ to ‘timesteps ‘ in host memory. Here timesteps means one discrete SNN update instant. The important operands are values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 288: `flat = values.reshape(timesteps, -1)` This assigns ‘values.reshape(timesteps, -1)‘ to ‘flat ‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are values: the value named ’values’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 289: `records: list[ProgramRecord] = []` This assigns ‘[]‘ to ‘records‘ in host memory. Here records means the number of descriptor records accepted since program start. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 290: `bindings: list[tuple[int, int, int]] = []` This assigns ‘[]‘ to ‘bindings‘ in host memory. Here bindings means the value named ’bindings’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 291: `for element_start in range(0, flat.shape[1], LIF_LANES):` This iterates element_start over ‘range(0, flat.shape[1], LIF_LANES)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 292: `element_count = min(LIF_LANES, flat.shape[1] - element_start)` This assigns ‘min(LIF_LANES, flat.shape[1] - element_start)‘ to ‘element_count ‘ in host memory. Here element_count means an integer count retained for control or measurable telemetry. The important operands are min: the value named ’min’ in this block; LIF_LANES: one parallel arithmetic element within a vector or tensor datapath; flat: the value named ’flat’ in this block. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 293: `for timestep in range(timesteps):` This iterates timestep over ‘range(timesteps)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 294: `currents = np.clip(` This statement continues through source line 298; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.clip(flat[timestep, element_start:element_start + element_count] >> 1, -(1 << 15), (1 << 15) - 1,).astype(np.int64).tolist()‘ to ‘currents ‘ in host memory. Here currents means the value named ’currents’ in this block. The important operands are clip: the value named ’clip’ in this block; flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 295: `flat[timestep, element_start:element_start + element_count] >> 1,` This is continuation line 2 of the 5-line logical statement that begins at source line 294. Its exact fragment is ‘flat[timestep, element_start:element_start + element_count] >> 1,‘. The important operands are flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant; element_start: the value named ’element start’ in this block. Read together, the complete operation is: This assigns ‘np.clip(flat[timestep, element_start:element_start + element_count] >> 1, -(1 << 15), (1 << 15) - 1,).astype(np.int64).tolist()‘ to ‘currents ‘ in host memory. Here currents means the value named ’currents’ in this block. The important operands are clip: the value named ’clip’ in this block; flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 296: `-(1 << 15),` This is continuation line 3 of the 5-line logical statement that begins at source line 294. Its exact fragment is ‘-(1 << 15),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.clip(flat[timestep, element_start:element_start + element_count] >> 1, -(1 << 15), (1 << 15) - 1,).astype(np.int64).tolist()‘ to ‘currents ‘ in host memory. Here currents means the value named ’currents’ in this block. The important operands are clip: the value named ’clip’ in this block; flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 297: `(1 << 15) - 1,` This is continuation line 4 of the 5-line logical statement that begins at source line 294. Its exact fragment is ‘(1 << 15) - 1,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.clip(flat[timestep, element_start:element_start + element_count] >> 1, -(1 << 15), (1 << 15) - 1,).astype(np.int64).tolist()‘ to ‘currents ‘ in host memory. Here currents means the value named ’currents’ in this block. The important operands are clip: the value named ’clip’ in this block; flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 298: `).astype(np.int64).tolist()` This is continuation line 5 of the 5-line logical statement that begins at source line 294. Its exact fragment is ‘).astype(np.int64).tolist()‘. The important operands are astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block; tolist: the value named ’tolist’ in this block. Read together, the complete operation is: This assigns ‘np.clip(flat[timestep, element_start:element_start + element_count] >> 1, -(1 << 15), (1 << 15) - 1,).astype(np.int64).tolist()‘ to ‘currents ‘ in host memory. Here currents means the value named ’currents’ in this block. The important operands are clip: the value named ’clip’ in this block; flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 299: `currents.extend([0] * (LIF_LANES - element_count))` This calls ‘currents.extend‘ with ‘[0] * (LIF_LANES - element_count)‘ inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 300: `records.append(ProgramRecord(` This statement continues through source line 309; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0,), pack_lif_beats(currents), 1,)‘ inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 301: `lif_command(` This is continuation line 2 of the 10-line logical statement that begins at source line 300. Its exact fragment is ‘lif_command(‘. The important operands are lif_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0,), pack_lif_beats(currents), 1,)‘ inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 302: `leak_shift,` This is continuation line 3 of the 10-line logical statement that begins at source line 300. Its exact fragment is ‘leak_shift,‘. The important operands are leak_shift: the retained fraction of prior membrane state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0,), pack_lif_beats(currents), 1,)‘ inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 303: `threshold_q10,` This is continuation line 4 of the 10-line logical statement that begins at source line 300. Its exact fragment is ‘threshold_q10,‘. The important operands are threshold_q10: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0,), pack_lif_beats(currents), 1,)‘ inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 304: `reset_q10,` This is continuation line 5 of the 10-line logical statement that begins at source line 300. Its exact fragment is ‘reset_q10,‘. The important operands are reset_q10: the value named ’reset q10’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0,), pack_lif_beats(currents), 1,)‘ inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 305: `clear_state=timestep == 0,` This is continuation line 6 of the 10-line logical statement that begins at source line 300. Its exact fragment is ‘clear_state=timestep == 0,‘. The important operands are clear_state: the finite-state-machine phase retained in flip-flops; timestep: one discrete SNN update instant. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0,), pack_lif_beats(currents), 1,)‘ inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 306: `),` This is continuation line 7 of the 10-line logical statement that begins at source line 300. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0,), pack_lif_beats(currents), 1,)‘ inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 307: `pack_lif_beats(currents),` This is continuation line 8 of the 10-line logical statement that begins at source line 300. Its exact fragment is ‘pack_lif_beats(currents),‘. The important operands are pack_lif_beats: the value named ’pack lif beats’ in this block; currents: the value named ’currents’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0,), pack_lif_beats(currents), 1,)‘ inside the function lif_sequence_on_accelerator, which

handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 308: `1,` This is continuation line 9 of the 10-line logical statement that begins at source line 300. Its exact fragment is '1,'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'records.append' with 'ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0,), pack_lif_beats(currents), 1,)' inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 309: `))` This is continuation line 10 of the 10-line logical statement that begins at source line 300. Its exact fragment is '))'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'records.append' with 'ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0,), pack_lif_beats(currents), 1,)' inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 310: `bindings.append((timestep, element_start, element_count))` This calls 'bindings.append' with '(timestep, element_start, element_count)' inside the function lif_sequence_on_accelerator, which handles lif sequence on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 311: `words = driver.execute_program(records, timeout_seconds=timeout_seconds)` This assigns 'driver.execute_pr timeout_seconds=timeout_seconds)' to 'words ' in host memory. Here words means the value named 'words' in this block. The important operands are driver: the value named 'driver' in this block; execute_program: the value named 'execute program' in this block; records: the number of descriptor records accepted since program start. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 312: `if len(words) != len(records):` This executes the following indented host-code branch only when 'len(words) != len(records)' is true. The important operands are len: the value named 'len' in this block; words: the value named 'words' in this block; records: the number of descriptor records accepted since program start. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 313: `raise RuntimeError(f"LIF program returned {len(words)} beats; expected {len(records)}")` This rejects an invalid state by raising 'RuntimeError(f"LIF program returned {len(words)} beats; expected {len(records)}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 314: `output = np.zeros(flat.shape, dtype=np.uint8)` This assigns 'np.zeros(flat.shape, dtype=np.uint8)' to 'output ' in host memory. Here output means the value named 'output' in this block. The important operands are zeros: the value named 'zeros' in this block; flat: the value named 'flat' in this block; shape: the value named 'shape' in this block. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 315: `for word, (timestep, element_start, element_count) in zip(words, bindings):` This iterates word, (timestep, element_start, element_count) over 'zip(words, bindings)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 316: `spike_word, _ = unpack_lif_result(word)` This assigns 'unpack_lif_result(word)' to 'spike_word, _ ' in host memory. Here spike_word means a binary event produced when a neuron crosses its threshold. The important operands are unpack_lif_result: the value named 'unpack lif result' in this block; word: the value named 'word' in this block. Context: the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 317: `for lane in range(element_count):` This iterates lane over 'range(element_count)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_sequence_on_accelerator, which handles lif sequence on accelerator.

Line 318: `output[timestep, element_start + lane] = (spike_word >> lane) & 1` Inside the function lif_sequence_on_a which handles lif sequence on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are output: the value named 'output' in this block; timestep: one discrete SNN update instant; element_start: the value named 'element start' in this block.

Line 319: `return output.reshape(values.shape)` This returns 'output.reshape(values.shape)' to the caller of the function lif_sequence_on_accelerator, which handles lif sequence on accelerator, ending this invocation. The important operands are output: the value named 'output' in this block; reshape: the value named 'reshape' in this block; values: the value named 'values' in this block.

Line 322: `def lif_sequence_with_trace_on_accelerator(` This starts function lif_sequence_with_trace_on_accelerator. Its indented body performs lif sequence with trace on accelerator as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 323: `driver: ProgramExecutor,` Inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are driver: the value named 'driver' in this block; ProgramExecutor: the value named 'program executor' in this block.

Line 324: `values_q10: np.ndarray,` Inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are values_q10: the value named 'values q10' in this block; ndarray: the value named 'ndarray' in this block.

Line 325: `*,` Inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 326: `threshold_q10: int = 1 << 10,` This assigns '1 << 10,' to 'threshold_q10' in host memory. Here threshold_q10 means the membrane level at which a neuron emits a spike. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 327: `leak_shift: int = 1,` This assigns '1,' to 'leak_shift' in host memory. Here leak_shift means the retained fraction of prior membrane state. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 328: `reset_q10: int = 0,` This assigns '0,' to 'reset_q10' in host memory. Here reset_q10 means the value named 'reset q10' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 329: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 330: `) -> tuple[np.ndarray, np.ndarray]:` Inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are tuple: the value named 'tuple' in this block; ndarray: the value named 'ndarray' in this block.

Line 331: `"""Run LIF in fabric and retain the pre-reset membrane required by BPTT."""` This is executable documentation attached to the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 333: `values = np.asarray(values_q10, dtype=np.int64)` This assigns ‘np.asarray(values_q10, dtype=np.int64)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are asarray: the value named ’asarray’ in this block; values_q10: the value named ’values q10’ in this block; dtype: the value named ’dtype’ in this block. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 334: `if values.ndim < 2 or values.shape[0] == 0:` This executes the following indented host-code branch only when ‘values.ndim < 2 or values.shape[0] == 0‘ is true. The important operands are values: the value named ’values’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 335: `raise ValueError("LIF input must have shape [timesteps, ...]")` This rejects an invalid state by raising ‘ValueError("LIF input must have shape [timesteps, ...]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 336: `if values.size and (values.min() < -(1 << 63) or values.max() > (1 << 63) - 1):` This executes the following indented host-code branch only when ‘values.size and (values.min() < -(1 << 63) or values.max() > (1 << 63) - 1)‘ is true. The important operands are values: the value named ’values’ in this block; size: the value named ’size’ in this block; and: the value named ’and’ in this block. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 337: `raise OverflowError("LIF input exceeds signed 64-bit preparation arithmetic")` This rejects an invalid state by raising ‘OverflowError("LIF input exceeds signed 64-bit preparation arithmetic")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 338: `timesteps = values.shape[0]` This assigns ‘values.shape[0]‘ to ‘timesteps ‘ in host memory. Here timesteps means one discrete SNN update instant. The important operands are values: the value named ’values’ in this block; shape: the value named ’shape’ in this block. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 339: `flat = values.reshape(timesteps, -1)` This assigns ‘values.reshape(timesteps, -1)‘ to ‘flat ‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are values: the value named ’values’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 340: `records: list[ProgramRecord] = []` This assigns ‘[]‘ to ‘records‘ in host memory. Here records means the number of descriptor records accepted since program start. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 341: `bindings: list[tuple[int, int, int]] = []` This assigns ‘[]‘ to ‘bindings‘ in host memory. Here bindings means the value named ’bindings’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 342: `for element_start in range(0, flat.shape[1], LIF_LANES):` This iterates element_start over ‘range(0, flat.shape[1], LIF_LANES)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 343: `element_count = min(LIF_LANES, flat.shape[1] - element_start)` This assigns ‘min(LIF_LANES, flat.shape[1] - element_start)‘ to ‘element_count ‘ in host memory. Here element_count means an integer count retained for control or measurable telemetry. The important operands are min: the value named ’min’ in this block; LIF_LANES: one parallel arithmetic element within a vector or tensor datapath; flat: the value named ’flat’ in this block. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 344: `for timestep in range(timesteps):` This iterates timestep over ‘range(timesteps)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_sequence_with_trace_on_ which handles lif sequence with trace on accelerator.

Line 345: `currents = np.clip(` This statement continues through source line 349; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.clip(flat[timestep, element_start:element_start + element_count] >> 1, -(1 << 15), (1 << 15) - 1,).astype(np.int64).tolist()‘ to ‘currents ‘ in host memory. Here currents means the value named ’currents’ in this block. The important operands are clip: the value named ’clip’ in this block; flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 346: `flat[timestep, element_start:element_start + element_count] >> 1,` This is continuation line 2 of the 5-line logical statement that begins at source line 345. Its exact fragment is ‘flat[timestep, element_start:element_start + element_count] >> 1,‘. The important operands are flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant; element_start: the value named ’element start’ in this block. Read together, the complete operation is: This assigns ‘np.clip(flat[timestep, element_start:element_start + element_count] >> 1, -(1 << 15), (1 << 15) - 1,).astype(np.int64).tolist()‘ to ‘currents ‘ in host memory. Here currents means the value named ’currents’ in this block. The important operands are clip: the value named ’clip’ in this block; flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 347: `-(1 << 15),` This is continuation line 3 of the 5-line logical statement that begins at source line 345. Its exact fragment is ‘-(1 << 15),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.clip(flat[timestep, element_start:element_start + element_count] >> 1, -(1 << 15), (1 << 15) - 1,).astype(np.int64).tolist()‘ to ‘currents ‘ in host memory. Here currents means the value named ’currents’ in this block. The important operands are clip: the value named ’clip’ in this block; flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 348: `(1 << 15) - 1,` This is continuation line 4 of the 5-line logical statement that begins at source line 345. Its exact fragment is ‘(1 << 15) - 1,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘np.clip(flat[timestep, element_start:element_start + element_count] >> 1, -(1 << 15), (1 << 15) - 1,).astype(np.int64).tolist()‘ to ‘currents ‘ in host memory. Here currents means the value named ’currents’ in this block. The important operands are clip: the value named ’clip’ in this block; flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 349: `).astype(np.int64).tolist()` This is continuation line 5 of the 5-line logical statement that begins at source line 345. Its exact fragment is ‘).astype(np.int64).tolist()‘. The important operands are astype: the value named ’astype’ in this block; int64: the value named ’int64’ in this block; tolist: the value named ’tolist’ in this block. Read together, the complete operation is: This assigns ‘np.clip(flat[timestep, element_start:element_start + element_count] >> 1, -(1 << 15), (1 << 15) - 1,).astype(np.int64).tolist()‘ to ‘currents ‘ in host memory. Here currents means the value named ’currents’ in this block. The important operands are clip: the value named ’clip’ in this block; flat: the value named ’flat’ in this block; timestep: one discrete SNN update instant. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 350: `currents.extend([0] * (LIF_LANES - element_count))` This calls ‘currents.extend‘ with ‘[0] * (LIF_LANES - element_count)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 351: `records.append(ProgramRecord(` This statement continues through source line 361; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 352: `lif_command(` This is continuation line 2 of the 11-line logical statement that begins at source line 351. Its exact fragment is ‘lif_command(‘. The important operands are lif_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 353: `leak_shift,` This is continuation line 3 of the 11-line logical statement that begins at source line 351. Its exact fragment is ‘leak_shift,‘. The important operands are leak_shift: the retained fraction of prior membrane state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 354: `threshold_q10,` This is continuation line 4 of the 11-line logical statement that begins at source line 351. Its exact fragment is ‘threshold_q10,‘. The important operands are threshold_q10: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 355: `reset_q10,` This is continuation line 5 of the 11-line logical statement that begins at source line 351. Its exact fragment is ‘reset_q10,‘. The important operands are reset_q10: the value named ’reset q10’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 356: `clear_state=timestep == 0,` This is continuation line 6 of the 11-line logical statement that begins at source line 351. Its exact fragment is ‘clear_state=timestep == 0,‘. The important operands are clear_state: the finite-state-machine phase retained in flip-flops; timestep: one discrete SNN update instant. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_ which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 357: `trace_state=True,` This is continuation line 7 of the 11-line logical statement that begins at source line 351. Its exact fragment is ‘trace_state=True,‘. The important operands are trace_state: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 358: `),` This is continuation line 8 of the 11-line logical statement that begins at source line 351. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 359: `pack_lif_beats(currents),` This is continuation line 9 of the 11-line logical statement that begins at source line 351. Its exact fragment is ‘pack_lif_beats(currents),‘. The important operands are pack_lif_beats: the value named ’pack lif beats’ in this block; currents: the value named ’currents’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_ which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 360: `13,` This is continuation line 10 of the 11-line logical statement that begins at source line 351. Its exact fragment is ‘13,‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 361: `))` This is continuation line 11 of the 11-line logical statement that begins at source line 351. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(lif_command(leak_shift, threshold_q10, reset_q10, clear_state=timestep == 0, trace_state=True,), pack_lif_beats(currents), 13,)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 362: `bindings.append((timestep, element_start, element_count))` This calls ‘bindings.append‘ with ‘(timestep, element_start, element_count)‘ inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 363: `words = driver.execute_program(records, timeout_seconds=timeout_seconds)` This assigns ‘driver.execute_pr timeout_seconds=timeout_seconds)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 364: `expected_words = 13 * len(records)` This assigns ‘13 * len(records)‘ to ‘expected_words ‘ in host memory. Here expected_words means the value named ’expected words’ in this block. The important operands are len: the value named ’len’ in this block; records: the number of descriptor records accepted since program start. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 365: `if len(words) != expected_words:` This executes the following indented host-code branch only when ‘len(words) != expected_words‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block; expected_words: the value named ’expected words’ in this block. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 366: `raise RuntimeError(` This statement continues through source line 367; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘RuntimeError(f"traced LIF

program returned {len(words)} beats; expected {expected_words}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 367: `f"traced LIF program returned {len(words)} beats; expected {expected_words}")` This is continuation line 2 of the 2-line logical statement that begins at source line 366. Its exact fragment is ‘f"traced LIF program returned {len(words)} beats; expected {expected_words}")‘. The important operands are f: the value named ’f’ in this block; traced: the value named ’traced’ in this block; LIF: the value named ’lif’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"traced LIF program returned {len(words)} beats; expected {expected_words}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 368: `spikes = np.zeros(flat.shape, dtype=np.uint8)` This assigns ‘np.zeros(flat.shape, dtype=np.uint8)‘ to ‘spikes ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are zeros: the value named ’zeros’ in this block; flat: the value named ’flat’ in this block; shape: the value named ’shape’ in this block. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 369: `membrane_trace = np.zeros(flat.shape, dtype=np.int64)` This assigns ‘np.zeros(flat.shape, dtype=np.int64)‘ to ‘membrane_trace ‘ in host memory. Here membrane_trace means the persistent LIF neuron state carrying charge between timesteps. The important operands are zeros: the value named ’zeros’ in this block; flat: the value named ’flat’ in this block; shape: the value named ’shape’ in this block. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 370: `for record_index, (timestep, element_start, element_count) in enumerate(bindings):` This iterates record_index, (timestep, element_start, element_count) over ‘enumerate(bindings)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 371: `start = record_index * 13` This assigns ‘record_index * 13‘ to ‘start ‘ in host memory. Here start means the value named ’start’ in this block. The important operands are record_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 372: `spike_word, _, membranes = unpack_lif_trace(words[start:start + 13])` This assigns ‘unpack_lif_trace(words[start:start + 13])‘ to ‘spike_word, _, membranes ‘ in host memory. Here spike_word means a binary event produced when a neuron crosses its threshold. The important operands are unpack_lif_trace: the value named ’unpack lif trace’ in this block; words: the value named ’words’ in this block; start: the value named ’start’ in this block. Context: the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 373: `for lane in range(element_count):` This iterates lane over ‘range(element_count)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator.

Line 374: `spikes[timestep, element_start + lane] = (spike_word >> lane) & 1` Inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are spikes: a binary event produced when a neuron crosses its threshold; timestep: one discrete SNN update instant; element_start: the value named ’element start’ in this block.

Line 375: `membrane_trace[timestep, element_start + lane] = membranes[lane]` Inside the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are membrane_trace: the persistent LIF neuron state carrying charge between timesteps; timestep: one discrete SNN update instant; element_start: the value named ’element start’ in this block.

Line 376: `return spikes.reshape(values.shape), membrane_trace.reshape(values.shape)` This returns ‘spikes.reshape(v membrane_trace.reshape(values.shape)‘ to the caller of the function lif_sequence_with_trace_on_accelerator, which handles lif sequence with trace on accelerator, ending this invocation. The important operands are spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block; values: the value named ’values’ in this block.

Line 379: `def requantize_projection_reference(` This starts function requantize_projection_reference. Its indented body performs requantize projection reference as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 380: `accumulators: np.ndarray,` Inside the function requantize_projection_reference, which handles requantize projection reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are accumulators: a widened running sum that prevents intermediate overflow; ndarray: the value named ’ndarray’ in this block.

Line 381: `parameters: ProjectionParameters,` Inside the function requantize_projection_reference, which handles requantize projection reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are parameters: the value named ’parameters’ in this block; ProjectionParameters: the value named ’projection parameters’ in this block.

Line 382: `) -> np.ndarray:` Inside the function requantize_projection_reference, which handles requantize projection reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are ndarray: the value named ’ndarray’ in this block.

Line 383: `"""Apply the exported per-channel Q15 fields exactly like vector operation 9."""` This is executable documentation attached to the function requantize_projection_reference, which handles requantize projection reference. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 385: `values = np.asarray(accumulators, dtype=np.int64)` This assigns ‘np.asarray(accumulators, dtype=np.int64)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are asarray: the value named ’asarray’ in this block; accumulators: a widened running sum that prevents intermediate overflow; dtype: the value named ’dtype’ in this block. Context: the function requantize_projection_reference, which handles requantize projection reference.

Line 386: `if values.ndim != 2 or values.shape[1] != parameters.weight_k_by_n.shape[1]:` This executes the following indented host-code branch only when ‘values.ndim != 2 or values.shape[1] != parameters.weight_k_by_n.shape[1]‘ is true. The important operands are values: the value named ’values’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function requantize_projection_reference, which handles requantize projection reference.

Line 387: `raise ValueError("accumulators must have shape [rows, projection output channels]")` This rejects an invalid state by raising ‘ValueError("accumulators must have shape [rows, projection output channels]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 388: `result = np.empty_like(values)` This assigns ‘np.empty_like(values)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are empty_like: the value named ’empty like’ in this block; values: the value named ’values’ in this block. Context: the function requantize_projection_reference, which handles requantize projection reference.

Line 389: `for channel in range(values.shape[1]):` This iterates channel over ‘range(values.shape[1])‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function requantize_projection_reference, which handles requantize projection reference.

Line 390: `effective_shift = 15 + int(parameters.binary_point_shift[channel])` This assigns '15 + int(parameters.bina to 'effective_shift ' in host memory. Here effective_shift means the value named 'effective shift' in this block. The important operands are parameters: the value named 'parameters' in this block; binary_point_shift: the value named 'binary point shift' in this block; channel: the value named 'channel' in this block. Context: the function requantize_projection_reference, which handles requantize projection reference.

Line 391: `product = values[:, channel] * int(parameters.multiplier_q15[channel])` This assigns 'values[:, channel] * int(parameters.multiplier_q15[channel])' to 'product ' in host memory. Here product means the value named 'product' in this block. The important operands are values: the value named 'values' in this block; channel: the value named 'channel' in this block; parameters: the value named 'parameters' in this block. Context: the function requantize_projection_reference, which handles requantize projection reference.

Line 392: `requantized = round_shift_signed(product, effective_shift)` This assigns 'round_shift_signed(product, effective_shift)' to 'requantized ' in host memory. Here requantized means the conversion of a wide accumulated result back into a bounded activation code. The important operands are round_shift_signed: the value named 'round shift signed' in this block; product: the value named 'product' in this block; effective_shift: the value named 'effective shift' in this block. Context: the function requantize_projection_reference, which handles requantize projection reference.

Line 393: `requantized += int(parameters.bias_q10[channel])` Inside the function requantize_projection_reference, which handles requantize projection reference, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are requantized: the conversion of a wide accumulated result back into a bounded activation code; parameters: the value named 'parameters' in this block; bias_q10: an additive learned offset applied after accumulation.

Line 394: `result[:, channel] = saturate_signed(requantized, 24)` This assigns 'saturate_signed(requantized, 24)' to 'result[' in host memory. Here result means the value named 'result' in this block. The important operands are saturate_signed: the value named 'saturate signed' in this block; requantized: the conversion of a wide accumulated result back into a bounded activation code. Context: the function requantize_projection_reference, which handles requantize projection reference.

Line 395: `return result` This returns 'result' to the caller of the function requantize_projection_reference, which handles requantize projection reference, ending this invocation. The important operands are result: the value named 'result' in this block.

Line 398: `def requantize_projection_on_accelerator(` This starts function requantize_projection_on_accelerator. Its indented body performs requantize projection on accelerator as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 399: `driver: ProgramExecutor,` Inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are driver: the value named 'driver' in this block; ProgramExecutor: the value named 'program executor' in this block.

Line 400: `accumulators: np.ndarray,` Inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are accumulators: a widened running sum that prevents intermediate overflow; ndarray: the value named 'ndarray' in this block.

Line 401: `parameters: ProjectionParameters,` Inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are parameters: the value named 'parameters' in this block; ProjectionParameters: the value named 'projection parameters' in this block.

Line 402: `*,` Inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 403: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 404: `) -> np.ndarray:` Inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are ndarray: the value named 'ndarray' in this block.

Line 405: `"""Execute per-channel folded BN scaling through the eight-lane vector RTL."""` This is executable documentation attached to the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 407: `values = np.asarray(accumulators, dtype=np.int64)` This assigns 'np.asarray(accumulators, dtype=np.int64)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are asarray: the value named 'asarray' in this block; accumulators: a widened running sum that prevents intermediate overflow; dtype: the value named 'dtype' in this block. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 408: `if values.ndim != 2 or values.shape[1] != parameters.weight_k_by_n.shape[1]:` This executes the following indented host-code branch only when 'values.ndim != 2 or values.shape[1] != parameters.weight_k_by_n.shape[1]' is true. The important operands are values: the value named 'values' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 409: `raise ValueError("accumulators must have shape [rows, projection output channels]")` This rejects an invalid state by raising 'ValueError("accumulators must have shape [rows, projection output channels]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 410: `if values.size and (values.min() < -(1 << 31) or values.max() > (1 << 31) - 1):` This executes the following indented host-code branch only when 'values.size and (values.min() < -(1 << 31) or values.max() > (1 << 31) - 1)' is true. The important operands are values: the value named 'values' in this block; size: the value named 'size' in this block; and: the value named 'and' in this block. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 411: `raise OverflowError("projection accumulators do not fit the vector ALU's signed 32-bit lanes")` This rejects an invalid state by raising 'OverflowError("projection accumulators do not fit the vector ALU's signed 32-bit lanes")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 413: `records: list[ProgramRecord] = []` This assigns '[]' to 'records' in host memory. Here records means the number of descriptor records accepted since program start. The expression is a literal or structural operator and has no hidden software state. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 414: `bindings: list[tuple[int, int, int]] = []` This assigns '[]' to 'bindings' in host memory. Here bindings means the value named 'bindings' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 415: `zero = [0] * VECTOR_LANES` This assigns '[0] * VECTOR_LANES' to 'zero ' in host memory. Here zero means the value named 'zero' in this block. The important operands are VECTOR_LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 416: `rows, channels = values.shape` This assigns 'values.shape' to 'rows, channels ' in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are values: the value named 'values' in this block; shape: the value named 'shape' in this block. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 417: `for channel in range(channels):` This iterates channel over 'range(channels)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 418: `command = vector_command(` This statement continues through source line 423; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'vector_command(int(VectorOperation.FLEX_REQUA multiplier_q15=int(parameters.multiplier_q15[channel]), right_shift=int(parameters.binary_point_shift[channel]), output_zero_point=int(parameters.bias_q10[channel]),)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 419: `int(VectorOperation.FLEX_REQUANTIZE),` This is continuation line 2 of the 6-line logical statement that begins at source line 418. Its exact fragment is 'int(VectorOperation.FLEX_REQUANTIZE),'. The important operands are VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=int(parameters.multiplier_q15[channel]), right_shift=int(parameters.binary_point_shift[channel]), output_zero_point=int(parameters.bias_q10[channel]),)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 420: `multiplier_q15=int(parameters.multiplier_q15[channel]),` This is continuation line 3 of the 6-line logical statement that begins at source line 418. Its exact fragment is 'multiplier_q15=int(parameters.multiplier_q15[channel]),'. The important operands are multiplier_q15: the value named 'multiplier q15' in this block; parameters: the value named 'parameters' in this block; channel: the value named 'channel' in this block. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=int(parameters.multiplier_q15[channel]), right_shift=int(parameters.binary_point_shift[channel]), output_zero_point=int(parameters.bias_q10[channel]),)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 421: `right_shift=int(parameters.binary_point_shift[channel]),` This is continuation line 4 of the 6-line logical statement that begins at source line 418. Its exact fragment is 'right_shift=int(parameters.binary_point_shift[channel]),'. The important operands are right_shift: the value named 'right shift' in this block; parameters: the value named 'parameters' in this block; binary_point_shift: the value named 'binary point shift' in this block. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=int(parameters.multiplier right_shift=int(parameters.binary_point_shift[channel]), output_zero_point=int(parameters.bias_q10[channel]),)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode,

and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 422: `output_zero_point=int(parameters.bias_q10[channel]),` This is continuation line 5 of the 6-line logical statement that begins at source line 418. Its exact fragment is 'output_zero_point=int(parameters.bias_q10[channel]),'. The important operands are output_zero_point: the integer code representing real numeric zero in affine quantization; parameters: the value named 'parameters' in this block; bias_q10: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=int(parameters.multiplier_q15[channel]), right_shift=int(parameters.binary_point_shift[channel]), output_zero_point=int(parameters.bias_q10[channel]),)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 423: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 418. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'vector_command(int(VectorOperation.FLEX_REQUANTIZE), multiplier_q15=int(parameters.multiplier_q15[channel]), right_shift=int(parameters.binary_point_shift[channel]), output_zero_point)' to 'command ' in host memory. Here command means the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; VectorOperation: the value named 'vector operation' in this block; FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 424: `for row_start in range(0, rows, VECTOR_LANES):` This iterates row_start over 'range(0, rows, VECTOR_LANES)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 425: `row_count = min(VECTOR_LANES, rows - row_start)` This assigns 'min(VECTOR_LANES, rows - row_start)' to 'row_count ' in host memory. Here row_count means one output-row position processed by the tensor tile. The important operands are min: the value named 'min' in this block; VECTOR_LANES: one parallel arithmetic element within a vector or tensor datapath; rows: one output-row position processed by the tensor tile. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 426: `lanes = values[row_start:row_start + row_count, channel].tolist()` This assigns 'values[row_start:row_start + row_count, channel].tolist()' to 'lanes ' in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are values: the value named 'values' in this block; row_start: one output-row position processed by the tensor tile; row_count: one output-row position processed by the tensor tile. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 427: `lanes.extend([0] * (VECTOR_LANES - row_count))` This calls 'lanes.extend' with '[0] * (VECTOR_LANES - row_count)' inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 428: `records.append(ProgramRecord(` This statement continues through source line 437; the explanation uses the complete expression rather than only the first visual fragment. This calls 'records.append' with 'ProgramRecord(command, pack_vector_beats(lanes, zero, clamp_minimum=-(1 << 23), clamp_maximum=(1 << 23) - 1,), 4,)' inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 429: `command,` This is continuation line 2 of the 10-line logical statement that begins at source line 428. Its exact fragment is ‘command,‘. The important operands are command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, zero, clamp_minimum=-(1 << 23), clamp_maximum=(1 << 23) - 1,), 4,)‘ inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 430: `pack_vector_beats(` This is continuation line 3 of the 10-line logical statement that begins at source line 428. Its exact fragment is ‘pack_vector_beats(‘. The important operands are pack_vector_beats: the value named ’pack vector beats’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, zero, clamp_minimum=-(1 << 23), clamp_maximum=(1 << 23) - 1,), 4,)‘ inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 431: `lanes,` This is continuation line 4 of the 10-line logical statement that begins at source line 428. Its exact fragment is ‘lanes,‘. The important operands are lanes: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, zero, clamp_minimum=-(1 << 23), clamp_maximum=(1 << 23) - 1,), 4,)‘ inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 432: `zero,` This is continuation line 5 of the 10-line logical statement that begins at source line 428. Its exact fragment is ‘zero,‘. The important operands are zero: the value named ’zero’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, zero, clamp_minimum=-(1 << 23), clamp_maximum=(1 << 23) - 1,), 4,)‘ inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 433: `clamp_minimum=-(1 << 23),` This is continuation line 6 of the 10-line logical statement that begins at source line 428. Its exact fragment is ‘clamp_minimum=-(1 << 23),‘. The important operands are clamp_minimum: the value named ’clamp minimum’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, zero, clamp_minimum=-(1 << 23), clamp_maximum=(1 << 23) - 1,), 4,)‘ inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 434: `clamp_maximum=(1 << 23) - 1,` This is continuation line 7 of the 10-line logical statement that begins at source line 428. Its exact fragment is ‘clamp_maximum=(1 << 23) - 1,‘. The important operands are clamp_maximum: the value named ’clamp maximum’ in this block. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, zero, clamp_minimum=-(1 << 23), clamp_maximum=(1 << 23) - 1,), 4,)‘ inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 435: `),` This is continuation line 8 of the 10-line logical statement that begins at source line 428. Its exact fragment is ‘),‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, zero, clamp_minimum=-(1 << 23), clamp_maximum=(1 << 23) - 1,), 4,)‘ inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 436: `4,` This is continuation line 9 of the 10-line logical statement that begins at source line 428. Its exact fragment is ‘4,‘. The expression is a literal or structural operator and has no hidden software state. Read to-

gether, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, zero, clamp_minimum=-(1 << 23), clamp_maximum=(1 << 23) - 1,), 4,)‘ inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 437: `))` This is continuation line 10 of the 10-line logical statement that begins at source line 428. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘records.append‘ with ‘ProgramRecord(command, pack_vector_beats(lanes, zero, clamp_minimum=-(1 << 23), clamp_maximum=(1 << 23) - 1,), 4,)‘ inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 438: `bindings.append((row_start, row_count, channel))` This calls ‘bindings.append‘ with ‘(row_start, row_count, channel)‘ inside the function requantize_projection_on_accelerator, which handles requantize projection on accelerator. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 440: `words = driver.execute_program(records, timeout_seconds=timeout_seconds)` This assigns ‘driver.execute_pr timeout_seconds=timeout_seconds)‘ to ‘words ‘ in host memory. Here words means the value named ’words’ in this block. The important operands are driver: the value named ’driver’ in this block; execute_program: the value named ’execute program’ in this block; records: the number of descriptor records accepted since program start. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 441: `if len(words) != 4 * len(records):` This executes the following indented host-code branch only when ‘len(words) != 4 * len(records)‘ is true. The important operands are len: the value named ’len’ in this block; words: the value named ’words’ in this block; records: the number of descriptor records accepted since program start. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 442: `raise RuntimeError(` This statement continues through source line 443; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘RuntimeError(f"requantizer returned {len(words)} beats; expected {4 * len(records)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 443: `f"requantizer returned {len(words)} beats; expected {4 * len(records)}")` This is continuation line 2 of the 2-line logical statement that begins at source line 442. Its exact fragment is ‘f"requantizer returned {len(words)} beats; expected {4 * len(records)}")‘. The important operands are f: the value named ’f’ in this block; requantizer: the conversion of a wide accumulated result back into a bounded activation code; returned: the value named ’returned’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘RuntimeError(f"requantizer returned {len(words)} beats; expected {4 * len(records)}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 444: `result = np.empty((rows, channels), dtype=np.int64)` This assigns ‘np.empty((rows, channels), dtype=np.int64 to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are empty: the value named ’empty’ in this block; rows: one output-row position processed by the tensor tile; channels: the value named ’channels’ in this block. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 445: `for record_index, (row_start, row_count, channel) in enumerate(bindings):` This iterates record_index, (row_start, row_count, channel) over ‘enumerate(bindings)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 446: `lanes = unpack_vector_result(words[4 * record_index:4 * record_index + 4])` This assigns ‘unpack_vector_result(words[4 * record_index:4 * record_index + 4])‘ to ‘lanes ‘ in host memory. Here lanes means one parallel arithmetic element within a vector or tensor datapath. The important operands are unpack_vector_result: the

value named 'unpack vector result' in this block; words: the value named 'words' in this block; record_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 447: `result[row_start:row_start + row_count, channel] = lanes[:row_count]` This assigns 'lanes[:row_count]' to 'result[row_start' in host memory. Here result means the value named 'result' in this block. The important operands are lanes: one parallel arithmetic element within a vector or tensor datapath; row_count: one output-row position processed by the tensor tile. Context: the function requantize_projection_on_accelerator, which handles requantize projection on accelerator.

Line 448: `return result` This returns 'result' to the caller of the function requantize_projection_on_accelerator, which handles requantize projection on accelerator, ending this invocation. The important operands are result: the value named 'result' in this block.

Line 451: `@dataclass` This decorator changes how the following class or function is constructed. '@dataclass' is applied at import time on the host and is part of the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it creates no FPGA circuit by itself.

Line 452: `class SpikingformerProjectionExecutor:` This defines class SpikingformerProjectionExecutor, which groups data and methods for spikingformer projection executor. Instances exist in host memory and organize the flow that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 453: `"""Run exported Conv-BN projections through tensor and vector hardware."""` This is executable documentation attached to the class SpikingformerProjectionExecutor, which handles spikingformer projection executor. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 455: `archive: SpikingformerParameterArchive` Inside the class SpikingformerProjectionExecutor, which handles spikingformer projection executor, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are archive: the value named 'archive' in this block; SpikingformerParameterArchive: the value named 'spikingformer parameter archive' in this block.

Line 456: `driver: ProgramExecutor` Inside the class SpikingformerProjectionExecutor, which handles spikingformer projection executor, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are driver: the value named 'driver' in this block; ProgramExecutor: the value named 'program executor' in this block.

Line 458: `@staticmethod` This decorator changes how the following class or function is constructed. '@staticmethod' is applied at import time on the host and is part of the class SpikingformerProjectionExecutor, which handles spikingformer projection executor; it creates no FPGA circuit by itself.

Line 459: `def _encoded_dense_weights(weight: np.ndarray) -> np.ndarray:` This starts function _encoded_dense_weig
Its indented body performs encoded dense weights as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 460: `return (weight.astype(np.int16) + 128).astype(np.uint8)` This returns '(weight.astype(np.int16) + 128).astype(np.uint8)' to the caller of the function _encoded_dense_weights, which handles encoded dense weights, ending this invocation. The important operands are weight: a learned coefficient multiplied by an activation; astype: the value named 'astype' in this block; int16: the value named 'int16' in this block.

Line 462: `def matrix(` This starts function matrix. Its indented body performs matrix as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 463: `self,` Inside the function matrix, which handles matrix, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 464: `name: str,` Inside the function matrix, which handles matrix, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are name: the value named 'name' in this block; str: the value named 'str' in this block.

Line 465: `activations: np.ndarray,` Inside the function matrix, which handles matrix, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named 'ndarray' in this block.

Line 466: `*,` Inside the function matrix, which handles matrix, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 467: `activation_zero_point: int = 0,` This assigns '0,' to 'activation_zero_point' in host memory. Here activation_zero_point means an input feature value consumed by a neuron or multiply-accumulate operation. The expression is a literal or structural operator and has no hidden software state. Context: the function matrix, which handles matrix.

Line 468: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function matrix, which handles matrix.

Line 469: `) -> np.ndarray:` Inside the function matrix, which handles matrix, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are ndarray: the value named 'ndarray' in this block.

Line 470: `"""Execute one exported Conv1d-style projection as a two-dimensional matrix."""` This is executable documentation attached to the function matrix, which handles matrix. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 472: `parameters = self.archive.projection(name)` This assigns 'self.archive.projection(name)' to 'parameters ' in host memory. Here parameters means the value named 'parameters' in this block. The important operands are archive: the value named 'archive' in this block; projection: the value named 'projection' in this block; name: the value named 'name' in this block. Context: the function matrix, which handles matrix.

Line 473: `values = np.asarray(activations)` This assigns 'np.asarray(activations)' to 'values ' in host memory. Here values means the value named 'values' in this block. The important operands are asarray: the value named 'asarray' in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function matrix, which handles matrix.

Line 474: `if values.ndim != 2 or values.shape[1] != parameters.weight_k_by_n.shape[0]:` This executes the following indented host-code branch only when 'values.ndim != 2 or values.shape[1] != parameters.weight_k_by_n.shape[0]' is true. The important operands are values: the value named 'values' in this block; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function matrix, which handles matrix.

Line 475: `raise ValueError("matrix activations do not match the projection reduction dimension")` This rejects an invalid state by raising 'ValueError("matrix activations do not match the projection reduction dimension")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 476: `if parameters.compute_opcode == "COMPUTE_BINARY":` This executes the following indented host-code branch only when ‘parameters.compute_opcode == "COMPUTE_BINARY"‘ is true. The important operands are parameters: the value named ’parameters’ in this block; compute_opcode: the value named ’compute opcode’ in this block; COMPUTE_BINARY: the value named ’compute binary’ in this block. Context: the function matrix, which handles matrix.

Line 477: `compiled = compile_spike_gemm(values, parameters.weight_k_by_n)` This assigns ‘compile_spike_gemm(value parameters.weight_k_by_n)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold; values: the value named ’values’ in this block; parameters: the value named ’parameters’ in this block. Context: the function matrix, which handles matrix.

Line 478: `elif parameters.compute_opcode == "COMPUTE_DENSE_OUTER":` This executes the following indented host-code branch only when ‘parameters.compute_opcode == "COMPUTE_DENSE_OUTER"‘ is true. The important operands are parameters: the value named ’parameters’ in this block; compute_opcode: the value named ’compute opcode’ in this block; COMPUTE_DENSE_OUTER: the value named ’compute dense outer’ in this block. Context: the function matrix, which handles matrix.

Line 479: `compiled = compile_u8_gemm(` This statement continues through source line 484; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compile_u8_gemm(values, self._encoded_dense_weigh activation_zero_point=activation_zero_point, weight_zero_point=128,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_gemm: the value named ’compile u8 gemm’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function matrix, which handles matrix.

Line 480: `values,` This is continuation line 2 of the 6-line logical statement that begins at source line 479. Its exact fragment is ‘values,‘. The important operands are values: the value named ’values’ in this block. Read together, the complete operation is: This assigns ‘compile_u8_gemm(values, self._encoded_dense_weights(parameters.weight_k_by_n), activation_zero_point=activation_zero_point, weight_zero_point=128,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_gemm: the value named ’compile u8 gemm’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function matrix, which handles matrix.

Line 481: `self._encoded_dense_weights(parameters.weight_k_by_n),` This is continuation line 3 of the 6-line logical statement that begins at source line 479. Its exact fragment is ‘self._encoded_dense_weights(parameters.weight_k_by_n),‘. The important operands are _encoded_dense_weights: a learned coefficient multiplied by an activation; parameters: the value named ’parameters’ in this block; weight_k_by_n: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘compile_u8_gemm(values, self._encoded_dense_weights(parameters.weight_k_by_n), activation_zero_point=activation_zero_point, weight_zero_point=128,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_gemm: the value named ’compile u8 gemm’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function matrix, which handles matrix.

Line 482: `activation_zero_point=activation_zero_point,` This is continuation line 4 of the 6-line logical statement that begins at source line 479. Its exact fragment is ‘activation_zero_point=activation_zero_point,‘. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘compile_u8_gemm(values, self._encoded_dense_weights(parameters.weigh activation_zero_point=activation_zero_point, weight_zero_point=128,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_gemm: the value named ’compile u8 gemm’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function matrix, which handles matrix.

Line 483: `weight_zero_point=128,` This is continuation line 5 of the 6-line logical statement that begins at source line 479. Its exact fragment is ‘weight_zero_point=128,‘. The important operands are weight_zero_point: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘compile_u8_gemm(values, self._encoded_dense_weights(parameters.weight_k_by_n), activation_zero_point=activation_zero_point, weight_zero_point=

)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_gemm: the value named ’compile u8 gemm’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function matrix, which handles matrix.

Line 484: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 479. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘compile_u8_gemm(values, self._encoded_dense_weights(parameters.weight_k_by_n), activation_zero_point=activation_zero_point, weight_zero_point=128,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_gemm: the value named ’compile u8 gemm’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function matrix, which handles matrix.

Line 485: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function matrix, which handles matrix.

Line 486: `raise ValueError(f"unsupported projection opcode {parameters.compute_opcode!r}")` This rejects an invalid state by raising ‘ValueError(f"unsupported projection opcode {parameters.compute_opcode!r}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 487: `accumulators = compiled.execute_batched(` This statement continues through source line 488; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compiled.execute_batched(self.driver, timeout_seconds=timeout_seconds)‘ to ‘accumulators ‘ in host memory. Here accumulators means a widened running sum that prevents intermediate overflow. The important operands are compiled: the value named ’compiled’ in this block; execute_batched: the value named ’execute batched’ in this block; driver: the value named ’driver’ in this block. Context: the function matrix, which handles matrix.

Line 488: `self.driver, timeout_seconds=timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 487. Its exact fragment is ‘self.driver, timeout_seconds=timeout_seconds)‘. The important operands are driver: the value named ’driver’ in this block; timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘compiled.execute_batched(self.driver, timeout_seconds=timeout_seconds)‘ to ‘accumulators ‘ in host memory. Here accumulators means a widened running sum that prevents intermediate overflow. The important operands are compiled: the value named ’compiled’ in this block; execute_batched: the value named ’execute batched’ in this block; driver: the value named ’driver’ in this block. Context: the function matrix, which handles matrix.

Line 489: `return requantize_projection_on_accelerator(` This statement continues through source line 490; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘requantize_projection_on_accelera
self.driver, accumulators, parameters, timeout_seconds=timeout_seconds)‘ to the caller of the function matrix, which handles matrix, ending this invocation. The important operands are requantize_projection_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named ’driver’ in this block; accumulators: a widened running sum that prevents intermediate overflow.

