Line 33: `ST_EXPONENT_DIFFERENCE = 5'd3,` This assigns a fixed binary encoding to state ST_EXPONENT_DIFFERENCE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 34: `ST_EXPONENT_QUANTIZE = 5'd4,` This assigns a fixed binary encoding to state ST_EXPONENT_QUANTIZE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 35: `ST_EXPONENT_ACCUMULATE = 5'd5,` This assigns a fixed binary encoding to state ST_EXPONENT_ACCUMULATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 36: `ST_RECIPROCAL_START = 5'd6,` This assigns a fixed binary encoding to state ST_RECIPROCAL_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 37: `ST_RECIPROCAL_WAIT = 5'd7,` This assigns a fixed binary encoding to state ST_RECIPROCAL_WAIT, which waits for both command completion and the declared output count. The encoding is visible in waveforms even though the source uses the readable name.

Line 38: `ST_OUTPUT_READ = 5'd8,` This assigns a fixed binary encoding to state ST_OUTPUT_READ, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 39: `ST_OUTPUT_MULTIPLY = 5'd9,` This assigns a fixed binary encoding to state ST_OUTPUT_MULTIPLY, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 40: `ST_OUTPUT_ROUND = 5'd10,` This assigns a fixed binary encoding to state ST_OUTPUT_ROUND, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 41: `ST_OUTPUT_HOLD = 5'd11,` This assigns a fixed binary encoding to state ST_OUTPUT_HOLD, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 42: `ST_EXPONENT_LATCH = 5'd12,` This assigns a fixed binary encoding to state ST_EXPONENT_LATCH, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 43: `ST_OUTPUT_LATCH = 5'd13,` This assigns a fixed binary encoding to state ST_OUTPUT_LATCH, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 44: `ST_OUTPUT_OPERANDS = 5'd14,` This assigns a fixed binary encoding to state ST_OUTPUT_OPERANDS, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 45: `ST_OUTPUT_PRODUCT_ADD = 5'd15,` This assigns a fixed binary encoding to state ST_OUTPUT_PRODUCT_ADD, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 46: `ST_EXPONENT_SHIFT = 5'd16,` This assigns a fixed binary encoding to state ST_EXPONENT_SHIFT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 47: `ST_EXPONENT_CLAMP = 5'd17` This statement continues through source line 48; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_EXPONENT_CLAMP, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 48: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 47. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_EXPONENT_CLAMP, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 50: `(* fsm_encoding = "one_hot" *) state_t state;` Within the module's structural declarations, this exact statement contributes to the block that implements power-of-two integer softmax normalization without floating-point exponent hardware. The important operands are fsm_encoding: the value named 'fsm encoding' in this block; one_hot: the value named 'one hot' in this block; state_t: the finite-state-machine phase retained in flip-flops.

Line 51: `(* ram_style = "block" *) logic signed [SCORE_BITS-1:0] score_mem [0:MAX_ITEMS-1];` Within the module's structural declarations, this exact statement contributes to the block that implements power-of-two integer softmax normalization without floating-point exponent hardware. The important operands are ram_style: the value named 'ram style' in this block; block: the value named 'block' in this block; SCORE_BITS: the value named 'score bits' in this block.

Line 52: `(* ram_style = "block" *) logic [15:0] exponent_mem [0:MAX_ITEMS-1];` Within the module's structural declarations, this exact statement contributes to the block that implements power-of-two integer softmax normalization without floating-point exponent hardware. The important operands are ram_style: the value named 'ram style' in this block; block: the value named 'block' in this block; exponent_mem: local FPGA storage addressed by surrounding index logic.