Line 490: `self.driver, accumulators, parameters, timeout_seconds=timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 489. Its exact fragment is ‘self.driver, accumulators, parameters, timeout_seconds=timeout_seconds)‘. The important operands are driver: the value named ’driver’ in this block; accumulators: a widened running sum that prevents intermediate overflow; parameters: the value named ’parameters’ in this block. Read together, the complete operation is: This returns ‘requantize_projection_on_accelerator(self.driver, accumulators, parameters, timeout_seconds=timeout_seconds)‘ to the caller of the function matrix, which handles matrix, ending this invocation. The important operands are requantize_projection_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named ’driver’ in this block; accumulators: a widened running sum that prevents intermediate overflow.

Line 492: `def conv2d(` This starts function conv2d. Its indented body performs conv2d as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 493: `self,` Inside the function conv2d, which handles conv2d, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 494: `name: str,` Inside the function conv2d, which handles conv2d, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are name: the value named 'name' in this block; str: the value named 'str' in this block.

Line 495: `activations: np.ndarray,` Inside the function conv2d, which handles conv2d, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are activations: an input feature value consumed by a neuron or multiply-accumulate operation; ndarray: the value named 'ndarray' in this block.

Line 496: `*,` Inside the function conv2d, which handles conv2d, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 497: `activation_zero_point: int = 0,` This assigns '0,' to 'activation_zero_point' in host memory. Here activation_zero_point means an input feature value consumed by a neuron or multiply-accumulate operation. The expression is a literal or structural operator and has no hidden software state. Context: the function conv2d, which handles conv2d.

Line 498: `stride: int | Sequence[int] = 1,` This assigns '1,' to 'stride' in host memory. Here stride means the value named 'stride' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function conv2d, which handles conv2d.

Line 499: `padding: int | Sequence[int] = 0,` This assigns '0,' to 'padding' in host memory. Here padding means the value named 'padding' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function conv2d, which handles conv2d.

Line 500: `dilation: int | Sequence[int] = 1,` This assigns '1,' to 'dilation' in host memory. Here dilation means the value named 'dilation' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function conv2d, which handles conv2d.

Line 501: `groups: int = 1,` This assigns '1,' to 'groups' in host memory. Here groups means the value named 'groups' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function conv2d, which handles conv2d.

Line 502: `timeout_seconds: float = 30.0,` This assigns '30.0,' to 'timeout_seconds' in host memory. Here timeout_seconds means the value named 'timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function conv2d, which handles conv2d.

Line 503: `) -> np.ndarray:` Inside the function conv2d, which handles conv2d, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are ndarray: the value named 'ndarray' in this block.

Line 504: `"""Execute one exported Conv2d-BN pair and return signed Q10 NCHW data."""` This is executable documentation attached to the function conv2d, which handles conv2d. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 506: `parameters = self.archive.projection(name)` This assigns 'self.archive.projection(name)' to 'parameters ' in host memory. Here parameters means the value named 'parameters' in this block. The important operands are archive: the value named 'archive' in this block; projection: the value named 'projection' in this block; name: the value named 'name' in this block. Context: the function conv2d, which handles conv2d.

Line 507: `if len(parameters.source_weight_shape) != 4:` This executes the following indented host-code branch only when ‘len(parameters.source_weight_shape) != 4‘ is true. The important operands are len: the value named ’len’ in this block; parameters: the value named ’parameters’ in this block; source_weight_shape: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 508: `raise ValueError(f"projection {name} is not Conv2d")` This rejects an invalid state by raising ‘ValueError(f"projection {name} is not Conv2d")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 509: `weight = parameters.weight_k_by_n.T.reshape(parameters.source_weight_shape)` This assigns ‘parameters.weight_k_by_n.T.reshape(parameters.source_weight_shape)‘ to ‘weight ‘ in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are parameters: the value named ’parameters’ in this block; weight_k_by_n: a learned coefficient multiplied by an activation; T: the value named ’t’ in this block. Context: the function conv2d, which handles conv2d.

Line 510: `values = np.asarray(activations)` This assigns ‘np.asarray(activations)‘ to ‘values ‘ in host memory. Here values means the value named ’values’ in this block. The important operands are asarray: the value named ’asarray’ in this block; activations: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function conv2d, which handles conv2d.

Line 511: `if parameters.compute_opcode == "COMPUTE_BINARY":` This executes the following indented host-code branch only when ‘parameters.compute_opcode == "COMPUTE_BINARY"‘ is true. The important operands are parameters: the value named ’parameters’ in this block; compute_opcode: the value named ’compute opcode’ in this block; COMPUTE_BINARY: the value named ’compute binary’ in this block. Context: the function conv2d, which handles conv2d.

Line 512: `compiled = compile_spike_conv2d(` This statement continues through source line 514; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compile_spike_conv2d(values, weight, stride=stride, padding=padding, dilation=dilation, groups=groups)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_spike_conv2d: a binary event produced when a neuron crosses its threshold; values: the value named ’values’ in this block; weight: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 513: `values, weight, stride=stride, padding=padding,` This is continuation line 2 of the 3-line logical statement that begins at source line 512. Its exact fragment is ‘values, weight, stride=stride, padding=padding,‘. The important operands are values: the value named ’values’ in this block; weight: a learned coefficient multiplied by an activation; stride: the value named ’stride’ in this block. Read together, the complete operation is: This assigns ‘compile_spike_conv2d(values, weight, stride=stride, padding=padding, dilation=dilation, groups=groups)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_spike_conv2d: a binary event produced when a neuron crosses its threshold; values: the value named ’values’ in this block; weight: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 514: `dilation=dilation, groups=groups)` This is continuation line 3 of the 3-line logical statement that begins at source line 512. Its exact fragment is ‘dilation=dilation, groups=groups)‘. The important operands are dilation: the value named ’dilation’ in this block; groups: the value named ’groups’ in this block. Read together, the complete operation is: This assigns ‘compile_spike_conv2d(values, weight, stride=stride, padding=padding, dilation=dilation, groups=groups)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_spike_conv2d: a binary event produced when a neuron crosses its threshold; values: the value named ’values’ in this block; weight: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 515: `elif parameters.compute_opcode == "COMPUTE_DENSE_OUTER":` This executes the following indented host-code branch only when ‘parameters.compute_opcode == "COMPUTE_DENSE_OUTER"‘ is true. The important operands are parameters: the value named ’parameters’ in this block; compute_opcode: the value named ’compute opcode’ in this block; COMPUTE_DENSE_OUTER: the value named ’compute dense outer’ in this block. Context: the function conv2d, which handles conv2d.

Line 516: `compiled = compile_u8_conv2d(` This statement continues through source line 525; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘compile_u8_conv2d(values, self._encoded_dense_weights(weight), activation_zero_point=activation_zero_point, weight_zero_point=128, stride=stride, padding=padding, dilation=dilation, groups=groups,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 517: `values,` This is continuation line 2 of the 10-line logical statement that begins at source line 516. Its exact fragment is ‘values,‘. The important operands are values: the value named ’values’ in this block. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(values, self._encoded_dense_weights(weight), activation_zero_point=activation_zero_point, weight_zero_point=128, stride=stride, padding=padding, dilation=dilation, groups=groups,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 518: `self._encoded_dense_weights(weight),` This is continuation line 3 of the 10-line logical statement that begins at source line 516. Its exact fragment is ‘self._encoded_dense_weights(weight),‘. The important operands are _encoded_dense_weights: a learned coefficient multiplied by an activation; weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(values, self._encoded_dense_weights(weight), activation_zero_point=activation_zero_point, weight_zero_point=128, stride=stride, padding=padding, dilation=dilation, groups=groups,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 519: `activation_zero_point=activation_zero_point,` This is continuation line 4 of the 10-line logical statement that begins at source line 516. Its exact fragment is ‘activation_zero_point=activation_zero_point,‘. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(values, self._encoded_dense_weights(weight), activation_zero_point=activation_zero_point, weight_zero_point=128, stride=stride, padding=padding, dilation=dilation, groups=groups,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 520: `weight_zero_point=128,` This is continuation line 5 of the 10-line logical statement that begins at source line 516. Its exact fragment is ‘weight_zero_point=128,‘. The important operands are weight_zero_point: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(values, self._encoded_dense_weights(weight), activation_zero_point=activation_zero_point, weight_zero_point=128, stride=stride, padding=padding, dilation=dilation, groups=groups,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 521: `stride=stride,` This is continuation line 6 of the 10-line logical statement that begins at source line 516. Its exact fragment is ‘stride=stride,‘. The important operands are stride: the value named ’stride’ in this block. Read together, the complete operation is: This assigns ‘compile_u8_conv2d(values, self._encoded_dense_weights(weight), activation_zero_point=activation_zero_point, weight_zero_point=128, stride=stride, padding=padding, dilation=dilation, groups=groups,)‘ to ‘compiled ‘ in host memory. Here compiled means the value named ’compiled’ in this block. The important operands are compile_u8_conv2d: the value named ’compile u8 conv2d’ in this block; values: the value named ’values’ in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 522: `padding=padding,` This is continuation line 7 of the 10-line logical statement that begins at source line 516. Its exact fragment is 'padding=padding,'. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'compile_u8_conv2d(values, self._encoded_dense_weights(weight), activation_zero_point=activation_zero_point, weight_zero_point=128, stride=stride, padding=padding, dilation=dilation, groups=groups,)' to 'compiled ' in host memory. Here compiled means the value named 'compiled' in this block. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block; values: the value named 'values' in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 523: `dilation=dilation,` This is continuation line 8 of the 10-line logical statement that begins at source line 516. Its exact fragment is 'dilation=dilation,'. The important operands are dilation: the value named 'dilation' in this block. Read together, the complete operation is: This assigns 'compile_u8_conv2d(values, self._encoded_dense_weights(weight), activation_zero_point=activation_zero_point, weight_zero_point=128, stride=stride, padding=padding, dilation=dilation, groups=groups,)' to 'compiled ' in host memory. Here compiled means the value named 'compiled' in this block. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block; values: the value named 'values' in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 524: `groups=groups,` This is continuation line 9 of the 10-line logical statement that begins at source line 516. Its exact fragment is 'groups=groups,'. The important operands are groups: the value named 'groups' in this block. Read together, the complete operation is: This assigns 'compile_u8_conv2d(values, self._encoded_dense_weights(weight), activation_zero_point=activation_zero_point, weight_zero_point=128, stride=stride, padding=padding, dilation=dilation, groups=groups,)' to 'compiled ' in host memory. Here compiled means the value named 'compiled' in this block. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block; values: the value named 'values' in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 525: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 516. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'compile_u8_conv2d(values, self._encoded_dense_weights(weight), activation_zero_point=activation_zero_point, weight_zero_point=128, stride=stride, padding=padding, dilation=dilation, groups=groups,)' to 'compiled ' in host memory. Here compiled means the value named 'compiled' in this block. The important operands are compile_u8_conv2d: the value named 'compile u8 conv2d' in this block; values: the value named 'values' in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation. Context: the function conv2d, which handles conv2d.

Line 526: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function conv2d, which handles conv2d.

Line 527: `raise ValueError(f"unsupported projection opcode {parameters.compute_opcode!r}")` This rejects an invalid state by raising 'ValueError(f"unsupported projection opcode {parameters.compute_opcode!r}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 528: `accumulator_nchw = compiled.execute_batched(` This statement continues through source line 529; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'compiled.execute_batched(self.driver, timeout_seconds=timeout_seconds)' to 'accumulator_nchw ' in host memory. Here accumulator_nchw means a widened running sum that prevents intermediate overflow. The important operands are compiled: the value named 'compiled' in this block; execute_batched: the value named 'execute batched' in this block; driver: the value named 'driver' in this block. Context: the function conv2d, which handles conv2d.

Line 529: `self.driver, timeout_seconds=timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 528. Its exact fragment is 'self.driver, timeout_seconds=timeout_seconds)'. The important operands are driver: the value named 'driver' in this block; timeout_seconds: the value named 'timeout seconds' in this block. Read together, the complete operation is: This assigns 'compiled.execute_batched(self.driver, timeout_seconds=timeout_seconds)' to 'accumulator_nchw ' in host memory. Here accumulator_nchw means a widened running sum that prevents intermediate overflow. The important operands are compiled: the value named 'compiled' in

this block; execute_batched: the value named 'execute batched' in this block; driver: the value named 'driver' in this block. Context: the function conv2d, which handles conv2d.

Line 530: `batch, channels, height, width = accumulator_nchw.shape` This assigns 'accumulator_nchw.shape' to 'batch, channels, height, width ' in host memory. Here batch means the value named 'batch' in this block. The important operands are accumulator_nchw: a widened running sum that prevents intermediate overflow; shape: the value named 'shape' in this block. Context: the function conv2d, which handles conv2d.

Line 531: `matrix = accumulator_nchw.transpose(0, 2, 3, 1).reshape(-1, channels)` This assigns 'accumulator_nchw.transpose(0, 2, 3, 1).reshape(-1, channels)' to 'matrix ' in host memory. Here matrix means the value named 'matrix' in this block. The important operands are accumulator_nchw: a widened running sum that prevents intermediate overflow; transpose: the value named 'transpose' in this block; reshape: the value named 'reshape' in this block. Context: the function conv2d, which handles conv2d.

Line 532: `quantized = requantize_projection_on_accelerator(` This statement continues through source line 533; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'requantize_projection_on_accelerator(self.driver, matrix, parameters, timeout_seconds=timeout_seconds)' to 'quantized ' in host memory. Here quantized means the value named 'quantized' in this block. The important operands are requantize_projection_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; matrix: the value named 'matrix' in this block. Context: the function conv2d, which handles conv2d.

Line 533: `self.driver, matrix, parameters, timeout_seconds=timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 532. Its exact fragment is 'self.driver, matrix, parameters, timeout_seconds=timeout_seconds)'. The important operands are driver: the value named 'driver' in this block; matrix: the value named 'matrix' in this block; parameters: the value named 'parameters' in this block. Read together, the complete operation is: This assigns 'requantize_projection_on_accelerator(self.driver, matrix, parameters, timeout_seconds=timeout_seconds)' to 'quantized ' in host memory. Here quantized means the value named 'quantized' in this block. The important operands are requantize_projection_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; matrix: the value named 'matrix' in this block. Context: the function conv2d, which handles conv2d.

Line 534: `return quantized.reshape(batch, height, width, channels).transpose(0, 3, 1, 2)` This returns 'quantized.reshape(batch, height, width, channels).transpose(0, 3, 1, 2)' to the caller of the function conv2d, which handles conv2d, ending this invocation. The important operands are quantized: the value named 'quantized' in this block; reshape: the value named 'reshape' in this block; batch: the value named 'batch' in this block.

Line 537: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it creates no FPGA circuit by itself.

Line 538: `class SpikingformerInferenceResult:` This defines class SpikingformerInferenceResult, which groups data and methods for spikingformer inference result. Instances exist in host memory and organize the flow that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 539: `"""Classifier result in both exact accumulator and represented float units."""` This is executable documentation attached to the class SpikingformerInferenceResult, which handles spikingformer inference result. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 541: `logits_accumulator: np.ndarray` Inside the class SpikingformerInferenceResult, which handles spikingformer inference result, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are logits_accumulator: a widened running sum that prevents intermediate overflow; ndarray: the value named 'ndarray' in this block.

Line 542: `logits: np.ndarray` Inside the class SpikingformerInferenceResult, which handles spikingformer inference result, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are logits: the ten unnormalized classifier scores used for argmax; ndarray: the value named 'ndarray' in this block.

Line 543: `predicted_class: np.ndarray` Inside the class SpikingformerInferenceResult, which handles spikingformer inference result, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are predicted_class: the value named 'predicted class' in this block; ndarray: the value named 'ndarray' in this block.

Line 546: `class SpikingformerAcceleratorModel:` This defines class SpikingformerAcceleratorModel, which groups data and methods for spikingformer accelerator model. Instances exist in host memory and organize the flow that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 547: `"""Full trained Spikingformer-4-384 inference graph on NeuraEdge primitives."""` This is executable documentation attached to the class SpikingformerAcceleratorModel, which handles spikingformer accelerator model. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 549: `def __init__(` This starts function ___init___. Its indented body performs init as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 550: `self,` Inside the function ___init___, which handles init, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 551: `archive: SpikingformerParameterArchive,` Inside the function ___init___, which handles init, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are archive: the value named 'archive' in this block; SpikingformerParameterArchive: the value named 'spikingformer parameter archive' in this block.

Line 552: `driver: ProgramExecutor,` Inside the function ___init___, which handles init, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are driver: the value named 'driver' in this block; ProgramExecutor: the value named 'program executor' in this block.

Line 553: `*,` Inside the function ___init___, which handles init, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The expression is a literal or structural operator and has no hidden software state.

Line 554: `layer_timeout_seconds: float = 120.0,` This assigns '120.0,' to 'layer_timeout_seconds' in host memory. Here layer_timeout_seconds means the value named 'layer timeout seconds' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 555: `) -> None:` Inside the function ___init___, which handles init, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are None: the value named 'none' in this block.

Line 556: `if layer_timeout_seconds <= 0:` This executes the following indented host-code branch only when 'layer_timeout_seconds <= 0' is true. The important operands are layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Context: the function ___init___, which handles init.

Line 557: `raise ValueError("layer_timeout_seconds must be positive")` This rejects an invalid state by raising ‘ValueError("layer_timeout_seconds must be positive")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 558: `self.archive = archive` This assigns ‘archive‘ to ‘self.archive ‘ in host memory. Here archive means the value named ’archive’ in this block. The important operands are archive: the value named ’archive’ in this block. Context: the function ___init___, which handles init.

Line 559: `self.driver = driver` This assigns ‘driver‘ to ‘self.driver ‘ in host memory. Here driver means the value named ’driver’ in this block. The important operands are driver: the value named ’driver’ in this block. Context: the function ___init___, which handles init.

Line 560: `self.projections = SpikingformerProjectionExecutor(archive, driver)` This assigns ‘SpikingformerProjectionExecutor(archive, driver)‘ to ‘self.projections ‘ in host memory. Here projections means the value named ’projections’ in this block. The important operands are SpikingformerProjectionExecutor: the value named ’spikingformer projection executor’ in this block; archive: the value named ’archive’ in this block; driver: the value named ’driver’ in this block. Context: the function ___init___, which handles init.

Line 561: `self.layer_timeout_seconds = layer_timeout_seconds` This assigns ‘layer_timeout_seconds‘ to ‘self.layer_timeo‘ in host memory. Here layer_timeout_seconds means the value named ’layer timeout seconds’ in this block. The important operands are layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Context: the function ___init___, which handles init.

Line 562: `fixed = archive.manifest.get("fixed_point")` This assigns ‘archive.manifest.get("fixed_point")‘ to ‘fixed ‘ in host memory. Here fixed means the value named ’fixed’ in this block. The important operands are archive: the value named ’archive’ in this block; manifest: the value named ’manifest’ in this block; get: the value named ’get’ in this block. Context: the function ___init___, which handles init.

Line 563: `if not isinstance(fixed, dict):` This executes the following indented host-code branch only when ‘not isinstance(fixed, dict)‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; fixed: the value named ’fixed’ in this block. Context: the function ___init___, which handles init.

Line 564: `raise ValueError("parameter archive has no fixed-point contract")` This rejects an invalid state by raising ‘ValueError("parameter archive has no fixed-point contract")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 565: `self.fractional_bits = int(fixed["activation_fractional_bits"])` This assigns ‘int(fixed["activation_fractio‘ to ‘self.fractional_bits ‘ in host memory. Here fractional_bits means the value named ’fractional bits’ in this block. The important operands are fixed: the value named ’fixed’ in this block; activation_fractional_bits: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function ___init___, which handles init.

Line 566: `self.fixed_scale = 1 << self.fractional_bits` This assigns ‘1 << self.fractional_bits‘ to ‘self.fixed_scale ‘ in host memory. Here fixed_scale means the real-value spacing represented by one quantized integer step. The important operands are fractional_bits: the value named ’fractional bits’ in this block. Context: the function ___init___, which handles init.

Line 567: `self.image_scale = float(fixed["image_input_scale"])` This assigns ‘float(fixed["image_input_scale"])‘ to ‘self.image_scale ‘ in host memory. Here image_scale means the real-value spacing represented by one quantized integer step. The important operands are float: the value named ’float’ in this block; fixed: the value named ’fixed’ in this block; image_input_scale: the real-value spacing represented by one quantized integer step. Context: the function ___init___, which handles init.

Line 568: `self.image_zero_point = int(fixed["image_input_zero_point"])` This assigns ‘int(fixed["image_input_zero_p to ‘self.image_zero_point ‘ in host memory. Here image_zero_point means the integer code representing real numeric zero in affine quantization. The important operands are fixed: the value named ’fixed’ in this block; image_input_zero_point: the integer code representing real numeric zero in affine quantization. Context: the function ___init___, which handles init.

Line 569: `self.head_activation_scale = float(fixed["head_activation_scale"])` This assigns ‘float(fixed["head_activat to ‘self.head_activation_scale ‘ in host memory. Here head_activation_scale means an input feature value consumed by a neuron or multiply-accumulate operation. The important operands are float: the value named ’float’ in this block; fixed: the value named ’fixed’ in this block; head_activation_scale: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function ___init___, which handles init.

Line 570: `required = {` This statement continues through source line 576; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(4) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(4) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 571: `*(f"patch_embed.block{index}" for index in range(5)),` This is continuation line 2 of the 7-line logical statement that begins at source line 570. Its exact fragment is ‘*(f"patch_embed.block{index}" for index in range(5)),‘. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(4) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(4) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 572: `*(f"block.{block}.attn.{name}"` This is continuation line 3 of the 7-line logical statement that begins at source line 570. Its exact fragment is ‘*(f"block.{block}.attn.{name}"‘. The important operands are f: the value named ’f’ in this block; block: the value named ’block’ in this block; attn: the value named ’attn’ in this block. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(4) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(4) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 573: `for block in range(4) for name in ("q", "k", "v", "proj")),` This is continuation line 4 of the 7-line logical statement that begins at source line 570. Its exact fragment is ‘for block in range(4) for name in ("q", "k", "v", "proj")),‘. The important operands are for: the value named ’for’ in this block; block: the value named ’block’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(4) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(4) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 574: `*(f"block.{block}.mlp.fc{layer}"` This is continuation line 5 of the 7-line logical statement that begins at source line 570. Its exact fragment is ‘*(f"block.{block}.mlp.fc{layer}"‘. The important operands are f: the value named ’f’ in this block; block: the value named ’block’ in this block; mlp: the value named ’mlp’ in this block. Read together, the complete operation is: This assigns ‘{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(4) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(4) for layer in (1, 2)), }‘ to ‘required ‘ in host memory. Here required means the value named ’required’ in this block. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Context: the function ___init___, which handles init.

Line 575: `for block in range(4) for layer in (1, 2)),` This is continuation line 6 of the 7-line logical statement that begins at source line 570. Its exact fragment is 'for block in range(4) for layer in (1, 2)),'. The important operands are for: the value named 'for' in this block; block: the value named 'block' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This assigns '{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(4) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(4) for layer in (1, 2)), }' to 'required ' in host memory. Here required means the value named 'required' in this block. The important operands are f: the value named 'f' in this block; patch_embed: the value named 'patch embed' in this block; block: the value named 'block' in this block. Context: the function ___init___, which handles init.

Line 576: `}` This is continuation line 7 of the 7-line logical statement that begins at source line 570. Its exact fragment is '}'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns '{ *(f"patch_embed.block{index}" for index in range(5)), *(f"block.{block}.attn.{name}" for block in range(4) for name in ("q", "k", "v", "proj")), *(f"block.{block}.mlp.fc{layer}" for block in range(4) for layer in (1, 2)), }' to 'required ' in host memory. Here required means the value named 'required' in this block. The important operands are f: the value named 'f' in this block; patch_embed: the value named 'patch embed' in this block; block: the value named 'block' in this block. Context: the function ___init___, which handles init.

Line 577: `missing = required - set(archive.projection_names)` This assigns 'required - set(archive.projection_names)' to 'missing ' in host memory. Here missing means the value named 'missing' in this block. The important operands are required: the value named 'required' in this block; set: the value named 'set' in this block; archive: the value named 'archive' in this block. Context: the function ___init___, which handles init.

Line 578: `if missing:` This executes the following indented host-code branch only when 'missing' is true. The important operands are missing: the value named 'missing' in this block. Context: the function ___init___, which handles init.

Line 579: `raise ValueError(f"parameter archive is missing projections: {sorted(missing)}")` This rejects an invalid state by raising 'ValueError(f"parameter archive is missing projections: {sorted(missing)}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 581: `def _lif(self, value: np.ndarray, *, threshold: float = 1.0) -> np.ndarray:` This starts function _lif. Its indented body performs lif as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 582: `return lif_sequence_on_accelerator(` This statement continues through source line 589; the explanation uses the complete expression rather than only the first visual fragment. This returns 'lif_sequence_on_accelerator(self.driver, value, threshold_q10=int(round(threshold * self.fixed_scale)), leak_shift=1, reset_q10=0, timeout_seconds=self.layer_)' to the caller of the function _lif, which handles lif, ending this invocation. The important operands are lif_sequence_on_accelerato the value named 'lif sequence on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block.

Line 583: `self.driver,` This is continuation line 2 of the 8-line logical statement that begins at source line 582. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This returns 'lif_sequence_on_accelerator(self.driver, value, threshold_q10=int(round(threshold * self.fixed_scale)), leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)' to the caller of the function _lif, which handles lif, ending this invocation. The important operands are lif_sequence_on_accelerator: the value named 'lif sequence on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block.

Line 584: `value,` This is continuation line 3 of the 8-line logical statement that begins at source line 582. Its exact fragment is 'value,'. The important operands are value: the value named 'value' in this block. Read together, the complete operation is: This returns 'lif_sequence_on_accelerator(self.driver, value, threshold_q10=int(round(threshold * self.fixed_scale)), leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)' to the caller of the function _lif, which handles lif, ending this invocation. The important operands are lif_sequence_on_accelerator: the value named 'lif sequence on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block.

Line 585: `threshold_q10=int(round(threshold * self.fixed_scale)),` This is continuation line 4 of the 8-line logical statement that begins at source line 582. Its exact fragment is 'threshold_q10=int(round(threshold * self.fixed_scale)),'. The important operands are threshold_q10: the membrane level at which a neuron emits a spike; round: the value named 'round' in this block; threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This returns 'lif_sequence_on_accelerator(self.driver, value, threshold_q10=int(round(threshold * self.fixed_scale)), leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)' to the caller of the function _lif, which handles lif, ending this invocation. The important operands are lif_sequence_on_accelerator: the value named 'lif sequence on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block.

Line 586: `leak_shift=1,` This is continuation line 5 of the 8-line logical statement that begins at source line 582. Its exact fragment is 'leak_shift=1,'. The important operands are leak_shift: the retained fraction of prior membrane state. Read together, the complete operation is: This returns 'lif_sequence_on_accelerator(self.driver, value, threshold_q10=int(round(threshold * self.fixed_scale)), leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)' to the caller of the function _lif, which handles lif, ending this invocation. The important operands are lif_sequence_on_accelerato the value named 'lif sequence on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block.

Line 587: `reset_q10=0,` This is continuation line 6 of the 8-line logical statement that begins at source line 582. Its exact fragment is 'reset_q10=0,'. The important operands are reset_q10: the value named 'reset q10' in this block. Read together, the complete operation is: This returns 'lif_sequence_on_accelerator(self.driver, value, threshold_q10=int(round(threshold * self.fixed_scale)), leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)' to the caller of the function _lif, which handles lif, ending this invocation. The important operands are lif_sequence_on_accelerato the value named 'lif sequence on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block.

Line 588: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 7 of the 8-line logical statement that begins at source line 582. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This returns 'lif_sequence_on_accelerator(self.driver, value, threshold_q10=int(round(threshold * self.fixed_scale)), leak_shift=1, reset_q10=0, timeout_seconds=self.layer_)' to the caller of the function _lif, which handles lif, ending this invocation. The important operands are lif_sequence_on_accelerato the value named 'lif sequence on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block.

Line 589: `)` This is continuation line 8 of the 8-line logical statement that begins at source line 582. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'lif_sequence_on_accelerator(self.driver, value, threshold_q10=int(round(threshold * self.fixed_scale)), leak_shift=1, reset_q10=0, timeout_seconds=self.layer_timeout_seconds,)' to the caller of the function _lif, which handles lif, ending this invocation. The important operands are lif_sequence_on_accelerator: the value named 'lif sequence on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block.

Line 591: `def _project_tokens(self, name: str, spikes: np.ndarray) -> np.ndarray:` This starts function _project_tokens. Its indented body performs project tokens as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 592: `if spikes.ndim != 4:` This executes the following indented host-code branch only when 'spikes.ndim != 4' is true. The important operands are spikes: a binary event produced when a neuron crosses its threshold; ndim: the value named 'ndim' in this block. Context: the function _project_tokens, which handles project tokens.

Line 593: `raise ValueError("token projection input must have shape [T,B,N,C]")` This rejects an invalid state by raising 'ValueError("token projection input must have shape [T,B,N,C]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 594: `timesteps, batch, tokens, channels = spikes.shape` This assigns ‘spikes.shape‘ to ‘timesteps, batch, tokens, channels ‘ in host memory. Here timesteps means one discrete SNN update instant. The important operands are spikes: a binary event produced when a neuron crosses its threshold; shape: the value named ’shape’ in this block. Context: the function _project_tokens, which handles project tokens.

Line 595: `rows = spikes.reshape(timesteps * batch * tokens, channels)` This assigns ‘spikes.reshape(timesteps * batch * tokens, channels)‘ to ‘rows ‘ in host memory. Here rows means one output-row position processed by the tensor tile. The important operands are spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _project_tokens, which handles project tokens.

Line 596: `result = self.projections.matrix(` This statement continues through source line 597; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self.projections.matrix(name, rows, timeout_seconds=self.layer_timeout_seconds)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; name: the value named ’name’ in this block. Context: the function _project_tokens, which handles project tokens.

Line 597: `name, rows, timeout_seconds=self.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 596. Its exact fragment is ‘name, rows, timeout_seconds=self.layer_timeout_seconds)‘. The important operands are name: the value named ’name’ in this block; rows: one output-row position processed by the tensor tile; timeout_seconds: the value named ’timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘self.projections.matrix(name, rows, timeout_seconds=self.layer_timeout_seconds)‘ to ‘result ‘ in host memory. Here result means the value named ’result’ in this block. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; name: the value named ’name’ in this block. Context: the function _project_tokens, which handles project tokens.

Line 598: `return result.reshape(timesteps, batch, tokens, -1)` This returns ‘result.reshape(timesteps, batch, tokens, -1)‘ to the caller of the function _project_tokens, which handles project tokens, ending this invocation. The important operands are result: the value named ’result’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant.

Line 600: `def _dynamic_binary_gemm(self, left: np.ndarray, right: np.ndarray) -> np.ndarray:` This starts function _dynamic_binary_gemm. Its indented body performs dynamic binary gemm as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 601: `program = compile_spike_gemm(left, right)` This assigns ‘compile_spike_gemm(left, right)‘ to ‘program ‘ in host memory. Here program means the value named ’program’ in this block. The important operands are compile_spike_gemm: a binary event produced when a neuron crosses its threshold; left: the value named ’left’ in this block; right: the value named ’right’ in this block. Context: the function _dynamic_binary_gemm, which handles dynamic binary gemm.

Line 602: `return program.execute_batched(` This statement continues through source line 603; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘program.execute_batched(self.driver, timeout_seconds=self.layer_timeout_seconds)‘ to the caller of the function _dynamic_binary_gemm, which handles dynamic binary gemm, ending this invocation. The important operands are program: the value named ’program’ in this block; execute_batched: the value named ’execute batched’ in this block; driver: the value named ’driver’ in this block.

Line 603: `self.driver, timeout_seconds=self.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 602. Its exact fragment is ‘self.driver, timeout_seconds=self.layer_timeout_seconds)‘. The important operands are driver: the value named ’driver’ in this block; timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This returns ‘program.execute_batched(self.driver, timeout_seconds=self.layer_timeout_seconds)‘ to the caller of the function _dynamic_binary_gemm, which handles dynamic binary gemm, ending this invocation. The

important operands are program: the value named 'program' in this block; execute_batched: the value named 'execute batched' in this block; driver: the value named 'driver' in this block.

Line 605: `def _dynamic_u8_gemm(self, left: np.ndarray, right: np.ndarray) -> np.ndarray:` This starts function _dynamic_u8_gemm. Its indented body performs dynamic u8 gemm as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 606: `program = compile_u8_gemm(left, right)` This assigns 'compile_u8_gemm(left, right)' to 'program ' in host memory. Here program means the value named 'program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; left: the value named 'left' in this block; right: the value named 'right' in this block. Context: the function _dynamic_u8_gemm, which handles dynamic u8 gemm.

Line 607: `return program.execute_batched(` This statement continues through source line 608; the explanation uses the complete expression rather than only the first visual fragment. This returns 'program.execute_batched(self.driver, timeout_seconds=self.layer_timeout_seconds)' to the caller of the function _dynamic_u8_gemm, which handles dynamic u8 gemm, ending this invocation. The important operands are program: the value named 'program' in this block; execute_batched: the value named 'execute batched' in this block; driver: the value named 'driver' in this block.

Line 608: `self.driver, timeout_seconds=self.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 607. Its exact fragment is 'self.driver, timeout_seconds=self.layer_timeout_seconds)'. The important operands are driver: the value named 'driver' in this block; timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This returns 'program.execute_batched(self.driver, timeout_seconds=self.layer_timeout_seconds)' to the caller of the function _dynamic_u8_gemm, which handles dynamic u8 gemm, ending this invocation. The important operands are program: the value named 'program' in this block; execute_batched: the value named 'execute batched' in this block; driver: the value named 'driver' in this block.

Line 610: `def _attention(self, block_index: int, value: np.ndarray) -> np.ndarray:` This starts function _attention. Its indented body performs attention as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 611: `timesteps, batch, channels, height, width = value.shape` This assigns 'value.shape' to 'timesteps, batch, channels, height, width ' in host memory. Here timesteps means one discrete SNN update instant. The important operands are value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function _attention, which handles attention.

Line 612: `tokens = height * width` This assigns 'height * width' to 'tokens ' in host memory. Here tokens means the value named 'tokens' in this block. The important operands are height: the value named 'height' in this block; width: the value named 'width' in this block. Context: the function _attention, which handles attention.

Line 613: `projection_spikes = self._lif(value)` This assigns 'self._lif(value)' to 'projection_spikes ' in host memory. Here projection_spikes means a binary event produced when a neuron crosses its threshold. The important operands are _lif: the value named 'lif' in this block; value: the value named 'value' in this block. Context: the function _attention, which handles attention.

Line 614: `token_spikes = projection_spikes.reshape(` This statement continues through source line 615; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'projection_spikes.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2)' to 'token_spikes ' in host memory. Here token_spikes means a binary event produced when a neuron crosses its threshold. The important operands are projection_spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _attention, which handles attention.

Line 615: `timesteps, batch, channels, tokens).transpose(0, 1, 3, 2)` This is continuation line 2 of the 2-line logical statement that begins at source line 614. Its exact fragment is ‘timesteps, batch, channels, tokens).transpose(0, 1, 3, 2)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This assigns ‘projection_spikes.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2)‘ to ‘token_spikes ‘ in host memory. Here token_spikes means a binary event produced when a neuron crosses its threshold. The important operands are projection_spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention, which handles attention.

Line 616: `prefix = f"block.{block_index}.attn"` This assigns ‘f"block.{block_index}.attn"‘ to ‘prefix ‘ in host memory. Here prefix means the value named ’prefix’ in this block. The important operands are f: the value named ’f’ in this block; block: the value named ’block’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the function _attention, which handles attention.

Line 617: `query = self._lif(self._project_tokens(f"{prefix}.q", token_spikes))` This assigns ‘self._lif(self._project_ token_spikes))‘ to ‘query ‘ in host memory. Here query means the value named ’query’ in this block. The important operands are _lif: the value named ’lif’ in this block; _project_tokens: the value named ’project tokens’ in this block; f: the value named ’f’ in this block. Context: the function _attention, which handles attention.

Line 618: `key = self._lif(self._project_tokens(f"{prefix}.k", token_spikes))` This assigns ‘self._lif(self._project_to token_spikes))‘ to ‘key ‘ in host memory. Here key means the value named ’key’ in this block. The important operands are _lif: the value named ’lif’ in this block; _project_tokens: the value named ’project tokens’ in this block; f: the value named ’f’ in this block. Context: the function _attention, which handles attention.

Line 619: `projected_value = self._lif(self._project_tokens(f"{prefix}.v", token_spikes))` This assigns ‘self._lif(self._project_tokens(f"{prefix}.v", token_spikes))‘ to ‘projected_value ‘ in host memory. Here projected_value means the value named ’projected value’ in this block. The important operands are _lif: the value named ’lif’ in this block; _project_tokens: the value named ’project tokens’ in this block; f: the value named ’f’ in this block. Context: the function _attention, which handles attention.

Line 621: `heads = 12` This assigns ‘12‘ to ‘heads ‘ in host memory. Here heads means the value named ’heads’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _attention, which handles attention.

Line 622: `if channels % heads:` This executes the following indented host-code branch only when ‘channels % heads‘ is true. The important operands are channels: the value named ’channels’ in this block; heads: the value named ’heads’ in this block. Context: the function _attention, which handles attention.

Line 623: `raise ValueError("attention channels must divide into 12 heads")` This rejects an invalid state by raising ‘ValueError("attention channels must divide into 12 heads")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 624: `head_dim = channels // heads` This assigns ‘channels // heads‘ to ‘head_dim ‘ in host memory. Here head_dim means the value named ’head dim’ in this block. The important operands are channels: the value named ’channels’ in this block; heads: the value named ’heads’ in this block. Context: the function _attention, which handles attention.

Line 625: `query = query.reshape(timesteps, batch, tokens, heads, head_dim).transpose(0, 1, 3, 2, 4)` This assigns ‘query.reshape(timesteps, batch, tokens, heads, head_dim).transpose(0, 1, 3, 2, 4)‘ to ‘query ‘ in host memory. Here query means the value named ’query’ in this block. The important operands are query: the value named ’query’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention, which handles attention.

Line 626: `key = key.reshape(timesteps, batch, tokens, heads, head_dim).transpose(0, 1, 3, 2, 4)` This assigns ‘key.reshape(timesteps, batch, tokens, heads, head_dim).transpose(0, 1, 3, 2, 4)‘ to ‘key ‘ in host memory. Here key means the value named ’key’ in this block. The important operands are key: the value named ’key’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention, which handles attention.

Line 627: `projected_value = projected_value.reshape(` This statement continues through source line 628; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘projected_value.reshape(timesteps, batch, tokens, heads, head_dim).transpose(0, 1, 3, 2, 4)‘ to ‘projected_value ‘ in host memory. Here projected_value means the value named ’projected value’ in this block. The important operands are projected_value: the value named ’projected value’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention, which handles attention.

Line 628: `timesteps, batch, tokens, heads, head_dim).transpose(0, 1, 3, 2, 4)` This is continuation line 2 of the 2-line logical statement that begins at source line 627. Its exact fragment is ‘timesteps, batch, tokens, heads, head_dim).transpose(0, 1, 3, 2, 4)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; tokens: the value named ’tokens’ in this block. Read together, the complete operation is: This assigns ‘projected_value.reshape(timesteps, batch, tokens, heads, head_dim).transpose(0, 1, 3, 2, 4)‘ to ‘projected_value ‘ in host memory. Here projected_value means the value named ’projected value’ in this block. The important operands are projected_value: the value named ’projected value’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant. Context: the function _attention, which handles attention.

Line 629: `attention_value = np.empty(` This statement continues through source line 630; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘np.empty((timesteps, batch, heads, tokens, head_dim), dtype=np.int64)‘ to ‘attention_value ‘ in host memory. Here attention_value means the value named ’attention value’ in this block. The important operands are empty: the value named ’empty’ in this block; timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block. Context: the function _attention, which handles attention.

Line 630: `(timesteps, batch, heads, tokens, head_dim), dtype=np.int64)` This is continuation line 2 of the 2-line logical statement that begins at source line 629. Its exact fragment is ‘(timesteps, batch, heads, tokens, head_dim), dtype=np.int64)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; heads: the value named ’heads’ in this block. Read together, the complete operation is: This assigns ‘np.empty((timesteps, batch, heads, tokens, head_dim), dtype=np.int64)‘ to ‘attention_value ‘ in host memory. Here attention_value means the value named ’attention value’ in this block. The important operands are empty: the value named ’empty’ in this block; timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block. Context: the function _attention, which handles attention.

Line 631: `for timestep in range(timesteps):` This iterates timestep over ‘range(timesteps)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _attention, which handles attention.

Line 632: `for batch_index in range(batch):` This iterates batch_index over ‘range(batch)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _attention, which handles attention.

Line 633: `for head in range(heads):` This iterates head over ‘range(heads)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _attention, which handles attention.

Line 634: `scores = self._dynamic_binary_gemm(` This statement continues through source line 637; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self._dynamic_binary_gemm(query[timestep, batch_index, head], key[timestep, batch_index, head].T,)‘ to ‘scores ‘ in host memory. Here scores means the value named ’scores’ in this block. The important operands are _dynamic_binary_gemm: the value named ’dynamic binary gemm’ in this block; query: the value named ’query’ in this block; timestep: one discrete SNN update instant. Context: the function _attention, which handles attention.

Line 635: `query[timestep, batch_index, head],` This is continuation line 2 of the 4-line logical statement that begins at source line 634. Its exact fragment is 'query[timestep, batch_index, head],'. The important operands are query: the value named 'query' in this block; timestep: one discrete SNN update instant; batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns 'self._dynamic_binary_gemm(query[timestep, batch_index, head], key[timestep, batch_index, head].T,)' to 'scores ' in host memory. Here scores means the value named 'scores' in this block. The important operands are _dynamic_binary_gemm: the value named 'dynamic binary gemm' in this block; query: the value named 'query' in this block; timestep: one discrete SNN update instant. Context: the function _attention, which handles attention.

Line 636: `key[timestep, batch_index, head].T,` This is continuation line 3 of the 4-line logical statement that begins at source line 634. Its exact fragment is 'key[timestep, batch_index, head].T,'. The important operands are key: the value named 'key' in this block; timestep: one discrete SNN update instant; batch_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns 'self._dynamic_binary_gemm(query[timestep, batch_index, head], key[timestep, batch_index, head].T,)' to 'scores ' in host memory. Here scores means the value named 'scores' in this block. The important operands are _dynamic_binary_gemm: the value named 'dynamic binary gemm' in this block; query: the value named 'query' in this block; timestep: one discrete SNN update instant. Context: the function _attention, which handles attention.

Line 637: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 634. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self._dynamic_binary_gemm(query[timestep, batch_index, head], key[timestep, batch_index, head].T,)' to 'scores ' in host memory. Here scores means the value named 'scores' in this block. The important operands are _dynamic_binary_gemm: the value named 'dynamic binary gemm' in this block; query: the value named 'query' in this block; timestep: one discrete SNN update instant. Context: the function _attention, which handles attention.

Line 638: `if scores.min() < 0 or scores.max() > 255:` This executes the following indented host-code branch only when 'scores.min() $<$ 0 or scores.max() $>$ 255' is true. The important operands are scores: the value named 'scores' in this block; min: the value named 'min' in this block; or: the value named 'or' in this block. Context: the function _attention, which handles attention.

Line 639: `raise OverflowError("binary QK score does not fit the dynamic-u8 AV path")` This rejects an invalid state by raising 'OverflowError("binary QK score does not fit the dynamic-u8 AV path")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 640: `attention_value[timestep, batch_index, head] = self._dynamic_u8_gemm(` This statement continues through source line 643; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self._dynamic_u8_gemm(scores.astype(np.uint8), projected_value[timestep, batch_index, head].astype(np.uint8),)' to 'attention_value[timestep, batch_index, head] ' in host memory. Here attention_value means the value named 'attention value' in this block. The important operands are _dynamic_u8_gemm: the value named 'dynamic u8 gemm' in this block; scores: the value named 'scores' in this block; astype: the value named 'astype' in this block. Context: the function _attention, which handles attention.

Line 641: `scores.astype(np.uint8),` This is continuation line 2 of the 4-line logical statement that begins at source line 640. Its exact fragment is 'scores.astype(np.uint8),'. The important operands are scores: the value named 'scores' in this block; astype: the value named 'astype' in this block; uint8: the value named 'uint8' in this block. Read together, the complete operation is: This assigns 'self._dynamic_u8_gemm(scores.astype(np.uint8), projected_value[timestep, batch_index, head].astype(np.uint8),)' to 'attention_value[timestep, batch_index, head] ' in host memory. Here attention_value means the value named 'attention value' in this block. The important operands are _dynamic_u8_gemm: the value named 'dynamic u8 gemm' in this block; scores: the value named 'scores' in this block; astype: the value named 'astype' in this block. Context: the function _attention, which handles attention.

Line 642: `projected_value[timestep, batch_index, head].astype(np.uint8),` This is continuation line 3 of the 4-line logical statement that begins at source line 640. Its exact fragment is 'projected_value[timestep, batch_index, head].astype(np.uint8),'. The important operands are projected_value: the value named 'projected value' in this block; timestep: one discrete SNN update instant; batch_index: an integer selecting one tensor element, lane, bank, or state

entry. Read together, the complete operation is: This assigns ‘self._dynamic_u8_gemm(scores.astype(np.uint8), projected_value[timestep, batch_index, head].astype(np.uint8),)‘ to ‘attention_value[timestep, batch_index, head] ‘ in host memory. Here attention_value means the value named ’attention value’ in this block. The important operands are _dynamic_u8_gemm: the value named ’dynamic u8 gemm’ in this block; scores: the value named ’scores’ in this block; astype: the value named ’astype’ in this block. Context: the function _attention, which handles attention.

Line 643: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 640. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘self._dynamic_u8_gemm(scores.astype(np.uint8), projected_value[timestep, batch_index, head].astype(np.uint8),)‘ to ‘attention_value[timestep, batch_index, head] ‘ in host memory. Here attention_value means the value named ’attention value’ in this block. The important operands are _dynamic_u8_gemm: the value named ’dynamic u8 gemm’ in this block; scores: the value named ’scores’ in this block; astype: the value named ’astype’ in this block. Context: the function _attention, which handles attention.

Line 644: `attention_q10 = attention_value * (self.fixed_scale // 8)` This assigns ‘attention_value * (self.fixed_scale // 8)‘ to ‘attention_q10 ‘ in host memory. Here attention_q10 means the value named ’attention q10’ in this block. The important operands are attention_value: the value named ’attention value’ in this block; fixed_scale: the real-value spacing represented by one quantized integer step. Context: the function _attention, which handles attention.

Line 645: `merged = attention_q10.transpose(0, 1, 2, 4, 3).reshape(` This statement continues through source line 646; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘attention_q10.transpose(0, 1, 2, 4, 3).reshape(timesteps, batch, channels, tokens)‘ to ‘merged ‘ in host memory. Here merged means the value named ’merged’ in this block. The important operands are attention_q10: the value named ’attention q10’ in this block; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _attention, which handles attention.

Line 646: `timesteps, batch, channels, tokens)` This is continuation line 2 of the 2-line logical statement that begins at source line 645. Its exact fragment is ‘timesteps, batch, channels, tokens)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This assigns ‘attention_q10.transpose(0, 1, 2, 4, 3).reshape(timesteps, batch, channels, tokens)‘ to ‘merged ‘ in host memory. Here merged means the value named ’merged’ in this block. The important operands are attention_q10: the value named ’attention q10’ in this block; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _attention, which handles attention.

Line 647: `attention_spikes = self._lif(merged, threshold=0.5)` This assigns ‘self._lif(merged, threshold=0.5)‘ to ‘attention_spikes ‘ in host memory. Here attention_spikes means a binary event produced when a neuron crosses its threshold. The important operands are _lif: the value named ’lif’ in this block; merged: the value named ’merged’ in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function _attention, which handles attention.

Line 648: `output_rows = attention_spikes.transpose(0, 1, 3, 2).reshape(` This statement continues through source line 649; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘attention_spikes.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are attention_spikes: a binary event produced when a neuron crosses its threshold; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _attention, which handles attention.

Line 649: `timesteps * batch * tokens, channels)` This is continuation line 2 of the 2-line logical statement that begins at source line 648. Its exact fragment is ‘timesteps * batch * tokens, channels)‘. The important operands are timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block; tokens: the value named ’tokens’ in this block. Read together, the complete operation is: This assigns ‘attention_spikes.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)‘ to ‘output_rows ‘ in host memory. Here output_rows means one output-row position processed by the tensor tile. The important operands are attention_spikes: a binary event produced when a neuron crosses its threshold; transpose: the value named ’transpose’ in this block; reshape: the value named ’reshape’ in this block. Context: the function _attention, which handles attention.

Line 650: `output = self.projections.matrix(` This statement continues through source line 652; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self.projections.matrix(f"{prefix}.proj", output_rows, timeout_seconds=self.layer_timeout_seconds)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _attention, which handles attention.

Line 651: `f"{prefix}.proj", output_rows,` This is continuation line 2 of the 3-line logical statement that begins at source line 650. Its exact fragment is ‘f"{prefix}.proj", output_rows,‘. The important operands are f: the value named ’f’ in this block; prefix: the value named ’prefix’ in this block; proj: the value named ’proj’ in this block. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"{prefix}.proj", output_rows, timeout_seconds=self.layer_timeout_seconds)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _attention, which handles attention.

Line 652: `timeout_seconds=self.layer_timeout_seconds)` This is continuation line 3 of the 3-line logical statement that begins at source line 650. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds)‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘self.projections.matrix(f"{prefix}.proj", output_rows, timeout_seconds=self.layer_timeout_seconds)‘ to ‘output ‘ in host memory. Here output means the value named ’output’ in this block. The important operands are projections: the value named ’projections’ in this block; matrix: the value named ’matrix’ in this block; f: the value named ’f’ in this block. Context: the function _attention, which handles attention.

Line 653: `return output.reshape(timesteps, batch, tokens, channels).transpose(` This statement continues through source line 654; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘output.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(timesteps, batch, channels, height, width)‘ to the caller of the function _attention, which handles attention, ending this invocation. The important operands are output: the value named ’output’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant.

Line 654: `0, 1, 3, 2).reshape(timesteps, batch, channels, height, width)` This is continuation line 2 of the 2-line logical statement that begins at source line 653. Its exact fragment is ‘0, 1, 3, 2).reshape(timesteps, batch, channels, height, width)‘. The important operands are reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant; batch: the value named ’batch’ in this block. Read together, the complete operation is: This returns ‘output.reshape(timesteps, batch, tokens, channels).transpose(0, 1, 3, 2).reshape(timesteps, batch, channels, height, width)‘ to the caller of the function _attention, which handles attention, ending this invocation. The important operands are output: the value named ’output’ in this block; reshape: the value named ’reshape’ in this block; timesteps: one discrete SNN update instant.

Line 656: `def _mlp(self, block_index: int, value: np.ndarray) -> np.ndarray:` This starts function _mlp. Its indented body performs mlp as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 657: `timesteps, batch, channels, height, width = value.shape` This assigns ‘value.shape‘ to ‘timesteps, batch, channels, height, width ‘ in host memory. Here timesteps means one discrete SNN update instant. The important operands are value: the value named ’value’ in this block; shape: the value named ’shape’ in this block. Context: the function _mlp, which handles mlp.

Line 658: `tokens = height * width` This assigns ‘height * width‘ to ‘tokens ‘ in host memory. Here tokens means the value named ’tokens’ in this block. The important operands are height: the value named ’height’ in this block; width: the value named ’width’ in this block. Context: the function _mlp, which handles mlp.

Line 659: `first_spikes = self._lif(value)` This assigns ‘self._lif(value)‘ to ‘first_spikes ‘ in host memory. Here first_spikes means a binary event produced when a neuron crosses its threshold. The important operands are _lif: the

value named 'lif' in this block; value: the value named 'value' in this block. Context: the function _mlp, which handles mlp.

Line 660: `first_rows = first_spikes.reshape(` This statement continues through source line 662; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'first_spikes.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)' to 'first_rows ' in host memory. Here first_rows means one output-row position processed by the tensor tile. The important operands are first_spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _mlp, which handles mlp.

Line 661: `timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(` This is continuation line 2 of the 3-line logical statement that begins at source line 660. Its exact fragment is 'timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape('. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; channels: the value named 'channels' in this block. Read together, the complete operation is: This assigns 'first_spikes.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)' to 'first_rows ' in host memory. Here first_rows means one output-row position processed by the tensor tile. The important operands are first_spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _mlp, which handles mlp.

Line 662: `timesteps * batch * tokens, channels)` This is continuation line 3 of the 3-line logical statement that begins at source line 660. Its exact fragment is 'timesteps * batch * tokens, channels)'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; tokens: the value named 'tokens' in this block. Read together, the complete operation is: This assigns 'first_spikes.reshape(timesteps, batch, channels, tokens).transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, channels)' to 'first_rows ' in host memory. Here first_rows means one output-row position processed by the tensor tile. The important operands are first_spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _mlp, which handles mlp.

Line 663: `hidden = self.projections.matrix(` This statement continues through source line 665; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self.projections.matrix(f"block.{block_index}.mlp.fc1", first_rows, timeout_seconds=self.layer_timeout_seconds)' to 'hidden ' in host memory. Here hidden means the value named 'hidden' in this block. The important operands are projections: the value named 'projections' in this block; matrix: the value named 'matrix' in this block; f: the value named 'f' in this block. Context: the function _mlp, which handles mlp.

Line 664: `f"block.{block_index}.mlp.fc1", first_rows,` This is continuation line 2 of the 3-line logical statement that begins at source line 663. Its exact fragment is 'f"block.{block_index}.mlp.fc1", first_rows,'. The important operands are f: the value named 'f' in this block; block: the value named 'block' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This assigns 'self.projections.matrix(f"block.{block_index}.mlp.fc1", first_rows, timeout_seconds=self.layer_timeout_seconds)' to 'hidden ' in host memory. Here hidden means the value named 'hidden' in this block. The important operands are projections: the value named 'projections' in this block; matrix: the value named 'matrix' in this block; f: the value named 'f' in this block. Context: the function _mlp, which handles mlp.

Line 665: `timeout_seconds=self.layer_timeout_seconds)` This is continuation line 3 of the 3-line logical statement that begins at source line 663. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds)'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'self.projections.matrix(f"block.{block_index}.mlp.fc1", first_rows, timeout_seconds=self.layer_timeout_seconds)' to 'hidden ' in host memory. Here hidden means the value named 'hidden' in this block. The important operands are projections: the value named 'projections' in this block; matrix: the value named 'matrix' in this block; f: the value named 'f' in this block. Context: the function _mlp, which handles mlp.

Line 666: `hidden_channels = hidden.shape[1]` This assigns 'hidden.shape[1]' to 'hidden_channels ' in host memory. Here hidden_channels means the value named 'hidden channels' in this block. The important operands are hidden:

the value named 'hidden' in this block; shape: the value named 'shape' in this block. Context: the function _mlp, which handles mlp.

Line 667: `hidden = hidden.reshape(timesteps, batch, tokens, hidden_channels).transpose(0, 1, 3, 2)` This assigns 'hidden.reshape(timesteps, batch, tokens, hidden_channels).transpose(0, 1, 3, 2)' to 'hidden ' in host memory. Here hidden means the value named 'hidden' in this block. The important operands are hidden: the value named 'hidden' in this block; reshape: the value named 'reshape' in this block; timesteps: one discrete SNN update instant. Context: the function _mlp, which handles mlp.

Line 668: `hidden_spikes = self._lif(hidden)` This assigns 'self._lif(hidden)' to 'hidden_spikes ' in host memory. Here hidden_spikes means a binary event produced when a neuron crosses its threshold. The important operands are _lif: the value named 'lif' in this block; hidden: the value named 'hidden' in this block. Context: the function _mlp, which handles mlp.

Line 669: `second_rows = hidden_spikes.transpose(0, 1, 3, 2).reshape(` This statement continues through source line 670; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'hidden_spikes.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, hidden_channels)' to 'second_rows ' in host memory. Here second_rows means one output-row position processed by the tensor tile. The important operands are hidden_spikes: a binary event produced when a neuron crosses its threshold; transpose: the value named 'transpose' in this block; reshape: the value named 'reshape' in this block. Context: the function _mlp, which handles mlp.

Line 670: `timesteps * batch * tokens, hidden_channels)` This is continuation line 2 of the 2-line logical statement that begins at source line 669. Its exact fragment is 'timesteps * batch * tokens, hidden_channels)'. The important operands are timesteps: one discrete SNN update instant; batch: the value named 'batch' in this block; tokens: the value named 'tokens' in this block. Read together, the complete operation is: This assigns 'hidden_spikes.transpose(0, 1, 3, 2).reshape(timesteps * batch * tokens, hidden_channels)' to 'second_rows ' in host memory. Line 677: `def _tokenizer(self, image_u8: np.ndarray) -> np.ndarray:` This starts function _tokenizer. Its indented body performs tokenizer as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 678: `batch = image_u8.shape[0]` This assigns ‘image_u8.shape[0]‘ to ‘batch ‘ in host memory. Here batch means the value named ’batch’ in this block. The important operands are image_u8: the value named ’image u8’ in this block; shape: the value named ’shape’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 679: `first = self.projections.conv2d(` This statement continues through source line 685; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeou)‘ to ‘first ‘ in host memory. Here first means the value named ’first’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; patch_embed: the value named ’patch embed’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 680: `"patch_embed.block0",` This is continuation line 2 of the 7-line logical statement that begins at source line 679. Its exact fragment is ‘"patch_embed.block0",‘. The important operands are patch_embed: the value named ’patch embed’ in this block; block0: the value named ’block0’ in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘first ‘ in host memory. Here first means the value named ’first’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; patch_embed: the value named ’patch embed’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 681: `image_u8,` This is continuation line 3 of the 7-line logical statement that begins at source line 679. Its exact fragment is ‘image_u8,‘. The important operands are image_u8: the value named ’image u8’ in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘first ‘ in host memory. Here first means the value named ’first’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; patch_embed: the value named ’patch embed’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 682: `activation_zero_point=self.image_zero_point,` This is continuation line 4 of the 7-line logical statement that begins at source line 679. Its exact fragment is ‘activation_zero_point=self.image_zero_point,‘. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation; image_zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This assigns ‘self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘first ‘ in host memory. Here first means the value named ’first’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the

value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 683: `padding=1,` This is continuation line 5 of the 7-line logical statement that begins at source line 679. Its exact fragment is 'padding=1,'. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'first ' in host memory. Here first means the value named 'first' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 684: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 6 of the 7-line logical statement that begins at source line 679. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeou)' to 'first ' in host memory. Here first means the value named 'first' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 685: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 679. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self.projections.conv2d("patch_embed.block0", image_u8, activation_zero_point=self.image_zero_point, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'first ' in host memory. Here first means the value named 'first' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; patch_embed: the value named 'patch embed' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 686: `value = np.repeat(first[np.newaxis], 4, axis=0)` This assigns 'np.repeat(first[np.newaxis], 4, axis=0)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are repeat: the value named 'repeat' in this block; first: the value named 'first' in this block; newaxis: the value named 'newaxis' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 687: `for index in (1, 2):` This iterates index over '(1, 2)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _tokenizer, which handles tokenizer.

Line 688: `spikes = self._lif(value)` This assigns 'self._lif(value)' to 'spikes ' in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are _lif: the value named 'lif' in this block; value: the value named 'value' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 689: `flat = spikes.reshape(-1, *spikes.shape[2:])` This assigns 'spikes.reshape(-1, *spikes.shape[2:])' to 'flat ' in host memory. Here flat means the value named 'flat' in this block. The important operands are spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named 'reshape' in this block; shape: the value named 'shape' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 690: `projected = self.projections.conv2d(` This statement continues through source line 695; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self.projections.conv2d(f"patch_embed.block{index}", flat, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'projected ' in host memory. Here projected means the value named 'projected' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; f: the value named 'f' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 691: `f"patch_embed.block{index}",` This is continuation line 2 of the 6-line logical statement that begins at source line 690. Its exact fragment is 'f"patch_embed.block{index}",'. The important operands are f: the value named 'f' in this block; patch_embed: the value named 'patch embed' in this block; block: the value named 'block' in this

block. Read together, the complete operation is: This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", flat, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 692: `flat,` This is continuation line 3 of the 6-line logical statement that begins at source line 690. Its exact fragment is ‘flat,‘. The important operands are flat: the value named ’flat’ in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", flat, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 693: `padding=1,` This is continuation line 4 of the 6-line logical statement that begins at source line 690. Its exact fragment is ‘padding=1,‘. The important operands are padding: the value named ’padding’ in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", flat, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 694: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 690. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", flat, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 695: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 690. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", flat, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 696: `value = projected.reshape(4, batch, *projected.shape[1:])` This assigns ‘projected.reshape(4, batch, *projected.shape[1:])‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are projected: the value named ’projected’ in this block; reshape: the value named ’reshape’ in this block; batch: the value named ’batch’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 697: `for index in (3, 4):` This iterates index over ‘(3, 4)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _tokenizer, which handles tokenizer.

Line 698: `spikes = self._lif(value)` This assigns ‘self._lif(value)‘ to ‘spikes ‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The important operands are _lif: the value named ’lif’ in this block; value: the value named ’value’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 699: `flat = spikes.reshape(-1, *spikes.shape[2:])` This assigns ‘spikes.reshape(-1, *spikes.shape[2:])‘ to ‘flat ‘ in host memory. Here flat means the value named ’flat’ in this block. The important operands are spikes: a binary event produced when a neuron crosses its threshold; reshape: the value named ’reshape’ in this block; shape: the value named ’shape’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 700: `pooled = binary_max_pool2d_on_accelerator(` This statement continues through source line 704; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘binary_max_pool2d_on_accelerator self.driver, flat, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘pooled ‘ in host memory. Here pooled means the value named ’pooled’ in this block. The important operands are binary_max_pool2d_on_accelerator: the value named ’binary max pool2d on accelerator’ in this block; driver: the value named ’driver’ in this block; flat: the value named ’flat’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 701: `self.driver,` This is continuation line 2 of the 5-line logical statement that begins at source line 700. Its exact fragment is ‘self.driver,‘. The important operands are driver: the value named ’driver’ in this block. Read together, the complete operation is: This assigns ‘binary_max_pool2d_on_accelerator(self.driver, flat, timeout_seconds=self.layer_timeout_se)‘ to ‘pooled ‘ in host memory. Here pooled means the value named ’pooled’ in this block. The important operands are binary_max_pool2d_on_accelerator: the value named ’binary max pool2d on accelerator’ in this block; driver: the value named ’driver’ in this block; flat: the value named ’flat’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 702: `flat,` This is continuation line 3 of the 5-line logical statement that begins at source line 700. Its exact fragment is ‘flat,‘. The important operands are flat: the value named ’flat’ in this block. Read together, the complete operation is: This assigns ‘binary_max_pool2d_on_accelerator(self.driver, flat, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘pooled ‘ in host memory. Here pooled means the value named ’pooled’ in this block. The important operands are binary_max_pool2d_on_accelerator: the value named ’binary max pool2d on accelerator’ in this block; driver: the value named ’driver’ in this block; flat: the value named ’flat’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 703: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 4 of the 5-line logical statement that begins at source line 700. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds,‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This assigns ‘binary_max_pool2d_on_accelerator(self.driver, flat, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘pooled ‘ in host memory. Here pooled means the value named ’pooled’ in this block. The important operands are binary_max_pool2d_on_accelerat the value named ’binary max pool2d on accelerator’ in this block; driver: the value named ’driver’ in this block; flat: the value named ’flat’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 704: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 700. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘binary_max_pool2d_on_accelerator(self.driver, flat, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘pooled ‘ in host memory. Here pooled means the value named ’pooled’ in this block. The important operands are binary_max_pool2d_on_accelerator: the value named ’binary max pool2d on accelerator’ in this block; driver: the value named ’driver’ in this block; flat: the value named ’flat’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 705: `projected = self.projections.conv2d(` This statement continues through source line 710; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", pooled, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 706: `f"patch_embed.block{index}",` This is continuation line 2 of the 6-line logical statement that begins at source line 705. Its exact fragment is ‘f"patch_embed.block{index}",‘. The important operands are f: the value named ’f’ in this block; patch_embed: the value named ’patch embed’ in this block; block: the value named ’block’ in this block. Read together, the complete operation is: This assigns ‘self.projections.conv2d(f"patch_embed.block{index}", pooled, padding=1, timeout_seconds=self.layer_timeout_seconds,)‘ to ‘projected ‘ in host memory. Here projected means the value named ’projected’ in this block. The important operands are projections: the value named ’projections’ in this block; conv2d: the value named ’conv2d’ in this block; f: the value named ’f’ in this block. Context: the function _tokenizer, which handles tokenizer.

Line 707: `pooled,` This is continuation line 3 of the 6-line logical statement that begins at source line 705. Its exact fragment is 'pooled,'. The important operands are pooled: the value named 'pooled' in this block. Read together, the complete operation is: This assigns 'self.projections.conv2d(f"patch_embed.block{index}", pooled, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'projected ' in host memory. Here projected means the value named 'projected' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; f: the value named 'f' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 708: `padding=1,` This is continuation line 4 of the 6-line logical statement that begins at source line 705. Its exact fragment is 'padding=1,'. The important operands are padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'self.projections.conv2d(f"patch_embed.block{index}", pooled, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'projected ' in host memory. Here projected means the value named 'projected' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; f: the value named 'f' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 709: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 5 of the 6-line logical statement that begins at source line 705. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'self.projections.conv2d(f"patch_embed.block{index}", pooled, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'projected ' in host memory. Here projected means the value named 'projected' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; f: the value named 'f' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 710: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 705. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'self.projections.conv2d(f"patch_embed.block{index}", pooled, padding=1, timeout_seconds=self.layer_timeout_seconds,)' to 'projected ' in host memory. Here projected means the value named 'projected' in this block. The important operands are projections: the value named 'projections' in this block; conv2d: the value named 'conv2d' in this block; f: the value named 'f' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 711: `value = projected.reshape(4, batch, *projected.shape[1:])` This assigns 'projected.reshape(4, batch, *projected.shape[1:])' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are projected: the value named 'projected' in this block; reshape: the value named 'reshape' in this block; batch: the value named 'batch' in this block. Context: the function _tokenizer, which handles tokenizer.

Line 712: `return value` This returns 'value' to the caller of the function _tokenizer, which handles tokenizer, ending this invocation. The important operands are value: the value named 'value' in this block.

Line 714: `def infer(self, normalized_image: np.ndarray) -> SpikingformerInferenceResult:` This starts function infer. Its indented body performs infer as part of the file that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations; it runs only when called.

Line 715: `"""Run normalized CIFAR-10 NCHW images through the complete trained graph."""` This is executable documentation attached to the function infer, which handles infer. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 717: `image = np.asarray(normalized_image, dtype=np.float32)` This assigns 'np.asarray(normalized_image, dtype=np.float32)' to 'image ' in host memory. Here image means the value named 'image' in this block. The important operands are asarray: the value named 'asarray' in this block; normalized_image: the value named 'normalized image' in this block; dtype: the value named 'dtype' in this block. Context: the function infer, which handles infer.

Line 718: `if image.ndim != 4 or image.shape[1:] != (3, 32, 32) or image.shape[0] == 0:` This executes the following indented host-code branch only when ‘image.ndim != 4 or image.shape[1:] != (3, 32, 32) or image.shape[0] == 0‘ is true. The important operands are image: the value named ’image’ in this block; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function infer, which handles infer.

Line 719: `raise ValueError("input must have shape [batch,3,32,32]")` This rejects an invalid state by raising ‘ValueError("input must have shape [batch,3,32,32]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 720: `image_u8 = np.rint(image / self.image_scale + self.image_zero_point)` This assigns ‘np.rint(image / self.image_scale + self.image_zero_point)‘ to ‘image_u8 ‘ in host memory. Here image_u8 means the value named ’image u8’ in this block. The important operands are rint: the value named ’rint’ in this block; image: the value named ’image’ in this block; image_scale: the real-value spacing represented by one quantized integer step. Context: the function infer, which handles infer.

Line 721: `image_u8 = np.clip(image_u8, 0, 255).astype(np.uint8)` This assigns ‘np.clip(image_u8, 0, 255).astype(np.uint to ‘image_u8 ‘ in host memory. Here image_u8 means the value named ’image u8’ in this block. The important operands are clip: the value named ’clip’ in this block; image_u8: the value named ’image u8’ in this block; astype: the value named ’astype’ in this block. Context: the function infer, which handles infer.

Line 722: `self.driver.execute_program((ProgramRecord(clear_status_command()),),` This statement continues through source line 723; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘self.driver.execute_program‘ with ‘(ProgramRecord(clear_status_command()),), timeout_seconds=self.layer_timeout_secon inside the function infer, which handles infer. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 723: `timeout_seconds=self.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 722. Its exact fragment is ‘timeout_seconds=self.layer_timeout_seconds)‘. The important operands are timeout_seconds: the value named ’timeout seconds’ in this block; layer_timeout_seconds: the value named ’layer timeout seconds’ in this block. Read together, the complete operation is: This calls ‘self.driver.execute_program‘ with ‘(ProgramRecord(clear_status_command()),), timeout_seconds=self.layer_timeout_seconds‘ inside the function infer, which handles infer. The call advances the host-side job that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations.

Line 724: `value = self._tokenizer(image_u8)` This assigns ‘self._tokenizer(image_u8)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are _tokenizer: the value named ’tokenizer’ in this block; image_u8: the value named ’image u8’ in this block. Context: the function infer, which handles infer.

Line 725: `for block_index in range(4):` This iterates block_index over ‘range(4)‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function infer, which handles infer.

Line 726: `attention = self._attention(block_index, value)` This assigns ‘self._attention(block_index, value)‘ to ‘attention ‘ in host memory. Here attention means the value named ’attention’ in this block. The important operands are _attention: the value named ’attention’ in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; value: the value named ’value’ in this block. Context: the function infer, which handles infer.

Line 727: `value = vector_binary_on_accelerator(` This statement continues through source line 729; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘vector_binary_on_accelerator(self.driver, VectorOperation.ADD_SAT, value, attention, timeout_seconds=self.layer_timeout_seconds)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are vector_binary_on_accelerator: the value named ’vector binary on accelerator’ in this block; driver: the value named ’driver’ in this block; VectorOperation: the value named ’vector operation’ in this block. Context: the function infer, which handles infer.

Line 728: `self.driver, VectorOperation.ADD_SAT, value, attention,` This is continuation line 2 of the 3-line logical statement that begins at source line 727. Its exact fragment is 'self.driver, VectorOperation.ADD_SAT, value, attention,'. The important operands are driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block; ADD_SAT: the value named 'add sat' in this block. Read together, the complete operation is: This assigns 'vector_binary_on_accelerator(self.driver, VectorOperation.ADD_SAT, value, attention, timeout_seconds=self.layer_timeout_seconds)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are vector_binary_on_accelerator: the value named 'vector binary on accelerator' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function infer, which handles infer.

Line 729: `timeout_seconds=self.layer_timeout_seconds)` This is continuation line 3 of the 3-line logical statement that begins at source line 727. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds)'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'vector_binary_on_accelerator(self.driver, VectorOperation.ADD_SAT, value, attention, timeout_seconds=self.layer_timeout_secon to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are vector_binary_on_accelerator: the value named 'vector binary on accelerator' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function infer, which handles infer.

Line 730: `mlp = self._mlp(block_index, value)` This assigns 'self._mlp(block_index, value)' to 'mlp ' in host memory. Here mlp means the value named 'mlp' in this block. The important operands are _mlp: the value named 'mlp' in this block; block_index: an integer selecting one tensor element, lane, bank, or state entry; value: the value named 'value' in this block. Context: the function infer, which handles infer.

Line 731: `value = vector_binary_on_accelerator(` This statement continues through source line 733; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'vector_binary_on_accelerator(self.driver, VectorOperation.ADD_SAT, value, mlp, timeout_seconds=self.layer_timeout_seconds)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are vector_binary_on_accelerator: the value named 'vector binary on accelerator' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function infer, which handles infer.

Line 732: `self.driver, VectorOperation.ADD_SAT, value, mlp,` This is continuation line 2 of the 3-line logical statement that begins at source line 731. Its exact fragment is 'self.driver, VectorOperation.ADD_SAT, value, mlp,'. The important operands are driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block; ADD_SAT: the value named 'add sat' in this block. Read together, the complete operation is: This assigns 'vector_binary_on_accelerator(self.driver, VectorOperation.ADD_SAT, value, mlp, timeout_seconds=self.layer_timeout_seconds)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are vector_binary_on_accelerator: the value named 'vector binary on accelerator' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function infer, which handles infer.

Line 733: `timeout_seconds=self.layer_timeout_seconds)` This is continuation line 3 of the 3-line logical statement that begins at source line 731. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds)'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'vector_binary_on_accelerator(self.driver, VectorOperation.ADD_SAT, value, mlp, timeout_seconds=self.layer_timeout_seconds)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are vector_binary_on_accelerator: the value named 'vector binary on accelerator' in this block; driver: the value named 'driver' in this block; VectorOperation: the value named 'vector operation' in this block. Context: the function infer, which handles infer.

Line 735: `pooled_sum = global_spatiotemporal_sum_on_accelerator(` This statement continues through source line 739; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'global_spatiotemporal_ self.driver, value, timeout_seconds=self.layer_timeout_seconds,)' to 'pooled_sum ' in host memory. Here pooled_sum means the value named 'pooled sum' in this block. The important operands are global_spatiotemporal_sum_on_accelerator:

the value named 'global spatiotemporal sum on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block. Context: the function infer, which handles infer.

Line 736: `self.driver,` This is continuation line 2 of the 5-line logical statement that begins at source line 735. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'global_spatiotemporal_sum_on_accelerator(self.driver, value, timeout_seconds=self.layer_timeout_seconds,)' to 'pooled_sum ' in host memory. Here pooled_sum means the value named 'pooled sum' in this block. The important operands are global_spatiotemporal_sum_on_accelerator: the value named 'global spatiotemporal sum on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block. Context: the function infer, which handles infer.

Line 737: `value,` This is continuation line 3 of the 5-line logical statement that begins at source line 735. Its exact fragment is 'value,'. The important operands are value: the value named 'value' in this block. Read together, the complete operation is: This assigns 'global_spatiotemporal_sum_on_accelerator(self.driver, value, timeout_seconds=self.layer_timeout_seco)' to 'pooled_sum ' in host memory. Here pooled_sum means the value named 'pooled sum' in this block. The important operands are global_spatiotemporal_sum_on_accelerator: the value named 'global spatiotemporal sum on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block. Context: the function infer, which handles infer.

Line 738: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 4 of the 5-line logical statement that begins at source line 735. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'global_spatiotemporal_sum_on_accele self.driver, value, timeout_seconds=self.layer_timeout_seconds,)' to 'pooled_sum ' in host memory. Here pooled_sum means the value named 'pooled sum' in this block. The important operands are global_spatiotemporal_sum_on_accelerator: the value named 'global spatiotemporal sum on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block. Context: the function infer, which handles infer.

Line 739: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 735. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'global_spatiotemporal_sum_on_accelerator(self.driver, value, timeout_seconds=self.layer_timeout_seconds,)' to 'pooled_sum ' in host memory. Here pooled_sum means the value named 'pooled sum' in this block. The important operands are global_spatiotemporal_sum_on_accelerator: the value named 'global spatiotemporal sum on accelerator' in this block; driver: the value named 'driver' in this block; value: the value named 'value' in this block. Context: the function infer, which handles infer.

Line 740: `divisor = value.shape[0] * value.shape[3] * value.shape[4]` This assigns 'value.shape[0] * value.shape[3] * value.shape[4]' to 'divisor ' in host memory. Here divisor means the value named 'divisor' in this block. The important operands are value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function infer, which handles infer.

Line 741: `denominator = divisor * self.fixed_scale * self.head_activation_scale` This assigns 'divisor * self.fixed_scale * self.head_activation_scale' to 'denominator ' in host memory. Here denominator means the value named 'denominator' in this block. The important operands are divisor: the value named 'divisor' in this block; fixed_scale: the real-value spacing represented by one quantized integer step; head_activation_scale: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function infer, which handles infer.

Line 742: `integer_denominator = int(round(denominator))` This assigns 'int(round(denominator))' to 'integer_denominator ' in host memory. Here integer_denominator means the value named 'integer denominator' in this block. The important operands are round: the value named 'round' in this block; denominator: the value named 'denominator' in this block. Context: the function infer, which handles infer.

Line 743: `if (not math.isclose(denominator, integer_denominator, rel_tol=0.0, abs_tol=1e-9)` Inside the function infer, which handles infer, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are not: the

value named 'not' in this block; math: the value named 'math' in this block; isclose: the value named 'isclose' in this block.

Line 744: `or integer_denominator <= 0` Inside the function infer, which handles infer, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are or: the value named 'or' in this block; integer_denominator: the value named 'integer denominator' in this block.

Line 745: `or integer_denominator & (integer_denominator - 1)):` Inside the function infer, which handles infer, this statement advances the host implementation that maps all tokenizer, spiking attention, MLP, residual, reduction, and classifier stages to hardware operations. The important operands are or: the value named 'or' in this block; integer_denominator: the value named 'integer denominator' in this block.

Line 746: `raise ValueError("head pooling denominator must be an exact positive power of two")` This rejects an invalid state by raising 'ValueError("head pooling denominator must be an exact positive power of two")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 747: `head_integer = power_of_two_requantize_on_accelerator(` This statement continues through source line 754; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'power_of_two_requan self.driver, pooled_sum, division_shift=integer_denominator.bit_length() - 1, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_timeout_seconds,).astype(np.int16)' to 'head_integer ' in host memory. Here head_integer means the value named 'head integer' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; pooled_sum: the value named 'pooled sum' in this block. Context: the function infer, which handles infer.

Line 748: `self.driver,` This is continuation line 2 of the 8-line logical statement that begins at source line 747. Its exact fragment is 'self.driver,'. The important operands are driver: the value named 'driver' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(self.driver, pooled_sum, division_shift=integer_denominator.bit_length() - 1, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_tim).astype(np.int16)' to 'head_integer ' in host memory. Here head_integer means the value named 'head integer' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; pooled_sum: the value named 'pooled sum' in this block. Context: the function infer, which handles infer.

Line 749: `pooled_sum,` This is continuation line 3 of the 8-line logical statement that begins at source line 747. Its exact fragment is 'pooled_sum,'. The important operands are pooled_sum: the value named 'pooled sum' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(self.driver, pooled_sum, division_shift=integer_denominator.bit_length() - 1, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_).astype(np.int16)' to 'head_integer ' in host memory. Here head_integer means the value named 'head integer' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; pooled_sum: the value named 'pooled sum' in this block. Context: the function infer, which handles infer.

Line 750: `division_shift=integer_denominator.bit_length() - 1,` This is continuation line 4 of the 8-line logical statement that begins at source line 747. Its exact fragment is 'division_shift=integer_denominator.bit_length() - 1,'. The important operands are division_shift: the value named 'division shift' in this block; integer_denominator: the value named 'integer denominator' in this block; bit_length: the value named 'bit length' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(self.driver, pooled_sum, division_shift=integer_denominator.bit_length() - 1, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_tim).astype(np.int16)' to 'head_integer ' in host memory. Here head_integer means the value named 'head integer' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; pooled_sum: the value named 'pooled sum' in this block. Context: the function infer, which handles infer.

Line 751: `clamp_minimum=-128,` This is continuation line 5 of the 8-line logical statement that begins at source line 747. Its exact fragment is 'clamp_minimum=-128,'. The important operands are clamp_minimum: the value named 'clamp minimum' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(self.driver, pooled_sum, division_shift=integer_denominator.bit_length() - 1, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_timeout_seconds,).astype(np.int16)' to 'head_integer ' in host memory. Here head_integer means the value named 'head integer' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; pooled_sum: the value named 'pooled sum' in this block. Context: the function infer, which handles infer.

Line 752: `clamp_maximum=127,` This is continuation line 6 of the 8-line logical statement that begins at source line 747. Its exact fragment is 'clamp_maximum=127,'. The important operands are clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(self.driver, pooled_sum, division_shift=integer_denominator.bit_length() - 1, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_timeout_seconds,).astype(np.int16)' to 'head_integer ' in host memory. Here head_integer means the value named 'head integer' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; pooled_sum: the value named 'pooled sum' in this block. Context: the function infer, which handles infer.

Line 753: `timeout_seconds=self.layer_timeout_seconds,` This is continuation line 7 of the 8-line logical statement that begins at source line 747. Its exact fragment is 'timeout_seconds=self.layer_timeout_seconds,'. The important operands are timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelera self.driver, pooled_sum, division_shift=integer_denominator.bit_length() - 1, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_timeout_seconds,).astype(np.int16)' to 'head_integer ' in host memory. Here head_integer means the value named 'head integer' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; pooled_sum: the value named 'pooled sum' in this block. Context: the function infer, which handles infer.

Line 754: `).astype(np.int16)` This is continuation line 8 of the 8-line logical statement that begins at source line 747. Its exact fragment is ').astype(np.int16)'. The important operands are astype: the value named 'astype' in this block; int16: the value named 'int16' in this block. Read together, the complete operation is: This assigns 'power_of_two_requantize_on_accelerator(self.driver, pooled_sum, division_shift=integer_denominator.bit_length() - 1, clamp_minimum=-128, clamp_maximum=127, timeout_seconds=self.layer_timeout_seconds,).astype(np.int16)' to 'head_integer ' in host memory. Here head_integer means the value named 'head integer' in this block. The important operands are power_of_two_requantize_on_accelerator: the conversion of a wide accumulated result back into a bounded activation code; driver: the value named 'driver' in this block; pooled_sum: the value named 'pooled sum' in this block. Context: the function infer, which handles infer.

Line 755: `head = self.archive.head` This assigns 'self.archive.head' to 'head ' in host memory. Here head means the value named 'head' in this block. The important operands are archive: the value named 'archive' in this block; head: the value named 'head' in this block. Context: the function infer, which handles infer.

Line 756: `head_program = compile_u8_gemm(` This statement continues through source line 762; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'compile_u8_gemm((head_integer + 128).astype(np.uint8), self.projections._encoded_dense_weights(head.weight_k_by_n), activation_zero_point=128, weight_zero_point=128, bias=head.bias_accumulator_units,)' to 'head_program ' in host memory. Here head_program means the value named 'head program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; head_integer: the value named 'head integer' in this block; astype: the value named 'astype' in this block. Context: the function infer, which handles infer.

Line 757: `(head_integer + 128).astype(np.uint8),` This is continuation line 2 of the 7-line logical statement that begins at source line 756. Its exact fragment is '(head_integer + 128).astype(np.uint8),'. The important operands are head_integer: the value named 'head integer' in this block; astype: the value named 'astype' in this block; uint8: the value named 'uint8' in this block. Read together, the complete operation is: This assigns 'compile_u8_gemm((head_integer + 128).astype(np.uint8), self.projections._encoded_dense_weights(head.weight_k_by_n), activation_zero_point=128, weight_zero_point=128, bias=head.bias_accumulator_units,)' to 'head_program ' in host memory. Here head_program

means the value named 'head program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; head_integer: the value named 'head integer' in this block; astype: the value named 'astype' in this block. Context: the function infer, which handles infer.

Line 758: `self.projections._encoded_dense_weights(head.weight_k_by_n),` This is continuation line 3 of the 7-line logical statement that begins at source line 756. Its exact fragment is 'self.projections._encoded_dense_weights(head.weight_k_ The important operands are projections: the value named 'projections' in this block; _encoded_dense_weights: a learned coefficient multiplied by an activation; head: the value named 'head' in this block. Read together, the complete operation is: This assigns 'compile_u8_gemm((head_integer + 128).astype(np.uint8), self.projections._encoded_dense_weights(head.weight activation_zero_point=128, weight_zero_point=128, bias=head.bias_accumulator_units,)' to 'head_program ' in host memory. Here head_program means the value named 'head program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; head_integer: the value named 'head integer' in this block; astype: the value named 'astype' in this block. Context: the function infer, which handles infer.

Line 759: `activation_zero_point=128,` This is continuation line 4 of the 7-line logical statement that begins at source line 756. Its exact fragment is 'activation_zero_point=128,'. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns 'compile_u8_gemm((head_integer + 128).astype(np.uint8), self.projections._encoded_dense_weights(head.weight_k_by_ activation_zero_point=128, weight_zero_point=128, bias=head.bias_accumulator_units,)' to 'head_program ' in host memory. Here head_program means the value named 'head program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; head_integer: the value named 'head integer' in this block; astype: the value named 'astype' in this block. Context: the function infer, which handles infer.

Line 760: `weight_zero_point=128,` This is continuation line 5 of the 7-line logical statement that begins at source line 756. Its exact fragment is 'weight_zero_point=128,'. The important operands are weight_zero_point: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns 'compile_u8_gemm((head_integer + 128).astype(np.uint8), self.projections._encoded_dense_weights(head.weight_k_by_n), activation_zero_point= weight_zero_point=128, bias=head.bias_accumulator_units,)' to 'head_program ' in host memory. Here head_program means the value named 'head program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; head_integer: the value named 'head integer' in this block; astype: the value named 'astype' in this block. Context: the function infer, which handles infer.

Line 761: `bias=head.bias_accumulator_units,` This is continuation line 6 of the 7-line logical statement that begins at source line 756. Its exact fragment is 'bias=head.bias_accumulator_units,'. The important operands are bias: an additive learned offset applied after accumulation; head: the value named 'head' in this block; bias_accumulator_units: an additive learned offset applied after accumulation. Read together, the complete operation is: This assigns 'compile_u8_gemm((head_integer + 128).astype(np.uint8), self.projections._encoded_dense_weights(head.weight_k_by_n), activation_zero_point=128, weight_zero_point=128, bias=head.bias_accumulator_units,)' to 'head_program ' in host memory. Here head_program means the value named 'head program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; head_integer: the value named 'head integer' in this block; astype: the value named 'astype' in this block. Context: the function infer, which handles infer.

Line 762: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 756. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'compile_u8_gemm((head_integer + 128).astype(np.uint8), self.projections._encoded_dense_weights(head.w activation_zero_point=128, weight_zero_point=128, bias=head.bias_accumulator_units,)' to 'head_program ' in host memory. Here head_program means the value named 'head program' in this block. The important operands are compile_u8_gemm: the value named 'compile u8 gemm' in this block; head_integer: the value named 'head integer' in this block; astype: the value named 'astype' in this block. Context: the function infer, which handles infer.

Line 763: `logits_accumulator = head_program.execute_batched(` This statement continues through source line 764; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'head_program.execute_ba self.driver, timeout_seconds=self.layer_timeout_seconds)' to 'logits_accumulator ' in host memory. Here logits_accumulator means a widened running sum that prevents intermediate overflow. The important operands are head_program: the value named 'head program' in this block; execute_batched: the value named 'execute batched' in this block; driver: the value named 'driver' in this block. Context: the function infer, which handles infer.

Line 764: `self.driver, timeout_seconds=self.layer_timeout_seconds)` This is continuation line 2 of the 2-line logical statement that begins at source line 763. Its exact fragment is 'self.driver, timeout_seconds=self.layer_timeout_seconds)'. The important operands are driver: the value named 'driver' in this block; timeout_seconds: the value named 'timeout seconds' in this block; layer_timeout_seconds: the value named 'layer timeout seconds' in this block. Read together, the complete operation is: This assigns 'head_program.execute_batched(self.driver, timeout_seconds=self.layer_timeout_seconds)' to 'logits_accumulator ' in host memory. Here logits_accumulator means a widened running sum that prevents intermediate overflow. The important operands are head_program: the value named 'head program' in this block; execute_batched: the value named 'execute batched' in this block; driver: the value named 'driver' in this block. Context: the function infer, which handles infer.

Line 765: `head_manifest = self.archive.manifest["head"]` This assigns 'self.archive.manifest["head"]' to 'head_manifest ' in host memory. Here head_manifest means the value named 'head manifest' in this block. The important operands are archive: the value named 'archive' in this block; manifest: the value named 'manifest' in this block; head: the value named 'head' in this block. Context: the function infer, which handles infer.

Line 766: `accumulator_scale = float(head_manifest["accumulator_scale"])` This assigns 'float(head_manifest["accumula to 'accumulator_scale ' in host memory. Here accumulator_scale means a widened running sum that prevents intermediate overflow. The important operands are float: the value named 'float' in this block; head_manifest: the value named 'head manifest' in this block; accumulator_scale: a widened running sum that prevents intermediate overflow. Context: the function infer, which handles infer.

Line 767: `logits = logits_accumulator.astype(np.float64) * accumulator_scale` This assigns 'logits_accumulator.astyp * accumulator_scale' to 'logits ' in host memory. Here logits means the ten unnormalized classifier scores used for argmax. The important operands are logits_accumulator: a widened running sum that prevents intermediate overflow; astype: the value named 'astype' in this block; float64: the value named 'float64' in this block. Context: the function infer, which handles infer.

Line 768: `return SpikingformerInferenceResult(` This statement continues through source line 772; the explanation uses the complete expression rather than only the first visual fragment. This returns 'SpikingformerInferenceResult(logits_accumulator=logits_accumulator, logits=logits, predicted_class=np.argmax(logits_accumulator, axis=1),)' to the caller of the function infer, which handles infer, ending this invocation. The important operands are SpikingformerInferenceResult: the value named 'spikingformer inference result' in this block; logits_accumulator: a widened running sum that prevents intermediate overflow; logits: the ten unnormalized classifier scores used for argmax.

Line 769: `logits_accumulator=logits_accumulator,` This is continuation line 2 of the 5-line logical statement that begins at source line 768. Its exact fragment is 'logits_accumulator=logits_accumulator,'. The important operands are logits_accumulator: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This returns 'SpikingformerInferenceResult(logits_accumulator=logits_accumulator, logits=logits, predicted_class=np.argmax(logits_accumulator, axis=1),)' to the caller of the function infer, which handles infer, ending this invocation. The important operands are SpikingformerInferenceResult: the value named 'spikingformer inference result' in this block; logits_accumulator: a widened running sum that prevents intermediate overflow; logits: the ten unnormalized classifier scores used for argmax.

Line 770: `logits=logits,` This is continuation line 3 of the 5-line logical statement that begins at source line 768. Its exact fragment is 'logits=logits,'. The important operands are logits: the ten unnormalized classifier scores used for argmax. Read together, the complete operation is: This returns 'SpikingformerInferenceResult(logits_accumulator=logits_accumul logits=logits, predicted_class=np.argmax(logits_accumulator, axis=1),)' to the caller of the function infer, which handles infer, ending this invocation. The important operands are SpikingformerInferenceResult: the value named 'spikingformer inference result' in this block; logits_accumulator: a widened running sum that prevents intermediate overflow; logits: the ten unnormalized classifier scores used for argmax.

Line 771: `predicted_class=np.argmax(logits_accumulator, axis=1),` This is continuation line 4 of the 5-line logical statement that begins at source line 768. Its exact fragment is 'predicted_class=np.argmax(logits_accumulator, axis=1),'. The important operands are predicted_class: the value named 'predicted class' in this block; argmax: the value named 'argmax' in this block; logits_accumulator: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This returns 'SpikingformerInferenceResult(logits_accumulator=logits_accumulator,

logits=logits, predicted_class=np.argmax(logits_accumulator, axis=1),)‘ to the caller of the function infer, which handles infer, ending this invocation. The important operands are SpikingformerInferenceResult: the value named 'spikingformer inference result' in this block; logits_accumulator: a widened running sum that prevents intermediate overflow; logits: the ten unnormalized classifier scores used for argmax.

Line 772:) This is continuation line 5 of the 5-line logical statement that begins at source line 768. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns ‘SpikingformerInferenceResult(logits_accumulator=logits_accumulator, logits=logits, predicted_class=np.argmax(logits_accumulator, axis=1),)‘ to the caller of the function infer, which handles infer, ending this invocation. The important operands are SpikingformerInferenceResult: the value named 'spikingformer inference result' in this block; logits_accumulator: a widened running sum that prevents intermediate overflow; logits: the ten unnormalized classifier scores used for argmax.

41 software/spikingformer_parameters.py

Role in the complete system: validates and exposes typed read-only views of the aligned parameter archive.

41.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to validates and exposes typed read-only views of the aligned parameter archive.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: ProjectionParameters, HeadParameters, SpikingformerParameterArchive. Functions: ___init___, _integer_field, _nonnegative_dimension, _verify_hash, _projection_objects, _section_names, section, projection_names, projection, head. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

41.3 Line annotations

Line 1: `"""Strict reader for the exported NeuraEdge Spikingformer parameter archive."""` This is executable documentation attached to the file whose role is to validates and exposes typed read-only views of the aligned parameter archive. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to validates and exposes typed read-only views of the aligned parameter archive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import hashlib` This imports the named Python API so the file whose role is to validates and exposes typed read-only views of the aligned parameter archive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `import json` This imports the named Python API so the file whose role is to validates and exposes typed read-only views of the aligned parameter archive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from dataclasses import dataclass` This imports the named Python API so the file whose role is to validates and exposes typed read-only views of the aligned parameter archive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 8: `from pathlib import Path` This imports the named Python API so the file whose role is to validates and exposes typed read-only views of the aligned parameter archive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `from typing import Any, Mapping` This imports the named Python API so the file whose role is to validates and exposes typed read-only views of the aligned parameter archive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 11: `import numpy as np` This imports the named Python API so the file whose role is to validates and exposes typed read-only views of the aligned parameter archive can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 14: `FORMAT = "neuraedge-spikingformer-parameters-v1"` This assigns ‘"neuraedge-spikingformer-parameters-v1"‘ to ‘FORMAT ‘ in host memory. Here FORMAT means the value named ’format’ in this block. The important operands are neuraedge: the value named ’neuraedge’ in this block; spikingformer: the value named ’spikingformer’ in this block; parameters: the value named ’parameters’ in this block. Context: the file whose role is to validates and exposes typed read-only views of the aligned parameter archive.