Line 53: `logic [8:0] item_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, item_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 54: `logic [4:0] difference_shift_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, difference_shift_r is the value named 'difference shift r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 55: `logic [8:0] load_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 56: `logic [8:0] load_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_remaining_r is the value named 'load remaining r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 57: `logic [8:0] exponent_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, exponent_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 58: `logic [8:0] exponent_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, exponent_remaining_r is the value named 'exponent remaining r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 59: `logic [8:0] output_index_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_index_r is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 60: `logic [8:0] output_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_remaining_r is the number of command result beats still expected. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 61: `logic signed [SCORE_BITS-1:0] maximum_score_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, maximum_score_r is the value named 'maximum score r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 62: `logic [23:0] denominator_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, denominator_r is the value named 'denominator r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 63: `logic [31:0] reciprocal_q31_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, reciprocal_q31_r is the value named 'reciprocal q31 r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 64: `logic [15:0] output_exponent_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_exponent_r is the value named 'output exponent r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 65: `logic [15:0] output_exponent_ram_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_exponent_ram_r is the value named 'output exponent ram r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 66: `logic [15:0] multiply_exponent_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiply_exponent_r is the value named 'multiply exponent r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 67: `logic [31:0] multiply_reciprocal_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiply_reciprocal_r is the value named 'multiply reciprocal r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 68: `logic signed [SCORE_BITS-1:0] exponent_score_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, exponent_score_r is the value named 'exponent score r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 69: `logic signed [SCORE_BITS-1:0] exponent_score_ram_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, exponent_score_ram_r is the value named 'exponent score ram r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 70: `logic [SCORE_BITS:0] exponent_difference_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, exponent_difference_r is the value named 'exponent difference r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 71: `logic [SCORE_BITS:0] shifted_difference_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, shifted_difference_r is the value named 'shifted difference r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 72: `logic [4:0] exponent_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, exponent_r is the value named 'exponent r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 73: `logic [15:0] unnormalized_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, unnormalized_r is the value named 'unnormalized r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 74: `logic [31:0] probability_product_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, probability_product_r is the value named 'probability product r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 75: `logic [31:0] probability_low_product_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, probability_low_product_r is the value named 'probability low product r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 76: `logic [31:0] probability_high_product_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, probability_high_product_r is the value named 'probability high product r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 77: `logic probability_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, probability_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 78: `(* use_dsp = "yes" *) wire [31:0] probability_low_product =` Within the module's structural declarations, this exact statement contributes to the block that implements power-of-two integer softmax normalization without floating-point exponent hardware. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; probability_low_product: the value named 'probability low product' in this block.

Line 79: `multiply_exponent_r * multiply_reciprocal_r[15:0];` Within the module's structural declarations, this exact statement contributes to the block that implements power-of-two integer softmax normalization without floating-point exponent hardware. The important operands are multiply_exponent_r: the value named 'multiply exponent r' in this block; multiply_reciprocal_r: the value named 'multiply reciprocal r' in this block.

Line 80: `(* use_dsp = "yes" *) wire [31:0] probability_high_product =` Within the module's structural declarations, this exact statement contributes to the block that implements power-of-two integer softmax normalization without floating-point exponent hardware. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; probability_high_product: the value named 'probability high product' in this block.

Line 81: `multiply_exponent_r * multiply_reciprocal_r[31:16];` Within the module's structural declarations, this exact statement contributes to the block that implements power-of-two integer softmax normalization without floating-point exponent hardware. The important operands are multiply_exponent_r: the value named 'multiply exponent r' in this block; multiply_reciprocal_r: the value named 'multiply reciprocal r' in this block.

Line 83: `logic divider_input_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 84: `wire divider_input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 85: `wire divider_output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 86: `logic divider_output_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 87: `wire [31:0] divider_quotient;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_quotient is the value named 'divider quotient' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 88: `wire divider_zero;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_zero is the value named 'divider zero' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 90: `neuraedge_udivider #(.NUMERATOR_BITS(32)) u_divider (` This instantiates module neuraedge_udivider as u_divider. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 91: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port ‘clk‘ to parent expression ‘clk), .rst_n(rst_n‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 92: `.input_valid(divider_input_valid), .input_ready(divider_input_ready),` This connects the child instance's named port 'input_valid' to parent expression 'divider_input_valid), .input_ready(divider_input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 93: `.numerator(32'd2147483647), .denominator({8'd0, denominator_r}),` This connects the child instance's named port 'numerator' to parent expression '32'd2147483647), .denominator({8'd0, denominator_r}'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named '32'd2147483647), .denominator({8'd0, denominator r}' in this block.

Line 94: `.output_valid(divider_output_valid), .output_ready(divider_output_ready),` This connects the child instance's named port 'output_valid' to parent expression 'divider_output_valid), .output_ready(divider_output_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 95: `.quotient(divider_quotient), .remainder(),` This connects the child instance's named port 'quotient' to parent expression 'divider_quotient), .remainder('. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'divider quotient), .remainder(' in this block.

Line 96: `.divide_by_zero(divider_zero)` This connects the child instance's named port 'divide_by_zero' to parent expression 'divider_zero'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'divider zero' in this block.