Line 17: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to validates and exposes typed read-only views of the aligned parameter archive; it creates no FPGA circuit by itself.

Line 18: `class ProjectionParameters:` This defines class ProjectionParameters, which groups data and methods for projection parameters. Instances exist in host memory and organize the flow that validates and exposes typed read-only views of the aligned parameter archive.

Line 19: `"""Integer tensors consumed by one folded Conv-BN hardware projection."""` This is executable documentation attached to the class ProjectionParameters, which handles projection parameters. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 21: `name: str` Inside the class ProjectionParameters, which handles projection parameters, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are name: the value named ’name’ in this block; str: the value named ’str’ in this block.

Line 22: `weight_k_by_n: np.ndarray` Inside the class ProjectionParameters, which handles projection parameters, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are weight_k_by_n: a learned coefficient multiplied by an activation; ndarray: the value named ’ndarray’ in this block.

Line 23: `bias_q10: np.ndarray` Inside the class ProjectionParameters, which handles projection parameters, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are bias_q10: an additive learned offset applied after accumulation; ndarray: the value named 'ndarray' in this block.

Line 24: `multiplier_q15: np.ndarray` Inside the class ProjectionParameters, which handles projection parameters, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are multiplier_q15: the value named 'multiplier q15' in this block; ndarray: the value named 'ndarray' in this block.

Line 25: `binary_point_shift: np.ndarray` Inside the class ProjectionParameters, which handles projection parameters, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are binary_point_shift: the value named 'binary point shift' in this block; ndarray: the value named 'ndarray' in this block.

Line 26: `compute_opcode: str` Inside the class ProjectionParameters, which handles projection parameters, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are compute_opcode: the value named 'compute opcode' in this block; str: the value named 'str' in this block.

Line 27: `source_weight_shape: tuple[int, ...]` Inside the class ProjectionParameters, which handles projection parameters, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are source_weight_shape: a learned coefficient multiplied by an activation; tuple: the value named 'tuple' in this block.

Line 28: `output_fractional_bits: int` Inside the class ProjectionParameters, which handles projection parameters, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are output_fractional_bits: the value named 'output fractional bits' in this block.

Line 31: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to validates and exposes typed read-only views of the aligned parameter archive; it creates no FPGA circuit by itself.

Line 32: `class HeadParameters:` This defines class HeadParameters, which groups data and methods for head parameters. Instances exist in host memory and organize the flow that validates and exposes typed read-only views of the aligned parameter archive.

Line 33: `"""Integer classifier matrix and bias in accumulator units."""` This is executable documentation attached to the class HeadParameters, which handles head parameters. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 35: `weight_k_by_n: np.ndarray` Inside the class HeadParameters, which handles head parameters, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are weight_k_by_n: a learned coefficient multiplied by an activation; ndarray: the value named 'ndarray' in this block.

Line 36: `bias_accumulator_units: np.ndarray` Inside the class HeadParameters, which handles head parameters, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are bias_accumulator_units: an additive learned offset applied after accumulation; ndarray: the value named 'ndarray' in this block.

Line 39: `class SpikingformerParameterArchive:` This defines class SpikingformerParameterArchive, which groups data and methods for spikingformer parameter archive. Instances exist in host memory and organize the flow that validates and exposes typed read-only views of the aligned parameter archive.

Line 40: `"""Validated, read-only view of one binary parameter package."""` This is executable documentation attached to the class SpikingformerParameterArchive, which handles spikingformer parameter archive. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 42: `def __init__(self, manifest_path: str | Path, *, verify_hashes: bool = True) -> None:` This starts function ___init___. Its indented body performs init as part of the file that validates and exposes typed read-only views of the aligned parameter archive; it runs only when called.

Line 43: `self.manifest_path = Path(manifest_path).expanduser().resolve()` This assigns ‘Path(manifest_path).expandu to ‘self.manifest_path ‘ in host memory. Here manifest_path means the value named ’manifest path’ in this block. The important operands are Path: the value named ’path’ in this block; manifest_path: the value named ’manifest path’ in this block; expanduser: the value named ’expanduser’ in this block. Context: the function ___init___, which handles init.

Line 44: `manifest_object = json.loads(self.manifest_path.read_text(encoding="ascii"))` This assigns ‘json.loads(self to ‘manifest_object ‘ in host memory. Here manifest_object means the value named ’manifest object’ in this block. The important operands are json: the value named ’json’ in this block; loads: the value named ’loads’ in this block; manifest_path: the value named ’manifest path’ in this block. Context: the function ___init___, which handles init.

Line 45: `if not isinstance(manifest_object, Mapping):` This executes the following indented host-code branch only when ‘not isinstance(manifest_object, Mapping)‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; manifest_object: the value named ’manifest object’ in this block. Context: the function ___init___, which handles init.

Line 46: `raise ValueError("parameter manifest root must be an object")` This rejects an invalid state by raising ‘ValueError("parameter manifest root must be an object")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 47: `self.manifest: Mapping[str, Any] = manifest_object` This assigns ‘manifest_object‘ to ‘self.manifest‘ in host memory. Here manifest means the value named ’manifest’ in this block. The important operands are manifest_object: the value named ’manifest object’ in this block. Context: the function ___init___, which handles init.

Line 48: `if self.manifest.get("format") != FORMAT:` This executes the following indented host-code branch only when ‘self.manifest.get("format") != FORMAT‘ is true. The important operands are manifest: the value named ’manifest’ in this block; get: the value named ’get’ in this block; format: the value named ’format’ in this block. Context: the function ___init___, which handles init.

Line 49: `raise ValueError(f"unsupported parameter format {self.manifest.get('format')!r}")` This rejects an invalid state by raising ‘ValueError(f"unsupported parameter format {self.manifest.get(’format’)!r}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 51: `binary_name = self.manifest.get("binary_file")` This assigns ‘self.manifest.get("binary_file")‘ to ‘binary_name ‘ in host memory. Here binary_name means the value named ’binary name’ in this block. The important operands are manifest: the value named ’manifest’ in this block; get: the value named ’get’ in this block; binary_file: the value named ’binary file’ in this block. Context: the function ___init___, which handles init.

Line 52: `if not isinstance(binary_name, str) or Path(binary_name).name != binary_name:` This executes the following indented host-code branch only when ‘not isinstance(binary_name, str) or Path(binary_name).name != binary_name‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; binary_name: the value named ’binary name’ in this block. Context: the function ___init___, which handles init.

Line 53: `raise ValueError("binary_file must be a file name beside the manifest")` This rejects an invalid state by raising ‘ValueError("binary_file must be a file name beside the manifest")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 54: `self.binary_path = self.manifest_path.parent / binary_name` This assigns ‘self.manifest_path.parent / binary_name‘ to ‘self.binary_path ‘ in host memory. Here binary_path means the value named ’binary path’ in this block. The important operands are manifest_path: the value named ’manifest path’ in this block; parent: the value named ’parent’ in this block; binary_name: the value named ’binary name’ in this block. Context: the function ___init___, which handles init.

Line 55: `self._binary = self.binary_path.read_bytes()` This assigns ‘self.binary_path.read_bytes()‘ to ‘self._binary ‘ in host memory. Here _binary means the value named ’binary’ in this block. The important operands are binary_path: the value named ’binary path’ in this block; read_bytes: the value named ’read bytes’ in this block. Context: the function ___init___, which handles init.

Line 56: `declared_bytes = self._integer_field(self.manifest, "binary_bytes")` This assigns ‘self._integer_field(self.m "binary_bytes")‘ to ‘declared_bytes ‘ in host memory. Here declared_bytes means the value named ’declared bytes’ in this block. The important operands are _integer_field: the value named ’integer field’ in this block; manifest: the value named ’manifest’ in this block; binary_bytes: the value named ’binary bytes’ in this block. Context: the function ___init___, which handles init.

Line 57: `if len(self._binary) != declared_bytes:` This executes the following indented host-code branch only when ‘len(self._binary) != declared_bytes‘ is true. The important operands are len: the value named ’len’ in this block; _binary: the value named ’binary’ in this block; declared_bytes: the value named ’declared bytes’ in this block. Context: the function ___init___, which handles init.

Line 58: `raise ValueError(` This statement continues through source line 59; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘ValueError(f"parameter binary has {len(self._binary)} bytes; expected {declared_bytes}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 59: `f"parameter binary has {len(self._binary)} bytes; expected {declared_bytes}")` This is continuation line 2 of the 2-line logical statement that begins at source line 58. Its exact fragment is ‘f"parameter binary has {len(self._binary)} bytes; expected {declared_bytes}")‘. The important operands are f: the value named ’f’ in this block; parameter: the value named ’parameter’ in this block; binary: the value named ’binary’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘ValueError(f"parameter binary has {len(self._binary)} bytes; expected {declared_bytes}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 60: `if verify_hashes:` This executes the following indented host-code branch only when ‘verify_hashes‘ is true. The important operands are verify_hashes: the value named ’verify hashes’ in this block. Context: the function ___init___, which handles init.

Line 61: `self._verify_hash(self._binary, self.manifest.get("binary_sha256"), "binary")` This calls ‘self._verify_ha with ‘self._binary, self.manifest.get("binary_sha256"), "binary"‘ inside the function ___init___, which handles init. The call advances the host-side job that validates and exposes typed read-only views of the aligned parameter archive.

Line 63: `alignment = self._integer_field(self.manifest, "alignment_bytes")` This assigns ‘self._integer_field(self.man "alignment_bytes")‘ to ‘alignment ‘ in host memory. Here alignment means the value named ’alignment’ in this block. The important operands are _integer_field: the value named ’integer field’ in this block; manifest: the value named ’manifest’ in this block; alignment_bytes: the value named ’alignment bytes’ in this block. Context: the function ___init___, which handles init.

Line 64: `if alignment <= 0 or alignment & (alignment - 1):` This executes the following indented host-code branch only when ‘alignment <= 0 or alignment & (alignment - 1)‘ is true. The important operands are alignment: the value named ’alignment’ in this block; or: the value named ’or’ in this block. Context: the function ___init___, which handles init.

Line 65: `raise ValueError("alignment_bytes must be a positive power of two")` This rejects an invalid state by raising ‘ValueError("alignment_bytes must be a positive power of two")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 66: `section_objects = self.manifest.get("sections")` This assigns ‘self.manifest.get("sections")‘ to ‘section_objects ‘ in host memory. Here section_objects means the value named ’section objects’ in this block. The important operands are manifest: the value named ’manifest’ in this block; get: the value named ’get’ in this block; sections: the value named ’sections’ in this block. Context: the function ___init___, which handles init.

Line 67: `if not isinstance(section_objects, list) or not section_objects:` This executes the following indented host-code branch only when ‘not isinstance(section_objects, list) or not section_objects‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; section_objects: the value named ’section objects’ in this block. Context: the function ___init___, which handles init.

Line 68: `raise ValueError("manifest must contain a nonempty sections list")` This rejects an invalid state by raising ‘ValueError("manifest must contain a nonempty sections list")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 69: `self._sections: dict[str, np.ndarray] = {}` This assigns ‘{}‘ to ‘self._sections‘ in host memory. Here _sections means the value named ’sections’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 70: `occupied_end = 0` This assigns ‘0‘ to ‘occupied_end ‘ in host memory. Here occupied_end means the value named ’occupied end’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 71: `for section_object in section_objects:` This iterates section_object over ‘section_objects‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function ___init___, which handles init.

Line 72: `if not isinstance(section_object, Mapping):` This executes the following indented host-code branch only when ‘not isinstance(section_object, Mapping)‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; section_object: the value named ’section object’ in this block. Context: the function ___init___, which handles init.

Line 73: `raise ValueError("each section must be an object")` This rejects an invalid state by raising ‘ValueError("each section must be an object")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 74: `name = section_object.get("name")` This assigns ‘section_object.get("name")‘ to ‘name ‘ in host memory. Here name means the value named ’name’ in this block. The important operands are section_object: the value named ’section object’ in this block; get: the value named ’get’ in this block; name: the value named ’name’ in this block. Context: the function ___init___, which handles init.

Line 75: `if not isinstance(name, str) or not name or name in self._sections:` This executes the following indented host-code branch only when ‘not isinstance(name, str) or not name or name in self._sections‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; name: the value named ’name’ in this block. Context: the function ___init___, which handles init.

Line 76: `raise ValueError(f"invalid or duplicate section name {name!r}")` This rejects an invalid state by raising ‘ValueError(f"invalid or duplicate section name {name!r}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 77: `offset = self._integer_field(section_object, "offset")` This assigns ‘self._integer_field(section_object, "offset")‘ to ‘offset ‘ in host memory. Here offset means the value named ’offset’ in this block. The important operands are _integer_field: the value named ’integer field’ in this block; section_object: the value named ’section object’ in this block; offset: the value named ’offset’ in this block. Context: the function ___init___, which handles init.

Line 78: `length = self._integer_field(section_object, "length")` This assigns ‘self._integer_field(section_object, "length")‘ to ‘length ‘ in host memory. Here length means the value named ’length’ in this block. The important operands are _integer_field: the value named ’integer field’ in this block; section_object: the value named ’section object’ in this block; length: the value named ’length’ in this block. Context: the function ___init___, which handles init.

Line 79: `if offset % alignment:` This executes the following indented host-code branch only when ‘offset % alignment‘ is true. The important operands are offset: the value named ’offset’ in this block; alignment: the value named ’alignment’ in this block. Context: the function ___init___, which handles init.

Line 80: `raise ValueError(f"section {name} offset {offset} is not {alignment}-byte aligned")` This rejects an invalid state by raising ‘ValueError(f"section {name} offset {offset} is not {alignment}-byte aligned")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 81: `if offset < occupied_end:` This executes the following indented host-code branch only when ‘offset < occupied_end‘ is true. The important operands are offset: the value named ’offset’ in this block; occupied_end: the value named ’occupied end’ in this block. Context: the function ___init___, which handles init.

Line 82: `raise ValueError(f"section {name} overlaps a preceding section")` This rejects an invalid state by raising ‘ValueError(f"section {name} overlaps a preceding section")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 83: `if length < 0 or offset + length > len(self._binary):` This executes the following indented host-code branch only when ‘length < 0 or offset + length > len(self._binary)‘ is true. The important operands are length: the value named ’length’ in this block; or: the value named ’or’ in this block; offset: the value named ’offset’ in this block. Context: the function ___init___, which handles init.

Line 84: `raise ValueError(f"section {name} is outside the parameter binary")` This rejects an invalid state by raising ‘ValueError(f"section {name} is outside the parameter binary")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 85: `dtype_value = section_object.get("dtype")` This assigns ‘section_object.get("dtype")‘ to ‘dtype_value ‘ in host memory. Here dtype_value means the value named ’dtype value’ in this block. The important operands are section_object: the value named ’section object’ in this block; get: the value named ’get’ in this block; dtype: the value named ’dtype’ in this block. Context: the function ___init___, which handles init.

Line 86: `shape_value = section_object.get("shape")` This assigns ‘section_object.get("shape")‘ to ‘shape_value ‘ in host memory. Here shape_value means the value named ’shape value’ in this block. The important operands are section_object: the value named ’section object’ in this block; get: the value named ’get’ in this block; shape: the value named ’shape’ in this block. Context: the function ___init___, which handles init.

Line 87: `if not isinstance(dtype_value, str) or not isinstance(shape_value, list):` This executes the following indented host-code branch only when ‘not isinstance(dtype_value, str) or not isinstance(shape_value, list)‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; dtype_value: the value named ’dtype value’ in this block. Context: the function ___init___, which handles init.

Line 88: `raise ValueError(f"section {name} has invalid dtype or shape metadata")` This rejects an invalid state by raising ‘ValueError(f"section {name} has invalid dtype or shape metadata")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 89: `dtype = np.dtype(dtype_value)` This assigns ‘np.dtype(dtype_value)‘ to ‘dtype ‘ in host memory. Here dtype means the value named ’dtype’ in this block. The important operands are dtype: the value named ’dtype’ in this block; dtype_value: the value named ’dtype value’ in this block. Context: the function ___init___, which handles init.

Line 90: `shape = tuple(self._nonnegative_dimension(value, name) for value in shape_value)` This assigns ‘tuple(self._nonnegative_dimension(value, name) for value in shape_value)‘ to ‘shape ‘ in host memory. Here shape means the value named ’shape’ in this block. The important operands are tuple: the value named ’tuple’ in this block; _nonnegative_dimension: the value named ’nonnegative dimension’ in this block; value: the value named ’value’ in this block. Context: the function ___init___, which handles init.

Line 91: `expected_length = int(np.prod(shape, dtype=np.int64)) * dtype.itemsize` This assigns ‘int(np.prod(shape, dtype=np.int64)) * dtype.itemsize‘ to ‘expected_length ‘ in host memory. Here expected_length means the value named ’expected length’ in this block. The important operands are prod: the value named ’prod’ in this block; shape: the value named ’shape’ in this block; dtype: the value named ’dtype’ in this block. Context: the function ___init___, which handles init.

Line 92: `if length != expected_length:` This executes the following indented host-code branch only when ‘length != expected_length‘ is true. The important operands are length: the value named ’length’ in this block; expected_length: the value named ’expected length’ in this block. Context: the function ___init___, which handles init.

Line 93: `raise ValueError(` This statement continues through source line 94; the explanation uses the complete expression rather than only the first visual fragment. This rejects an invalid state by raising ‘ValueError(f"section {name} has {length} bytes; dtype/shape require {expected_length}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 94: `f"section {name} has {length} bytes; dtype/shape require {expected_length}")` This is continuation line 2 of the 2-line logical statement that begins at source line 93. Its exact fragment is ‘f"section {name} has {length} bytes; dtype/shape require {expected_length}")‘. The important operands are f: the value named ’f’ in this block; section: the value named ’section’ in this block; name: the value named ’name’ in this block. Read together, the complete operation is: This rejects an invalid state by raising ‘ValueError(f"section {name} has {length} bytes; dtype/shape require {expected_length}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 95: `payload = self._binary[offset:offset + length]` This assigns ‘self._binary[offset:offset + length]‘ to ‘payload ‘ in host memory. Here payload means stream data belonging to the current command. The important operands are _binary: the value named ’binary’ in this block; offset: the value named ’offset’ in this block; length: the value named ’length’ in this block. Context: the function ___init___, which handles init.

Line 96: `if verify_hashes:` This executes the following indented host-code branch only when ‘verify_hashes‘ is true. The important operands are verify_hashes: the value named ’verify hashes’ in this block. Context: the function ___init___, which handles init.

Line 97: `self._verify_hash(payload, section_object.get("sha256"), f"section {name}")` This calls ‘self._verify_hash with ‘payload, section_object.get("sha256"), f"section {name}"‘ inside the function ___init___, which handles init. The call advances the host-side job that validates and exposes typed read-only views of the aligned parameter archive.

Line 98: `array = np.frombuffer(payload, dtype=dtype).reshape(shape)` This assigns ‘np.frombuffer(payload, dtype=dtype).reshape(shape)‘ to ‘array ‘ in host memory. Here array means the value named ’array’ in this block. The important operands are frombuffer: local storage that decouples producer and consumer timing; payload: stream data belonging to the current command; dtype: the value named ’dtype’ in this block. Context: the function ___init___, which handles init.

Line 99: `array.flags.writeable = False` This assigns ‘False‘ to ‘array.flags.writeable ‘ in host memory. Here writeable means the value named ’writeable’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 100: `self._sections[name] = array` This assigns ‘array‘ to ‘self._sections[name] ‘ in host memory. Here _sections means the value named ’sections’ in this block. The important operands are array: the value named ’array’ in this block. Context: the function ___init___, which handles init.

Line 101: `occupied_end = offset + length` This assigns ‘offset + length‘ to ‘occupied_end ‘ in host memory. Here occupied_end means the value named ’occupied end’ in this block. The important operands are offset: the value named ’offset’ in this block; length: the value named ’length’ in this block. Context: the function ___init___, which handles init.

Line 103: `declared_section_names = set(self._sections)` This assigns ‘set(self._sections)‘ to ‘declared_section_names ‘ in host memory. Here declared_section_names means the value named ’declared section names’ in this block. The important operands are set: the value named ’set’ in this block; _sections: the value named ’sections’ in this block. Context: the function ___init___, which handles init.

Line 104: `referenced_section_names: set[str] = set()` This assigns ‘set()‘ to ‘referenced_section_names‘ in host memory. Here referenced_section_names means the value named ’referenced section names’ in this block. The important operands are set: the value named ’set’ in this block. Context: the function ___init___, which handles init.

Line 105: `for projection in self._projection_objects():` This iterates projection over ‘self._projection_objects()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function ___init___, which handles init.

Line 106: `referenced_section_names.update(self._section_names(projection, "projection"))` This calls ‘referenced_section_names.update‘ with ‘self._section_names(projection, "projection")‘ inside the function ___init___, which handles init. The call advances the host-side job that validates and exposes typed read-only views of the aligned parameter archive.

Line 107: `head = self.manifest.get("head")` This assigns ‘self.manifest.get("head")‘ to ‘head ‘ in host memory. Here head means the value named ’head’ in this block. The important operands are manifest: the value named ’manifest’ in this block; get: the value named ’get’ in this block; head: the value named ’head’ in this block. Context: the function ___init___, which handles init.

Line 108: `if not isinstance(head, Mapping):` This executes the following indented host-code branch only when ‘not isinstance(head, Mapping)‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; head: the value named ’head’ in this block. Context: the function ___init___, which handles init.

Line 109: `raise ValueError("manifest head must be an object")` This rejects an invalid state by raising ‘ValueError("manifest head must be an object")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 110: `referenced_section_names.update(self._section_names(head, "head"))` This calls ‘referenced_section_names. with ‘self._section_names(head, "head")‘ inside the function ___init___, which handles init. The call advances the host-side job that validates and exposes typed read-only views of the aligned parameter archive.

Line 111: `if referenced_section_names != declared_section_names:` This executes the following indented host-code branch only when ‘referenced_section_names != declared_section_names‘ is true. The important operands are referenced_section_names: the value named ’referenced section names’ in this block; declared_section_names: the value named ’declared section names’ in this block. Context: the function ___init___, which handles init.

Line 112: `missing = sorted(declared_section_names - referenced_section_names)` This assigns ‘sorted(declared_sectior - referenced_section_names)‘ to ‘missing ‘ in host memory. Here missing means the value named ’missing’ in this block. The important operands are sorted: the value named ’sorted’ in this block; declared_section_names: the value named ’declared section names’ in this block; referenced_section_names: the value named ’referenced section names’ in this block. Context: the function ___init___, which handles init.

Line 113: `unknown = sorted(referenced_section_names - declared_section_names)` This assigns ‘sorted(referenced_secti - declared_section_names)‘ to ‘unknown ‘ in host memory. Here unknown means the value named ’unknown’ in this block. The important operands are sorted: the value named ’sorted’ in this block; referenced_section_names: the value named ’referenced section names’ in this block; declared_section_names: the value named ’declared section names’ in this block. Context: the function ___init___, which handles init.

Line 114: `raise ValueError(f"section reference mismatch: unreferenced={missing}, unknown={unknown}")` This rejects an invalid state by raising ‘ValueError(f"section reference mismatch: unreferenced={missing}, unknown={unknown}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 116: `@staticmethod` This decorator changes how the following class or function is constructed. ‘@staticmethod‘ is applied at import time on the host and is part of the class SpikingformerParameterArchive, which handles spikingformer parameter archive; it creates no FPGA circuit by itself.

Line 117: `def _integer_field(mapping: Mapping[str, Any], name: str) -> int:` This starts function _integer_field. Its indented body performs integer field as part of the file that validates and exposes typed read-only views of the aligned parameter archive; it runs only when called.

Line 118: `value = mapping.get(name)` This assigns ‘mapping.get(name)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are mapping: the value named ’mapping’ in this block; get: the value named ’get’ in this block; name: the value named ’name’ in this block. Context: the function _integer_field, which handles integer field.

Line 119: `if isinstance(value, bool) or not isinstance(value, int):` This executes the following indented host-code branch only when ‘isinstance(value, bool) or not isinstance(value, int)‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; value: the value named ’value’ in this block; bool: the value named ’bool’ in this block. Context: the function _integer_field, which handles integer field.

Line 120: `raise ValueError(f"{name} must be an integer")` This rejects an invalid state by raising ‘ValueError(f"{name} must be an integer")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 121: `return value` This returns ‘value‘ to the caller of the function _integer_field, which handles integer field, ending this invocation. The important operands are value: the value named ’value’ in this block.

Line 123: `@staticmethod` This decorator changes how the following class or function is constructed. ‘@staticmethod‘ is applied at import time on the host and is part of the class SpikingformerParameterArchive, which handles spikingformer parameter archive; it creates no FPGA circuit by itself.

Line 124: `def _nonnegative_dimension(value: Any, section_name: str) -> int:` This starts function _nonnegative_dimension. Its indented body performs nonnegative dimension as part of the file that validates and exposes typed read-only views of the aligned parameter archive; it runs only when called.

Line 125: `if isinstance(value, bool) or not isinstance(value, int) or value < 0:` This executes the following indented host-code branch only when ‘isinstance(value, bool) or not isinstance(value, int) or value < 0‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; value: the value named ’value’ in this block; bool: the value named ’bool’ in this block. Context: the function _nonnegative_dimension, which handles nonnegative dimension.

Line 126: `raise ValueError(f"section {section_name} has an invalid shape dimension")` This rejects an invalid state by raising 'ValueError(f"section {section_name} has an invalid shape dimension")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 127: `return value` This returns 'value' to the caller of the function _nonnegative_dimension, which handles nonnegative dimension, ending this invocation. The important operands are value: the value named 'value' in this block.

Line 129: `@staticmethod` This decorator changes how the following class or function is constructed. '@staticmethod' is applied at import time on the host and is part of the class SpikingformerParameterArchive, which handles spikingformer parameter archive; it creates no FPGA circuit by itself.

Line 130: `def _verify_hash(payload: bytes, expected: Any, description: str) -> None:` This starts function _verify_hash. Its indented body performs verify hash as part of the file that validates and exposes typed read-only views of the aligned parameter archive; it runs only when called.

Line 131: `if not isinstance(expected, str) or len(expected) != 64:` This executes the following indented host-code branch only when 'not isinstance(expected, str) or len(expected) != 64' is true. The important operands are not: the value named 'not' in this block; isinstance: the value named 'isinstance' in this block; expected: the value named 'expected' in this block. Context: the function _verify_hash, which handles verify hash.

Line 132: `raise ValueError(f"{description} SHA-256 metadata is invalid")` This rejects an invalid state by raising 'ValueError(f"{description} SHA-256 metadata is invalid")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 133: `actual = hashlib.sha256(payload).hexdigest()` This assigns 'hashlib.sha256(payload).hexdigest()' to 'actual ' in host memory. Here actual means the value named 'actual' in this block. The important operands are hashlib: the value named 'hashlib' in this block; sha256: the value named 'sha256' in this block; payload: stream data belonging to the current command. Context: the function _verify_hash, which handles verify hash.

Line 134: `if actual != expected.lower():` This executes the following indented host-code branch only when 'actual != expected.lower()' is true. The important operands are actual: the value named 'actual' in this block; expected: the value named 'expected' in this block; lower: the value named 'lower' in this block. Context: the function _verify_hash, which handles verify hash.

Line 135: `raise ValueError(f"{description} SHA-256 mismatch: {actual} != {expected}")` This rejects an invalid state by raising 'ValueError(f"{description} SHA-256 mismatch: {actual} != {expected}")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 137: `def _projection_objects(self) -> list[Mapping[str, Any]]:` This starts function _projection_objects. Its indented body performs projection objects as part of the file that validates and exposes typed read-only views of the aligned parameter archive; it runs only when called.

Line 138: `projections = self.manifest.get("projections")` This assigns 'self.manifest.get("projections")' to 'projections ' in host memory. Here projections means the value named 'projections' in this block. The important operands are manifest: the value named 'manifest' in this block; get: the value named 'get' in this block; projections: the value named 'projections' in this block. Context: the function _projection_objects, which handles projection objects.

Line 139: `if not isinstance(projections, list):` This executes the following indented host-code branch only when 'not isinstance(projections, list)' is true. The important operands are not: the value named 'not' in this block; isinstance: the value named 'isinstance' in this block; projections: the value named 'projections' in this block. Context: the function _projection_objects, which handles projection objects.

Line 140: `raise ValueError("manifest projections must be a list")` This rejects an invalid state by raising ‘ValueError("manifest projections must be a list")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 141: `if not all(isinstance(item, Mapping) for item in projections):` This executes the following indented host-code branch only when ‘not all(isinstance(item, Mapping) for item in projections)‘ is true. The important operands are not: the value named ’not’ in this block; all: the value named ’all’ in this block; isinstance: the value named ’isinstance’ in this block. Context: the function _projection_objects, which handles projection objects.

Line 142: `raise ValueError("each projection must be an object")` This rejects an invalid state by raising ‘ValueError("each projection must be an object")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 143: `return projections` This returns ‘projections‘ to the caller of the function _projection_objects, which handles projection objects, ending this invocation. The important operands are projections: the value named ’projections’ in this block.

Line 145: `@staticmethod` This decorator changes how the following class or function is constructed. ‘@staticmethod‘ is applied at import time on the host and is part of the class SpikingformerParameterArchive, which handles spikingformer parameter archive; it creates no FPGA circuit by itself.

Line 146: `def _section_names(owner: Mapping[str, Any], owner_kind: str) -> list[str]:` This starts function _section_names. Its indented body performs section names as part of the file that validates and exposes typed read-only views of the aligned parameter archive; it runs only when called.

Line 147: `sections = owner.get("sections")` This assigns ‘owner.get("sections")‘ to ‘sections ‘ in host memory. Here sections means the value named ’sections’ in this block. The important operands are owner: the value named ’owner’ in this block; get: the value named ’get’ in this block; sections: the value named ’sections’ in this block. Context: the function _section_names, which handles section names.

Line 148: `if not isinstance(sections, list):` This executes the following indented host-code branch only when ‘not isinstance(sections, list)‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; sections: the value named ’sections’ in this block. Context: the function _section_names, which handles section names.

Line 149: `raise ValueError(f"{owner_kind} sections must be a list")` This rejects an invalid state by raising ‘ValueError(f"{owner_kind} sections must be a list")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 150: `names: list[str] = []` This assigns ‘[]‘ to ‘names‘ in host memory. Here names means the value named ’names’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function _section_names, which handles section names.

Line 151: `for section in sections:` This iterates section over ‘sections‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _section_names, which handles section names.

Line 152: `if not isinstance(section, Mapping) or not isinstance(section.get("name"), str):` This executes the following indented host-code branch only when ‘not isinstance(section, Mapping) or not isinstance(section.get("name"), str)‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; section: the value named ’section’ in this block. Context: the function _section_names, which handles section names.

Line 153: `raise ValueError(f"{owner_kind} has an invalid section reference")` This rejects an invalid state by raising ‘ValueError(f"{owner_kind} has an invalid section reference")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 154: `names.append(section["name"])` This calls ‘names.append‘ with ‘section["name"]‘ inside the function _section_names, which handles section names. The call advances the host-side job that validates and exposes typed read-only views of the aligned parameter archive.

Line 155: `return names` This returns ‘names‘ to the caller of the function _section_names, which handles section names, ending this invocation. The important operands are names: the value named ’names’ in this block.

Line 157: `def section(self, name: str) -> np.ndarray:` This starts function section. Its indented body performs section as part of the file that validates and exposes typed read-only views of the aligned parameter archive; it runs only when called.

Line 158: `try:` This is explicit host-side failure handling inside the function section, which handles section; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 159: `return self._sections[name]` This returns ‘self._sections[name]‘ to the caller of the function section, which handles section, ending this invocation. The important operands are _sections: the value named ’sections’ in this block; name: the value named ’name’ in this block.

Line 160: `except KeyError as error:` This is explicit host-side failure handling inside the function section, which handles section; it ensures malformed artifacts, DMA errors, and tool failures are surfaced or cleaned up deterministically.

Line 161: `raise KeyError(f"parameter section {name!r} does not exist") from error` This rejects an invalid state by raising ‘KeyError(f"parameter section {name!r} does not exist") from error‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 163: `@property` This decorator changes how the following class or function is constructed. ‘@property‘ is applied at import time on the host and is part of the class SpikingformerParameterArchive, which handles spikingformer parameter archive; it creates no FPGA circuit by itself.

Line 164: `def projection_names(self) -> tuple[str, ...]:` This starts function projection_names. Its indented body performs projection names as part of the file that validates and exposes typed read-only views of the aligned parameter archive; it runs only when called.

Line 165: `return tuple(str(item.get("name")) for item in self._projection_objects())` This returns ‘tuple(str(item.get("name")) for item in self._projection_objects())‘ to the caller of the function projection_names, which handles projection names, ending this invocation. The important operands are tuple: the value named ’tuple’ in this block; str: the value named ’str’ in this block; item: the value named ’item’ in this block.

Line 167: `def projection(self, name: str) -> ProjectionParameters:` This starts function projection. Its indented body performs projection as part of the file that validates and exposes typed read-only views of the aligned parameter archive; it runs only when called.

Line 168: `matches = [item for item in self._projection_objects() if item.get("name") == name]` Inside the function projection, which handles projection, this statement advances the host implementation that validates and exposes typed read-only views of the aligned parameter archive. The important operands are matches: the value named ’matches’ in this block; item: the value named ’item’ in this block; for: the value named ’for’ in this block.

Line 169: `if len(matches) != 1:` This executes the following indented host-code branch only when ‘len(matches) != 1‘ is true. The important operands are len: the value named ’len’ in this block; matches: the value named ’matches’ in this block. Context: the function projection, which handles projection.

Line 170: `raise KeyError(f"projection {name!r} does not exist uniquely")` This rejects an invalid state by raising ‘KeyError(f"projection {name!r} does not exist uniquely")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 171: `owner = matches[0]` This assigns ‘matches[0]‘ to ‘owner ‘ in host memory. Here owner means the value named ’owner’ in this block. The important operands are matches: the value named ’matches’ in this block. Context: the function projection, which handles projection.

Line 172: `section_names = self._section_names(owner, f"projection {name}")` This assigns ‘self._section_names(owner, f"projection {name}")‘ to ‘section_names ‘ in host memory. Here section_names means the value named ’section names’ in this block. The important operands are _section_names: the value named ’section names’ in this block; owner: the value named ’owner’ in this block; f: the value named ’f’ in this block. Context: the function projection, which handles projection.

Line 173: `expected_suffixes = (` This statement continues through source line 176; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(".weight_k_by_n_int8", ".bias_q10", ".multiplier_q15", ".binary_point_shift",)‘ to ‘expected_suffixes ‘ in host memory. Here expected_suffixes means the value named ’expected suffixes’ in this block. The important operands are weight_k_by_n_int8: a learned coefficient multiplied by an activation; bias_q10: an additive learned offset applied after accumulation; multiplier_q15: the value named ’multiplier q15’ in this block. Context: the function projection, which handles projection.

Line 174: `".weight_k_by_n_int8", ".bias_q10", ".multiplier_q15",` This is continuation line 2 of the 4-line logical statement that begins at source line 173. Its exact fragment is ‘".weight_k_by_n_int8", ".bias_q10", ".multiplier_q15",‘. The important operands are weight_k_by_n_int8: a learned coefficient multiplied by an activation; bias_q10: an additive learned offset applied after accumulation; multiplier_q15: the value named ’multiplier q15’ in this block. Read together, the complete operation is: This assigns ‘(".weight_k_by_n_int8", ".bias_q10", ".multiplier_q15", ".binary_point_shift",)‘ to ‘expected_suffixes ‘ in host memory. Here expected_suffixes means the value named ’expected suffixes’ in this block. The important operands are weight_k_by_n_int8: a learned coefficient multiplied by an activation; bias_q10: an additive learned offset applied after accumulation; multiplier_q15: the value named ’multiplier q15’ in this block. Context: the function projection, which handles projection.

Line 175: `".binary_point_shift",` This is continuation line 3 of the 4-line logical statement that begins at source line 173. Its exact fragment is ‘".binary_point_shift",‘. The important operands are binary_point_shift: the value named ’binary point shift’ in this block. Read together, the complete operation is: This assigns ‘(".weight_k_by_n_int8", ".bias_q10", ".multiplier_q15", ".binary_point_shift",)‘ to ‘expected_suffixes ‘ in host memory. Here expected_suffixes means the value named ’expected suffixes’ in this block. The important operands are weight_k_by_n_int8: a learned coefficient multiplied by an activation; bias_q10: an additive learned offset applied after accumulation; multiplier_q15: the value named ’multiplier q15’ in this block. Context: the function projection, which handles projection.

Line 176: `)` This is continuation line 4 of the 4-line logical statement that begins at source line 173. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘(".weight_k_by_n_int8", ".bias_q10", ".multiplier_q15", ".binary_point_shift",)‘ to ‘expected_suffixes ‘ in host memory. Here expected_suffixes means the value named ’expected suffixes’ in this block. The important operands are weight_k_by_n_int8: a learned coefficient multiplied by an activation; bias_q10: an additive learned offset applied after accumulation; multiplier_q15: the value named ’multiplier q15’ in this block. Context: the function projection, which handles projection.

Line 177: `selected: list[np.ndarray] = []` This assigns ‘[]‘ to ‘selected‘ in host memory. Here selected means the value named ’selected’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function projection, which handles projection.

Line 178: `for suffix in expected_suffixes:` This iterates suffix over ‘expected_suffixes‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function projection, which handles projection.

Line 179: `suffix_matches = [entry for entry in section_names if entry.endswith(suffix)]` This assigns '[entry for entry in section_names if entry.endswith(suffix)]' to 'suffix_matches ' in host memory. Here suffix_matches means the value named 'suffix matches' in this block. The important operands are entry: the value named 'entry' in this block; for: the value named 'for' in this block; in: the value named 'in' in this block. Context: the function projection, which handles projection.

Line 180: `if len(suffix_matches) != 1:` This executes the following indented host-code branch only when 'len(suffix_matches != 1' is true. The important operands are len: the value named 'len' in this block; suffix_matches: the value named 'suffix matches' in this block. Context: the function projection, which handles projection.

Line 181: `raise ValueError(f"projection {name} must reference one {suffix} section")` This rejects an invalid state by raising 'ValueError(f"projection {name} must reference one {suffix} section")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 182: `selected.append(self.section(suffix_matches[0]))` This calls 'selected.append' with 'self.section(suffix_matches inside the function projection, which handles projection. The call advances the host-side job that validates and exposes typed read-only views of the aligned parameter archive.

Line 183: `weight, bias, multiplier, shift = selected` This assigns 'selected' to 'weight, bias, multiplier, shift ' in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are selected: the value named 'selected' in this block. Context: the function projection, which handles projection.

Line 184: `if weight.ndim != 2 or any(value.ndim != 1 for value in selected[1:]):` This executes the following indented host-code branch only when 'weight.ndim != 2 or any(value.ndim != 1 for value in selected[1:])' is true. The important operands are weight: a learned coefficient multiplied by an activation; ndim: the value named 'ndim' in this block; or: the value named 'or' in this block. Context: the function projection, which handles projection.

Line 185: `raise ValueError(f"projection {name} section ranks are invalid")` This rejects an invalid state by raising 'ValueError(f"projection {name} section ranks are invalid")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 186: `if not (weight.shape[1] == len(bias) == len(multiplier) == len(shift)):` This executes the following indented host-code branch only when 'not (weight.shape[1] == len(bias) == len(multiplier) == len(shift))' is true. The important operands are not: the value named 'not' in this block; weight: a learned coefficient multiplied by an activation; shape: the value named 'shape' in this block. Context: the function projection, which handles projection.

Line 187: `raise ValueError(f"projection {name} output-channel metadata is inconsistent")` This rejects an invalid state by raising 'ValueError(f"projection {name} output-channel metadata is inconsistent")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 188: `source_shape_object = owner.get("source_weight_shape")` This assigns 'owner.get("source_weight_shape")' to 'source_shape_object ' in host memory. Here source_shape_object means the value named 'source shape object' in this block. The important operands are owner: the value named 'owner' in this block; get: the value named 'get' in this block; source_weight_shape: a learned coefficient multiplied by an activation. Context: the function projection, which handles projection.

Line 189: `if not isinstance(source_shape_object, list):` This executes the following indented host-code branch only when 'not isinstance(source_shape_object, list)' is true. The important operands are not: the value named 'not' in this block; isinstance: the value named 'isinstance' in this block; source_shape_object: the value named 'source shape object' in this block. Context: the function projection, which handles projection.

Line 190: `raise ValueError(f"projection {name} has no source weight shape")` This rejects an invalid state by raising 'ValueError(f"projection {name} has no source weight shape")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 191: `source_shape = tuple(` This statement continues through source line 193; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘tuple(self._nonnegative_dimension(value, f"projection {name}") for value in source_shape_object)‘ to ‘source_shape ‘ in host memory. Here source_shape means the value named ’source shape’ in this block. The important operands are tuple: the value named ’tuple’ in this block; _nonnegative_dimension: the value named ’nonnegative dimension’ in this block; value: the value named ’value’ in this block. Context: the function projection, which handles projection.

Line 192: `self._nonnegative_dimension(value, f"projection {name}")` This is continuation line 2 of the 3-line logical statement that begins at source line 191. Its exact fragment is ‘self._nonnegative_dimension(value, f"projection {name}")‘. The important operands are _nonnegative_dimension: the value named ’nonnegative dimension’ in this block; value: the value named ’value’ in this block; f: the value named ’f’ in this block. Read together, the complete operation is: This assigns ‘tuple(self._nonnegative_dimension(value, f"projection {name}") for value in source_shape_object)‘ to ‘source_shape ‘ in host memory. Here source_shape means the value named ’source shape’ in this block. The important operands are tuple: the value named ’tuple’ in this block; _nonnegative_dimension: the value named ’nonnegative dimension’ in this block; value: the value named ’value’ in this block. Context: the function projection, which handles projection.

Line 193: `for value in source_shape_object)` This is continuation line 3 of the 3-line logical statement that begins at source line 191. Its exact fragment is ‘for value in source_shape_object)‘. The important operands are for: the value named ’for’ in this block; value: the value named ’value’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘tuple(self._nonnegative_dimension(value, f"projection {name}") for value in source_shape_object)‘ to ‘source_shape ‘ in host memory. Here source_shape means the value named ’source shape’ in this block. The important operands are tuple: the value named ’tuple’ in this block; _nonnegative_dimension: the value named ’nonnegative dimension’ in this block; value: the value named ’value’ in this block. Context: the function projection, which handles projection.

Line 194: `if len(source_shape) not in (3, 4) or source_shape[0] != weight.shape[1]:` This executes the following indented host-code branch only when ‘len(source_shape) not in (3, 4) or source_shape[0] != weight.shape[1]‘ is true. The important operands are len: the value named ’len’ in this block; source_shape: the value named ’source shape’ in this block; not: the value named ’not’ in this block. Context: the function projection, which handles projection.

Line 195: `raise ValueError(f"projection {name} source weight shape is inconsistent")` This rejects an invalid state by raising ‘ValueError(f"projection {name} source weight shape is inconsistent")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 196: `fractional_bits = self._integer_field(owner, "output_fractional_bits")` This assigns ‘self._integer_field(o "output_fractional_bits")‘ to ‘fractional_bits ‘ in host memory. Here fractional_bits means the value named ’fractional bits’ in this block. The important operands are _integer_field: the value named ’integer field’ in this block; owner: the value named ’owner’ in this block; output_fractional_bits: the value named ’output fractional bits’ in this block. Context: the function projection, which handles projection.

Line 197: `return ProjectionParameters(` This statement continues through source line 199; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘ProjectionParameters(name, weight, bias, multiplier, shift, str(owner.get("compute_opcode")), source_shape, fractional_bits)‘ to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block; name: the value named ’name’ in this block; weight: a learned coefficient multiplied by an activation.

Line 198: `name, weight, bias, multiplier, shift, str(owner.get("compute_opcode")),` This is continuation line 2 of the 3-line logical statement that begins at source line 197. Its exact fragment is ‘name, weight, bias, multiplier, shift, str(owner.get("compute_opcode")),‘. The important operands are name: the value named ’name’ in this block; weight: a learned coefficient multiplied by an activation; bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This returns ‘ProjectionParameters(name, weight, bias, multiplier, shift, str(owner.get("compute_opcode")), source_shape, fractional_bits)‘ to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named ’projection

parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 199: `source_shape, fractional_bits)` This is continuation line 3 of the 3-line logical statement that begins at source line 197. Its exact fragment is 'source_shape, fractional_bits)'. The important operands are source_shape: the value named 'source shape' in this block; fractional_bits: the value named 'fractional bits' in this block. Read together, the complete operation is: This returns 'ProjectionParameters(name, weight, bias, multiplier, shift, str(owner.get("compute_opcode source_shape, fractional_bits)' to the caller of the function projection, which handles projection, ending this invocation. The important operands are ProjectionParameters: the value named 'projection parameters' in this block; name: the value named 'name' in this block; weight: a learned coefficient multiplied by an activation.

Line 201: `@property` This decorator changes how the following class or function is constructed. '@property' is applied at import time on the host and is part of the class SpikingformerParameterArchive, which handles spikingformer parameter archive; it creates no FPGA circuit by itself.

Line 202: `def head(self) -> HeadParameters:` This starts function head. Its indented body performs head as part of the file that validates and exposes typed read-only views of the aligned parameter archive; it runs only when called.

Line 203: `owner = self.manifest["head"]` This assigns 'self.manifest["head"]' to 'owner ' in host memory. Here owner means the value named 'owner' in this block. The important operands are manifest: the value named 'manifest' in this block; head: the value named 'head' in this block. Context: the function head, which handles head.

Line 204: `names = self._section_names(owner, "head")` This assigns 'self._section_names(owner, "head")' to 'names ' in host memory. Here names means the value named 'names' in this block. The important operands are _section_names: the value named 'section names' in this block; owner: the value named 'owner' in this block; head: the value named 'head' in this block. Context: the function head, which handles head.

Line 205: `weight_names = [name for name in names if name.endswith(".weight_k_by_n_int8")]` This assigns '[name for name in names if name.endswith(".weight_k_by_n_int8")]' to 'weight_names ' in host memory. Here weight_names means a learned coefficient multiplied by an activation. The important operands are name: the value named 'name' in this block; for: the value named 'for' in this block; in: the value named 'in' in this block. Context: the function head, which handles head.

Line 206: `bias_names = [name for name in names if name.endswith(".bias_accumulator_units")]` This assigns '[name for name in names if name.endswith(".bias_accumulator_units")]' to 'bias_names ' in host memory. Here bias_names means an additive learned offset applied after accumulation. The important operands are name: the value named 'name' in this block; for: the value named 'for' in this block; in: the value named 'in' in this block. Context: the function head, which handles head.

Line 207: `if len(weight_names) != 1 or len(bias_names) != 1:` This executes the following indented host-code branch only when 'len(weight_names) != 1 or len(bias_names) != 1' is true. The important operands are len: the value named 'len' in this block; weight_names: a learned coefficient multiplied by an activation; or: the value named 'or' in this block. Context: the function head, which handles head.

Line 208: `raise ValueError("head must reference one weight and one bias section")` This rejects an invalid state by raising 'ValueError("head must reference one weight and one bias section")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 209: `weight = self.section(weight_names[0])` This assigns 'self.section(weight_names[0])' to 'weight ' in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are section: the value named 'section' in this block; weight_names: a learned coefficient multiplied by an activation. Context: the function head, which handles head.

Line 210: `bias = self.section(bias_names[0])` This assigns ‘self.section(bias_names[0])‘ to ‘bias ‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are section: the value named ’section’ in this block; bias_names: an additive learned offset applied after accumulation. Context: the function head, which handles head.

Line 211: `if weight.ndim != 2 or bias.ndim != 1 or weight.shape[1] != len(bias):` This executes the following indented host-code branch only when ‘weight.ndim != 2 or bias.ndim != 1 or weight.shape[1] != len(bias)‘ is true. The important operands are weight: a learned coefficient multiplied by an activation; ndim: the value named ’ndim’ in this block; or: the value named ’or’ in this block. Context: the function head, which handles head.

Line 212: `raise ValueError("head section shapes are inconsistent")` This rejects an invalid state by raising ‘ValueError("head section shapes are inconsistent")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 213: `return HeadParameters(weight, bias)` This returns ‘HeadParameters(weight, bias)‘ to the caller of the function head, which handles head, ending this invocation. The important operands are HeadParameters: the value named ’head parameters’ in this block; weight: a learned coefficient multiplied by an activation; bias: an additive learned offset applied after accumulation.

42 software/spikingformer_quantization.py

Role in the complete system: defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

42.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: QuantizedWeight, HardwareEmulationReport, FixedPointHardResetLIF. Functions: quantize_cifar_input_u8, fake_fixed_point, prepare_hardware_emulation, _replace_lif_modules, input_scale_from_domain, _install_projection_requantizers, _projection_hook, as_dict, ___init___, forward, requantize. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

Line 1: `"""Quantization functions that mirror the implemented NeuraEdge arithmetic."""` This is executable documentation attached to the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 3: `from __future__ import annotations` This imports the named Python API so the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 5: `import copy` This imports the named Python API so the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 6: `from dataclasses import asdict, dataclass` This imports the named Python API so the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 7: `from typing import Literal` This imports the named Python API so the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 9: `import torch` This imports the named Python API so the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 10: `import torch.nn as nn` This imports the named Python API so the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 12: `from neuraedge_golden import quantize_flexible_scale` This imports the named Python API so the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 13: `from spikingformer_reference import MultiStepHardResetLIF, Spikingformer` This imports the named Python API so the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 16: `WeightGranularity = Literal["tensor", "channel"]` This assigns ‘Literal["tensor", "channel"]‘ to ‘WeightGranularity ‘ in host memory. Here WeightGranularity means a learned coefficient multiplied by an activation. The important operands are Literal: the value named ’literal’ in this block; tensor: the value named ’tensor’ in this block; channel: the value named ’channel’ in this block. Context: the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 19: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it creates no FPGA circuit by itself.

Line 20: `class QuantizedWeight:` This defines class QuantizedWeight, which groups data and methods for quantized weight. Instances exist in host memory and organize the flow that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 21: `module: str` Inside the class QuantizedWeight, which handles quantized weight, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are module: the value named ’module’ in this block; str: the value named ’str’ in this block.

Line 22: `shape: tuple[int, ...]` Inside the class QuantizedWeight, which handles quantized weight, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are shape: the value named 'shape' in this block; tuple: the value named 'tuple' in this block.

Line 23: `granularity: WeightGranularity` Inside the class QuantizedWeight, which handles quantized weight, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are granularity: the value named 'granularity' in this block; WeightGranularity: a learned coefficient multiplied by an activation.

Line 24: `integer_minimum: int` Inside the class QuantizedWeight, which handles quantized weight, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are integer_minimum: the value named 'integer minimum' in this block.

Line 25: `integer_maximum: int` Inside the class QuantizedWeight, which handles quantized weight, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are integer_maximum: the value named 'integer maximum' in this block.

Line 26: `scale_minimum: float` Inside the class QuantizedWeight, which handles quantized weight, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are scale_minimum: the real-value spacing represented by one quantized integer step; float: the value named 'float' in this block.

Line 27: `scale_maximum: float` Inside the class QuantizedWeight, which handles quantized weight, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are scale_maximum: the real-value spacing represented by one quantized integer step; float: the value named 'float' in this block.

Line 28: `mean_absolute_error: float` Inside the class QuantizedWeight, which handles quantized weight, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are mean_absolute_error: the arithmetic average used by normalization; float: the value named 'float' in this block.

Line 29: `maximum_absolute_error: float` Inside the class QuantizedWeight, which handles quantized weight, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are maximum_absolute_error: the value named 'maximum absolute error' in this block; float: the value named 'float' in this block.

Line 32: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. '@dataclass(frozen=True)' is applied at import time on the host and is part of the file whose role is to defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it creates no FPGA circuit by itself.

Line 33: `class HardwareEmulationReport:` This defines class HardwareEmulationReport, which groups data and methods for hardware emulation report. Instances exist in host memory and organize the flow that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 34: `fractional_bits: int` Inside the class HardwareEmulationReport, which handles hardware emulation report, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are fractional_bits: the value named 'fractional bits' in this block.

Line 35: `fixed_point_scale: int` Inside the class HardwareEmulationReport, which handles hardware emulation report, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are fixed_point_scale: the real-value spacing represented by one quantized integer step.

Line 36: `input_scale: float` Inside the class HardwareEmulationReport, which handles hardware emulation report, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are input_scale: the real-value spacing represented by one quantized integer step; float: the value named 'float' in this block.

Line 37: `input_zero_point: int` Inside the class HardwareEmulationReport, which handles hardware emulation report, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are input_zero_point: the integer code representing real numeric zero in affine quantization.

Line 38: `head_activation_scale: float` Inside the class HardwareEmulationReport, which handles hardware emulation report, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are head_activation_scale: an input feature value consumed by a neuron or multiply-accumulate operation; float: the value named 'float' in this block.

Line 39: `head_accumulator_scale: float` Inside the class HardwareEmulationReport, which handles hardware emulation report, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are head_accumulator_scale: a widened running sum that prevents intermediate overflow; float: the value named 'float' in this block.

Line 40: `weight_granularity: WeightGranularity` Inside the class HardwareEmulationReport, which handles hardware emulation report, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are weight_granularity: a learned coefficient multiplied by an activation; WeightGranularity: a learned coefficient multiplied by an activation.

Line 41: `quantized_weights: tuple[QuantizedWeight, ...]` Inside the class HardwareEmulationReport, which handles hardware emulation report, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are quantized_weights: a learned coefficient multiplied by an activation; tuple: the value named 'tuple' in this block; QuantizedWeight: a learned coefficient multiplied by an activation.

Line 43: `def as_dict(self) -> dict[str, object]:` This starts function as_dict. Its indented body performs as dict as part of the file that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 44: `result = asdict(self)` This assigns ‘asdict(self)‘ to ‘result ‘ in host memory. Here result means the value named 'result' in this block. The important operands are asdict: the value named 'asdict' in this block. Context: the function as_dict, which handles as dict.

Line 45: `result["quantized_weights"] = [asdict(item) for item in self.quantized_weights]` Inside the function as_dict, which handles as dict, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are result: the value named 'result' in this block; quantized_weights: a learned coefficient multiplied by an activation; asdict: the value named 'asdict' in this block.

Line 46: `return result` This returns ‘result‘ to the caller of the function as_dict, which handles as dict, ending this invocation. The important operands are result: the value named 'result' in this block.

Line 49: `class FixedPointHardResetLIF(MultiStepHardResetLIF):` This defines class FixedPointHardResetLIF, which groups data and methods for fixed point hard reset lif. Instances exist in host memory and organize the flow that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 50: `"""Bit-exact model of "neuraedge_lif_bank" for one logical vector.` This is executable documentation attached to the class FixedPointHardResetLIF, which handles fixed point hard reset lif. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 52: `The RTL first leaks "v" by "v - (v >>> 1)" and then adds a signed` Inside the class FixedPointHardResetLIF which handles fixed point hard reset lif, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are The: the value named 'the' in this block; RTL: the value named 'rtl' in this block; first: the value named 'first' in this block.

Line 53: `16-bit current. Supplying "x >>> 1" as that current implements the` Inside the class FixedPointHardResetL which handles fixed point hard reset lif, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are bit: the value named 'bit' in this block; current: the value named 'current' in this block; Supplying: the value named 'supplying' in this block.

Line 54: `checkpoint equation "v/2 + x/2" with deterministic integer rounding.` Inside the class FixedPointHardReset which handles fixed point hard reset lif, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are checkpoint: the value named 'checkpoint' in this block; equation: the value named 'equation' in this block; v: the value named 'v' in this block.

Line 55: `Membranes saturate to signed 24-bit values before the threshold test.` Inside the class FixedPointHardResetLIF, which handles fixed point hard reset lif, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are Membranes: the persistent LIF neuron state carrying charge between timesteps; saturate: the value named 'saturate' in this block; to: the value named 'to' in this block.

Line 56: `"""` This is executable documentation attached to the class FixedPointHardResetLIF, which handles fixed point hard reset lif. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 58: `def __init__(self, *, threshold: float, fractional_bits: int) -> None:` This starts function ___init___. Its indented body performs init as part of the file that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 59: `super().__init__(tau=2.0, threshold=threshold)` This calls 'super' with ').___init___(tau=2.0, threshold=threshold' inside the function ___init___, which handles init. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 60: `if not 0 <= fractional_bits <= 14:` This executes the following indented host-code branch only when 'not 0 <= fractional_bits <= 14' is true. The important operands are not: the value named 'not' in this block; fractional_bits: the value named 'fractional bits' in this block. Context: the function ___init___, which handles init.

Line 61: `raise ValueError("fractional_bits must keep halved current in signed 16 bits")` This rejects an invalid state by raising 'ValueError("fractional_bits must keep halved current in signed 16 bits")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 62: `self.fractional_bits = fractional_bits` This assigns 'fractional_bits' to 'self.fractional_bits ' in host memory. Here fractional_bits means the value named 'fractional bits' in this block. The important operands are fractional_bits: the value named 'fractional bits' in this block. Context: the function ___init___, which handles init.

Line 63: `self.fixed_scale = 1 << fractional_bits` This assigns '1 << fractional_bits' to 'self.fixed_scale ' in host memory. Here fixed_scale means the real-value spacing represented by one quantized integer step. The important operands are fractional_bits: the value named 'fractional bits' in this block. Context: the function ___init___, which handles init.

Line 64: `self.threshold_integer = int(round(threshold * self.fixed_scale))` This assigns 'int(round(threshold * self.fixed_scale))' to 'self.threshold_integer ' in host memory. Here threshold_integer means the membrane level at which a neuron emits a spike. The important operands are round: the value named 'round' in this block; threshold: the membrane level at which a neuron emits a spike; fixed_scale: the real-value spacing represented by one quantized integer step. Context: the function ___init___, which handles init.

Line 66: `def forward(self, sequence: torch.Tensor) -> torch.Tensor:` This starts function forward. Its indented body performs forward as part of the file that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 67: `input_integer = torch.round(sequence * self.fixed_scale).to(torch.int64)` This assigns 'torch.round(sequer * self.fixed_scale).to(torch.int64)' to 'input_integer ' in host memory. Here input_integer means the value named 'input integer' in this block. The important operands are torch: the value named 'torch' in this block; round: the value named 'round' in this block; sequence: the value named 'sequence' in this block. Context: the function forward, which handles forward.

Line 68: `voltage = torch.zeros_like(input_integer[0])` This assigns 'torch.zeros_like(input_integer[0])' to 'voltage ' in host memory. Here voltage means the value named 'voltage' in this block. The important operands are torch: the value named 'torch' in this block; zeros_like: the value named 'zeros like' in this block; input_integer: the value named 'input integer' in this block. Context: the function forward, which handles forward.

Line 69: `spikes: list[torch.Tensor] = []` This assigns '[]' to 'spikes' in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the function forward, which handles forward.

Line 70: `minimum_membrane = -(1 << 23)` This assigns '-(1 << 23)' to 'minimum_membrane ' in host memory. Here minimum_membrane means the persistent LIF neuron state carrying charge between timesteps. The expression is a literal or structural operator and has no hidden software state. Context: the function forward, which handles forward.

Line 71: `maximum_membrane = (1 << 23) - 1` This assigns '(1 << 23) - 1' to 'maximum_membrane ' in host memory. Here maximum_membrane means the persistent LIF neuron state carrying charge between timesteps. The expression is a literal or structural operator and has no hidden software state. Context: the function forward, which handles forward.

Line 72: `for timestep in range(input_integer.shape[0]):` This iterates timestep over 'range(input_integer.shape[0])'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function forward, which handles forward.

Line 73: `current = torch.bitwise_right_shift(input_integer[timestep], 1)` This assigns 'torch.bitwise_right_shift(inp 1)' to 'current ' in host memory. Here current means the value named 'current' in this block. The important operands are torch: the value named 'torch' in this block; bitwise_right_shift: the value named 'bitwise right shift' in this block; input_integer: the value named 'input integer' in this block. Context: the function forward, which handles forward.

Line 74: `current = current.clamp(-(1 << 15), (1 << 15) - 1)` This assigns 'current.clamp(-(1 << 15), (1 << 15) - 1)' to 'current ' in host memory. Here current means the value named 'current' in this block. The important operands are current: the value named 'current' in this block; clamp: the value named 'clamp' in this block. Context: the function forward, which handles forward.

Line 75: `leaked = voltage - torch.bitwise_right_shift(voltage, 1)` This assigns ‘voltage - torch.bitwise_right_shift(vol 1)‘ to ‘leaked ‘ in host memory. Here leaked means the retained fraction of prior membrane state. The important operands are voltage: the value named ’voltage’ in this block; torch: the value named ’torch’ in this block; bitwise_right_shift: the value named ’bitwise right shift’ in this block. Context: the function forward, which handles forward.

Line 76: `voltage = (leaked + current).clamp(minimum_membrane, maximum_membrane)` This assigns ‘(leaked + current).clamp(minimum_membrane, maximum_membrane)‘ to ‘voltage ‘ in host memory. Here voltage means the value named ’voltage’ in this block. The important operands are leaked: the retained fraction of prior membrane state; current: the value named ’current’ in this block; clamp: the value named ’clamp’ in this block. Context: the function forward, which handles forward.

Line 77: `spike = voltage >= self.threshold_integer` Inside the function forward, which handles forward, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are spike: a binary event produced when a neuron crosses its threshold; voltage: the value named ’voltage’ in this block; threshold_integer: the membrane level at which a neuron emits a spike.

Line 78: `voltage = torch.where(spike, torch.zeros_like(voltage), voltage)` This assigns ‘torch.where(spike, torch.zeros_like(voltage), voltage)‘ to ‘voltage ‘ in host memory. Here voltage means the value named ’voltage’ in this block. The important operands are torch: the value named ’torch’ in this block; where: the value named ’where’ in this block; spike: a binary event produced when a neuron crosses its threshold. Context: the function forward, which handles forward.

Line 79: `spikes.append(spike.to(sequence.dtype))` This calls ‘spikes.append‘ with ‘spike.to(sequence.dtype)‘ inside the function forward, which handles forward. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 80: `return torch.stack(spikes, dim=0)` This returns ‘torch.stack(spikes, dim=0)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are torch: the value named ’torch’ in this block; stack: the value named ’stack’ in this block; spikes: a binary event produced when a neuron crosses its threshold.

Line 83: `def quantize_cifar_input_u8(image: torch.Tensor) -> tuple[torch.Tensor, float, int]:` This starts function quantize_cifar_input_u8. Its indented body performs quantize cifar input u8 as part of the file that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 84: `"""Quantize the complete legal normalized CIFAR-10 input domain to uint8."""` This is executable documentation attached to the function quantize_cifar_input_u8, which handles quantize cifar input u8. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 86: `mean = torch.tensor((0.4914, 0.4822, 0.4465), device=image.device)` This assigns ‘torch.tensor((0.4914, 0.4822, 0.4465), device=image.device)‘ to ‘mean ‘ in host memory. Here mean means the arithmetic average used by normalization. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block; device: the value named ’device’ in this block. Context: the function quantize_cifar_input_u8, which handles quantize cifar input u8.

Line 87: `standard_deviation = torch.tensor((0.2470, 0.2435, 0.2616), device=image.device)` This assigns ‘torch.tensor((0.2470, 0.2435, 0.2616), device=image.device)‘ to ‘standard_deviation ‘ in host memory. Here standard_deviation means the value named ’standard deviation’ in this block. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block; device: the value named ’device’ in this block. Context: the function quantize_cifar_input_u8, which handles quantize cifar input u8.

Line 88: `minimum = float(torch.min(-mean / standard_deviation).cpu())` This assigns ‘float(torch.min(-mean / standard_deviation).cpu())‘ to ‘minimum ‘ in host memory. Here minimum means the value named ’minimum’ in this block. The important operands are float: the value named ’float’ in this block; torch: the value named ’torch’ in this block; min: the value named ’min’ in this block. Context: the function quantize_cifar_input_u8, which handles quantize cifar input u8.

Line 89: `maximum = float(torch.max((1.0 - mean) / standard_deviation).cpu())` This assigns ‘float(torch.max((1.0 - mean) / standard_deviation).cpu())‘ to ‘maximum ‘ in host memory. Here maximum means the value named ’maximum’ in this block. The important operands are float: the value named ’float’ in this block; torch: the value named ’torch’ in this block; max: the value named ’max’ in this block. Context: the function quantize_cifar_input_u8, which handles quantize cifar input u8.

Line 90: `scale = (maximum - minimum) / 255.0` This assigns ‘(maximum - minimum) / 255.0‘ to ‘scale ‘ in host memory. Here scale means the real-value spacing represented by one quantized integer step. The important operands are maximum: the value named ’maximum’ in this block; minimum: the value named ’minimum’ in this block. Context: the function quantize_cifar_input_u8, which handles quantize cifar input u8.

Line 91: `zero_point = int(round(-minimum / scale))` This assigns ‘int(round(-minimum / scale))‘ to ‘zero_point ‘ in host memory. Here zero_point means the integer code representing real numeric zero in affine quantization. The important operands are round: the value named ’round’ in this block; minimum: the value named ’minimum’ in this block; scale: the real-value spacing represented by one quantized integer step. Context: the function quantize_cifar_input_u8, which handles quantize cifar input u8.

Line 92: `integer = torch.round(image / scale + zero_point).clamp(0, 255)` This assigns ‘torch.round(image / scale + zero_point).clamp(0, 255)‘ to ‘integer ‘ in host memory. Here integer means the value named ’integer’ in this block. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; image: the value named ’image’ in this block. Context: the function quantize_cifar_input_u8, which handles quantize cifar input u8.

Line 93: `return (integer - zero_point) * scale, scale, zero_point` This returns ‘(integer - zero_point) * scale, scale, zero_point‘ to the caller of the function quantize_cifar_input_u8, which handles quantize cifar input u8, ending this invocation. The important operands are integer: the value named ’integer’ in this block; zero_point: the integer code representing real numeric zero in affine quantization; scale: the real-value spacing represented by one quantized integer step.

Line 96: `def fake_fixed_point(value: torch.Tensor, fractional_bits: int) -> torch.Tensor:` This starts function fake_fixed_point. Its indented body performs fake fixed point as part of the file that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 97: `"""Round and saturate an analog activation to signed 24-bit fixed point."""` This is executable documentation attached to the function fake_fixed_point, which handles fake fixed point. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 99: `scale = 1 << fractional_bits` This assigns ‘1 << fractional_bits‘ to ‘scale ‘ in host memory. Here scale means the real-value spacing represented by one quantized integer step. The important operands are fractional_bits: the value named ’fractional bits’ in this block. Context: the function fake_fixed_point, which handles fake fixed point.

Line 100: `integer = torch.round(value * scale).clamp(-(1 << 23), (1 << 23) - 1)` This assigns ‘torch.round(value * scale).clamp(-(1 << 23), (1 << 23) - 1)‘ to ‘integer ‘ in host memory. Here integer means the value named ’integer’ in this block. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; value: the value named ’value’ in this block. Context: the function fake_fixed_point, which handles fake fixed point.

Line 101: `return integer / scale` This returns ‘integer / scale‘ to the caller of the function fake_fixed_point, which handles fake fixed point, ending this invocation. The important operands are integer: the value named ’integer’ in this block; scale: the real-value spacing represented by one quantized integer step.

Line 104: `def prepare_hardware_emulation(` This starts function prepare_hardware_emulation. Its indented body performs prepare hardware emulation as part of the file that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 105: `model: Spikingformer,` Inside the function prepare_hardware_emulation, which handles prepare hardware emulation, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are model: the value named ’model’ in this block; Spikingformer: the value named ’spikingformer’ in this block.

Line 106: `*,` Inside the function prepare_hardware_emulation, which handles prepare hardware emulation, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The expression is a literal or structural operator and has no hidden software state.

Line 107: `fractional_bits: int = 10,` This assigns ‘10,‘ to ‘fractional_bits‘ in host memory. Here fractional_bits means the value named ’fractional bits’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 108: `weight_granularity: WeightGranularity = "tensor",` This assigns ‘"tensor",‘ to ‘weight_granularity‘ in host memory. Here weight_granularity means a learned coefficient multiplied by an activation. The important operands are tensor: the value named ’tensor’ in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 109: `head_activation_scale: float = 0.125,` This assigns ‘0.125,‘ to ‘head_activation_scale‘ in host memory. Here head_activation_scale means an input feature value consumed by a neuron or multiply-accumulate operation. The expression is a literal or structural operator and has no hidden software state. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 110: `) -> tuple[Spikingformer, HardwareEmulationReport]:` Inside the function prepare_hardware_emulation, which handles prepare hardware emulation, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are tuple: the value named ’tuple’ in this block; Spikingformer: the value named ’spikingformer’ in this block; HardwareEmulationReport: the value named ’hardware emulation report’ in this block.

Line 111: `"""Clone a trained model and apply the arithmetic supported by the RTL.` This is executable documentation attached to the function prepare_hardware_emulation, which handles prepare hardware emulation. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 113: `Conv/linear weights become signed int8 and are immediately dequantized for` Inside the function prepare_hardware_emulation, which handles prepare hardware emulation, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are Conv: the value named ’conv’ in this block; linear: the value named ’linear’ in this block; weights: a learned coefficient multiplied by an activation.

Line 114: `PyTorch execution. This is algebraically equivalent to an int32 hardware` Inside the function prepare_hardware_emulation, which handles prepare hardware emulation, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are PyTorch: the value named ’py torch’ in this block; execution: the value named ’execution’ in this block; This: the value named ’this’ in this block.

Line 115: `accumulator followed by its recorded scale. BatchNorm outputs are rounded` Inside the function prepare_hardware_emulation, which handles prepare hardware emulation, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are accumulator: a widened running sum that prevents intermediate overflow; followed: the value named 'followed' in this block; by: the value named 'by' in this block.

Line 116: `to the common signed fixed-point format used by residuals and LIF neurons.` Inside the function prepare_hardware_emulation, which handles prepare hardware emulation, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are to: the value named 'to' in this block; the: the value named 'the' in this block; common: the value named 'common' in this block.

Line 117: `"""` This is executable documentation attached to the function prepare_hardware_emulation, which handles prepare hardware emulation. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 119: `if weight_granularity not in {"tensor", "channel"}:` This executes the following indented host-code branch only when 'weight_granularity not in {"tensor", "channel"}' is true. The important operands are weight_granularity: a learned coefficient multiplied by an activation; not: the value named 'not' in this block; in: the value named 'in' in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 120: `raise ValueError("weight_granularity must be tensor or channel")` This rejects an invalid state by raising 'ValueError("weight_granularity must be tensor or channel")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 121: `if not 0 <= fractional_bits <= 14:` This executes the following indented host-code branch only when 'not 0 <= fractional_bits <= 14' is true. The important operands are not: the value named 'not' in this block; fractional_bits: the value named 'fractional bits' in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 122: `raise ValueError("fractional_bits must be in [0, 14]")` This rejects an invalid state by raising 'ValueError("fractional_bits must be in [0, 14]")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 123: `if head_activation_scale <= 0.0:` This executes the following indented host-code branch only when 'head_activation_scale <= 0.0' is true. The important operands are head_activation_scale: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 124: `raise ValueError("head_activation_scale must be positive")` This rejects an invalid state by raising 'ValueError("head_activation_scale must be positive")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 125: `quantized_model = copy.deepcopy(model).eval()` This assigns 'copy.deepcopy(model).eval()' to 'quantized_model ' in host memory. Here quantized_model means the value named 'quantized model' in this block. The important operands are copy: the value named 'copy' in this block; deepcopy: the value named 'deepcopy' in this block; model: the value named 'model' in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 126: `weight_reports: list[QuantizedWeight] = []` This assigns '[]' to 'weight_reports' in host memory. Here weight_reports means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 127: `weight_scales: dict[str, torch.Tensor] = {}` This assigns '{}' to 'weight_scales' in host memory. Here weight_scales means a learned coefficient multiplied by an activation. The expression is a literal or structural operator and has no hidden software state. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 129: `for name, module in quantized_model.named_modules():` This iterates name, module over 'quantized_model.nam Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 130: `if not isinstance(module, (nn.Conv1d, nn.Conv2d, nn.Linear)):` This executes the following indented host-code branch only when 'not isinstance(module, (nn.Conv1d, nn.Conv2d, nn.Linear))' is true. The important operands are not: the value named 'not' in this block; isinstance: the value named 'isinstance' in this block; module: the value named 'module' in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 131: `continue` Inside the function prepare_hardware_emulation, which handles prepare hardware emulation, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are continue: the value named 'continue' in this block.

Line 132: `weight = module.weight.detach()` This assigns 'module.weight.detach()' to 'weight ' in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are module: the value named 'module' in this block; weight: a learned coefficient multiplied by an activation; detach: the value named 'detach' in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 133: `if weight_granularity == "channel":` This executes the following indented host-code branch only when 'weight_granularity == "channel"' is true. The important operands are weight_granularity: a learned coefficient multiplied by an activation; channel: the value named 'channel' in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 134: `dimensions = tuple(range(1, weight.ndim))` This assigns 'tuple(range(1, weight.ndim))' to 'dimensions ' in host memory. Here dimensions means the value named 'dimensions' in this block. The important operands are tuple: the value named 'tuple' in this block; range: the value named 'range' in this block; weight: a learned coefficient multiplied by an activation. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 135: `maximum = weight.abs().amax(dim=dimensions, keepdim=True)` This assigns 'weight.abs().amax(dim=dimensions keepdim=True)' to 'maximum ' in host memory. Here maximum means the value named 'maximum' in this block. The important operands are weight: a learned coefficient multiplied by an activation; abs: the value named 'abs' in this block; amax: the value named 'amax' in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 136: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 137: `maximum = weight.abs().amax().reshape((1,) * weight.ndim)` This assigns 'weight.abs().amax().reshape((1,) * weight.ndim)' to 'maximum ' in host memory. Here maximum means the value named 'maximum' in this block. The important operands are weight: a learned coefficient multiplied by an activation; abs: the value named 'abs' in this block; amax: the value named 'amax' in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 138: `scale = torch.where(maximum > 0, maximum / 127.0, torch.ones_like(maximum))` This assigns 'torch.where(m > 0, maximum / 127.0, torch.ones_like(maximum))' to 'scale ' in host memory. Here scale means the real-value spacing represented by one quantized integer step. The important operands are torch: the value named 'torch' in this block; where: the value named 'where' in this block; maximum: the value named 'maximum' in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 139: `integer = torch.round(weight / scale).clamp(-127, 127)` This assigns ‘torch.round(weight / scale).clamp(-127, 127)‘ to ‘integer ‘ in host memory. Here integer means the value named ’integer’ in this block. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; weight: a learned coefficient multiplied by an activation. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 140: `dequantized = integer * scale` This assigns ‘integer * scale‘ to ‘dequantized ‘ in host memory. Here dequantized means the value named ’dequantized’ in this block. The important operands are integer: the value named ’integer’ in this block; scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 141: `error = (dequantized - weight).abs()` This assigns ‘(dequantized - weight).abs()‘ to ‘error ‘ in host memory. Here error means the value named ’error’ in this block. The important operands are dequantized: the value named ’dequantized’ in this block; weight: a learned coefficient multiplied by an activation; abs: the value named ’abs’ in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 142: `module.weight.data.copy_(dequantized)` This calls ‘module.weight.data.copy_‘ with ‘dequantized‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 143: `weight_scales[name] = scale.detach().reshape(-1)` This assigns ‘scale.detach().reshape(-1)‘ to ‘weight_scales[na‘ in host memory. Here weight_scales means a learned coefficient multiplied by an activation. The important operands are scale: the real-value spacing represented by one quantized integer step; detach: the value named ’detach’ in this block; reshape: the value named ’reshape’ in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 144: `weight_reports.append(QuantizedWeight(` This statement continues through source line 154; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘weight_reports.append‘ with ‘QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.ami integer_maximum=int(integer.amax().item()), scale_minimum=float(scale.amin().item()), scale_maximum=float(scale.amax().ite mean_absolute_error=float(error.mean().item()), maximum_absolute_error=float(error.amax().item()),)‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 145: `module=name,` This is continuation line 2 of the 11-line logical statement that begins at source line 144. Its exact fragment is ‘module=name,‘. The important operands are module: the value named ’module’ in this block; name: the value named ’name’ in this block. Read together, the complete operation is: This calls ‘weight_reports.append‘ with ‘QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.ami integer_maximum=int(integer.amax().item()), scale_minimum=float(scale.amin().item()), scale_maximum=float(scale.amax().ite mean_absolute_error=float(error.mean().item()), maximum_absolute_error=float(error.amax().item()),)‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 146: `shape=tuple(weight.shape),` This is continuation line 3 of the 11-line logical statement that begins at source line 144. Its exact fragment is ‘shape=tuple(weight.shape),‘. The important operands are shape: the value named ’shape’ in this block; tuple: the value named ’tuple’ in this block; weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls ‘weight_reports.append‘ with ‘QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.amin().item()), integer_maximum=int(integer.amax().item()), scale_minimum=float(scale.amin().item()), scale_maximum=float(scale.amax().ite mean_absolute_error=float(error.mean().item()), maximum_absolute_error=float(error.amax().item()),)‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 147: `granularity=weight_granularity,` This is continuation line 4 of the 11-line logical statement that begins at source line 144. Its exact fragment is 'granularity=weight_granularity,'. The important operands are granularity: the value named 'granularity' in this block; weight_granularity: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls 'weight_reports.append' with 'QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.amin().item()), integer_maximum=int(integer.amax().item()), scale_minimum=float(scale.amin().item()), scale_maximum=float(scale.amax().ite mean_absolute_error=float(error.mean().item()), maximum_absolute_error=float(error.amax().item()),)' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 148: `integer_minimum=int(integer.amin().item()),` This is continuation line 5 of the 11-line logical statement that begins at source line 144. Its exact fragment is 'integer_minimum=int(integer.amin().item()),'. The important operands are integer_minimum: the value named 'integer minimum' in this block; integer: the value named 'integer' in this block; amin: the value named 'amin' in this block. Read together, the complete operation is: This calls 'weight_reports.append' with 'QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.amin().item()), integer_maximum=int(integer.amax().item()), scale_minimum=float(scale.amin().i scale_maximum=float(scale.amax().item()), mean_absolute_error=float(error.mean().item()), maximum_absolute_error=float(er)' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 149: `integer_maximum=int(integer.amax().item()),` This is continuation line 6 of the 11-line logical statement that begins at source line 144. Its exact fragment is 'integer_maximum=int(integer.amax().item()),'. The important operands are integer_maximum: the value named 'integer maximum' in this block; integer: the value named 'integer' in this block; amax: the value named 'amax' in this block. Read together, the complete operation is: This calls 'weight_reports.append' with 'QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.amin().item()), integer_maximum=int(integer.amax().item()), scale_minimum=float(scale.amin().i scale_maximum=float(scale.amax().item()), mean_absolute_error=float(error.mean().item()), maximum_absolute_error=float(er)' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 150: `scale_minimum=float(scale.amin().item()),` This is continuation line 7 of the 11-line logical statement that begins at source line 144. Its exact fragment is 'scale_minimum=float(scale.amin().item()),'. The important operands are scale_minimum: the real-value spacing represented by one quantized integer step; float: the value named 'float' in this block; scale: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This calls 'weight_reports.append' with 'QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.amin().item()), integer_maximum=int(integer.amax().item()), scale_minimum=float(scale.amin().item()), scale_maximum=float(scale.amax().item()), mean_absolute_error=float(error.mean() maximum_absolute_error=float(error.amax().item()),)' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 151: `scale_maximum=float(scale.amax().item()),` This is continuation line 8 of the 11-line logical statement that begins at source line 144. Its exact fragment is 'scale_maximum=float(scale.amax().item()),'. The important operands are scale_maximum: the real-value spacing represented by one quantized integer step; float: the value named 'float' in this block; scale: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This calls 'weight_reports.append' with 'QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.amin().item()), integer_maximum=int(integer.amax().item()), scale_minimum=float(scale.amin().item()), scale_maximum=float(scale.amax().item()), mean_absolute_error=float(error.mean() maximum_absolute_error=float(error.amax().item()),)' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 152: `mean_absolute_error=float(error.mean().item()),` This is continuation line 9 of the 11-line logical statement that begins at source line 144. Its exact fragment is 'mean_absolute_error=float(error.mean().item()),'. The important operands are mean_absolute_error: the arithmetic average used by normalization; float: the value

named 'float' in this block; error: the value named 'error' in this block. Read together, the complete operation is: This calls ‘weight_reports.append‘ with ‘QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.amin().item()), integer_maximum=int(integer.amax().item()), scale_minim scale_maximum=float(scale.amax().item()), mean_absolute_error=float(error.mean().item()), maximum_absolute_error=float(e)‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 153: `maximum_absolute_error=float(error.amax().item()),` This is continuation line 10 of the 11-line logical statement that begins at source line 144. Its exact fragment is ‘maximum_absolute_error=float(error.amax().item()),‘. The important operands are maximum_absolute_error: the value named 'maximum absolute error' in this block; float: the value named 'float' in this block; error: the value named 'error' in this block. Read together, the complete operation is: This calls ‘weight_reports.append‘ with ‘QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.amin().item()), integer_maximum=int(integer.amax().item()), scale_minim scale_maximum=float(scale.amax().item()), mean_absolute_error=float(error.mean().item()), maximum_absolute_error=float(e)‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 154: `))` This is continuation line 11 of the 11-line logical statement that begins at source line 144. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘weight_reports.append‘ with ‘QuantizedWeight(module=name, shape=tuple(weight.shape), granularity=weight_granularity, integer_minimum=int(integer.amin().item()), integer_maximum=int(integer.amax().item()), scale_minimum=float(scale.amin().item()), scale_maximum=float(scale.amax().item()), mean_absolute_error=float(error.mean() maximum_absolute_error=float(error.amax().item()),)‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 156: `_replace_lif_modules(quantized_model, fractional_bits)` This calls ‘_replace_lif_modules‘ with ‘quantized_model, fractional_bits‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 157: `_install_projection_requantizers(` This statement continues through source line 162; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘_install_projection_requantizers‘ with ‘ quantized_model, weight_scales, fractional_bits=fractional_bits, image_input_scale=input_scale_from_domain(), ‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 158: `quantized_model,` This is continuation line 2 of the 6-line logical statement that begins at source line 157. Its exact fragment is ‘quantized_model,‘. The important operands are quantized_model: the value named 'quantized model' in this block. Read together, the complete operation is: This calls ‘_install_projection_requantizers‘ with ‘ quantized_model, weight_scales, fractional_bits=fractional_bits, image_input_scale=input_scale_from_domain(), ‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 159: `weight_scales,` This is continuation line 3 of the 6-line logical statement that begins at source line 157. Its exact fragment is ‘weight_scales,‘. The important operands are weight_scales: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls ‘_install_projection_requantizers‘ with ‘ quantized_model, weight_scales, fractional_bits=fractional_bits, image_input_scale=input_scale_from_domain(), ‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 160: `fractional_bits=fractional_bits,` This is continuation line 4 of the 6-line logical statement that begins at source line 157. Its exact fragment is 'fractional_bits=fractional_bits,'. The important operands are fractional_bits: the value named 'fractional bits' in this block. Read together, the complete operation is: This calls '_install_projection_requantizers' with ' quantized_model, weight_scales, fractional_bits=fractional_bits, image_input_scale=input_ ' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 161: `image_input_scale=input_scale_from_domain(),` This is continuation line 5 of the 6-line logical statement that begins at source line 157. Its exact fragment is 'image_input_scale=input_scale_from_domain(),'. The important operands are image_input_scale: the real-value spacing represented by one quantized integer step; input_scale_from_domain: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This calls '_install_projection_requantizers' with ' quantized_model, weight_scales, fractional_bits=fractional_bits, image_input_scale=input_scale_from_domain(), ' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 162: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 157. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls '_install_projection_requantizers' with ' quantized_model, weight_scales, fractional_bits=fractional_bits, image_input_scale=input_scale_from_domain(), ' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 163: `quantized_model.head.register_forward_pre_hook(` This statement continues through source line 166; the explanation uses the complete expression rather than only the first visual fragment. This calls 'quantized_model.head.register_fo with ' lambda _module, inputs, scale=head_activation_scale: (torch.round(inputs[0] / scale).clamp(-128, 127) * scale,)' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 164: `lambda _module, inputs, scale=head_activation_scale: (` This is continuation line 2 of the 4-line logical statement that begins at source line 163. Its exact fragment is 'lambda _module, inputs, scale=head_activation_scale: ('. The important operands are lambda: the value named 'lambda' in this block; _module: the value named 'module' in this block; inputs: the value named 'inputs' in this block. Read together, the complete operation is: This calls 'quantized_model.head.register_forward_pre_hook' with ' lambda _module, inputs, scale=head_activation_scale: (torch.round(inputs[0] / scale).clamp(-128, 127) * scale,)' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 165: `torch.round(inputs[0] / scale).clamp(-128, 127) * scale,` This is continuation line 3 of the 4-line logical statement that begins at source line 163. Its exact fragment is 'torch.round(inputs[0] / scale).clamp(-128, 127) * scale,'. The important operands are torch: the value named 'torch' in this block; round: the value named 'round' in this block; inputs: the value named 'inputs' in this block. Read together, the complete operation is: This calls 'quantized_model.head.register_forward_pre_hook' with ' lambda _module, inputs, scale=head_activation_scale: (torch.round(inputs[0] / scale).clamp(-128, 127) * scale,)' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 166: `))` This is continuation line 4 of the 4-line logical statement that begins at source line 163. Its exact fragment is '))'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls 'quantized_model.head.register_forward_pre_hook' with ' lambda _module, inputs, scale=head_activation_scale: (torch.round(inputs[0] / scale).clamp(-128, 127) * scale,)' inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 167: `head_weight_scale = float(quantized_model.head.weight.detach().abs().amax().item()) / 127.0` This assigns ‘float(quantized_model.head.weight.detach().abs().amax().item()) / 127.0‘ to ‘head_weight_scale ‘ in host memory. Here head_weight_scale means a learned coefficient multiplied by an activation. The important operands are float: the value named ’float’ in this block; quantized_model: the value named ’quantized model’ in this block; head: the value named ’head’ in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 168: `head_accumulator_scale = head_activation_scale * head_weight_scale` This assigns ‘head_activation_scale * head_weight_scale‘ to ‘head_accumulator_scale ‘ in host memory. Here head_accumulator_scale means a widened running sum that prevents intermediate overflow. The important operands are head_activation_scale: an input feature value consumed by a neuron or multiply-accumulate operation; head_weight_scale: a learned coefficient multiplied by an activation. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 169: `if quantized_model.head.bias is not None:` This executes the following indented host-code branch only when ‘quantized_model.head.bias is not None‘ is true. The important operands are quantized_model: the value named ’quantized model’ in this block; head: the value named ’head’ in this block; bias: an additive learned offset applied after accumulation. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 170: `quantized_model.head.bias.data.copy_(` This statement continues through source line 172; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘quantized_model.head.bias.data.copy_‘ with ‘ torch.round(quantized_model.head.bias.detach() / head_accumulator_scale) * head_accumulator_scale‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 171: `torch.round(quantized_model.head.bias.detach() / head_accumulator_scale)` This is continuation line 2 of the 3-line logical statement that begins at source line 170. Its exact fragment is ‘torch.round(quantized_model.head.bias.deta / head_accumulator_scale)‘. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; quantized_model: the value named ’quantized model’ in this block. Read together, the complete operation is: This calls ‘quantized_model.head.bias.data.copy_‘ with ‘ torch.round(quantized_model.head.bias.detach() / head_accumulator_scale) * head_accumulator_scale‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 172: `* head_accumulator_scale)` This is continuation line 3 of the 3-line logical statement that begins at source line 170. Its exact fragment is ‘* head_accumulator_scale)‘. The important operands are head_accumulator_scale: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This calls ‘quantized_model.head.bias.data.copy_‘ with ‘ torch.round(quantized_model.head.bias.detach() / head_accumulator_scale) * head_accumulator_scale‘ inside the function prepare_hardware_emulation, which handles prepare hardware emulation. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 174: `input_probe = torch.zeros(1, 3, 1, 1)` This assigns ‘torch.zeros(1, 3, 1, 1)‘ to ‘input_probe ‘ in host memory. Here input_probe means the value named ’input probe’ in this block. The important operands are torch: the value named ’torch’ in this block; zeros: the value named ’zeros’ in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 175: `_, input_scale, input_zero_point = quantize_cifar_input_u8(input_probe)` This assigns ‘quantize_cifar_input_u8(input_probe)‘ to ‘_, input_scale, input_zero_point ‘ in host memory. Here _ means the value named ” in this block. The important operands are quantize_cifar_input_u8: the value named ’quantize cifar input u8’ in this block; input_probe: the value named ’input probe’ in this block. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 176: `report = HardwareEmulationReport(` This statement continues through source line 185; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘HardwareEmulationReport(fractional_bits=fractional_bits, fixed_point_scale=1 << fractional_bits, input_scale=input_scale, input_zero_point=input_zero_p

head_activation_scale=head_activation_scale, head_accumulator_scale=head_accumulator_scale, weight_granularity=weight_
quantized_weights=tuple(weight_reports),)‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are HardwareEmulationReport: the value named ’hardware emulation report’ in this block; fractional_bits: the value named ’fractional bits’ in this block; fixed_point_scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 177: `fractional_bits=fractional_bits,` This is continuation line 2 of the 10-line logical statement that begins at source line 176. Its exact fragment is ‘fractional_bits=fractional_bits,‘. The important operands are fractional_bits: the value named ’fractional bits’ in this block. Read together, the complete operation is: This assigns ‘HardwareEmulationReport(fractional_bits=fractional_bits, fixed_point_scale=1 << fractional_bits, input_scale=input_scale, input_zero_point=input_zero_point, head_activation_scale=head_activation_scale, head_accumulator_scale=head_accumulato
weight_granularity=weight_granularity, quantized_weights=tuple(weight_reports),)‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are HardwareEmulationReport: the value named ’hardware emulation report’ in this block; fractional_bits: the value named ’fractional bits’ in this block; fixed_point_scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 178: `fixed_point_scale=1 << fractional_bits,` This is continuation line 3 of the 10-line logical statement that begins at source line 176. Its exact fragment is ‘fixed_point_scale=1 << fractional_bits,‘. The important operands are fixed_point_scale: the real-value spacing represented by one quantized integer step; fractional_bits: the value named ’fractional bits’ in this block. Read together, the complete operation is: This assigns ‘HardwareEmulationReport(fractional_bits=fractional_bits, fixed_point_scale=1 << fractional_bits, input_scale=input_scale, input_zero_point=input_zero_point, head_activation_scale=head_activation_scale, head_accumulator_scale=head_accumulato
weight_granularity=weight_granularity, quantized_weights=tuple(weight_reports),)‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are HardwareEmulationReport: the value named ’hardware emulation report’ in this block; fractional_bits: the value named ’fractional bits’ in this block; fixed_point_scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 179: `input_scale=input_scale,` This is continuation line 4 of the 10-line logical statement that begins at source line 176. Its exact fragment is ‘input_scale=input_scale,‘. The important operands are input_scale: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This assigns ‘HardwareEmulationReport(fractional_bits=fractional_bits, fixed_point_scale=1 << fractional_bits, input_scale=input_scale, input_zero_point=input_zero_point, head_activation_scale=head_activation_scale, head_accumulator_scale=head_accumulato
weight_granularity=weight_granularity, quantized_weights=tuple(weight_reports),)‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are HardwareEmulationReport: the value named ’hardware emulation report’ in this block; fractional_bits: the value named ’fractional bits’ in this block; fixed_point_scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 180: `input_zero_point=input_zero_point,` This is continuation line 5 of the 10-line logical statement that begins at source line 176. Its exact fragment is ‘input_zero_point=input_zero_point,‘. The important operands are input_zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This assigns ‘HardwareEmulationReport(fractional_bits=fractional_bits, fixed_point_scale=1 << fractional_bits, input_scale=input_scale, input_zero_point=input_zero_point, head_activation_scale=head_activation_scale, head_accumulator_scale=head_accumulator_scale, weight_granularity=weight_granularity, quantized_weights=tuple(weight_re
)‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are HardwareEmulationReport: the value named ’hardware emulation report’ in this block; fractional_bits: the value named ’fractional bits’ in this block; fixed_point_scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 181: `head_activation_scale=head_activation_scale,` This is continuation line 6 of the 10-line logical statement that begins at source line 176. Its exact fragment is ‘head_activation_scale=head_activation_scale,‘. The important operands are head_activation_scale: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This assigns ‘HardwareEmulationReport(fractional_bits=fractional_bits, fixed_point_scale=1 << fractional_bits, input_scale=input_scale, input_zero_point=input_zero_point, head_activation_scale=

head_accumulator_scale=head_accumulator_scale, weight_granularity=weight_granularity, quantized_weights=tuple(weight_re)‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are HardwareEmulationReport: the value named ’hardware emulation report’ in this block; fractional_bits: the value named ’fractional bits’ in this block; fixed_point_scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 182: `head_accumulator_scale=head_accumulator_scale,` This is continuation line 7 of the 10-line logical statement that begins at source line 176. Its exact fragment is ‘head_accumulator_scale=head_accumulator_scale,‘. The important operands are head_accumulator_scale: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This assigns ‘HardwareEmulationReport(fractional_bits=fractional_bits, fixed_point_scale=1 << fractional_bits, input_scale=input_scale, input_zero_point=input_zero_point, head_activation_scale= head_accumulator_scale=head_accumulator_scale, weight_granularity=weight_granularity, quantized_weights=tuple(weight_re)‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are HardwareEmulationReport: the value named ’hardware emulation report’ in this block; fractional_bits: the value named ’fractional bits’ in this block; fixed_point_scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 183: `weight_granularity=weight_granularity,` This is continuation line 8 of the 10-line logical statement that begins at source line 176. Its exact fragment is ‘weight_granularity=weight_granularity,‘. The important operands are weight_granularity: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘HardwareEmulationReport(fractional_bits=fractional_bits, fixed_point_scale=1 << fractional_bits, input_scale=input_scale, input_zero_point=input_zero_point, head_activation_scale=head_activation_scale, head_accumulator weight_granularity=weight_granularity, quantized_weights=tuple(weight_reports),)‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are HardwareEmulationReport: the value named ’hardware emulation report’ in this block; fractional_bits: the value named ’fractional bits’ in this block; fixed_point_scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 184: `quantized_weights=tuple(weight_reports),` This is continuation line 9 of the 10-line logical statement that begins at source line 176. Its exact fragment is ‘quantized_weights=tuple(weight_reports),‘. The important operands are quantized_weights: a learned coefficient multiplied by an activation; tuple: the value named ’tuple’ in this block; weight_reports: a learned coefficient multiplied by an activation. Read together, the complete operation is: This assigns ‘HardwareEmulationReport(fractional_bits=fractional_bits, fixed_point_scale=1 << fractional_bits, input_scale=input_scale, input_zero_point=input_zero_point, head_activation_scale=head_activation_scale, head_accumulator weight_granularity=weight_granularity, quantized_weights=tuple(weight_reports),)‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are HardwareEmulationReport: the value named ’hardware emulation report’ in this block; fractional_bits: the value named ’fractional bits’ in this block; fixed_point_scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 185: `)` This is continuation line 10 of the 10-line logical statement that begins at source line 176. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns ‘HardwareEmulationReport(fractional_bits=fractional_bits, fixed_point_scale=1 << fractional_bits, input_scale=input_scale, input_zero_point=input_zero_point, head_activation_scale=head_activation_scale, head_accumulator_scale=head_accumulator_scale, weight_granularity=weight_granularity, quantized_weights=tuple(weight_re)‘ to ‘report ‘ in host memory. Here report means the value named ’report’ in this block. The important operands are HardwareEmulationReport: the value named ’hardware emulation report’ in this block; fractional_bits: the value named ’fractional bits’ in this block; fixed_point_scale: the real-value spacing represented by one quantized integer step. Context: the function prepare_hardware_emulation, which handles prepare hardware emulation.