Line 97: `);` Within the module's structural declarations, this exact statement contributes to the block that implements power-of-two integer softmax normalization without floating-point exponent hardware. The expression is a literal or structural operator and has no hidden software state.

Line 99: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 100: `start_ready = state == ST_IDLE;` This makes start_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_IDLE'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 101: `score_ready = state == ST_LOAD;` This makes score_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_LOAD'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LOAD: the value named 'st load' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 102: `probability_valid = state == ST_OUTPUT_HOLD;` This makes probability_valid, the producer's statement that its current payload is meaningful, equal to 'state == ST_OUTPUT_HOLD'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_OUTPUT_HOLD: the value named 'st output hold' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 103: `probability_index = output_index_r;` This makes probability_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'output_index_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 104: `probability_last = probability_last_r;` This makes probability_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘probability_last_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are probability_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 105: `divider_input_valid = state == ST_RECIPROCAL_START;` This makes divider_input_valid, the producer’s statement that its current payload is meaningful, equal to ‘state == ST_RECIPROCAL_START‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_RECIPROCAL_START: the value named ’st reciprocal start’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 106: `divider_output_ready = state == ST_RECIPROCAL_WAIT;` This makes divider_output_ready, the consumer’s statement that it can accept a payload this cycle, equal to ‘state == ST_RECIPROCAL_WAIT‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_RECIPROCAL_WAIT: the value named ’st reciprocal wait’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 107: `debug_maximum_score = maximum_score_r;` This makes debug_maximum_score, the value named ’debug maximum score’ in this block, equal to ‘maximum_score_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are maximum_score_r: the value named ’maximum score r’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 108: `debug_denominator = denominator_r;` This makes debug_denominator, the value named ’debug denominator’ in this block, equal to ‘denominator_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are denominator_r: the value named ’denominator r’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 109: `debug_reciprocal_q31 = reciprocal_q31_r;` This makes debug_reciprocal_q31, the value named ’debug reciprocal q31’ in this block, equal to ‘reciprocal_q31_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are reciprocal_q31_r: the value named ’reciprocal q31 r’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 110: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 112: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with ‘<=‘ inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator’s notion of cycles and persistent state.

Line 113: `if (!rst_n) begin` This is the reset branch for ‘(!rst_n‘. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 114: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 115: `item_count_r <= 9'd0;` This makes item_count_r, an integer count retained for control or measurable telemetry, equal to ‘9’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 116: `difference_shift_r <= 5'd0;` This makes difference_shift_r, the value named 'difference shift r' in this block, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 117: `load_index <= 9'd0;` This makes load_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 118: `load_remaining_r <= 9'd0;` This makes load_remaining_r, the value named 'load remaining r' in this block, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 119: `exponent_index <= 9'd0;` This makes exponent_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 120: `exponent_remaining_r <= 9'd0;` This makes exponent_remaining_r, the value named 'exponent remaining r' in this block, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 121: `output_index_r <= 9'd0;` This makes output_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 122: `output_remaining_r <= 9'd0;` This makes output_remaining_r, the number of command result beats still expected, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 123: `maximum_score_r <= {1'b1, {(SCORE_BITS-1){1'b0}}};` This makes maximum_score_r, the value named 'maximum score r' in this block, equal to '{1'b1, {(SCORE_BITS-1){1'b0}}}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block; SCORE_BITS: the value named 'score bits' in this block; b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 124: `denominator_r <= 24'd0;` This makes denominator_r, the value named 'denominator r' in this block, equal to '24'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 125: `reciprocal_q31_r <= 32'd0;` This makes reciprocal_q31_r, the value named 'reciprocal q31 r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 126: `output_exponent_r <= 16'd0;` This makes output_exponent_r, the value named 'output exponent r' in this block, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 127: `output_exponent_ram_r <= 16'd0;` This makes output_exponent_ram_r, the value named 'output exponent ram r' in this block, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 128: `multiply_exponent_r <= 16'd0;` This makes multiply_exponent_r, the value named 'multiply exponent r' in this block, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 129: `multiply_reciprocal_r <= 32'd0;` This makes multiply_reciprocal_r, the value named 'multiply reciprocal r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 130: `exponent_score_r <= '0;` This makes exponent_score_r, the value named 'exponent score r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 131: `exponent_score_ram_r <= '0;` This makes exponent_score_ram_r, the value named 'exponent score ram r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 132: `exponent_difference_r <= '0;` This makes exponent_difference_r, the value named 'exponent difference r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 133: `shifted_difference_r <= '0;` This makes shifted_difference_r, the value named 'shifted difference r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 134: `exponent_r <= 5'd0;` This makes exponent_r, the value named 'exponent r' in this block, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 135: `unnormalized_r <= 16'd0;` This makes unnormalized_r, the value named 'unnormalized r' in this block, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 136: `probability_product_r <= 32'd0;` This makes probability_product_r, the value named 'probability product r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 137: `probability_low_product_r <= 32'd0;` This makes probability_low_product_r, the value named 'probability low product r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 138: `probability_high_product_r <= 32'd0;` This makes probability_high_product_r, the value named 'probability high product r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 139: `probability_last_r <= 1'b0;` This makes probability_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 140: `probability_q15 <= 16'd0;` This makes probability_q15, the value named 'probability q15' in this block, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 141: `config_error <= 1'b0;` This makes config_error, the value named 'config error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 142: `cycle_count <= 32'd0;` This makes cycle_count, an integer count retained for control or measurable telemetry, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 143: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 144: `if (state != ST_IDLE) cycle_count <= cycle_count + 1'b1;` This condition selects the following hardware branch only when 'state != ST_IDLE' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 145: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 146: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 147: `if (start_valid) begin` This condition selects the following hardware branch only when 'start_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are start_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 148: `cycle_count <= 32'd0;` This makes cycle_count, an integer count retained for control or measurable telemetry, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 149: `config_error <= item_count == 0` This statement continues through source line 150; the explanation uses the complete expression rather than only the first visual fragment. This makes config_error, the value named 'config error' in this block, equal to 'item_count == 0 || item_count > 9'(MAX_ITEMS)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are item_count: an integer count retained for control or measurable telemetry; MAX_ITEMS: the value named 'max items' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 150: `|| item_count > 9'(MAX_ITEMS);` This is continuation line 2 of the 2-line logical statement that begins at source line 149. Its exact fragment is '|| item_count > 9'(MAX_ITEMS);'. The important operands are item_count: an integer count retained for control or measurable telemetry; MAX_ITEMS: the value named 'max items' in this block. Read together, the complete operation is: This makes config_error, the value named 'config error' in this block, equal to 'item_count == 0 || item_count > 9'(MAX_ITEMS)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are item_count: an integer count retained for control or measurable telemetry; MAX_ITEMS: the value named 'max items' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 151: `if (item_count == 0 || item_count > 9'(MAX_ITEMS)) begin` This condition selects the following hardware branch only when 'item_count == 0 || item_count > 9'(MAX_ITEMS)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are item_count: an integer count retained for control or measurable telemetry; MAX_ITEMS: the value named 'max items' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 152: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 153: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 154: `item_count_r <= item_count;` This makes item_count_r, an integer count retained for control or measurable telemetry, equal to 'item_count'. It updates after the active clock edge together with other nonblocking assignments. The important operands are item_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 155: `difference_shift_r <= difference_shift;` This makes difference_shift_r, the value named 'difference shift r' in this block, equal to 'difference_shift'. It updates after the active clock edge together with other nonblocking assignments. The important operands are difference_shift: the value named 'difference shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 156: `load_index <= 9'd0;` This makes load_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 157: `load_remaining_r <= item_count;` This makes load_remaining_r, the value named 'load remaining r' in this block, equal to 'item_count'. It updates after the active clock edge together with other nonblocking assignments. The important operands are item_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 158: `maximum_score_r <= {1'b1, {(SCORE_BITS-1){1'b0}}};` This makes maximum_score_r, the value named 'maximum score r' in this block, equal to '{1'b1, {(SCORE_BITS-1){1'b0}}}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block; SCORE_BITS: the value named 'score bits' in this block; b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 159: `denominator_r <= 24'd0;` This makes denominator_r, the value named 'denominator r' in this block, equal to '24'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 160: `state <= ST_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LOAD'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD: the value named 'st load' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 161: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 162: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 163: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 165: `ST_LOAD: begin` This is the ST_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 166: `if (score_valid) begin` This condition selects the following hardware branch only when 'score_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are score_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 167: `logic expected_last;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.. Specifically, expected_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 168: `expected_last = load_remaining_r == 9'd1;` This makes expected_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'load_remaining_r == 9'd1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_remaining_r: the value named 'load remaining r' in this block; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 169: `score_mem[load_index[7:0]] <= score_value;` This makes score_mem[load_index[7:0]], local FPGA storage addressed by surrounding index logic, equal to 'score_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are score_value: the value named 'score value' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 170: `if (score_value > maximum_score_r) maximum_score_r <= score_value;` This condition selects the following hardware branch only when ‘score_value > maximum_score_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are score_value: the value named ’score value’ in this block; maximum_score_r: the value named ’maximum score r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 171: `if (score_last != expected_last) config_error <= 1'b1;` This condition selects the following hardware branch only when ‘score_last != expected_last‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are score_last: the AXI-Stream marker for the final beat of a packet or command payload; expected_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 172: `if (expected_last) begin` This condition selects the following hardware branch only when ‘expected_last‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are expected_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 173: `exponent_index <= 9'd0;` This makes exponent_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘9’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 174: `exponent_remaining_r <= item_count_r;` This makes exponent_remaining_r, the value named ’exponent remaining r’ in this block, equal to ‘item_count_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are item_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 175: `state <= ST_EXPONENT_READ;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_EXPONENT_READ‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_EXPONENT_READ: the value named ’st exponent read’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 176: `end else if (score_last) begin` This condition selects the following hardware branch only when ‘score_last‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are score_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 177: `config_error <= 1'b1;` This makes config_error, the value named ’config error’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 178: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 179: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 180: `load_index <= load_index + 1'b1;` This makes load_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'load_index + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 181: `load_remaining_r <= load_remaining_r - 1'b1;` This makes load_remaining_r, the value named 'load remaining r' in this block, equal to 'load_remaining_r - 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_remaining_r: the value named 'load remaining r' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 182: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 183: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 184: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 186: `ST_EXPONENT_READ: begin` This is the ST_EXPONENT_READ case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_READ, the machine performs the named control phase..