Line 186: `return quantized_model, report` This returns ‘quantized_model, report‘ to the caller of the function prepare_hardware_emulation, which handles prepare hardware emulation, ending this invocation. The important operands are quantized_model: the value named ’quantized model’ in this block; report: the value named ’report’ in this block.

Line 189: `def _replace_lif_modules(module: nn.Module, fractional_bits: int) -> None:` This starts function _replace_lif_modules. Its indented body performs replace lif modules as part of the file that defines calibration,

signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 190: `for name, child in list(module.named_children()):` This iterates name, child over ‘list(module.named_children Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _replace_lif_modules, which handles replace lif modules.

Line 191: `if isinstance(child, MultiStepHardResetLIF):` This executes the following indented host-code branch only when ‘isinstance(child, MultiStepHardResetLIF)‘ is true. The important operands are isinstance: the value named ’isinstance’ in this block; child: the value named ’child’ in this block; MultiStepHardResetLIF: the value named ’multi step hard reset lif’ in this block. Context: the function _replace_lif_modules, which handles replace lif modules.

Line 192: `setattr(module, name, FixedPointHardResetLIF(` This statement continues through source line 195; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘setattr‘ with ‘module, name, FixedPointHardResetLIF(threshold=child.threshold, fractional_bits=fractional_bits,)‘ inside the function _replace_lif_modules, which handles replace lif modules. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 193: `threshold=child.threshold,` This is continuation line 2 of the 4-line logical statement that begins at source line 192. Its exact fragment is ‘threshold=child.threshold,‘. The important operands are threshold: the membrane level at which a neuron emits a spike; child: the value named ’child’ in this block. Read together, the complete operation is: This calls ‘setattr‘ with ‘module, name, FixedPointHardResetLIF(threshold=child.threshold, fractional_bits=fractional_bits,)‘ inside the function _replace_lif_modules, which handles replace lif modules. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 194: `fractional_bits=fractional_bits,` This is continuation line 3 of the 4-line logical statement that begins at source line 192. Its exact fragment is ‘fractional_bits=fractional_bits,‘. The important operands are fractional_bits: the value named ’fractional bits’ in this block. Read together, the complete operation is: This calls ‘setattr‘ with ‘module, name, FixedPointHardResetLIF(threshold=child.threshold, fractional_bits=fractional_bits,)‘ inside the function _replace_lif_modules, which handles replace lif modules. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 195: `))` This is continuation line 4 of the 4-line logical statement that begins at source line 192. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘setattr‘ with ‘module, name, FixedPointHardResetLIF(threshold=child.threshold, fractional_bits=fractional_bits,)‘ inside the function _replace_lif_modules, which handles replace lif modules. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 196: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function _replace_lif_modules, which handles replace lif modules.

Line 197: `_replace_lif_modules(child, fractional_bits)` This calls ‘_replace_lif_modules‘ with ‘child, fractional_bits‘ inside the function _replace_lif_modules, which handles replace lif modules. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 200: `def input_scale_from_domain() -> float:` This starts function input_scale_from_domain. Its indented body performs input scale from domain as part of the file that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 201: `probe = torch.zeros(1, 3, 1, 1)` This assigns ‘torch.zeros(1, 3, 1, 1)‘ to ‘probe ‘ in host memory. Here probe means the value named ’probe’ in this block. The important operands are torch: the value named ’torch’ in this block; zeros: the value named ’zeros’ in this block. Context: the function input_scale_from_domain, which handles input scale from domain.

Line 202: `_, scale, _ = quantize_cifar_input_u8(probe)` This assigns ‘quantize_cifar_input_u8(probe)‘ to ‘_, scale, _ ‘ in host memory. Here _ means the value named ” in this block. The important operands are quantize_cifar_input_u8: the value named ’quantize cifar input u8’ in this block; probe: the value named ’probe’ in this block. Context: the function input_scale_from_domain, which handles input scale from domain.

Line 203: `return scale` This returns ‘scale‘ to the caller of the function input_scale_from_domain, which handles input scale from domain, ending this invocation. The important operands are scale: the real-value spacing represented by one quantized integer step.

Line 206: `def _install_projection_requantizers(` This starts function _install_projection_requantizers. Its indented body performs install projection requantizers as part of the file that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 207: `model: Spikingformer,` Inside the function _install_projection_requantizers, which handles install projection requantizers, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are model: the value named ’model’ in this block; Spikingformer: the value named ’spikingformer’ in this block.

Line 208: `weight_scales: dict[str, torch.Tensor],` Inside the function _install_projection_requantizers, which handles install projection requantizers, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are weight_scales: a learned coefficient multiplied by an activation; dict: the value named ’dict’ in this block; str: the value named ’str’ in this block.

Line 209: `*,` Inside the function _install_projection_requantizers, which handles install projection requantizers, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The expression is a literal or structural operator and has no hidden software state.

Line 210: `fractional_bits: int,` Inside the function _install_projection_requantizers, which handles install projection requantizers, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are fractional_bits: the value named ’fractional bits’ in this block.

Line 211: `image_input_scale: float,` Inside the function _install_projection_requantizers, which handles install projection requantizers, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are image_input_scale: the real-value spacing represented by one quantized integer step; float: the value named ’float’ in this block.

Line 212: `) -> None:` Inside the function _install_projection_requantizers, which handles install projection requantizers, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are None: the value named ’none’ in this block.

Line 213: `modules = dict(model.named_modules())` This assigns ‘dict(model.named_modules())‘ to ‘modules ‘ in host memory. Here modules means the value named ’modules’ in this block. The important operands are dict: the value named ’dict’ in this block; model: the value named ’model’ in this block; named_modules: the value named ’named modules’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 214: `output_scale = 1 << fractional_bits` This assigns ‘1 << fractional_bits‘ to ‘output_scale ‘ in host memory. Here output_scale means the real-value spacing represented by one quantized integer step. The important operands are fractional_bits: the value named ’fractional bits’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 215: `for batch_norm_name, batch_norm in modules.items():` This iterates batch_norm_name, batch_norm over ‘modules.items()‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function _install_projection_requantizers, which handles install projection requantizers.

Line 216: `if not isinstance(batch_norm, (nn.BatchNorm1d, nn.BatchNorm2d)):` This executes the following indented host-code branch only when ‘not isinstance(batch_norm, (nn.BatchNorm1d, nn.BatchNorm2d))‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; batch_norm: the value named ’batch norm’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 217: `continue` Inside the function _install_projection_requantizers, which handles install projection requantizers, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are continue: the value named ’continue’ in this block.

Line 218: `if not batch_norm_name.endswith("_bn"):` This executes the following indented host-code branch only when ‘not batch_norm_name.endswith("_bn")‘ is true. The important operands are not: the value named ’not’ in this block; batch_norm_name: the value named ’batch norm name’ in this block; endswith: the value named ’endswith’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 219: `raise ValueError(f"cannot locate projection for {batch_norm_name}")` This rejects an invalid state by raising ‘ValueError(f"cannot locate projection for {batch_norm_name}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 220: `convolution_name = batch_norm_name[:-3] + "_conv"` This assigns ‘batch_norm_name[:-3] + "_conv"‘ to ‘convolution_name ‘ in host memory. Here convolution_name means the value named ’convolution name’ in this block. The important operands are batch_norm_name: the value named ’batch norm name’ in this block; _conv: the value named ’conv’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 221: `convolution = modules.get(convolution_name)` This assigns ‘modules.get(convolution_name)‘ to ‘convolution ‘ in host memory. Here convolution means the value named ’convolution’ in this block. The important operands are modules: the value named ’modules’ in this block; get: the value named ’get’ in this block; convolution_name: the value named ’convolution name’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 222: `if not isinstance(convolution, (nn.Conv1d, nn.Conv2d)):` This executes the following indented host-code branch only when ‘not isinstance(convolution, (nn.Conv1d, nn.Conv2d))‘ is true. The important operands are not: the value named ’not’ in this block; isinstance: the value named ’isinstance’ in this block; convolution: the value named ’convolution’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 223: `raise ValueError(f"cannot locate {convolution_name}")` This rejects an invalid state by raising ‘ValueError(f"cannot locate {convolution_name}")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 224: `raw_weight_scale = weight_scales[convolution_name]` This assigns ‘weight_scales[convolution_name]‘ to ‘raw_weight_scale ‘ in host memory. Here raw_weight_scale means a learned coefficient multiplied by an activation. The important operands are weight_scales: a learned coefficient multiplied by an activation; convolution_name: the value named ’convolution name’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 225: `if raw_weight_scale.numel() == 1:` This executes the following indented host-code branch only when ‘raw_weight_scale.numel() == 1‘ is true. The important operands are raw_weight_scale: a learned coefficient multiplied by an activation; numel: the value named ’numel’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 226: `weight_scale = raw_weight_scale.repeat(convolution.out_channels)` This assigns ‘raw_weight_scale.repeat(c to ‘weight_scale ‘ in host memory. Here weight_scale means a learned coefficient multiplied by an activation. The important operands are raw_weight_scale: a learned coefficient multiplied by an activation; repeat: the value named ’repeat’ in this block; convolution: the value named ’convolution’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 227: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function _install_projection_requantizers, which handles install projection requantizers.

Line 228: `weight_scale = raw_weight_scale` This assigns ‘raw_weight_scale‘ to ‘weight_scale ‘ in host memory. Here weight_scale means a learned coefficient multiplied by an activation. The important operands are raw_weight_scale: a learned coefficient multiplied by an activation. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 229: `projection_input_scale = (` This statement continues through source line 230; the explanation uses the complete expression rather than only the first visual fragment. Inside the function _install_projection_requantizers, which handles install projection requantizers, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are projection_input_scale: the real-value spacing represented by one quantized integer step; image_input_scale: the real-value spacing represented by one quantized integer step; convolution_name: the value named ’convolution name’ in this block.

Line 230: `image_input_scale if convolution_name == "patch_embed.block0_conv" else 1.0)` This is continuation line 2 of the 2-line logical statement that begins at source line 229. Its exact fragment is ‘image_input_scale if convolution_name == "patch_embed.block0_conv" else 1.0)‘. The important operands are image_input_scale: the real-value spacing represented by one quantized integer step; convolution_name: the value named ’convolution name’ in this block; patch_embed: the value named ’patch embed’ in this block. Read together, the complete operation is: Inside the function _install_projection_requantizers, which handles install projection requantizers, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are projection_input_scale: the real-value spacing represented by one quantized integer step; image_input_scale: the real-value spacing represented by one quantized integer step; convolution_name: the value named ’convolution name’ in this block.

Line 231: `bn_scale = batch_norm.weight.detach() / torch.sqrt(` This statement continues through source line 232; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘batch_norm.weight.detach(/ torch.sqrt(batch_norm.running_var.detach() + batch_norm.eps)‘ to ‘bn_scale ‘ in host memory. Here bn_scale means the real-value spacing represented by one quantized integer step. The important operands are batch_norm: the value named ’batch norm’ in this block; weight: a learned coefficient multiplied by an activation; detach: the value named ’detach’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 232: `batch_norm.running_var.detach() + batch_norm.eps)` This is continuation line 2 of the 2-line logical statement that begins at source line 231. Its exact fragment is ‘batch_norm.running_var.detach() + batch_norm.eps)‘. The important operands are batch_norm: the value named ’batch norm’ in this block; running_var: the value named ’running var’ in this block; detach: the value named ’detach’ in this block. Read together, the complete operation is: This assigns ‘batch_norm.weight.detach() / torch.sqrt(batch_norm.running_var.detach() + batch_norm.eps)‘ to ‘bn_scale ‘ in host memory. Here bn_scale means the real-value spacing represented by one quantized integer step. The important operands are batch_norm: the value named ’batch norm’ in this block; weight: a learned coefficient multiplied by an activation; detach: the value named ’detach’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 233: `factor = projection_input_scale * weight_scale * bn_scale * output_scale` This assigns ‘projection_input_scale * weight_scale * bn_scale * output_scale‘ to ‘factor ‘ in host memory. Here factor means the value named ’factor’ in this block. The important operands are projection_input_scale: the real-value spacing represented by one quantized integer step; weight_scale: a learned coefficient multiplied by an activation; bn_scale: the real-value spacing represented by one quantized integer step. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 234: `multiplier_and_shift = [quantize_flexible_scale(float(item)) for item in factor]` This assigns ‘[quantize_flexible_scale(float(item)) for item in factor]‘ to ‘multiplier_and_shift ‘ in host memory. Here multiplier_and_shift means the value named ’multiplier and shift’ in this block. The important operands are quantize_flexible_scale: the real-value spacing represented by one quantized integer step; float: the value named ’float’ in this block; item: the value named ’item’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 235: `multiplier = torch.tensor(` This statement continues through source line 236; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘torch.tensor([item[0] for item in multiplier_and_shift], dtype=torch.int64)‘ to ‘multiplier ‘ in host memory. Here multiplier means the value named ’multiplier’ in this block. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block; item: the value named ’item’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 236: `[item[0] for item in multiplier_and_shift], dtype=torch.int64)` This is continuation line 2 of the 2-line logical statement that begins at source line 235. Its exact fragment is ‘[item[0] for item in multiplier_and_shift], dtype=torch.int64)‘. The important operands are item: the value named ’item’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘torch.tensor([item[0] for item in multiplier_and_shift], dtype=torch.int64)‘ to ‘multiplier ‘ in host memory. Here multiplier means the value named ’multiplier’ in this block. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block; item: the value named ’item’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 237: `effective_shift = torch.tensor(` This statement continues through source line 238; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘torch.tensor([15 + item[1] for item in multiplier_and_shift], dtype=torch.int64)‘ to ‘effective_shift ‘ in host memory. Here effective_shift means the value named ’effective shift’ in this block. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block; item: the value named ’item’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 238: `[15 + item[1] for item in multiplier_and_shift], dtype=torch.int64)` This is continuation line 2 of the 2-line logical statement that begins at source line 237. Its exact fragment is ‘[15 + item[1] for item in multiplier_and_shift], dtype=torch.int64)‘. The important operands are item: the value named ’item’ in this block; for: the value named ’for’ in this block; in: the value named ’in’ in this block. Read together, the complete operation is: This assigns ‘torch.tensor([15 + item[1] for item in multiplier_and_shift], dtype=torch.int64)‘ to ‘effective_shift ‘ in host memory. Here effective_shift means the value named ’effective shift’ in this block. The important operands are torch: the value named ’torch’ in this block; tensor: the value named ’tensor’ in this block; item: the value named ’item’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 239: `if convolution.bias is None:` This executes the following indented host-code branch only when ‘convolution.bias is None‘ is true. The important operands are convolution: the value named ’convolution’ in this block; bias: an additive learned offset applied after accumulation; is: the value named ’is’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 240: `convolution_bias = torch.zeros_like(batch_norm.running_mean)` This assigns ‘torch.zeros_like(batch_norm.ru
to ‘convolution_bias ‘ in host memory. Here convolution_bias means an additive learned offset applied after accumulation. The important operands are torch: the value named ’torch’ in this block; zeros_like: the value named ’zeros like’ in this block; batch_norm: the value named ’batch norm’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 241: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function _install_projection_requantizers, which handles install projection requantizers.

Line 242: `convolution_bias = convolution.bias.detach()` This assigns ‘convolution.bias.detach()‘ to ‘convolution_bias ‘ in host memory. Here convolution_bias means an additive learned offset applied after accumulation. The important operands are convolution: the value named ’convolution’ in this block; bias: an additive learned offset applied after accumulation; detach: the value named ’detach’ in this block. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 243: `folded_bias = (` This statement continues through source line 245; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘((convolution_bias - batch_norm.running_mean.detach()) * bn_scale + batch_norm.bias.detach())‘ to ‘folded_bias ‘ in host memory. Here folded_bias means an additive learned offset applied after accumulation. The important operands are convolution_bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; running_mean: the arithmetic average used by normalization. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 244: `(convolution_bias - batch_norm.running_mean.detach()) * bn_scale` This is continuation line 2 of the 3-line logical statement that begins at source line 243. Its exact fragment is ‘(convolution_bias - batch_norm.running_mean.deta * bn_scale‘. The important operands are convolution_bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; running_mean: the arithmetic average used by normalization. Read together, the complete operation is: This assigns ‘((convolution_bias - batch_norm.running_mean.detach()) * bn_scale + batch_norm.bias.detach())‘ to ‘folded_bias ‘ in host memory. Here folded_bias means an additive learned offset applied after accumulation. The important operands are convolution_bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; running_mean: the arithmetic average used by normalization. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 245: `+ batch_norm.bias.detach())` This is continuation line 3 of the 3-line logical statement that begins at source line 243. Its exact fragment is ‘+ batch_norm.bias.detach())‘. The important operands are batch_norm: the value named ’batch norm’ in this block; bias: an additive learned offset applied after accumulation; detach: the value named ’detach’ in this block. Read together, the complete operation is: This assigns ‘((convolution_bias - batch_norm.running_mean.detach()) * bn_scale + batch_norm.bias.detach())‘ to ‘folded_bias ‘ in host memory. Here folded_bias means an additive learned offset applied after accumulation. The important operands are convolution_bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; running_mean: the arithmetic average used by normalization. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 246: `bias_integer = torch.round(folded_bias * output_scale).to(torch.int64)` This assigns ‘torch.round(folded_ * output_scale).to(torch.int64)‘ to ‘bias_integer ‘ in host memory. Here bias_integer means an additive learned offset applied after accumulation. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; folded_bias: an additive learned offset applied after accumulation. Context: the function _install_projection_requantizers, which handles install projection requantizers.

Line 247: `batch_norm.register_forward_hook(_projection_hook(` This statement continues through source line 255; the explanation uses the complete expression rather than only the first visual fragment. This calls ‘batch_norm.register_forward with ‘_projection_hook(convolution_bias=convolution_bias, projection_input_scale=projection_input_scale, weight_scale=wei multiplier=multiplier, effective_shift=effective_shift, bias_integer=bias_integer, output_scale=output_scale,)‘ inside the function _install_projection_requantizers, which handles install projection requantizers. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 248: `convolution_bias=convolution_bias,` This is continuation line 2 of the 9-line logical statement that begins at source line 247. Its exact fragment is ‘convolution_bias=convolution_bias,‘. The important operands are convolution_bias: an additive learned offset applied after accumulation. Read together, the complete operation is: This calls ‘batch_norm.register_forward_hook‘ with ‘_projection_hook(convolution_bias=convolution_bias, projection_input_scale=projection_input_scale, weight_scale=weight_scale, multiplier=multiplier, effective_shift=effective_shift, bias_integer=bias_integer, output_scale=output_scale,)‘ inside the function _install_projection_requantizers, which

handles install projection requantizers. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 249: `projection_input_scale=projection_input_scale,` This is continuation line 3 of the 9-line logical statement that begins at source line 247. Its exact fragment is 'projection_input_scale=projection_input_scale,'. The important operands are projection_input_scale: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This calls 'batch_norm.register_forward_hook' with '_projection_hook(convolution_bias=convolution_bias, projection_input_scale=projection_input_scale, weight_scale=weight_scale, multiplier=multiplier, effective_shift=effective_shift, bias_integer=bias_integer, output_scale=output_scale,)' inside the function _install_projection_requantizers, which handles install projection requantizers. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 250: `weight_scale=weight_scale,` This is continuation line 4 of the 9-line logical statement that begins at source line 247. Its exact fragment is 'weight_scale=weight_scale,'. The important operands are weight_scale: a learned coefficient multiplied by an activation. Read together, the complete operation is: This calls 'batch_norm.register_forward_hook' with '_projection_hook(convolution_bias=convolution_bias, projection_input_scale=projection_input_scale, weight_scale=wei multiplier=multiplier, effective_shift=effective_shift, bias_integer=bias_integer, output_scale=output_scale,)' inside the function _install_projection_requantizers, which handles install projection requantizers. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 251: `multiplier=multiplier,` This is continuation line 5 of the 9-line logical statement that begins at source line 247. Its exact fragment is 'multiplier=multiplier,'. The important operands are multiplier: the value named 'multiplier' in this block. Read together, the complete operation is: This calls 'batch_norm.register_forward_hook' with '_projection_hook(convolution_bias=convolution_bias, projection_input_scale=projection_input_scale, weight_scale=weight_scale, multiplier=multiplier, effective_shift=effective_shift, bias_integer=bias_integer, output_scale=output_scale,)' inside the function _install_projection_requantizers, which handles install projection requantizers. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 252: `effective_shift=effective_shift,` This is continuation line 6 of the 9-line logical statement that begins at source line 247. Its exact fragment is 'effective_shift=effective_shift,'. The important operands are effective_shift: the value named 'effective shift' in this block. Read together, the complete operation is: This calls 'batch_norm.register_forward_hook' with '_projection_hook(convolution_bias=convolution_bias, projection_input_scale=proj weight_scale=weight_scale, multiplier=multiplier, effective_shift=effective_shift, bias_integer=bias_integer, output_scale=outpu)' inside the function _install_projection_requantizers, which handles install projection requantizers. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 253: `bias_integer=bias_integer,` This is continuation line 7 of the 9-line logical statement that begins at source line 247. Its exact fragment is 'bias_integer=bias_integer,'. The important operands are bias_integer: an additive learned offset applied after accumulation. Read together, the complete operation is: This calls 'batch_norm.register_forward_hook' with '_projection_hook(convolution_bias=convolution_bias, projection_input_scale=projection_input_scale, weight_scale=wei multiplier=multiplier, effective_shift=effective_shift, bias_integer=bias_integer, output_scale=output_scale,)' inside the function _install_projection_requantizers, which handles install projection requantizers. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 254: `output_scale=output_scale,` This is continuation line 8 of the 9-line logical statement that begins at source line 247. Its exact fragment is 'output_scale=output_scale,'. The important operands are output_scale: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This calls 'batch_norm.register_forward_hook' with '_projection_hook(convolution_bias=convolution_bias, projection_input_scale=proj weight_scale=weight_scale, multiplier=multiplier, effective_shift=effective_shift, bias_integer=bias_integer, output_scale=outpu)' inside the function _install_projection_requantizers, which handles install projection requantizers. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 255: `))` This is continuation line 9 of the 9-line logical statement that begins at source line 247. Its exact fragment is ‘))‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This calls ‘batch_norm.register_forward_hook‘ with ‘_projection_hook(convolution_bias=convolution_bias, projection_input_scale=projection_input_scale, weight_scale=weight_scale, multiplier=multiplier, effective_shift=effective_shift, bias_integer=bias_integer, output_scale=output_scale,)‘ inside the function _install_projection_ which handles install projection requantizers. The call advances the host-side job that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math.

Line 258: `def _projection_hook(` This starts function _projection_hook. Its indented body performs projection hook as part of the file that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 259: `*,` Inside the function _projection_hook, which handles projection hook, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The expression is a literal or structural operator and has no hidden software state.

Line 260: `convolution_bias: torch.Tensor,` Inside the function _projection_hook, which handles projection hook, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are convolution_bias: an additive learned offset applied after accumulation; torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 261: `projection_input_scale: float,` Inside the function _projection_hook, which handles projection hook, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are projection_input_scale: the real-value spacing represented by one quantized integer step; float: the value named ’float’ in this block.

Line 262: `weight_scale: torch.Tensor,` Inside the function _projection_hook, which handles projection hook, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are weight_scale: a learned coefficient multiplied by an activation; torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 263: `multiplier: torch.Tensor,` Inside the function _projection_hook, which handles projection hook, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are multiplier: the value named ’multiplier’ in this block; torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 264: `effective_shift: torch.Tensor,` Inside the function _projection_hook, which handles projection hook, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are effective_shift: the value named ’effective shift’ in this block; torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 265: `bias_integer: torch.Tensor,` Inside the function _projection_hook, which handles projection hook, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are bias_integer: an additive learned offset applied after accumulation; torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 266: `output_scale: int,` Inside the function _projection_hook, which handles projection hook, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are output_scale: the real-value spacing represented by one quantized integer step.

Line 267: `):` Inside the function _projection_hook, which handles projection hook, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The expression is a literal or structural operator and has no hidden software state.

Line 268: `def requantize(` This starts function requantize. Its indented body performs requantize as part of the file that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math; it runs only when called.

Line 269: `_module: nn.Module,` Inside the function requantize, which handles requantize, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are _module: the value named 'module' in this block; nn: the value named 'nn' in this block; Module: the value named 'module' in this block.

Line 270: `inputs: tuple[torch.Tensor, ...],` Inside the function requantize, which handles requantize, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are inputs: the value named 'inputs' in this block; tuple: the value named 'tuple' in this block; torch: the value named 'torch' in this block.

Line 271: `_output: torch.Tensor,` Inside the function requantize, which handles requantize, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are _output: the value named 'output' in this block; torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 272: `) -> torch.Tensor:` Inside the function requantize, which handles requantize, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 273: `convolution_output = inputs[0]` This assigns ‘inputs[0]‘ to ‘convolution_output ‘ in host memory. Here convolution_output means the value named 'convolution output' in this block. The important operands are inputs: the value named 'inputs' in this block. Context: the function requantize, which handles requantize.

Line 274: `channel_shape = (1, -1) + (1,) * (convolution_output.ndim - 2)` This assigns ‘(1, -1) + (1,) * (convolution_output.ndim - 2)‘ to ‘channel_shape ‘ in host memory. Here channel_shape means the value named 'channel shape' in this block. The important operands are convolution_output: the value named 'convolution output' in this block; ndim: the value named 'ndim' in this block. Context: the function requantize, which handles requantize.

Line 275: `device = convolution_output.device` This assigns ‘convolution_output.device‘ to ‘device ‘ in host memory. Here device means the value named 'device' in this block. The important operands are convolution_output: the value named 'convolution output' in this block; device: the value named 'device' in this block. Context: the function requantize, which handles requantize.

Line 276: `bias = convolution_bias.to(device).reshape(channel_shape)` This assigns ‘convolution_bias.to(device).reshape
to ‘bias ‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are convolution_bias: an additive learned offset applied after accumulation; to: the value named 'to' in this block; device: the value named 'device' in this block. Context: the function requantize, which handles requantize.

Line 277: `accumulator_scale = (` This statement continues through source line 278; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘(weight_scale.to(device).reshape(channel_shape) * projection_input_scale)‘ to ‘accumulator_scale ‘ in host memory. Here accumulator_scale means a widened running sum that prevents intermediate overflow. The important operands are weight_scale: a learned coefficient multiplied by an activation; to: the value named 'to' in this block; device: the value named 'device' in this block. Context: the function requantize, which handles requantize.

Line 278: `weight_scale.to(device).reshape(channel_shape) * projection_input_scale)` This is continuation line 2 of the 2-line logical statement that begins at source line 277. Its exact fragment is ‘weight_scale.to(device).reshape(channel_sha
* projection_input_scale)‘. The important operands are weight_scale: a learned coefficient multiplied by an activation; to: the value named 'to' in this block; device: the value named 'device' in this block. Read together, the complete

operation is: This assigns ‘(weight_scale.to(device).reshape(channel_shape) * projection_input_scale)‘ to ‘accumulator_scale ‘ in host memory. Here accumulator_scale means a widened running sum that prevents intermediate overflow. The important operands are weight_scale: a learned coefficient multiplied by an activation; to: the value named ’to’ in this block; device: the value named ’device’ in this block. Context: the function requantize, which handles requantize.

Line 279: `accumulator = torch.round(` This statement continues through source line 280; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘torch.round((convolution_output - bias) / accumulator_scale).to(torch.int64)‘ to ‘accumulator ‘ in host memory. Here accumulator means a widened running sum that prevents intermediate overflow. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; convolution_output: the value named ’convolution output’ in this block. Context: the function requantize, which handles requantize.

Line 280: `(convolution_output - bias) / accumulator_scale).to(torch.int64)` This is continuation line 2 of the 2-line logical statement that begins at source line 279. Its exact fragment is ‘(convolution_output - bias) / accumulator_scale).to(torch.int64)‘. The important operands are convolution_output: the value named ’convolution output’ in this block; bias: an additive learned offset applied after accumulation; accumulator_scale: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This assigns ‘torch.round((convolution_output - bias) / accumulator_scale).to(torch.int64)‘ to ‘accumulator ‘ in host memory. Here accumulator means a widened running sum that prevents intermediate overflow. The important operands are torch: the value named ’torch’ in this block; round: the value named ’round’ in this block; convolution_output: the value named ’convolution output’ in this block. Context: the function requantize, which handles requantize.

Line 281: `q15 = multiplier.to(device).reshape(channel_shape)` This assigns ‘multiplier.to(device).reshape(channel_shape to ‘q15 ‘ in host memory. Here q15 means the value named ’q15’ in this block. The important operands are multiplier: the value named ’multiplier’ in this block; to: the value named ’to’ in this block; device: the value named ’device’ in this block. Context: the function requantize, which handles requantize.

Line 282: `shifts = effective_shift.to(device).reshape(channel_shape)` This assigns ‘effective_shift.to(device).reshape(to ‘shifts ‘ in host memory. Here shifts means the value named ’shifts’ in this block. The important operands are effective_shift: the value named ’effective shift’ in this block; to: the value named ’to’ in this block; device: the value named ’device’ in this block. Context: the function requantize, which handles requantize.

Line 283: `product = accumulator * q15` This assigns ‘accumulator * q15‘ to ‘product ‘ in host memory. Here product means the value named ’product’ in this block. The important operands are accumulator: a widened running sum that prevents intermediate overflow; q15: the value named ’q15’ in this block. Context: the function requantize, which handles requantize.

Line 284: `magnitude = product.abs()` This assigns ‘product.abs()‘ to ‘magnitude ‘ in host memory. Here magnitude means the value named ’magnitude’ in this block. The important operands are product: the value named ’product’ in this block; abs: the value named ’abs’ in this block. Context: the function requantize, which handles requantize.

Line 285: `rounding_bias = torch.where(` This statement continues through source line 289; the explanation uses the complete expression rather than only the first visual fragment. Inside the function requantize, which handles requantize, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are rounding_bias: an additive learned offset applied after accumulation; torch: the value named ’torch’ in this block; where: the value named ’where’ in this block.

Line 286: `shifts == 0,` This is continuation line 2 of the 5-line logical statement that begins at source line 285. Its exact fragment is ‘shifts == 0,‘. The important operands are shifts: the value named ’shifts’ in this block. Read together, the complete operation is: Inside the function requantize, which handles requantize, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are rounding_bias: an additive learned offset applied after accumulation; torch: the value named ’torch’ in this block; where: the value named ’where’ in this block.

Line 287: `torch.zeros_like(shifts),` This is continuation line 3 of the 5-line logical statement that begins at source line 285. Its exact fragment is 'torch.zeros_like(shifts),'. The important operands are torch: the value named 'torch' in this block; zeros_like: the value named 'zeros like' in this block; shifts: the value named 'shifts' in this block. Read together, the complete operation is: Inside the function requantize, which handles requantize, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are rounding_bias: an additive learned offset applied after accumulation; torch: the value named 'torch' in this block; where: the value named 'where' in this block.

Line 288: `torch.bitwise_left_shift(torch.ones_like(shifts), shifts - 1),` This is continuation line 4 of the 5-line logical statement that begins at source line 285. Its exact fragment is 'torch.bitwise_left_shift(torch.ones_like(shifts), shifts - 1),'. The important operands are torch: the value named 'torch' in this block; bitwise_left_shift: the value named 'bitwise left shift' in this block; ones_like: the value named 'ones like' in this block. Read together, the complete operation is: Inside the function requantize, which handles requantize, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are rounding_bias: an additive learned offset applied after accumulation; torch: the value named 'torch' in this block; where: the value named 'where' in this block.

Line 289: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 285. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: Inside the function requantize, which handles requantize, this statement advances the host implementation that defines calibration, signed/unsigned affine quantization, rounding, saturation, and folded projection math. The important operands are rounding_bias: an additive learned offset applied after accumulation; torch: the value named 'torch' in this block; where: the value named 'where' in this block.

Line 290: `rounded_magnitude = torch.bitwise_right_shift(` This statement continues through source line 291; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'torch.bitwise_right_shift(magnitude + rounding_bias, shifts)' to 'rounded_magnitude ' in host memory. Here rounded_magnitude means the value named 'rounded magnitude' in this block. The important operands are torch: the value named 'torch' in this block; bitwise_right_shift: the value named 'bitwise right shift' in this block; magnitude: the value named 'magnitude' in this block. Context: the function requantize, which handles requantize.

Line 291: `magnitude + rounding_bias, shifts)` This is continuation line 2 of the 2-line logical statement that begins at source line 290. Its exact fragment is 'magnitude + rounding_bias, shifts)'. The important operands are magnitude: the value named 'magnitude' in this block; rounding_bias: an additive learned offset applied after accumulation; shifts: the value named 'shifts' in this block. Read together, the complete operation is: This assigns 'torch.bitwise_right_shift(magnitude + rounding_bias, shifts)' to 'rounded_magnitude ' in host memory. Here rounded_magnitude means the value named 'rounded magnitude' in this block. The important operands are torch: the value named 'torch' in this block; bitwise_right_shift: the value named 'bitwise right shift' in this block; magnitude: the value named 'magnitude' in this block. Context: the function requantize, which handles requantize.

Line 292: `rounded = torch.where(product < 0, -rounded_magnitude, rounded_magnitude)` This assigns 'torch.where(pro
< 0, -rounded_magnitude, rounded_magnitude)' to 'rounded ' in host memory. Here rounded means the value named 'rounded' in this block. The important operands are torch: the value named 'torch' in this block; where: the value named 'where' in this block; product: the value named 'product' in this block. Context: the function requantize, which handles requantize.

Line 293: `quantized = rounded + bias_integer.to(device).reshape(channel_shape)` This assigns 'rounded + bias_integer.to(device).reshape(channel_shape)' to 'quantized ' in host memory. Here quantized means the value named 'quantized' in this block. The important operands are rounded: the value named 'rounded' in this block; bias_integer: an additive learned offset applied after accumulation; to: the value named 'to' in this block. Context: the function requantize, which handles requantize.

Line 294: `quantized = quantized.clamp(-(1 << 23), (1 << 23) - 1)` This assigns 'quantized.clamp(-(1 << 23), (1 << 23) - 1)' to 'quantized ' in host memory. Here quantized means the value named 'quantized' in this block. The important operands are quantized: the value named 'quantized' in this block; clamp: the value named 'clamp' in this block. Context: the function requantize, which handles requantize.

Line 295: `return quantized.to(convolution_output.dtype) / output_scale` This returns ‘quantized.to(convolution_outpu / output_scale‘ to the caller of the function requantize, which handles requantize, ending this invocation. The important operands are quantized: the value named ’quantized’ in this block; to: the value named ’to’ in this block; convolution_output: the value named ’convolution output’ in this block.

Line 297: `return requantize` This returns ‘requantize‘ to the caller of the function _projection_hook, which handles projection hook, ending this invocation. The important operands are requantize: the conversion of a wide accumulated result back into a bounded activation code.

43 software/spikingformer_reference.py

Role in the complete system: reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

43.1 Beginner architecture map

Dataflow responsibility The source checkpoint is reconstructed with its original timestep and spike behavior. A separate hardware-emulation path applies exported integer coefficients, allowing full-test accuracy and per-logit disagreement to be measured before board execution.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: MultiStepHardResetLIF, MLP, SpikingSelfAttention, SpikingTransformer, SpikingTokenizer, Spikingformer, LoadedCheckpoint. Functions: load_checkpoint, fold_batch_norm, _split_heads, _observe, ___init___, forward, ___init___, forward, ___init___, forward, ___init___, forward, ___init___, forward, ___init___, forward. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

43.2 Complete source

```
"""Checkpoint-faithful Spikingformer inference and hardware preparation.

The upstream CIFAR-10 implementation fixes every neuron to a four-step,
hard-reset leaky integrate-and-fire (LIF) model.  This module reproduces that
inference graph with ordinary PyTorch operators.  It deliberately avoids a
CuPy dependency so the reference remains executable on CPU and on any CUDA
device supported by PyTorch.

Module and parameter names match the upstream checkpoint exactly.  A strict
load therefore detects missing, unexpected, or shape-incompatible tensors
before any accuracy or hardware-equivalence result is accepted.
"""

Line 18: `from typing import Any, Callable, Mapping` This imports the named Python API so the file whose role is to reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 20: `import torch` This imports the named Python API so the file whose role is to reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 21: `import torch.nn as nn` This imports the named Python API so the file whose role is to reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 24: `TensorObserver = Callable[[str, torch.Tensor, bool], None]` This assigns ‘Callable[[str, torch.Tensor, bool], None]‘ to ‘TensorObserver ‘ in host memory. Here TensorObserver means the value named ’tensor observer’ in this block. The important operands are Callable: the value named ’callable’ in this block; str: the value named ’str’ in this block; torch: the value named ’torch’ in this block. Context: the file whose role is to reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 27: `class MultiStepHardResetLIF(nn.Module):` This defines class MultiStepHardResetLIF, which groups data and methods for multi step hard reset lif. Instances exist in host memory and organize the flow that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 28: `"""Exact inference equation of the upstream "MultiStepLIFNode".` This is executable documentation attached to the class MultiStepHardResetLIF, which handles multi step hard reset lif. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 30: `With the checkpoint's "tau=2", "decay_input=True" and "v_reset=0",` Inside the class MultiStepHardResetLIF, which handles multi step hard reset lif, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are With: the value named ’with’ in this block; the: the value named ’the’ in this block; checkpoint: the value named ’checkpoint’ in this block.

Line 31: `each timestep first computes "v_pre = v + (x - v) / 2". A spike is one` Inside the class MultiStepHardResetLIF, which handles multi step hard reset lif, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are each: the value named ’each’ in this block; timestep: one discrete SNN update instant; first: the value named ’first’ in this block.

Line 32: `where "v_pre >= threshold". Spiking lanes are then reset to zero while` Inside the class MultiStepHardResetLIF, which handles multi step hard reset lif, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are where: the value named 'where' in this block; v_pre: the value named 'v pre' in this block; threshold: the membrane level at which a neuron emits a spike.

Line 33: `all other lanes retain "v_pre" for the next timestep.` Inside the class MultiStepHardResetLIF, which handles multi step hard reset lif, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are all: the value named 'all' in this block; other: the value named 'other' in this block; lanes: one parallel arithmetic element within a vector or tensor datapath.

Line 35: `The state is intentionally local to one call. This is equivalent to the` Inside the class MultiStepHardResetLIF, which handles multi step hard reset lif, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are The: the value named 'the' in this block; state: the finite-state-machine phase retained in flip-flops; is: the value named 'is' in this block.

Line 36: `upstream validation loop, which invokes "functional.reset_net" after` Inside the class MultiStepHardResetI which handles multi step hard reset lif, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are upstream: the value named 'upstream' in this block; validation: the producer's statement that its current payload is meaningful; loop: the value named 'loop' in this block.

Line 37: `every image batch.` Inside the class MultiStepHardResetLIF, which handles multi step hard reset lif, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are every: the value named 'every' in this block; image: the value named 'image' in this block; batch: the value named 'batch' in this block.

Line 38: `"""` This is executable documentation attached to the class MultiStepHardResetLIF, which handles multi step hard reset lif. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 40: `def __init__(self, *, tau: float = 2.0, threshold: float = 1.0) -> None:` This starts function ___init___. Its indented body performs init as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 41: `super().__init__()` This calls 'super' with ').___init___(' inside the function ___init___, which handles init. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 42: `if tau <= 1.0:` This executes the following indented host-code branch only when 'tau <= 1.0' is true. The important operands are tau: the value named 'tau' in this block. Context: the function ___init___, which handles init.

Line 43: `raise ValueError("tau must be greater than one")` This rejects an invalid state by raising 'ValueError("tau must be greater than one")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 44: `self.tau = float(tau)` This assigns 'float(tau)' to 'self.tau ' in host memory. Here tau means the value named 'tau' in this block. The important operands are float: the value named 'float' in this block; tau: the value named 'tau' in this block. Context: the function ___init___, which handles init.

Line 45: `self.threshold = float(threshold)` This assigns ‘float(threshold)‘ to ‘self.threshold ‘ in host memory. Here threshold means the membrane level at which a neuron emits a spike. The important operands are float: the value named ’float’ in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function ___init___, which handles init.

Line 47: `def forward(self, sequence: torch.Tensor) -> torch.Tensor:` This starts function forward. Its indented body performs forward as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 48: `if sequence.ndim < 2:` This executes the following indented host-code branch only when ‘sequence.ndim < 2‘ is true. The important operands are sequence: the value named ’sequence’ in this block; ndim: the value named ’ndim’ in this block. Context: the function forward, which handles forward.

Line 49: `raise ValueError("a multi-step LIF input must have shape [T, ...]")` This rejects an invalid state by raising ‘ValueError("a multi-step LIF input must have shape [T, ...]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 50: `voltage = torch.zeros_like(sequence[0])` This assigns ‘torch.zeros_like(sequence[0])‘ to ‘voltage ‘ in host memory. Here voltage means the value named ’voltage’ in this block. The important operands are torch: the value named ’torch’ in this block; zeros_like: the value named ’zeros like’ in this block; sequence: the value named ’sequence’ in this block. Context: the function forward, which handles forward.

Line 51: `spikes: list[torch.Tensor] = []` This assigns ‘[]‘ to ‘spikes‘ in host memory. Here spikes means a binary event produced when a neuron crosses its threshold. The expression is a literal or structural operator and has no hidden software state. Context: the function forward, which handles forward.

Line 52: `for timestep in range(sequence.shape[0]):` This iterates timestep over ‘range(sequence.shape[0])‘. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function forward, which handles forward.

Line 53: `voltage = voltage + (sequence[timestep] - voltage) / self.tau` This assigns ‘voltage + (sequence[timestep] - voltage) / self.tau‘ to ‘voltage ‘ in host memory. Here voltage means the value named ’voltage’ in this block. The important operands are voltage: the value named ’voltage’ in this block; sequence: the value named ’sequence’ in this block; timestep: one discrete SNN update instant. Context: the function forward, which handles forward.

Line 54: `spike = (voltage >= self.threshold).to(sequence.dtype)` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are spike: a binary event produced when a neuron crosses its threshold; voltage: the value named ’voltage’ in this block; threshold: the membrane level at which a neuron emits a spike.

Line 55: `voltage = voltage * (1.0 - spike)` This assigns ‘voltage * (1.0 - spike)‘ to ‘voltage ‘ in host memory. Here voltage means the value named ’voltage’ in this block. The important operands are voltage: the value named ’voltage’ in this block; spike: a binary event produced when a neuron crosses its threshold. Context: the function forward, which handles forward.

Line 56: `spikes.append(spike)` This calls ‘spikes.append‘ with ‘spike‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 57: `return torch.stack(spikes, dim=0)` This returns ‘torch.stack(spikes, dim=0)‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are torch: the value named ’torch’ in this block; stack: the value named ’stack’ in this block; spikes: a binary event produced when a neuron crosses its threshold.

Line 60: `class MLP(nn.Module):` This defines class MLP, which groups data and methods for mlp. Instances exist in host memory and organize the flow that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 61: `"""Spikingformer's two 1x1-convolution feed-forward projections."""` This is executable documentation attached to the class MLP, which handles mlp. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 63: `def __init__(self, channels: int, hidden_channels: int) -> None:` This starts function ___init___. Its indented body performs init as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 64: `super().__init__()` This calls 'super' with ').___init___(' inside the function ___init___, which handles init. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 65: `self.mlp1_lif = MultiStepHardResetLIF()` This assigns 'MultiStepHardResetLIF()' to 'self.mlp1_lif ' in host memory. Here mlp1_lif means the value named 'mlp1 lif' in this block. The important operands are MultiStepHardResetLIF: the value named 'multi step hard reset lif' in this block. Context: the function ___init___, which handles init.

Line 66: `self.mlp1_conv = nn.Conv2d(channels, hidden_channels, kernel_size=1)` This assigns 'nn.Conv2d(channels, hidden_channels, kernel_size=1)' to 'self.mlp1_conv ' in host memory. Here mlp1_conv means the value named 'mlp1 conv' in this block. The important operands are nn: the value named 'nn' in this block; Conv2d: the value named 'conv2d' in this block; channels: the value named 'channels' in this block. Context: the function ___init___, which handles init.

Line 67: `self.mlp1_bn = nn.BatchNorm2d(hidden_channels)` This assigns 'nn.BatchNorm2d(hidden_channels)' to 'self.mlp1_bn ' in host memory. Here mlp1_bn means the value named 'mlp1 bn' in this block. The important operands are nn: the value named 'nn' in this block; BatchNorm2d: the value named 'batch norm2d' in this block; hidden_channels: the value named 'hidden channels' in this block. Context: the function ___init___, which handles init.

Line 68: `self.mlp2_lif = MultiStepHardResetLIF()` This assigns 'MultiStepHardResetLIF()' to 'self.mlp2_lif ' in host memory. Here mlp2_lif means the value named 'mlp2 lif' in this block. The important operands are MultiStepHardResetLIF: the value named 'multi step hard reset lif' in this block. Context: the function ___init___, which handles init.

Line 69: `self.mlp2_conv = nn.Conv2d(hidden_channels, channels, kernel_size=1)` This assigns 'nn.Conv2d(hidden_cha channels, kernel_size=1)' to 'self.mlp2_conv ' in host memory. Here mlp2_conv means the value named 'mlp2 conv' in this block. The important operands are nn: the value named 'nn' in this block; Conv2d: the value named 'conv2d' in this block; hidden_channels: the value named 'hidden channels' in this block. Context: the function ___init___, which handles init.

Line 70: `self.mlp2_bn = nn.BatchNorm2d(channels)` This assigns 'nn.BatchNorm2d(channels)' to 'self.mlp2_bn ' in host memory. Here mlp2_bn means the value named 'mlp2 bn' in this block. The important operands are nn: the value named 'nn' in this block; BatchNorm2d: the value named 'batch norm2d' in this block; channels: the value named 'channels' in this block. Context: the function ___init___, which handles init.

Line 71: `self.hidden_channels = hidden_channels` This assigns 'hidden_channels' to 'self.hidden_channels ' in host memory. Here hidden_channels means the value named 'hidden channels' in this block. The important operands are hidden_channels: the value named 'hidden channels' in this block. Context: the function ___init___, which handles init.

Line 73: `def forward(` This starts function forward. Its indented body performs forward as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 74: `self,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 75: `value: torch.Tensor,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are value: the value named 'value' in this block; torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 76: `*,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 77: `prefix: str,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are prefix: the value named 'prefix' in this block; str: the value named 'str' in this block.

Line 78: `observer: TensorObserver | None,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are observer: the value named 'observer' in this block; TensorObserver: the value named 'tensor observer' in this block; None: the value named 'none' in this block.

Line 79: `) -> torch.Tensor:` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 80: `time_steps, batch, channels, height, width = value.shape` This assigns 'value.shape' to 'time_steps, batch, channels, height, width ' in host memory. Here time_steps means the value named 'time steps' in this block. The important operands are value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function forward, which handles forward.

Line 81: `value = self.mlp1_lif(value)` This assigns 'self.mlp1_lif(value)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are mlp1_lif: the value named 'mlp1 lif' in this block; value: the value named 'value' in this block. Context: the function forward, which handles forward.

Line 82: `_observe(observer, f"{prefix}.mlp1_lif", value, True)` This calls '_observe' with 'observer, f"{prefix}.mlp1_lif value, True' inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 83: `value = self.mlp1_conv(value.flatten(0, 1))` This assigns 'self.mlp1_conv(value.flatten(0, 1))' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are mlp1_conv: the value named 'mlp1 conv' in this block; value: the value named 'value' in this block; flatten: the value named 'flatten' in this block. Context: the function forward, which handles forward.

Line 84: `value = self.mlp1_bn(value).reshape(` This statement continues through source line 85; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self.mlp1_bn(value).reshape(time_steps, batch, self.hidden_channels, height, width)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are mlp1_bn: the value named 'mlp1 bn' in this block; value: the value named 'value' in this block; reshape: the value named 'reshape' in this block. Context: the function forward, which handles forward.

Line 85: `time_steps, batch, self.hidden_channels, height, width)` This is continuation line 2 of the 2-line logical statement that begins at source line 84. Its exact fragment is 'time_steps, batch, self.hidden_channels, height, width)'. The important operands are time_steps: the value named 'time steps' in this block; batch: the value named 'batch' in this block; hidden_channels: the value named 'hidden channels' in this block. Read together, the complete operation is: This assigns 'self.mlp1_bn(value).reshape(time_steps, batch, self.hidden_channels, height, width)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are mlp1_bn: the value named 'mlp1 bn' in this block; value: the value named 'value' in this block; reshape: the value named 'reshape' in this block. Context: the function forward, which handles forward.

Line 86: `_observe(observer, f"{prefix}.mlp1_bn", value, False)` This calls '_observe' with 'observer, f"{prefix}.mlp1_bn value, False' inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 87: `value = self.mlp2_lif(value)` This assigns 'self.mlp2_lif(value)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are mlp2_lif: the value named 'mlp2 lif' in this block; value: the value named 'value' in this block. Context: the function forward, which handles forward.

Line 88: `_observe(observer, f"{prefix}.mlp2_lif", value, True)` This calls '_observe' with 'observer, f"{prefix}.mlp2_lif value, True' inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 89: `value = self.mlp2_conv(value.flatten(0, 1))` This assigns 'self.mlp2_conv(value.flatten(0, 1))' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are mlp2_conv: the value named 'mlp2 conv' in this block; value: the value named 'value' in this block; flatten: the value named 'flatten' in this block. Context: the function forward, which handles forward.

Line 90: `value = self.mlp2_bn(value).reshape(` This statement continues through source line 91; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self.mlp2_bn(value).reshape(time_steps, batch, channels, height, width)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are mlp2_bn: the value named 'mlp2 bn' in this block; value: the value named 'value' in this block; reshape: the value named 'reshape' in this block. Context: the function forward, which handles forward.

Line 91: `time_steps, batch, channels, height, width)` This is continuation line 2 of the 2-line logical statement that begins at source line 90. Its exact fragment is 'time_steps, batch, channels, height, width)'. The important operands are time_steps: the value named 'time steps' in this block; batch: the value named 'batch' in this block; channels: the value named 'channels' in this block. Read together, the complete operation is: This assigns 'self.mlp2_bn(value).reshape(time_steps, batch, channels, height, width)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are mlp2_bn: the value named 'mlp2 bn' in this block; value: the value named 'value' in this block; reshape: the value named 'reshape' in this block. Context: the function forward, which handles forward.

Line 92: `_observe(observer, f"{prefix}.mlp2_bn", value, False)` This calls '_observe' with 'observer, f"{prefix}.mlp2_bn value, False' inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 93: `return value` This returns 'value' to the caller of the function forward, which handles forward, ending this invocation. The important operands are value: the value named 'value' in this block.

Line 96: `class SpikingSelfAttention(nn.Module):` This defines class SpikingSelfAttention, which groups data and methods for spiking self attention. Instances exist in host memory and organize the flow that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 97: `"""Binary Q/K/V self-attention used by the trained checkpoint."""` This is executable documentation attached to the class SpikingSelfAttention, which handles spiking self attention. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 99: `def __init__(self, channels: int, heads: int) -> None:` This starts function ___init___. Its indented body performs init as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 100: `super().__init__()` This calls ‘super‘ with ‘).___init___(‘ inside the function ___init___, which handles init. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 101: `if channels % heads:` This executes the following indented host-code branch only when ‘channels % heads‘ is true. The important operands are channels: the value named ’channels’ in this block; heads: the value named ’heads’ in this block. Context: the function ___init___, which handles init.

Line 102: `raise ValueError("channels must be divisible by heads")` This rejects an invalid state by raising ‘ValueError("channels must be divisible by heads")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 103: `self.channels = channels` This assigns ‘channels‘ to ‘self.channels ‘ in host memory. Here channels means the value named ’channels’ in this block. The important operands are channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 104: `self.heads = heads` This assigns ‘heads‘ to ‘self.heads ‘ in host memory. Here heads means the value named ’heads’ in this block. The important operands are heads: the value named ’heads’ in this block. Context: the function ___init___, which handles init.

Line 105: `self.head_dim = channels // heads` This assigns ‘channels // heads‘ to ‘self.head_dim ‘ in host memory. Here head_dim means the value named ’head dim’ in this block. The important operands are channels: the value named ’channels’ in this block; heads: the value named ’heads’ in this block. Context: the function ___init___, which handles init.

Line 106: `self.proj_lif = MultiStepHardResetLIF()` This assigns ‘MultiStepHardResetLIF()‘ to ‘self.proj_lif ‘ in host memory. Here proj_lif means the value named ’proj lif’ in this block. The important operands are MultiStepHardResetLIF: the value named ’multi step hard reset lif’ in this block. Context: the function ___init___, which handles init.

Line 107: `self.q_conv = nn.Conv1d(channels, channels, kernel_size=1, bias=False)` This assigns ‘nn.Conv1d(channels, channels, kernel_size=1, bias=False)‘ to ‘self.q_conv ‘ in host memory. Here q_conv means the value named ’q conv’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv1d: the value named ’conv1d’ in this block; channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 108: `self.q_bn = nn.BatchNorm1d(channels)` This assigns ‘nn.BatchNorm1d(channels)‘ to ‘self.q_bn ‘ in host memory. Here q_bn means the value named ’q bn’ in this block. The important operands are nn: the value named ’nn’ in this block; BatchNorm1d: the value named ’batch norm1d’ in this block; channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 109: `self.q_lif = MultiStepHardResetLIF()` This assigns ‘MultiStepHardResetLIF()‘ to ‘self.q_lif ‘ in host memory. Here q_lif means the value named ’q lif’ in this block. The important operands are MultiStepHardResetLIF: the value named ’multi step hard reset lif’ in this block. Context: the function ___init___, which handles init.

Line 110: `self.k_conv = nn.Conv1d(channels, channels, kernel_size=1, bias=False)` This assigns ‘nn.Conv1d(channels, channels, kernel_size=1, bias=False)‘ to ‘self.k_conv ‘ in host memory. Here k_conv means the value named ’k conv’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv1d: the value named ’conv1d’ in this block; channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 111: `self.k_bn = nn.BatchNorm1d(channels)` This assigns ‘nn.BatchNorm1d(channels)‘ to ‘self.k_bn ‘ in host memory. Here k_bn means the value named ’k bn’ in this block. The important operands are nn: the value named ’nn’ in this block; BatchNorm1d: the value named ’batch norm1d’ in this block; channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 112: `self.k_lif = MultiStepHardResetLIF()` This assigns ‘MultiStepHardResetLIF()‘ to ‘self.k_lif ‘ in host memory. Here k_lif means the value named ’k lif’ in this block. The important operands are MultiStepHardResetLIF: the value named ’multi step hard reset lif’ in this block. Context: the function ___init___, which handles init.

Line 113: `self.v_conv = nn.Conv1d(channels, channels, kernel_size=1, bias=False)` This assigns ‘nn.Conv1d(channels, channels, kernel_size=1, bias=False)‘ to ‘self.v_conv ‘ in host memory. Here v_conv means the value named ’v conv’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv1d: the value named ’conv1d’ in this block; channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 114: `self.v_bn = nn.BatchNorm1d(channels)` This assigns ‘nn.BatchNorm1d(channels)‘ to ‘self.v_bn ‘ in host memory. Here v_bn means the value named ’v bn’ in this block. The important operands are nn: the value named ’nn’ in this block; BatchNorm1d: the value named ’batch norm1d’ in this block; channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 115: `self.v_lif = MultiStepHardResetLIF()` This assigns ‘MultiStepHardResetLIF()‘ to ‘self.v_lif ‘ in host memory. Here v_lif means the value named ’v lif’ in this block. The important operands are MultiStepHardResetLIF: the value named ’multi step hard reset lif’ in this block. Context: the function ___init___, which handles init.

Line 116: `self.attn_lif = MultiStepHardResetLIF(threshold=0.5)` This assigns ‘MultiStepHardResetLIF(threshold=0.5)‘ to ‘self.attn_lif ‘ in host memory. Here attn_lif means the value named ’attn lif’ in this block. The important operands are MultiStepHardResetLIF: the value named ’multi step hard reset lif’ in this block; threshold: the membrane level at which a neuron emits a spike. Context: the function ___init___, which handles init.

Line 117: `self.proj_conv = nn.Conv1d(channels, channels, kernel_size=1)` This assigns ‘nn.Conv1d(channels, channels, kernel_size=1)‘ to ‘self.proj_conv ‘ in host memory. Here proj_conv means the value named ’proj conv’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv1d: the value named ’conv1d’ in this block; channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 118: `self.proj_bn = nn.BatchNorm1d(channels)` This assigns ‘nn.BatchNorm1d(channels)‘ to ‘self.proj_bn ‘ in host memory. Here proj_bn means the value named ’proj bn’ in this block. The important operands are nn: the value named ’nn’ in this block; BatchNorm1d: the value named ’batch norm1d’ in this block; channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 120: `def forward(` This starts function forward. Its indented body performs forward as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 121: `self,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 122: `value: torch.Tensor,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are value: the value named ’value’ in this block; torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 123: `*,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 124: `prefix: str,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are prefix: the value named 'prefix' in this block; str: the value named 'str' in this block.

Line 125: `observer: TensorObserver | None,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are observer: the value named 'observer' in this block; TensorObserver: the value named 'tensor observer' in this block; None: the value named 'none' in this block.

Line 126: `) -> torch.Tensor:` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 127: `time_steps, batch, channels, height, width = value.shape` This assigns 'value.shape' to 'time_steps, batch, channels, height, width ' in host memory. Here time_steps means the value named 'time steps' in this block. The important operands are value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function forward, which handles forward.

Line 128: `value = self.proj_lif(value)` This assigns 'self.proj_lif(value)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are proj_lif: the value named 'proj lif' in this block; value: the value named 'value' in this block. Context: the function forward, which handles forward.

Line 129: `_observe(observer, f"{prefix}.proj_lif", value, True)` This calls '_observe' with 'observer, f"{prefix}.proj_li value, True' inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 130: `value = value.flatten(3)` This assigns 'value.flatten(3)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are value: the value named 'value' in this block; flatten: the value named 'flatten' in this block. Context: the function forward, which handles forward.

Line 131: `tokens = value.shape[-1]` This assigns 'value.shape[-1]' to 'tokens ' in host memory. Here tokens means the value named 'tokens' in this block. The important operands are value: the value named 'value' in this block; shape: the value named 'shape' in this block. Context: the function forward, which handles forward.

Line 132: `projection_input = value.flatten(0, 1)` This assigns 'value.flatten(0, 1)' to 'projection_input ' in host memory. Here projection_input means the value named 'projection input' in this block. The important operands are value: the value named 'value' in this block; flatten: the value named 'flatten' in this block. Context: the function forward, which handles forward.

Line 134: `query = self.q_bn(self.q_conv(projection_input)).reshape(` This statement continues through source line 135; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'self.q_bn(self.q_conv(time_steps, batch, channels, tokens)' to 'query ' in host memory. Here query means the value named 'query' in this block. The important operands are q_bn: the value named 'q bn' in this block; q_conv: the value named 'q conv' in this block; projection_input: the value named 'projection input' in this block. Context: the function forward, which handles forward.

Line 135: `time_steps, batch, channels, tokens)` This is continuation line 2 of the 2-line logical statement that begins at source line 134. Its exact fragment is 'time_steps, batch, channels, tokens)'. The important operands are time_steps: the value named 'time steps' in this block; batch: the value named 'batch' in this block; channels: the value named 'channels' in this block. Read together, the complete operation is: This assigns 'self.q_bn(self.q_conv(projection_input)).resh time_steps, batch, channels, tokens)' to 'query ' in host memory. Here query means the value named 'query' in this block. The important operands are q_bn: the value named 'q bn' in this block; q_conv: the value named 'q conv' in this block; projection_input: the value named 'projection input' in this block. Context: the function forward, which handles forward.

Line 136: `query = self.q_lif(query)` This assigns ‘self.q_lif(query)‘ to ‘query ‘ in host memory. Here query means the value named ’query’ in this block. The important operands are q_lif: the value named ’q lif’ in this block; query: the value named ’query’ in this block. Context: the function forward, which handles forward.

Line 137: `_observe(observer, f"{prefix}.q_lif", query, True)` This calls ‘_observe‘ with ‘observer, f"{prefix}.q_lif", query, True‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 138: `key = self.k_bn(self.k_conv(projection_input)).reshape(` This statement continues through source line 139; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self.k_bn(self.k_conv(p time_steps, batch, channels, tokens)‘ to ‘key ‘ in host memory. Here key means the value named ’key’ in this block. The important operands are k_bn: the value named ’k bn’ in this block; k_conv: the value named ’k conv’ in this block; projection_input: the value named ’projection input’ in this block. Context: the function forward, which handles forward.

Line 139: `time_steps, batch, channels, tokens)` This is continuation line 2 of the 2-line logical statement that begins at source line 138. Its exact fragment is ‘time_steps, batch, channels, tokens)‘. The important operands are time_steps: the value named ’time steps’ in this block; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This assigns ‘self.k_bn(self.k_conv(projection_input)).resh time_steps, batch, channels, tokens)‘ to ‘key ‘ in host memory. Here key means the value named ’key’ in this block. The important operands are k_bn: the value named ’k bn’ in this block; k_conv: the value named ’k conv’ in this block; projection_input: the value named ’projection input’ in this block. Context: the function forward, which handles forward.

Line 140: `key = self.k_lif(key)` This assigns ‘self.k_lif(key)‘ to ‘key ‘ in host memory. Here key means the value named ’key’ in this block. The important operands are k_lif: the value named ’k lif’ in this block; key: the value named ’key’ in this block. Context: the function forward, which handles forward.

Line 141: `_observe(observer, f"{prefix}.k_lif", key, True)` This calls ‘_observe‘ with ‘observer, f"{prefix}.k_lif", key, True‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 142: `value_projection = self.v_bn(self.v_conv(projection_input)).reshape(` This statement continues through source line 143; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘self.v_bn(self.v_conv(projection_input)).reshape(time_steps, batch, channels, tokens)‘ to ‘value_projection ‘ in host memory. Here value_projection means the value named ’value projection’ in this block. The important operands are v_bn: the value named ’v bn’ in this block; v_conv: the value named ’v conv’ in this block; projection_input: the value named ’projection input’ in this block. Context: the function forward, which handles forward.

Line 143: `time_steps, batch, channels, tokens)` This is continuation line 2 of the 2-line logical statement that begins at source line 142. Its exact fragment is ‘time_steps, batch, channels, tokens)‘. The important operands are time_steps: the value named ’time steps’ in this block; batch: the value named ’batch’ in this block; channels: the value named ’channels’ in this block. Read together, the complete operation is: This assigns ‘self.v_bn(self.v_conv(projection_input)).resh time_steps, batch, channels, tokens)‘ to ‘value_projection ‘ in host memory. Here value_projection means the value named ’value projection’ in this block. The important operands are v_bn: the value named ’v bn’ in this block; v_conv: the value named ’v conv’ in this block; projection_input: the value named ’projection input’ in this block. Context: the function forward, which handles forward.

Line 144: `value_projection = self.v_lif(value_projection)` This assigns ‘self.v_lif(value_projection)‘ to ‘value_projectio ‘ in host memory. Here value_projection means the value named ’value projection’ in this block. The important operands are v_lif: the value named ’v lif’ in this block; value_projection: the value named ’value projection’ in this block. Context: the function forward, which handles forward.

Line 145: `_observe(observer, f"{prefix}.v_lif", value_projection, True)` This calls '_observe' with 'observer, f"{prefix}.v_lif", value_projection, True' inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 147: `query = _split_heads(query, self.heads)` This assigns '_split_heads(query, self.heads)' to 'query ' in host memory. Here query means the value named 'query' in this block. The important operands are _split_heads: the value named 'split heads' in this block; query: the value named 'query' in this block; heads: the value named 'heads' in this block. Context: the function forward, which handles forward.

Line 148: `key = _split_heads(key, self.heads)` This assigns '_split_heads(key, self.heads)' to 'key ' in host memory. Here key means the value named 'key' in this block. The important operands are _split_heads: the value named 'split heads' in this block; key: the value named 'key' in this block; heads: the value named 'heads' in this block. Context: the function forward, which handles forward.

Line 149: `value_projection = _split_heads(value_projection, self.heads)` This assigns '_split_heads(value_projection self.heads)' to 'value_projection ' in host memory. Here value_projection means the value named 'value projection' in this block. The important operands are _split_heads: the value named 'split heads' in this block; value_projection: the value named 'value projection' in this block; heads: the value named 'heads' in this block. Context: the function forward, which handles forward.

Line 150: `attention = query @ key.transpose(-2, -1)` This assigns 'query @ key.transpose(-2, -1)' to 'attention ' in host memory. Here attention means the value named 'attention' in this block. The important operands are query: the value named 'query' in this block; key: the value named 'key' in this block; transpose: the value named 'transpose' in this block. Context: the function forward, which handles forward.

Line 151: `_observe(observer, f"{prefix}.qk", attention, False)` This calls '_observe' with 'observer, f"{prefix}.qk", attention, False' inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 152: `value = (attention @ value_projection) * 0.125` This assigns '(attention @ value_projection) * 0.125' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are attention: the value named 'attention' in this block; value_projection: the value named 'value projection' in this block. Context: the function forward, which handles forward.

Line 153: `_observe(observer, f"{prefix}.attention_value", value, False)` This calls '_observe' with 'observer, f"{prefix}.attention_value", value, False' inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 154: `value = value.transpose(3, 4).reshape(` This statement continues through source line 155; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'value.transpose(3, 4).reshape(time_steps, batch, channels, tokens)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are value: the value named 'value' in this block; transpose: the value named 'transpose' in this block; reshape: the value named 'reshape' in this block. Context: the function forward, which handles forward.

Line 155: `time_steps, batch, channels, tokens)` This is continuation line 2 of the 2-line logical statement that begins at source line 154. Its exact fragment is 'time_steps, batch, channels, tokens)'. The important operands are time_steps: the value named 'time steps' in this block; batch: the value named 'batch' in this block; channels: the value named 'channels' in this block. Read together, the complete operation is: This assigns 'value.transpose(3, 4).reshape(time_steps, batch, channels, tokens)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are value: the value named 'value' in this block; transpose: the value named 'transpose' in this block; reshape: the value named 'reshape' in this block. Context: the function forward, which handles forward.

Line 156: `value = self.attn_lif(value)` This assigns ‘self.attn_lif(value)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are attn_lif: the value named ’attn lif’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 157: `_observe(observer, f"{prefix}.attn_lif", value, True)` This calls ‘_observe‘ with ‘observer, f"{prefix}.attn_li value, True‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 158: `value = self.proj_bn(self.proj_conv(value.flatten(0, 1)))` This assigns ‘self.proj_bn(self.proj_conv(value.fl 1)))‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are proj_bn: the value named ’proj bn’ in this block; proj_conv: the value named ’proj conv’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 159: `value = value.reshape(time_steps, batch, channels, height, width)` This assigns ‘value.reshape(time_steps, batch, channels, height, width)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; reshape: the value named ’reshape’ in this block; time_steps: the value named ’time steps’ in this block. Context: the function forward, which handles forward.

Line 160: `_observe(observer, f"{prefix}.proj_bn", value, False)` This calls ‘_observe‘ with ‘observer, f"{prefix}.proj_b value, False‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 161: `return value` This returns ‘value‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are value: the value named ’value’ in this block.

Line 164: `class SpikingTransformer(nn.Module):` This defines class SpikingTransformer, which groups data and methods for spiking transformer. Instances exist in host memory and organize the flow that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 165: `"""One residual attention block followed by one residual spiking MLP."""` This is executable documentation attached to the class SpikingTransformer, which handles spiking transformer. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 167: `def __init__(self, channels: int, heads: int, mlp_ratio: int) -> None:` This starts function ___init___. Its indented body performs init as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 168: `super().__init__()` This calls ‘super‘ with ‘).___init___(‘ inside the function ___init___, which handles init. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 169: `# The upstream model creates these LayerNorm parameters but does not` The comment records this intent: The upstream model creates these LayerNorm parameters but does not It applies inside the function ___init___, which handles init.

Line 170: `# apply them in forward. Keeping them is required for strict loading.` The comment records this intent: apply them in forward. Keeping them is required for strict loading. It applies inside the function ___init___, which handles init.

Line 171: `self.norm1 = nn.LayerNorm(channels, eps=1e-6)` This assigns ‘nn.LayerNorm(channels, eps=1e-6)‘ to ‘self.norm1 ‘ in host memory. Here norm1 means the value named ’norm1’ in this block. The important operands are nn: the value named ’nn’ in this block; LayerNorm: the value named ’layer norm’ in this block; channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 172: `self.attn = SpikingSelfAttention(channels, heads)` This assigns ‘SpikingSelfAttention(channels, heads)‘ to ‘self.attn ‘ in host memory. Here attn means the value named ’attn’ in this block. The important operands are SpikingSelfAttention: the value named ’spiking self attention’ in this block; channels: the value named ’channels’ in this block; heads: the value named ’heads’ in this block. Context: the function ___init___, which handles init.

Line 173: `self.norm2 = nn.LayerNorm(channels, eps=1e-6)` This assigns ‘nn.LayerNorm(channels, eps=1e-6)‘ to ‘self.norm2 ‘ in host memory. Here norm2 means the value named ’norm2’ in this block. The important operands are nn: the value named ’nn’ in this block; LayerNorm: the value named ’layer norm’ in this block; channels: the value named ’channels’ in this block. Context: the function ___init___, which handles init.

Line 174: `self.mlp = MLP(channels, channels * mlp_ratio)` This assigns ‘MLP(channels, channels * mlp_ratio)‘ to ‘self.mlp ‘ in host memory. Here mlp means the value named ’mlp’ in this block. The important operands are MLP: the value named ’mlp’ in this block; channels: the value named ’channels’ in this block; mlp_ratio: the value named ’mlp ratio’ in this block. Context: the function ___init___, which handles init.

Line 176: `def forward(` This starts function forward. Its indented body performs forward as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 177: `self,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 178: `value: torch.Tensor,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are value: the value named ’value’ in this block; torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 179: `*,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 180: `prefix: str,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are prefix: the value named ’prefix’ in this block; str: the value named ’str’ in this block.

Line 181: `observer: TensorObserver | None,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are observer: the value named ’observer’ in this block; TensorObserver: the value named ’tensor observer’ in this block; None: the value named ’none’ in this block.

Line 182: `) -> torch.Tensor:` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 183: `value = value + self.attn(` This statement continues through source line 184; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘value + self.attn(value, prefix=f"{prefix}.attn", observer=observer)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; attn: the value named ’attn’ in this block; prefix: the value named ’prefix’ in this block. Context: the function forward, which handles forward.

Line 184: `value, prefix=f"{prefix}.attn", observer=observer)` This is continuation line 2 of the 2-line logical statement that begins at source line 183. Its exact fragment is ‘value, prefix=f"{prefix}.attn", observer=observer)‘. The important operands are value: the value named ’value’ in this block; prefix: the value named ’prefix’ in this block; f: the value named ’f’ in this block. Read together, the complete operation is: This assigns ‘value + self.attn(value, prefix=f"{prefix}.attn", observer=observer)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; attn: the value named ’attn’ in this block; prefix: the value named ’prefix’ in this block. Context: the function forward, which handles forward.

Line 185: `_observe(observer, f"{prefix}.attention_residual", value, False)` This calls ‘_observe‘ with ‘observer, f"{prefix}.attention_residual", value, False‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 186: `value = value + self.mlp(` This statement continues through source line 187; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘value + self.mlp(value, prefix=f"{prefix}.mlp", observer=observer)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; mlp: the value named ’mlp’ in this block; prefix: the value named ’prefix’ in this block. Context: the function forward, which handles forward.

Line 187: `value, prefix=f"{prefix}.mlp", observer=observer)` This is continuation line 2 of the 2-line logical statement that begins at source line 186. Its exact fragment is ‘value, prefix=f"{prefix}.mlp", observer=observer)‘. The important operands are value: the value named ’value’ in this block; prefix: the value named ’prefix’ in this block; f: the value named ’f’ in this block. Read together, the complete operation is: This assigns ‘value + self.mlp(value, prefix=f"{prefix}.mlp", observer=observer)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; mlp: the value named ’mlp’ in this block; prefix: the value named ’prefix’ in this block. Context: the function forward, which handles forward.

Line 188: `_observe(observer, f"{prefix}.mlp_residual", value, False)` This calls ‘_observe‘ with ‘observer, f"{prefix}.mlp_residual", value, False‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 189: `return value` This returns ‘value‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are value: the value named ’value’ in this block.

Line 192: `class SpikingTokenizer(nn.Module):` This defines class SpikingTokenizer, which groups data and methods for spiking tokenizer. Instances exist in host memory and organize the flow that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 193: `"""Five 3x3 convolutions that convert 32x32 RGB frames to 8x8 tokens."""` This is executable documentation attached to the class SpikingTokenizer, which handles spiking tokenizer. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 195: `def __init__(self, input_channels: int, embed_dim: int) -> None:` This starts function ___init___. Its indented body performs init as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 196: `super().__init__()` This calls ‘super‘ with ‘).___init___(‘ inside the function ___init___, which handles init. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 197: `widths = (embed_dim // 8, embed_dim // 4, embed_dim // 2, embed_dim)` This assigns ‘(embed_dim // 8, embed_dim // 4, embed_dim // 2, embed_dim)‘ to ‘widths ‘ in host memory. Here widths means the value named ’widths’ in this block. The important operands are embed_dim: the value named ’embed dim’ in this block. Context: the function ___init___, which handles init.

Line 198: `self.block0_conv = nn.Conv2d(` This statement continues through source line 199; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘nn.Conv2d(input_channels, widths[0], kernel_size=3, padding=1, bias=False)‘ to ‘self.block0_conv ‘ in host memory. Here block0_conv means the value named ’block0 conv’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv2d: the value named ’conv2d’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function ___init___, which handles init.

Line 199: `input_channels, widths[0], kernel_size=3, padding=1, bias=False)` This is continuation line 2 of the 2-line logical statement that begins at source line 198. Its exact fragment is ‘input_channels, widths[0], kernel_size=3, padding=1, bias=False)‘. The important operands are input_channels: the value named ’input channels’ in this block; widths: the value named ’widths’ in this block; kernel_size: the value named ’kernel size’ in this block. Read together, the complete operation is: This assigns ‘nn.Conv2d(input_channels, widths[0], kernel_size=3, padding=1, bias=False)‘ to ‘self.block0_conv ‘ in host memory. Here block0_conv means the value named ’block0 conv’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv2d: the value named ’conv2d’ in this block; input_channels: the value named ’input channels’ in this block. Context: the function ___init___, which handles init.

Line 200: `self.block0_bn = nn.BatchNorm2d(widths[0])` This assigns ‘nn.BatchNorm2d(widths[0])‘ to ‘self.block0_bn ‘ in host memory. Here block0_bn means the value named ’block0 bn’ in this block. The important operands are nn: the value named ’nn’ in this block; BatchNorm2d: the value named ’batch norm2d’ in this block; widths: the value named ’widths’ in this block. Context: the function ___init___, which handles init.

Line 201: `self.block1_lif = MultiStepHardResetLIF()` This assigns ‘MultiStepHardResetLIF()‘ to ‘self.block1_lif ‘ in host memory. Here block1_lif means the value named ’block1 lif’ in this block. The important operands are MultiStepHardResetLIF: the value named ’multi step hard reset lif’ in this block. Context: the function ___init___, which handles init.

Line 202: `self.block1_conv = nn.Conv2d(` This statement continues through source line 203; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘nn.Conv2d(widths[0], widths[1], kernel_size=3, padding=1, bias=False)‘ to ‘self.block1_conv ‘ in host memory. Here block1_conv means the value named ’block1 conv’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv2d: the value named ’conv2d’ in this block; widths: the value named ’widths’ in this block. Context: the function ___init___, which handles init.

Line 203: `widths[0], widths[1], kernel_size=3, padding=1, bias=False)` This is continuation line 2 of the 2-line logical statement that begins at source line 202. Its exact fragment is ‘widths[0], widths[1], kernel_size=3, padding=1, bias=False)‘. The important operands are widths: the value named ’widths’ in this block; kernel_size: the value named ’kernel size’ in this block; padding: the value named ’padding’ in this block. Read together, the complete operation is: This assigns ‘nn.Conv2d(widths[0], widths[1], kernel_size=3, padding=1, bias=False)‘ to ‘self.block1_conv ‘ in host memory. Here block1_conv means the value named ’block1 conv’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv2d: the value named ’conv2d’ in this block; widths: the value named ’widths’ in this block. Context: the function ___init___, which handles init.

Line 204: `self.block1_bn = nn.BatchNorm2d(widths[1])` This assigns ‘nn.BatchNorm2d(widths[1])‘ to ‘self.block1_bn ‘ in host memory. Here block1_bn means the value named ’block1 bn’ in this block. The important operands are nn: the value named ’nn’ in this block; BatchNorm2d: the value named ’batch norm2d’ in this block; widths: the value named ’widths’ in this block. Context: the function ___init___, which handles init.

Line 205: `self.block2_lif = MultiStepHardResetLIF()` This assigns ‘MultiStepHardResetLIF()‘ to ‘self.block2_lif ‘ in host memory. Here block2_lif means the value named ’block2 lif’ in this block. The important operands are MultiStepHardResetLIF: the value named ’multi step hard reset lif’ in this block. Context: the function ___init___, which handles init.

Line 206: `self.block2_conv = nn.Conv2d(` This statement continues through source line 207; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘nn.Conv2d(widths[1], widths[2], kernel_size=3, padding=1, bias=False)‘ to ‘self.block2_conv ‘ in host memory. Here block2_conv means the value named

'block2 conv' in this block. The important operands are nn: the value named 'nn' in this block; Conv2d: the value named 'conv2d' in this block; widths: the value named 'widths' in this block. Context: the function ___init___, which handles init.

Line 207: `widths[1], widths[2], kernel_size=3, padding=1, bias=False)` This is continuation line 2 of the 2-line logical statement that begins at source line 206. Its exact fragment is 'widths[1], widths[2], kernel_size=3, padding=1, bias=False)'. The important operands are widths: the value named 'widths' in this block; kernel_size: the value named 'kernel size' in this block; padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'nn.Conv2d(widths[1], widths[2], kernel_size=3, padding=1, bias=False)' to 'self.block2_conv ' in host memory. Here block2_conv means the value named 'block2 conv' in this block. The important operands are nn: the value named 'nn' in this block; Conv2d: the value named 'conv2d' in this block; widths: the value named 'widths' in this block. Context: the function ___init___, which handles init.

Line 208: `self.block2_bn = nn.BatchNorm2d(widths[2])` This assigns 'nn.BatchNorm2d(widths[2])' to 'self.block2_bn ' in host memory. Here block2_bn means the value named 'block2 bn' in this block. The important operands are nn: the value named 'nn' in this block; BatchNorm2d: the value named 'batch norm2d' in this block; widths: the value named 'widths' in this block. Context: the function ___init___, which handles init.

Line 209: `self.block3_lif = MultiStepHardResetLIF()` This assigns 'MultiStepHardResetLIF()' to 'self.block3_lif ' in host memory. Here block3_lif means the value named 'block3 lif' in this block. The important operands are MultiStepHardResetLIF: the value named 'multi step hard reset lif' in this block. Context: the function ___init___, which handles init.

Line 210: `self.block3_mp = nn.MaxPool2d(kernel_size=3, stride=2, padding=1)` This assigns 'nn.MaxPool2d(kernel_siz stride=2, padding=1)' to 'self.block3_mp ' in host memory. Here block3_mp means the value named 'block3 mp' in this block. The important operands are nn: the value named 'nn' in this block; MaxPool2d: the value named 'max pool2d' in this block; kernel_size: the value named 'kernel size' in this block. Context: the function ___init___, which handles init.

Line 211: `self.block3_conv = nn.Conv2d(` This statement continues through source line 212; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'nn.Conv2d(widths[2], widths[3], kernel_size=3, padding=1, bias=False)' to 'self.block3_conv ' in host memory. Here block3_conv means the value named 'block3 conv' in this block. The important operands are nn: the value named 'nn' in this block; Conv2d: the value named 'conv2d' in this block; widths: the value named 'widths' in this block. Context: the function ___init___, which handles init.

Line 212: `widths[2], widths[3], kernel_size=3, padding=1, bias=False)` This is continuation line 2 of the 2-line logical statement that begins at source line 211. Its exact fragment is 'widths[2], widths[3], kernel_size=3, padding=1, bias=False)'. The important operands are widths: the value named 'widths' in this block; kernel_size: the value named 'kernel size' in this block; padding: the value named 'padding' in this block. Read together, the complete operation is: This assigns 'nn.Conv2d(widths[2], widths[3], kernel_size=3, padding=1, bias=False)' to 'self.block3_conv ' in host memory. Here block3_conv means the value named 'block3 conv' in this block. The important operands are nn: the value named 'nn' in this block; Conv2d: the value named 'conv2d' in this block; widths: the value named 'widths' in this block. Context: the function ___init___, which handles init.

Line 213: `self.block3_bn = nn.BatchNorm2d(widths[3])` This assigns 'nn.BatchNorm2d(widths[3])' to 'self.block3_bn ' in host memory. Here block3_bn means the value named 'block3 bn' in this block. The important operands are nn: the value named 'nn' in this block; BatchNorm2d: the value named 'batch norm2d' in this block; widths: the value named 'widths' in this block. Context: the function ___init___, which handles init.

Line 214: `self.block4_lif = MultiStepHardResetLIF()` This assigns 'MultiStepHardResetLIF()' to 'self.block4_lif ' in host memory. Here block4_lif means the value named 'block4 lif' in this block. The important operands are MultiStepHardResetLIF: the value named 'multi step hard reset lif' in this block. Context: the function ___init___, which handles init.

Line 215: `self.block4_mp = nn.MaxPool2d(kernel_size=3, stride=2, padding=1)` This assigns ‘nn.MaxPool2d(kernel_siz stride=2, padding=1)‘ to ‘self.block4_mp ‘ in host memory. Here block4_mp means the value named ’block4 mp’ in this block. The important operands are nn: the value named ’nn’ in this block; MaxPool2d: the value named ’max pool2d’ in this block; kernel_size: the value named ’kernel size’ in this block. Context: the function ___init___, which handles init.

Line 216: `self.block4_conv = nn.Conv2d(` This statement continues through source line 217; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘nn.Conv2d(widths[3], widths[3], kernel_size=3, padding=1, bias=False)‘ to ‘self.block4_conv ‘ in host memory. Here block4_conv means the value named ’block4 conv’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv2d: the value named ’conv2d’ in this block; widths: the value named ’widths’ in this block. Context: the function ___init___, which handles init.

Line 217: `widths[3], widths[3], kernel_size=3, padding=1, bias=False)` This is continuation line 2 of the 2-line logical statement that begins at source line 216. Its exact fragment is ‘widths[3], widths[3], kernel_size=3, padding=1, bias=False)‘. The important operands are widths: the value named ’widths’ in this block; kernel_size: the value named ’kernel size’ in this block; padding: the value named ’padding’ in this block. Read together, the complete operation is: This assigns ‘nn.Conv2d(widths[3], widths[3], kernel_size=3, padding=1, bias=False)‘ to ‘self.block4_conv ‘ in host memory. Here block4_conv means the value named ’block4 conv’ in this block. The important operands are nn: the value named ’nn’ in this block; Conv2d: the value named ’conv2d’ in this block; widths: the value named ’widths’ in this block. Context: the function ___init___, which handles init.

Line 218: `self.block4_bn = nn.BatchNorm2d(widths[3])` This assigns ‘nn.BatchNorm2d(widths[3])‘ to ‘self.block4_bn ‘ in host memory. Here block4_bn means the value named ’block4 bn’ in this block. The important operands are nn: the value named ’nn’ in this block; BatchNorm2d: the value named ’batch norm2d’ in this block; widths: the value named ’widths’ in this block. Context: the function ___init___, which handles init.

Line 220: `def forward(` This starts function forward. Its indented body performs forward as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 221: `self,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 222: `value: torch.Tensor,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are value: the value named ’value’ in this block; torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 223: `*,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 224: `observer: TensorObserver | None,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are observer: the value named ’observer’ in this block; TensorObserver: the value named ’tensor observer’ in this block; None: the value named ’none’ in this block.

Line 225: `) -> torch.Tensor:` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 226: `time_steps, batch, _, height, width = value.shape` This assigns ‘value.shape‘ to ‘time_steps, batch, _, height, width ‘ in host memory. Here time_steps means the value named ’time steps’ in this block. The important operands are value: the value named ’value’ in this block; shape: the value named ’shape’ in this block. Context: the function forward, which handles forward.

Line 227: `value = self.block0_bn(self.block0_conv(value.flatten(0, 1)))` This assigns ‘self.block0_bn(self.block0_con 1)))‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block0_bn: the value named ’block0 bn’ in this block; block0_conv: the value named ’block0 conv’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 228: `value = value.reshape(time_steps, batch, -1, height, width)` This assigns ‘value.reshape(time_steps, batch, -1, height, width)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; reshape: the value named ’reshape’ in this block; time_steps: the value named ’time steps’ in this block. Context: the function forward, which handles forward.

Line 229: `_observe(observer, "patch_embed.block0_bn", value, False)` This calls ‘_observe‘ with ‘observer, "patch_embed.block0_bn", value, False‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 231: `value = self.block1_lif(value)` This assigns ‘self.block1_lif(value)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block1_lif: the value named ’block1 lif’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 232: `_observe(observer, "patch_embed.block1_lif", value, True)` This calls ‘_observe‘ with ‘observer, "patch_embed.block1_lif", value, True‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 233: `value = self.block1_bn(self.block1_conv(value.flatten(0, 1)))` This assigns ‘self.block1_bn(self.block1_con 1)))‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block1_bn: the value named ’block1 bn’ in this block; block1_conv: the value named ’block1 conv’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 234: `value = value.reshape(time_steps, batch, -1, height, width)` This assigns ‘value.reshape(time_steps, batch, -1, height, width)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; reshape: the value named ’reshape’ in this block; time_steps: the value named ’time steps’ in this block. Context: the function forward, which handles forward.

Line 235: `_observe(observer, "patch_embed.block1_bn", value, False)` This calls ‘_observe‘ with ‘observer, "patch_embed.block1_bn", value, False‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 237: `value = self.block2_lif(value)` This assigns ‘self.block2_lif(value)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block2_lif: the value named ’block2 lif’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 238: `_observe(observer, "patch_embed.block2_lif", value, True)` This calls ‘_observe‘ with ‘observer, "patch_embed.block2_lif", value, True‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 239: `value = self.block2_bn(self.block2_conv(value.flatten(0, 1)))` This assigns ‘self.block2_bn(self.block2_con 1)))‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block2_bn: the value named ’block2 bn’ in this block; block2_conv: the value named ’block2 conv’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 240: `value = value.reshape(time_steps, batch, -1, height, width)` This assigns ‘value.reshape(time_steps, batch, -1, height, width)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; reshape: the value named ’reshape’ in this block; time_steps: the value named ’time steps’ in this block. Context: the function forward, which handles forward.

Line 241: `_observe(observer, "patch_embed.block2_bn", value, False)` This calls ‘_observe‘ with ‘observer, "patch_embed.block2_bn", value, False‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 243: `value = self.block3_lif(value).flatten(0, 1)` This assigns ‘self.block3_lif(value).flatten(0, 1)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block3_lif: the value named ’block3 lif’ in this block; value: the value named ’value’ in this block; flatten: the value named ’flatten’ in this block. Context: the function forward, which handles forward.

Line 244: `_observe(observer, "patch_embed.block3_lif", value, True)` This calls ‘_observe‘ with ‘observer, "patch_embed.block3_lif", value, True‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 245: `value = self.block3_mp(value)` This assigns ‘self.block3_mp(value)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block3_mp: the value named ’block3 mp’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 246: `value = self.block3_bn(self.block3_conv(value))` This assigns ‘self.block3_bn(self.block3_conv(value))‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block3_bn: the value named ’block3 bn’ in this block; block3_conv: the value named ’block3 conv’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 247: `value = value.reshape(time_steps, batch, -1, height // 2, width // 2)` This assigns ‘value.reshape(time_s batch, -1, height // 2, width // 2)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; reshape: the value named ’reshape’ in this block; time_steps: the value named ’time steps’ in this block. Context: the function forward, which handles forward.

Line 248: `_observe(observer, "patch_embed.block3_bn", value, False)` This calls ‘_observe‘ with ‘observer, "patch_embed.block3_bn", value, False‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 250: `value = self.block4_lif(value).flatten(0, 1)` This assigns ‘self.block4_lif(value).flatten(0, 1)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block4_lif: the value named ’block4 lif’ in this block; value: the value named ’value’ in this block; flatten: the value named ’flatten’ in this block. Context: the function forward, which handles forward.

Line 251: `_observe(observer, "patch_embed.block4_lif", value, True)` This calls ‘_observe‘ with ‘observer, "patch_embed.block4_lif", value, True‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 252: `value = self.block4_mp(value)` This assigns ‘self.block4_mp(value)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block4_mp: the value named ’block4 mp’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 253: `value = self.block4_bn(self.block4_conv(value))` This assigns ‘self.block4_bn(self.block4_conv(value))‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are block4_bn: the value named ’block4 bn’ in this block; block4_conv: the value named ’block4 conv’ in this block; value: the value named ’value’ in this block. Context: the function forward, which handles forward.

Line 254: `value = value.reshape(time_steps, batch, -1, height // 4, width // 4)` This assigns ‘value.reshape(time_s batch, -1, height // 4, width // 4)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; reshape: the value named ’reshape’ in this block; time_steps: the value named ’time steps’ in this block. Context: the function forward, which handles forward.

Line 255: `_observe(observer, "patch_embed.block4_bn", value, False)` This calls ‘_observe‘ with ‘observer, "patch_embed.block4_bn", value, False‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 256: `return value` This returns ‘value‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are value: the value named ’value’ in this block.

Line 259: `class Spikingformer(nn.Module):` This defines class Spikingformer, which groups data and methods for spikingformer. Instances exist in host memory and organize the flow that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 260: `"""The exact Spikingformer-4-384 graph used by the CIFAR-10 run."""` This is executable documentation attached to the class Spikingformer, which handles spikingformer. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 262: `def __init__(` This starts function ___init___. Its indented body performs init as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 263: `self,` Inside the function ___init___, which handles init, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 264: `*,` Inside the function ___init___, which handles init, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 265: `time_steps: int = 4,` This assigns ‘4,‘ to ‘time_steps‘ in host memory. Here time_steps means the value named ’time steps’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 266: `input_channels: int = 3,` This assigns ‘3,‘ to ‘input_channels‘ in host memory. Here input_channels means the value named ’input channels’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 267: `classes: int = 10,` This assigns ‘10,‘ to ‘classes‘ in host memory. Here classes means the value named ’classes’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 268: `embed_dim: int = 384,` This assigns ‘384,‘ to ‘embed_dim‘ in host memory. Here embed_dim means the value named ’embed dim’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 269: `heads: int = 12,` This assigns ‘12,‘ to ‘heads‘ in host memory. Here heads means the value named ’heads’ in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 270: `depth: int = 4,` This assigns '4,' to 'depth' in host memory. Here depth means the value named 'depth' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 271: `mlp_ratio: int = 4,` This assigns '4,' to 'mlp_ratio' in host memory. Here mlp_ratio means the value named 'mlp ratio' in this block. The expression is a literal or structural operator and has no hidden software state. Context: the function ___init___, which handles init.

Line 272: `) -> None:` Inside the function ___init___, which handles init, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are None: the value named 'none' in this block.

Line 273: `super().__init__()` This calls 'super' with ').___init___(' inside the function ___init___, which handles init. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 274: `self.time_steps = time_steps` This assigns 'time_steps' to 'self.time_steps ' in host memory. Here time_steps means the value named 'time steps' in this block. The important operands are time_steps: the value named 'time steps' in this block. Context: the function ___init___, which handles init.

Line 275: `self.patch_embed = SpikingTokenizer(input_channels, embed_dim)` This assigns 'SpikingTokenizer(input_chan
embed_dim)' to 'self.patch_embed ' in host memory. Here patch_embed means the value named 'patch embed' in this block. The important operands are SpikingTokenizer: the value named 'spiking tokenizer' in this block; input_channels: the value named 'input channels' in this block; embed_dim: the value named 'embed dim' in this block. Context: the function ___init___, which handles init.

Line 276: `self.block = nn.ModuleList([` This statement continues through source line 279; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'nn.ModuleList([SpikingTransformer(embed_dim, heads, mlp_ratio) for _ in range(depth)])' to 'self.block ' in host memory. Here block means the value named 'block' in this block. The important operands are nn: the value named 'nn' in this block; ModuleList: the value named 'module list' in this block; SpikingTransformer: the value named 'spiking transformer' in this block. Context: the function ___init___, which handles init.

Line 277: `SpikingTransformer(embed_dim, heads, mlp_ratio)` This is continuation line 2 of the 4-line logical statement that begins at source line 276. Its exact fragment is 'SpikingTransformer(embed_dim, heads, mlp_ratio)'. The important operands are SpikingTransformer: the value named 'spiking transformer' in this block; embed_dim: the value named 'embed dim' in this block; heads: the value named 'heads' in this block. Read together, the complete operation is: This assigns 'nn.ModuleList([SpikingTransformer(embed_dim, heads, mlp_ratio) for _ in range(depth)])' to 'self.block ' in host memory. Here block means the value named 'block' in this block. The important operands are nn: the value named 'nn' in this block; ModuleList: the value named 'module list' in this block; SpikingTransformer: the value named 'spiking transformer' in this block. Context: the function ___init___, which handles init.

Line 278: `for _ in range(depth)` This is continuation line 3 of the 4-line logical statement that begins at source line 276. Its exact fragment is 'for _ in range(depth)'. The important operands are for: the value named 'for' in this block; _: the value named '' in this block; in: the value named 'in' in this block. Read together, the complete operation is: This assigns 'nn.ModuleList([SpikingTransformer(embed_dim, heads, mlp_ratio) for _ in range(depth)])' to 'self.block ' in host memory. Here block means the value named 'block' in this block. The important operands are nn: the value named 'nn' in this block; ModuleList: the value named 'module list' in this block; SpikingTransformer: the value named 'spiking transformer' in this block. Context: the function ___init___, which handles init.

Line 279: `])` This is continuation line 4 of the 4-line logical statement that begins at source line 276. Its exact fragment is '])'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'nn.ModuleList([SpikingTransformer(embed_dim, heads, mlp_ratio) for _ in range(depth)])' to 'self.block ' in host memory. Here block means the value named 'block' in this block. The important operands are

nn: the value named 'nn' in this block; ModuleList: the value named 'module list' in this block; SpikingTransformer: the value named 'spiking transformer' in this block. Context: the function ___init___, which handles init.

Line 280: `self.head = nn.Linear(embed_dim, classes)` This assigns 'nn.Linear(embed_dim, classes)' to 'self.head ' in host memory. Here head means the value named 'head' in this block. The important operands are nn: the value named 'nn' in this block; Linear: the value named 'linear' in this block; embed_dim: the value named 'embed dim' in this block. Context: the function ___init___, which handles init.

Line 282: `def forward(` This starts function forward. Its indented body performs forward as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 283: `self,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 284: `image: torch.Tensor,` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are image: the value named 'image' in this block; torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 285: `observer: TensorObserver | None = None,` This assigns 'None,' to 'observer' in host memory. Here observer means the value named 'observer' in this block. The important operands are None: the value named 'none' in this block. Context: the function forward, which handles forward.

Line 286: `) -> torch.Tensor:` Inside the function forward, which handles forward, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 287: `value = image.unsqueeze(0).repeat(self.time_steps, 1, 1, 1, 1)` This assigns 'image.unsqueeze(0).repeat(se 1, 1, 1, 1)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are image: the value named 'image' in this block; unsqueeze: the value named 'unsqueeze' in this block; repeat: the value named 'repeat' in this block. Context: the function forward, which handles forward.

Line 288: `_observe(observer, "input_repeated", value, False)` This calls '_observe' with 'observer, "input_repeated", value, False' inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 289: `value = self.patch_embed(value, observer=observer)` This assigns 'self.patch_embed(value, observer=observer) to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are patch_embed: the value named 'patch embed' in this block; value: the value named 'value' in this block; observer: the value named 'observer' in this block. Context: the function forward, which handles forward.

Line 290: `for index, transformer in enumerate(self.block):` This iterates index, transformer over 'enumerate(self.block)'. Each iteration repeats the indented host operation, commonly once per layer, tile, timestep, or test case in the function forward, which handles forward.

Line 291: `value = transformer(` This statement continues through source line 292; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'transformer(value, prefix=f"block.{index}", observer=observer)' to 'value ' in host memory. Here value means the value named 'value' in this block. The important operands are transformer: the value named 'transformer' in this block; value: the value named 'value' in this block; prefix: the value named 'prefix' in this block. Context: the function forward, which handles forward.

Line 292: `value, prefix=f"block.{index}", observer=observer)` This is continuation line 2 of the 2-line logical statement that begins at source line 291. Its exact fragment is ‘value, prefix=f"block.{index}", observer=observer)‘. The important operands are value: the value named ’value’ in this block; prefix: the value named ’prefix’ in this block; f: the value named ’f’ in this block. Read together, the complete operation is: This assigns ‘transformer(value, prefix=f"block.{index}", observer=observer)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are transformer: the value named ’transformer’ in this block; value: the value named ’value’ in this block; prefix: the value named ’prefix’ in this block. Context: the function forward, which handles forward.

Line 293: `value = value.flatten(3).mean(3)` This assigns ‘value.flatten(3).mean(3)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; flatten: the value named ’flatten’ in this block; mean: the arithmetic average used by normalization. Context: the function forward, which handles forward.

Line 294: `_observe(observer, "global_average_pool", value, False)` This calls ‘_observe‘ with ‘observer, "global_averag value, False‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 295: `value = self.head(value.mean(0))` This assigns ‘self.head(value.mean(0))‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are head: the value named ’head’ in this block; value: the value named ’value’ in this block; mean: the arithmetic average used by normalization. Context: the function forward, which handles forward.

Line 296: `_observe(observer, "head", value, False)` This calls ‘_observe‘ with ‘observer, "head", value, False‘ inside the function forward, which handles forward. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 297: `return value` This returns ‘value‘ to the caller of the function forward, which handles forward, ending this invocation. The important operands are value: the value named ’value’ in this block.

Line 300: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it creates no FPGA circuit by itself.

Line 301: `class LoadedCheckpoint:` This defines class LoadedCheckpoint, which groups data and methods for loaded checkpoint. Instances exist in host memory and organize the flow that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 302: `"""Strictly loaded model plus provenance stored by the training run."""` This is executable documentation attached to the class LoadedCheckpoint, which handles loaded checkpoint. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 304: `model: Spikingformer` Inside the class LoadedCheckpoint, which handles loaded checkpoint, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are model: the value named ’model’ in this block; Spikingformer: the value named ’spikingformer’ in this block.

Line 305: `epoch: int` Inside the class LoadedCheckpoint, which handles loaded checkpoint, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are epoch: the value named ’epoch’ in this block.

Line 306: `metric: float` Inside the class LoadedCheckpoint, which handles loaded checkpoint, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are metric: the value named ’metric’ in this block; float: the value named ’float’ in this block.

Line 307: `architecture: str` Inside the class LoadedCheckpoint, which handles loaded checkpoint, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are architecture: the value named 'architecture' in this block; str: the value named 'str' in this block.

Line 308: `checkpoint_path: Path` Inside the class LoadedCheckpoint, which handles loaded checkpoint, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are checkpoint_path: the value named 'checkpoint path' in this block; Path: the value named 'path' in this block.

Line 311: `def load_checkpoint(` This starts function load_checkpoint. Its indented body performs load checkpoint as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 312: `checkpoint_path: str | Path,` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are checkpoint_path: the value named 'checkpoint path' in this block; str: the value named 'str' in this block; Path: the value named 'path' in this block.

Line 313: `*,` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The expression is a literal or structural operator and has no hidden software state.

Line 314: `device: str | torch.device = "cpu",` This assigns ‘"cpu",‘ to ‘device‘ in host memory. Here device means the value named 'device' in this block. The important operands are cpu: the value named 'cpu' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 315: `) -> LoadedCheckpoint:` Inside the function load_checkpoint, which handles load checkpoint, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are LoadedCheckpoint: the value named 'loaded checkpoint' in this block.

Line 316: `"""Load the trained checkpoint and reject every state-dictionary mismatch."""` This is executable documentation attached to the function load_checkpoint, which handles load checkpoint. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 318: `path = Path(checkpoint_path).expanduser().resolve()` This assigns ‘Path(checkpoint_path).expanduser().resol
to ‘path ‘ in host memory. Here path means the value named 'path' in this block. The important operands are Path: the value named 'path' in this block; checkpoint_path: the value named 'checkpoint path' in this block; expanduser: the value named 'expanduser' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 319: `checkpoint: Mapping[str, Any] = torch.load(path, map_location="cpu")` This assigns ‘torch.load(path, map_location="cpu")‘ to ‘checkpoint‘ in host memory. Here checkpoint means the value named 'checkpoint' in this block. The important operands are torch: the value named 'torch' in this block; load: the value named 'load' in this block; path: the value named 'path' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 320: `arguments = checkpoint.get("args")` This assigns ‘checkpoint.get("args")‘ to ‘arguments ‘ in host memory. Here arguments means the value named 'arguments' in this block. The important operands are checkpoint: the value named 'checkpoint' in this block; get: the value named 'get' in this block; args: the value named 'args' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 321: `if arguments is None:` This executes the following indented host-code branch only when ‘arguments is None‘ is true. The important operands are arguments: the value named 'arguments' in this block; is: the value named 'is' in this block; None: the value named 'none' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 322: `raise ValueError("checkpoint does not contain its training arguments")` This rejects an invalid state by raising ‘ValueError("checkpoint does not contain its training arguments")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 323: `model = Spikingformer(` This statement continues through source line 331; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘Spikingformer(time_steps=int(getattr(arguments, "time_step")), input_channels=3, classes=int(getattr(arguments, "num_classes")), embed_dim=int(getattr(arguments, "dim")), heads=int(getattr(arguments, "num_heads")), depth=int(getattr(arguments, "depths", getattr(arguments, "layer"))), mlp_ratio=int(getattr(arguments, "mlp_ratio")),)‘ to ‘model ‘ in host memory. Here model means the value named ’model’ in this block. The important operands are Spikingformer: the value named ’spikingformer’ in this block; time_steps: the value named ’time steps’ in this block; getattr: the value named ’getattr’ in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 324: `time_steps=int(getattr(arguments, "time_step")),` This is continuation line 2 of the 9-line logical statement that begins at source line 323. Its exact fragment is ‘time_steps=int(getattr(arguments, "time_step")),‘. The important operands are time_steps: the value named ’time steps’ in this block; getattr: the value named ’getattr’ in this block; arguments: the value named ’arguments’ in this block. Read together, the complete operation is: This assigns ‘Spikingformer(time_steps=int(getattr(arguments, "time_step")), input_channels=3, classes=int(getattr(arguments, "num_classes")), embed_dim=int(getattr(arguments, "dim")), heads=int(getattr(arguments, "num_heads")), depth=int(getattr(arguments, "depths", getattr(arguments, "layer"))), mlp_ratio=int(getattr(arguments, "mlp_ratio")),)‘ to ‘model ‘ in host memory. Context: the function load_checkpoint, which handles load checkpoint.

Line 329: `depth=int(getattr(arguments, "depths", getattr(arguments, "layer"))),` This is continuation line 7 of the 9-line logical statement that begins at source line 323. Its exact fragment is 'depth=int(getattr(arguments, "depths", getattr(arguments, "layer"))),'. The important operands are depth: the value named 'depth' in this block; getattr: the value named 'getattr' in this block; arguments: the value named 'arguments' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=int(getattr(arguments, "time_step")), input_channels=3, classes=int(getattr(arguments, "num_classes")), embed_dim=int(getattr(arguments, "dim")), heads=int(getattr(
"num_heads")), depth=int(getattr(arguments, "depths", getattr(arguments, "layer"))), mlp_ratio=int(getattr(arguments, "mlp_ratio")),)' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; getattr: the value named 'getattr' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 330: `mlp_ratio=int(getattr(arguments, "mlp_ratio")),` This is continuation line 8 of the 9-line logical statement that begins at source line 323. Its exact fragment is 'mlp_ratio=int(getattr(arguments, "mlp_ratio")),'. The important operands are mlp_ratio: the value named 'mlp ratio' in this block; getattr: the value named 'getattr' in this block; arguments: the value named 'arguments' in this block. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=int(getattr(arguments, "time_step")), input_channels=3, classes=int(getattr(arguments, "num_classes")), embed_dim=int(getattr(arguments, "dim")), heads=int(getattr(arguments, "num_heads")), depth=int(getattr(ar
"depths", getattr(arguments, "layer"))), mlp_ratio=int(getattr(arguments, "mlp_ratio")),)' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; getattr: the value named 'getattr' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 331: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 323. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This assigns 'Spikingformer(time_steps=int(getattr(arguments, "time_step")), input_channels=3, classes=int(getattr(arguments, "num_classes")), embed_dim=int(getattr(arguments, "dim")), heads=int(getattr(arguments, "num_heads")), depth=int(getattr(arguments, "depths", getattr(arguments, "layer"))), mlp_ratio=int(getattr(arguments, "mlp_ratio")),)' to 'model ' in host memory. Here model means the value named 'model' in this block. The important operands are Spikingformer: the value named 'spikingformer' in this block; time_steps: the value named 'time steps' in this block; getattr: the value named 'getattr' in this block. Context: the function load_checkpoint, which handles load checkpoint.

Line 332: `state = checkpoint.get("state_dict")` This assigns 'checkpoint.get("state_dict")' to 'state ' in host memory. Here state means the finite-state-machine phase retained in flip-flops. The important operands are checkpoint: the value named 'checkpoint' in this block; get: the value named 'get' in this block; state_dict: the finite-state-machine phase retained in flip-flops. Context: the function load_checkpoint, which handles load checkpoint.

Line 333: `if not isinstance(state, Mapping):` This executes the following indented host-code branch only when 'not isinstance(state, Mapping)' is true. The important operands are not: the value named 'not' in this block; isinstance: the value named 'isinstance' in this block; state: the finite-state-machine phase retained in flip-flops. Context: the function load_checkpoint, which handles load checkpoint.

Line 334: `raise ValueError("checkpoint does not contain a state_dict mapping")` This rejects an invalid state by raising 'ValueError("checkpoint does not contain a state_dict mapping")'. Failing before DMA prevents mal-

formed shapes or artifacts from silently becoming hardware results.

Line 335: `model.load_state_dict(state, strict=True)` This calls ‘model.load_state_dict‘ with ‘state, strict=True‘ inside the function load_checkpoint, which handles load checkpoint. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 336: `model.eval().to(device)` This calls ‘model.eval‘ with ‘).to(device‘ inside the function load_checkpoint, which handles load checkpoint. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

Line 337: `return LoadedCheckpoint(` This statement continues through source line 343; the explanation uses the complete expression rather than only the first visual fragment. This returns ‘LoadedCheckpoint(model=model, epoch=int(checkpoint.get("epoch", -1)), metric=float(checkpoint.get("metric", float("nan"))), architecture=str(checkpoint.get("arch" "unknown")), checkpoint_path=path,)‘ to the caller of the function load_checkpoint, which handles load checkpoint, ending this invocation. The important operands are LoadedCheckpoint: the value named ’loaded checkpoint’ in this block; model: the value named ’model’ in this block; epoch: the value named ’epoch’ in this block.

Line 338: `model=model,` This is continuation line 2 of the 7-line logical statement that begins at source line 337. Its exact fragment is ‘model=model,‘. The important operands are model: the value named ’model’ in this block. Read together, the complete operation is: This returns ‘LoadedCheckpoint(model=model, epoch=int(checkpoint.get("epoch", -1)), metric=float(checkpoint.get("metric", float("nan"))), architecture=str(checkpoint.get("arch", "unknown")), checkpoint_path=path,)‘ to the caller of the function load_checkpoint, which handles load checkpoint, ending this invocation. The important operands are LoadedCheckpoint: the value named ’loaded checkpoint’ in this block; model: the value named ’model’ in this block; epoch: the value named ’epoch’ in this block.

Line 339: `epoch=int(checkpoint.get("epoch", -1)),` This is continuation line 3 of the 7-line logical statement that begins at source line 337. Its exact fragment is ‘epoch=int(checkpoint.get("epoch", -1)),‘. The important operands are epoch: the value named ’epoch’ in this block; checkpoint: the value named ’checkpoint’ in this block; get: the value named ’get’ in this block. Read together, the complete operation is: This returns ‘LoadedCheckpoint(model=model, epoch=int(checkpoint.get("epoch", -1)), metric=float(checkpoint.get("metric", float("nan"))), architecture=str(checkpoint.get("arch" "unknown")), checkpoint_path=path,)‘ to the caller of the function load_checkpoint, which handles load checkpoint, ending this invocation. The important operands are LoadedCheckpoint: the value named ’loaded checkpoint’ in this block; model: the value named ’model’ in this block; epoch: the value named ’epoch’ in this block.

Line 340: `metric=float(checkpoint.get("metric", float("nan"))),` This is continuation line 4 of the 7-line logical statement that begins at source line 337. Its exact fragment is ‘metric=float(checkpoint.get("metric", float("nan"))),‘. The important operands are metric: the value named ’metric’ in this block; float: the value named ’float’ in this block; checkpoint: the value named ’checkpoint’ in this block. Read together, the complete operation is: This returns ‘LoadedCheckpoint(model=model, epoch=int(checkpoint.get("epoch", -1)), metric=float(checkpoint.get("metric", float("nan"))), architecture=str(checkpoint.get("arch", "unknown")), checkpoint_path=path,)‘ to the caller of the function load_checkpoint, which handles load checkpoint, ending this invocation. The important operands are LoadedCheckpoint: the value named ’loaded checkpoint’ in this block; model: the value named ’model’ in this block; epoch: the value named ’epoch’ in this block.

Line 341: `architecture=str(checkpoint.get("arch", "unknown")),` This is continuation line 5 of the 7-line logical statement that begins at source line 337. Its exact fragment is ‘architecture=str(checkpoint.get("arch", "unknown")),‘. The important operands are architecture: the value named ’architecture’ in this block; str: the value named ’str’ in this block; checkpoint: the value named ’checkpoint’ in this block. Read together, the complete operation is: This returns ‘LoadedCheckpoint(model=model, epoch=int(checkpoint.get("epoch", -1)), metric=float(checkpoint.get("metric", float("nan"))), architecture=str(checkpoint.get("arch", "unknown")), checkpoint_path=path,)‘ to the caller of the function load_checkpoint, which handles load checkpoint, ending this invocation. The important operands are LoadedCheckpoint: the value named ’loaded checkpoint’ in this block; model: the value named ’model’ in this block; epoch: the value named ’epoch’ in this block.

Line 342: `checkpoint_path=path,` This is continuation line 6 of the 7-line logical statement that begins at source line 337. Its exact fragment is 'checkpoint_path=path,'. The important operands are checkpoint_path: the value named 'checkpoint path' in this block; path: the value named 'path' in this block. Read together, the complete operation is: This returns 'LoadedCheckpoint(model=model, epoch=int(checkpoint.get("epoch", -1)), metric=float(checkpoint.get("metric", float("nan"))), architecture=str(checkpoint.get("arch", "unknown")), checkpoint_path=path,)' to the caller of the function load_checkpoint, which handles load checkpoint, ending this invocation. The important operands are LoadedCheckpoint: the value named 'loaded checkpoint' in this block; model: the value named 'model' in this block; epoch: the value named 'epoch' in this block.

Line 343: `)` This is continuation line 7 of the 7-line logical statement that begins at source line 337. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This returns 'LoadedCheckpoint(model=model, epoch=int(checkpoint.get("epoch", -1)), metric=float(checkpoint.get("metric", float("nan"))), architecture=str(checkpoint.get("arch", "unknown")), checkpoint_path=path,)' to the caller of the function load_checkpoint, which handles load checkpoint, ending this invocation. The important operands are LoadedCheckpoint: the value named 'loaded checkpoint' in this block; model: the value named 'model' in this block; epoch: the value named 'epoch' in this block.

Line 346: `def fold_batch_norm(` This starts function fold_batch_norm. Its indented body performs fold batch norm as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 347: `convolution: nn.Conv1d | nn.Conv2d,` Inside the function fold_batch_norm, which handles fold batch norm, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are convolution: the value named 'convolution' in this block; nn: the value named 'nn' in this block; Conv1d: the value named 'conv1d' in this block.

Line 348: `batch_norm: nn.BatchNorm1d | nn.BatchNorm2d,` Inside the function fold_batch_norm, which handles fold batch norm, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are batch_norm: the value named 'batch norm' in this block; nn: the value named 'nn' in this block; BatchNorm1d: the value named 'batch norm1d' in this block.

Line 349: `) -> tuple[torch.Tensor, torch.Tensor]:` Inside the function fold_batch_norm, which handles fold batch norm, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are tuple: the value named 'tuple' in this block; torch: the value named 'torch' in this block; Tensor: the value named 'tensor' in this block.

Line 350: `"""Return convolution weight/bias tensors with evaluation BatchNorm folded.` This is executable documentation attached to the function fold_batch_norm, which handles fold batch norm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 352: `For each output channel "o", BatchNorm applies` Inside the function fold_batch_norm, which handles fold batch norm, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are For: the value named 'for' in this block; each: the value named 'each' in this block; output: the value named 'output' in this block.

Line 353: `"gamma[o] * (y - mean[o]) / sqrt(var[o] + eps) + beta[o]".` Inside the function fold_batch_norm, which handles fold batch norm, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are gamma: the learned multiplicative LayerNorm parameter; o: the value named 'o' in this block; y: the value named 'y' in this block.

Line 354: `Multiplying the convolution kernel and shifting its bias by those constants` Inside the function fold_batch_norm, which handles fold batch norm, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are

Multiplying: the value named 'multiplying' in this block; the: the value named 'the' in this block; convolution: the value named 'convolution' in this block.

Line 355: `produces exactly the same evaluation result up to floating-point rounding.` Inside the function fold_batch_norm, which handles fold batch norm, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are produces: the value named 'produces' in this block; exactly: the value named 'exactly' in this block; the: the value named 'the' in this block.

Line 356: `"""` This is executable documentation attached to the function fold_batch_norm, which handles fold batch norm. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 358: `if convolution.out_channels != batch_norm.num_features:` This executes the following indented host-code branch only when 'convolution.out_channels != batch_norm.num_features' is true. The important operands are convolution: the value named 'convolution' in this block; out_channels: the value named 'out channels' in this block; batch_norm: the value named 'batch norm' in this block. Context: the function fold_batch_norm, which handles fold batch norm.

Line 359: `raise ValueError("convolution and BatchNorm output widths differ")` This rejects an invalid state by raising 'ValueError("convolution and BatchNorm output widths differ")'. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 360: `weight = convolution.weight.detach()` This assigns 'convolution.weight.detach()' to 'weight ' in host memory. Here weight means a learned coefficient multiplied by an activation. The important operands are convolution: the value named 'convolution' in this block; weight: a learned coefficient multiplied by an activation; detach: the value named 'detach' in this block. Context: the function fold_batch_norm, which handles fold batch norm.

Line 361: `if convolution.bias is None:` This executes the following indented host-code branch only when 'convolution.bias is None' is true. The important operands are convolution: the value named 'convolution' in this block; bias: an additive learned offset applied after accumulation; is: the value named 'is' in this block. Context: the function fold_batch_norm, which handles fold batch norm.

Line 362: `bias = torch.zeros(` This statement continues through source line 363; the explanation uses the complete expression rather than only the first visual fragment. This assigns 'torch.zeros(convolution.out_channels, dtype=weight.dtype, device=weight.device)' to 'bias ' in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are torch: the value named 'torch' in this block; zeros: the value named 'zeros' in this block; convolution: the value named 'convolution' in this block. Context: the function fold_batch_norm, which handles fold batch norm.

Line 363: `convolution.out_channels, dtype=weight.dtype, device=weight.device)` This is continuation line 2 of the 2-line logical statement that begins at source line 362. Its exact fragment is 'convolution.out_channels, dtype=weight.dtype, device=weight.device)'. The important operands are convolution: the value named 'convolution' in this block; out_channels: the value named 'out channels' in this block; dtype: the value named 'dtype' in this block. Read together, the complete operation is: This assigns 'torch.zeros(convolution.out_channels, dtype=weight.dtype, device=weight.device)' to 'bias ' in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are torch: the value named 'torch' in this block; zeros: the value named 'zeros' in this block; convolution: the value named 'convolution' in this block. Context: the function fold_batch_norm, which handles fold batch norm.

Line 364: `else:` This begins the alternative host-code branch when the preceding condition was false, still inside the function fold_batch_norm, which handles fold batch norm.

Line 365: `bias = convolution.bias.detach()` This assigns ‘convolution.bias.detach()‘ to ‘bias ‘ in host memory. Here bias means an additive learned offset applied after accumulation. The important operands are convolution: the value named ’convolution’ in this block; bias: an additive learned offset applied after accumulation; detach: the value named ’detach’ in this block. Context: the function fold_batch_norm, which handles fold batch norm.

Line 366: `scale = batch_norm.weight.detach() / torch.sqrt(` This statement continues through source line 367; the explanation uses the complete expression rather than only the first visual fragment. This assigns ‘batch_norm.weight.detach() / torch.sqrt(batch_norm.running_var.detach() + batch_norm.eps)‘ to ‘scale ‘ in host memory. Here scale means the real-value spacing represented by one quantized integer step. The important operands are batch_norm: the value named ’batch norm’ in this block; weight: a learned coefficient multiplied by an activation; detach: the value named ’detach’ in this block. Context: the function fold_batch_norm, which handles fold batch norm.

Line 367: `batch_norm.running_var.detach() + batch_norm.eps)` This is continuation line 2 of the 2-line logical statement that begins at source line 366. Its exact fragment is ‘batch_norm.running_var.detach() + batch_norm.eps)‘. The important operands are batch_norm: the value named ’batch norm’ in this block; running_var: the value named ’running var’ in this block; detach: the value named ’detach’ in this block. Read together, the complete operation is: This assigns ‘batch_norm.weight.detach() / torch.sqrt(batch_norm.running_var.detach() + batch_norm.eps)‘ to ‘scale ‘ in host memory. Here scale means the real-value spacing represented by one quantized integer step. The important operands are batch_norm: the value named ’batch norm’ in this block; weight: a learned coefficient multiplied by an activation; detach: the value named ’detach’ in this block. Context: the function fold_batch_norm, which handles fold batch norm.

Line 368: `reshape = (scale.shape[0],) + (1,) * (weight.ndim - 1)` This assigns ‘(scale.shape[0],) + (1,) * (weight.ndim - 1)‘ to ‘reshape ‘ in host memory. Here reshape means the value named ’reshape’ in this block. The important operands are scale: the real-value spacing represented by one quantized integer step; shape: the value named ’shape’ in this block; weight: a learned coefficient multiplied by an activation. Context: the function fold_batch_norm, which handles fold batch norm.

Line 369: `folded_weight = weight * scale.reshape(reshape)` This assigns ‘weight * scale.reshape(reshape)‘ to ‘folded_weight ‘ in host memory. Here folded_weight means a learned coefficient multiplied by an activation. The important operands are weight: a learned coefficient multiplied by an activation; scale: the real-value spacing represented by one quantized integer step; reshape: the value named ’reshape’ in this block. Context: the function fold_batch_norm, which handles fold batch norm.

Line 370: `folded_bias = (bias - batch_norm.running_mean.detach()) * scale` This assigns ‘(bias - batch_norm.running_ * scale‘ to ‘folded_bias ‘ in host memory. Here folded_bias means an additive learned offset applied after accumulation. The important operands are bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; running_mean: the arithmetic average used by normalization. Context: the function fold_batch_norm, which handles fold batch norm.

Line 371: `folded_bias = folded_bias + batch_norm.bias.detach()` This assigns ‘folded_bias + batch_norm.bias.detach()‘ to ‘folded_bias ‘ in host memory. Here folded_bias means an additive learned offset applied after accumulation. The important operands are folded_bias: an additive learned offset applied after accumulation; batch_norm: the value named ’batch norm’ in this block; bias: an additive learned offset applied after accumulation. Context: the function fold_batch_norm, which handles fold batch norm.

Line 372: `return folded_weight, folded_bias` This returns ‘folded_weight, folded_bias‘ to the caller of the function fold_batch_norm, which handles fold batch norm, ending this invocation. The important operands are folded_weight: a learned coefficient multiplied by an activation; folded_bias: an additive learned offset applied after accumulation.

Line 375: `def _split_heads(value: torch.Tensor, heads: int) -> torch.Tensor:` This starts function _split_heads. Its indented body performs split heads as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 376: `time_steps, batch, channels, tokens = value.shape` This assigns ‘value.shape‘ to ‘time_steps, batch, channels, tokens ‘ in host memory. Here time_steps means the value named ’time steps’ in this block. The important operands are value: the value named ’value’ in this block; shape: the value named ’shape’ in this block. Context: the function _split_heads, which handles split heads.

Line 377: `head_dim = channels // heads` This assigns ‘channels // heads‘ to ‘head_dim ‘ in host memory. Here head_dim means the value named ’head dim’ in this block. The important operands are channels: the value named ’channels’ in this block; heads: the value named ’heads’ in this block. Context: the function _split_heads, which handles split heads.

Line 378: `value = value.transpose(-1, -2)` This assigns ‘value.transpose(-1, -2)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; transpose: the value named ’transpose’ in this block. Context: the function _split_heads, which handles split heads.

Line 379: `value = value.reshape(time_steps, batch, tokens, heads, head_dim)` This assigns ‘value.reshape(time_steps, batch, tokens, heads, head_dim)‘ to ‘value ‘ in host memory. Here value means the value named ’value’ in this block. The important operands are value: the value named ’value’ in this block; reshape: the value named ’reshape’ in this block; time_steps: the value named ’time steps’ in this block. Context: the function _split_heads, which handles split heads.

Line 380: `return value.permute(0, 1, 3, 2, 4)` This returns ‘value.permute(0, 1, 3, 2, 4)‘ to the caller of the function _split_heads, which handles split heads, ending this invocation. The important operands are value: the value named ’value’ in this block; permute: the value named ’permute’ in this block.

Line 383: `def _observe(` This starts function _observe. Its indented body performs observe as part of the file that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison; it runs only when called.

Line 384: `observer: TensorObserver | None,` Inside the function _observe, which handles observe, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are observer: the value named ’observer’ in this block; TensorObserver: the value named ’tensor observer’ in this block; None: the value named ’none’ in this block.

Line 385: `name: str,` Inside the function _observe, which handles observe, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are name: the value named ’name’ in this block; str: the value named ’str’ in this block.

Line 386: `value: torch.Tensor,` Inside the function _observe, which handles observe, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are value: the value named ’value’ in this block; torch: the value named ’torch’ in this block; Tensor: the value named ’tensor’ in this block.

Line 387: `is_spike: bool,` Inside the function _observe, which handles observe, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are is_spike: a binary event produced when a neuron crosses its threshold; bool: the value named ’bool’ in this block.

Line 388: `) -> None:` Inside the function _observe, which handles observe, this statement advances the host implementation that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison. The important operands are None: the value named ’none’ in this block.

Line 389: `if observer is not None:` This executes the following indented host-code branch only when ‘observer is not None‘ is true. The important operands are observer: the value named ’observer’ in this block; is: the value named ’is’ in this block; not: the value named ’not’ in this block. Context: the function _observe, which handles observe.

Line 390: `observer(name, value, is_spike)` This calls ‘observer‘ with ‘name, value, is_spike‘ inside the function _observe, which handles observe. The call advances the host-side job that reconstructs the trained source graph and its integer hardware-emulation path for accuracy comparison.

44 software/spikingformer_training_runtime.py

Role in the complete system: runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

44.1 Beginner architecture map

Dataflow responsibility Each epoch loads deterministic CIFAR-10 shards, executes the quantized forward graph, forms the supervised loss gradient, and dispatches hardware backward and optimizer descriptor programs. Updated parameter and velocity arrays are checkpointed atomically with epoch, sample cursor, RNG state, hashes, and metrics, so pause or power loss resumes from a committed minibatch boundary instead of replaying an ambiguous update.

Where it runs This is sequential host software. Python objects live in CPU memory; they become FPGA work only when the compiler packs a command or payload and the PYNQ driver transfers those bytes through AXI DMA or AXI-Lite.

Public structure Classes: FullTrainingDriver, BlockGradient, ParameterGradient, MasterTensor, TrainableSpikingformerState, LifTraceCache, TokenizerLayerCache, AttentionCache, MlpCache, TransformerBlockCache, SpikingformerTrainingCache, TrainingBackwardResult, TrainingStepResult, SpikingformerOnDeviceTrainer. Functions: __padded__lanes, execute__vector__tensor, execute__power__of__two__scale, normalize__gradient__s16, add__block__gradients, __required__right__shift, backward__requantize__projection, execute__linear__backward__block, execute__affine__backward__block execute__conv2d__backward__block, execute__softmax__q15, execute__cross__entropy__gradient__q15, __master__fractional__bits, execute__deploy__master, gradient__to__optimizer__q15, ___post__init___, reshape, transpose, ___post__init___, ___init___, projection__names, projection, head, _optimizer__coefficients. Each function annotation below names its enclosing function so an array operation is tied to the model, compiler, driver, test, or report phase that uses it.

Numeric and failure boundary Shapes, signedness, byte order, scaling, and saturation are part of the hardware contract. Validation exceptions are functional safety checks: rejecting malformed input before DMA is different from silently clipping, reshaping, or continuing with an incompatible artifact.

44.2 Complete source