Line 187: `exponent_score_ram_r <= score_mem[exponent_index[7:0]];` This makes exponent_score_ram_r, the value named 'exponent score ram r' in this block, equal to 'score_mem[exponent_index[7:0]]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are score_mem: local FPGA storage addressed by surrounding index logic; exponent_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_READ, the machine performs the named control phase..

Line 188: `state <= ST_EXPONENT_LATCH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_EXPONENT_LATCH'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_EXPONENT_LATCH: the value named 'st exponent latch' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_READ, the machine performs the named control phase..

Line 189: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_READ, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 191: `ST_EXPONENT_LATCH: begin` This is the ST_EXPONENT_LATCH case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_LATCH, the machine performs the named control phase..

Line 192: `exponent_score_r <= exponent_score_ram_r;` This makes exponent_score_r, the value named 'exponent score r' in this block, equal to 'exponent_score_ram_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are exponent_score_ram_r: the value named 'exponent score ram r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_LATCH, the machine performs the named control phase..

Line 193: `state <= ST_EXPONENT_DIFFERENCE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_EXPONENT_DIFFERENCE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_EXPONENT_DIFFERENCE: the value named 'st exponent difference' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_LATCH, the machine performs the named control phase..

Line 194: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_LATCH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 196: `ST_EXPONENT_DIFFERENCE: begin` This is the ST_EXPONENT_DIFFERENCE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_DIFFERENCE, the machine performs the named control phase..

Line 197: `exponent_difference_r <=` This statement continues through source line 198; the explanation uses the complete expression rather than only the first visual fragment. This makes exponent_difference_r, the value named 'exponent difference r' in this block, equal to '$signed(maximum_score_r) - $signed(exponent_score_r)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are maximum_score_r: the value named 'maximum score r' in this block; exponent_score_r: the value named 'exponent score r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_DIFFERENCE, the machine performs the named control phase..

Line 198: `$signed(maximum_score_r) - $signed(exponent_score_r);` This is continuation line 2 of the 2-line logical statement that begins at source line 197. Its exact fragment is '$signed(maximum_score_r) - $signed(exponent_score_r);'. The important operands are maximum_score_r: the value named 'maximum score r' in this block; exponent_score_r: the value named 'exponent score r' in this block. Read together, the complete operation is: This makes exponent_difference_r, the value named 'exponent difference r' in this block, equal to '$signed(maximum_score_r) - $signed(exponent_score_r)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are maximum_score_r: the value named 'maximum score r' in this block; exponent_score_r: the value named 'exponent score r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_DIFFERENCE, the machine performs the named control phase..

Line 199: `state <= ST_EXPONENT_SHIFT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_EXPONENT_SHIFT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_EXPONENT_SHIFT: the value named 'st exponent shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_DIFFERENCE, the machine performs the named control phase..