```
"""Full fixed-point Spikingformer training runtime for the NeuraEdge fabric.

The processing system owns graph scheduling and DDR tensors. Matrix derivatives,
surrogate-gradient recurrence, pooling scatter, vector arithmetic, softmax, and
SGDW updates are submitted to programmable-logic engines through the command ABI.

Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 29: `unpack_softmax_result,` This is continuation line 8 of the 11-line logical statement that begins at source line 22. Its exact fragment is 'unpack_softmax_result,'. The important operands are unpack_softmax_result: the value named 'unpack softmax result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 30: `unpack_vector_result,` This is continuation line 9 of the 11-line logical statement that begins at source line 22. Its exact fragment is 'unpack_vector_result,'. The important operands are unpack_vector_result: the value named 'unpack vector result' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 31: `vector_command,` This is continuation line 10 of the 11-line logical statement that begins at source line 22. Its exact fragment is 'vector_command,'. The important operands are vector_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 32: `)` This is continuation line 11 of the 11-line logical statement that begins at source line 22. Its exact fragment is ')'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 33: `from neuraedge_training import (` This statement continues through source line 41; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 34: `TrainingProgramExecutor,` This is continuation line 2 of the 9-line logical statement that begins at source line 33. Its exact fragment is 'TrainingProgramExecutor,'. The important operands are TrainingProgramExecutor: the value named 'training program executor' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 35: `compile_affine_backward,` This is continuation line 3 of the 9-line logical statement that begins at source line 33. Its exact fragment is 'compile_affine_backward,'. The important operands are compile_affine_backward: the value named 'compile affine backward' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 36: `compile_conv2d_backward,` This is continuation line 4 of the 9-line logical statement that begins at source line 33. Its exact fragment is 'compile_conv2d_backward,'. The important operands are compile_conv2d_backward: the value named 'compile conv2d backward' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 37: `compile_linear_backward,` This is continuation line 5 of the 9-line logical statement that begins at source line 33. Its exact fragment is 'compile_linear_backward,'. The important operands are compile_linear_backward: the value named 'compile linear backward' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 38: `execute_lif_bptt,` This is continuation line 6 of the 9-line logical statement that begins at source line 33. Its exact fragment is 'execute_lif_bptt,'. The important operands are execute_lif_bptt: the value named 'execute lif bptt' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 39: `execute_maxpool2d_backward,` This is continuation line 7 of the 9-line logical statement that begins at source line 33. Its exact fragment is 'execute_maxpool2d_backward,'. The important operands are execute_maxpool2d_backward: the value named 'execute maxpool2d backward' in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 40: `execute_sgdw_update,` This is continuation line 8 of the 9-line logical statement that begins at source line 33. Its exact fragment is 'execute_sgdw_update,'. The important operands are execute_sgdw_update: the value named 'execute sgdw update' in this block. Read together, the complete operation is: This imports the named Python API so

the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 41: `)` This is continuation line 9 of the 9-line logical statement that begins at source line 33. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 42: `from spikingformer_accelerator import (` This statement continues through source line 47; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 43: `SpikingformerInferenceResult,` This is continuation line 2 of the 6-line logical statement that begins at source line 42. Its exact fragment is ‘SpikingformerInferenceResult,‘. The important operands are SpikingformerInferenceResult: the value named ’spikingformer inference result’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 44: `SpikingformerProjectionExecutor,` This is continuation line 3 of the 6-line logical statement that begins at source line 42. Its exact fragment is ‘SpikingformerProjectionExecutor,‘. The important operands are SpikingformerProjectionExecutor: the value named ’spikingformer projection executor’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 45: `binary_max_pool2d_on_accelerator,` This is continuation line 4 of the 6-line logical statement that begins at source line 42. Its exact fragment is ‘binary_max_pool2d_on_accelerator,‘. The important operands are binary_max_pool2d_on_accelerator: the value named ’binary max pool2d on accelerator’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 46: `lif_sequence_with_trace_on_accelerator,` This is continuation line 5 of the 6-line logical statement that begins at source line 42. Its exact fragment is ‘lif_sequence_with_trace_on_accelerator,‘. The important operands are lif_sequence_with_trace_on_accelerator: the value named ’lif sequence with trace on accelerator’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 47: `)` This is continuation line 6 of the 6-line logical statement that begins at source line 42. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 48: `from spikingformer_parameters import (` This statement continues through source line 52; the explanation uses the complete expression rather than only the first visual fragment. This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 49: `HeadParameters,` This is continuation line 2 of the 5-line logical statement that begins at source line 48. Its exact fragment is ‘HeadParameters,‘. The important operands are HeadParameters: the value named ’head parameters’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 50: `ProjectionParameters,` This is continuation line 3 of the 5-line logical statement that begins at source line 48. Its exact fragment is ‘ProjectionParameters,‘. The important operands are ProjectionParameters: the value named ’projection parameters’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 51: `SpikingformerParameterArchive,` This is continuation line 4 of the 5-line logical statement that begins at source line 48. Its exact fragment is ‘SpikingformerParameterArchive,‘. The important operands are SpikingformerParameterArchive: the value named ’spikingformer parameter archive’ in this block. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 52: `)` This is continuation line 5 of the 5-line logical statement that begins at source line 48. Its exact fragment is ‘)‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This imports the named Python API so the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation can use it explicitly. Imports execute on the host processor and create no FPGA hardware.

Line 55: `VECTOR_LANES = 8` This assigns ‘8‘ to ‘VECTOR_LANES ‘ in host memory. Here VECTOR_LANES means one parallel arithmetic element within a vector or tensor datapath. The expression is a literal or structural operator and has no hidden software state. Context: the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 56: `MASTER_FORMAT = "neuraedge-spikingformer-trainable-state-v1"` This assigns ‘"neuraedge-spikingformer-trainable-state-v1"‘ to ‘MASTER_FORMAT ‘ in host memory. Here MASTER_FORMAT means the value named ’master format’ in this block. The important operands are neuraedge: the value named ’neuraedge’ in this block; spikingformer: the value named ’spikingformer’ in this block; trainable: the value named ’trainable’ in this block. Context: the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 57: `CHECKPOINT_FORMAT = "neuraedge-spikingformer-training-checkpoint-v1"` This assigns ‘"neuraedge-spikingformer-training-checkpoint-v1"‘ to ‘CHECKPOINT_FORMAT ‘ in host memory. Here CHECKPOINT_FORMAT means the value named ’checkpoint format’ in this block. The important operands are neuraedge: the value named ’neuraedge’ in this block; spikingformer: the value named ’spikingformer’ in this block; training: the value named ’training’ in this block. Context: the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 60: `class FullTrainingDriver(TrainingProgramExecutor, Protocol):` This defines class FullTrainingDriver, which groups data and methods for full training driver. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 61: `"""Command interface required by both forward inference and backward update."""` This is executable documentation attached to the class FullTrainingDriver, which handles full training driver. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 64: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10

training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 65: `class BlockGradient:` This defines class BlockGradient, which groups data and methods for block gradient. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 66: `"""Signed integer gradient plus its exact shared power-of-two exponent."""` This is executable documentation attached to the class BlockGradient, which handles block gradient. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 68: `values: np.ndarray` Inside the class BlockGradient, which handles block gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are values: the value named 'values' in this block; ndarray: the value named 'ndarray' in this block.

Line 69: `exponent: int` Inside the class BlockGradient, which handles block gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are exponent: the value named 'exponent' in this block.

Line 71: `def __post_init__(self) -> None:` This starts function ___post_init___. Its indented body performs post init as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 72: `values = np.asarray(self.values, dtype=np.int64)` This assigns ‘np.asarray(self.values, dtype=np.int64)‘ to ‘values ‘ in host memory. Here values means the value named 'values' in this block. The important operands are asarray: the value named 'asarray' in this block; values: the value named 'values' in this block; dtype: the value named 'dtype' in this block. Context: the function ___post_init___, which handles post init.

Line 73: `if values.size and (` This line opens or closes a multi-line Python expression inside the function ___post_init___, which handles post init; the neighboring lines supply its arguments or elements.

Line 74: `values.min() < -(1 << 31) or values.max() > (1 << 31) - 1` Inside the function ___post_init___, which handles post init, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are values: the value named 'values' in this block; min: the value named 'min' in this block; or: the value named 'or' in this block.

Line 75: `):` Inside the function ___post_init___, which handles post init, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The expression is a literal or structural operator and has no hidden software state.

Line 76: `raise OverflowError("block-gradient lanes must fit signed 32-bit")` This rejects an invalid state by raising ‘OverflowError("block-gradient lanes must fit signed 32-bit")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 77: `object.__setattr__(self, "values", values)` This calls ‘object.___setattr___‘ with ‘self, "values", values‘ inside the function ___post_init___, which handles post init. The call advances the host-side job that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 78: `if not -127 <= int(self.exponent) <= 127:` This executes the following indented host-code branch only when ‘not -127 <= int(self.exponent) <= 127‘ is true. The important operands are not: the value named 'not' in this block; exponent: the value named 'exponent' in this block. Context: the function ___post_init___, which handles post init.

Line 79: `raise ValueError("block-gradient exponent must be in [-127,127]")` This rejects an invalid state by raising ‘ValueError("block-gradient exponent must be in [-127,127]")‘. Failing before DMA prevents malformed shapes or artifacts from silently becoming hardware results.

Line 81: `def reshape(self, *shape: int) -> "BlockGradient":` This starts function reshape. Its indented body performs reshape as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 82: `return BlockGradient(self.values.reshape(*shape), self.exponent)` This returns ‘BlockGradient(self.values.re self.exponent)‘ to the caller of the function reshape, which handles reshape, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; reshape: the value named ’reshape’ in this block.

Line 84: `def transpose(self, *axes: int) -> "BlockGradient":` This starts function transpose. Its indented body performs transpose as part of the file that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it runs only when called.

Line 85: `return BlockGradient(self.values.transpose(*axes), self.exponent)` This returns ‘BlockGradient(self.values.t self.exponent)‘ to the caller of the function transpose, which handles transpose, ending this invocation. The important operands are BlockGradient: the signed loss derivative used to update a learned parameter; values: the value named ’values’ in this block; transpose: the value named ’transpose’ in this block.

Line 88: `@dataclass(frozen=True)` This decorator changes how the following class or function is constructed. ‘@dataclass(frozen=True)‘ is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 89: `class ParameterGradient:` This defines class ParameterGradient, which groups data and methods for parameter gradient. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.

Line 90: `"""Weight and bias derivatives emitted by one learned affine operator."""` This is executable documentation attached to the class ParameterGradient, which handles parameter gradient. It states the intended contract that tests and callers should enforce, but the text itself does not transform data or issue hardware work.

Line 92: `weight: BlockGradient` Inside the class ParameterGradient, which handles parameter gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are weight: a learned coefficient multiplied by an activation; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 93: `bias: BlockGradient` Inside the class ParameterGradient, which handles parameter gradient, this statement advances the host implementation that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation. The important operands are bias: an additive learned offset applied after accumulation; BlockGradient: the signed loss derivative used to update a learned parameter.

Line 96: `@dataclass` This decorator changes how the following class or function is constructed. ‘@dataclass‘ is applied at import time on the host and is part of the file whose role is to runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation; it creates no FPGA circuit by itself.

Line 97: `class MasterTensor:` This defines class MasterTensor, which groups data and methods for master tensor. Instances exist in host memory and organize the flow that runs resumable CIFAR-10 training through the accelerator command ABI with atomic checkpoints and validation.