Line 200: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_DIFFERENCE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 202: `ST_EXPONENT_SHIFT: begin` This is the ST_EXPONENT_SHIFT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_SHIFT, the machine performs the named control phase..

Line 203: `shifted_difference_r <= exponent_difference_r >> difference_shift_r;` This makes shifted_difference_r, the value named 'shifted difference r' in this block, equal to 'exponent_difference_r >> difference_shift_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are exponent_difference_r: the value named 'exponent difference r' in this block; difference_shift_r: the value named 'difference shift r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_SHIFT, the machine performs the named control phase..

Line 204: `state <= ST_EXPONENT_CLAMP;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_EXPONENT_CLAMP'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_EXPONENT_CLAMP: the value named 'st exponent clamp' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_SHIFT, the machine performs the named control phase..

Line 205: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_SHIFT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 207: `ST_EXPONENT_CLAMP: begin` This is the ST_EXPONENT_CLAMP case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_CLAMP, the machine performs the named control phase..

Line 208: `exponent_r <= shifted_difference_r > 15` This statement continues through source line 209; the explanation uses the complete expression rather than only the first visual fragment. This makes exponent_r, the value named 'exponent r' in this block, equal to 'shifted_difference_r > 15 ? 5'd15 : shifted_difference_r[4:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are shifted_difference_r: the value named 'shifted difference r' in this block; d15: the value named 'd15' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_CLAMP, the machine performs the named control phase..

Line 209: `? 5'd15 : shifted_difference_r[4:0];` This is continuation line 2 of the 2-line logical statement that begins at source line 208. Its exact fragment is '? 5'd15 : shifted_difference_r[4:0];'. The important operands are d15: the value named 'd15' in this block; shifted_difference_r: the value named 'shifted difference r' in this block. Read together, the complete operation is: This makes exponent_r, the value named 'exponent r' in this block, equal to 'shifted_difference_r > 15 ? 5'd15 : shifted_difference_r[4:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are shifted_difference_r: the value named 'shifted difference r' in this block; d15: the value named 'd15' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_CLAMP, the machine performs the named control phase..

Line 210: `state <= ST_EXPONENT_QUANTIZE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_EXPONENT_QUANTIZE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_EXPONENT_QUANTIZE: the value named 'st exponent quantize' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_CLAMP, the machine performs the named control phase..

Line 211: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_CLAMP, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 213: `ST_EXPONENT_QUANTIZE: begin` This is the ST_EXPONENT_QUANTIZE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_QUANTIZE, the machine performs the named control phase..

Line 214: `unnormalized_r <= 16'd1 << (15 - exponent_r);` This makes unnormalized_r, the value named 'unnormalized r' in this block, equal to '16'd1 << (15 - exponent_r)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d1: the value named 'd1' in this block; exponent_r: the value named 'exponent r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_QUANTIZE, the machine performs the named control phase..

Line 215: `state <= ST_EXPONENT_ACCUMULATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_EXPONENT_ACCUMULATE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_EXPONENT_ACCUMULATE: the value named 'st exponent accumulate' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_QUANTIZE, the machine performs the named control phase..

Line 216: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_QUANTIZE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 218: `ST_EXPONENT_ACCUMULATE: begin` This is the ST_EXPONENT_ACCUMULATE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase..

Line 219: `exponent_mem[exponent_index[7:0]] <= unnormalized_r;` This makes exponent_mem[exponent_index[7:0]], local FPGA storage addressed by surrounding index logic, equal to 'unnormalized_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are unnormalized_r: the value named 'unnormalized r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase..

Line 220: `denominator_r <= denominator_r + {8'd0, unnormalized_r};` This makes denominator_r, the value named 'denominator r' in this block, equal to 'denominator_r + {8'd0, unnormalized_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are denominator_r: the value named 'denominator r' in this block; d0: the value named 'd0' in this block; unnormalized_r: the value named 'unnormalized r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase..

Line 221: `if (exponent_remaining_r == 9'd1) begin` This condition selects the following hardware branch only when 'exponent_remaining_r == 9'd1' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are exponent_remaining_r: the value named 'exponent remaining r' in this block; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase..

Line 222: `state <= ST_RECIPROCAL_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_RECIPROCAL_START'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_RECIPROCAL_START: the value named 'st reciprocal start' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase..

Line 223: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 224: `exponent_index <= exponent_index + 1'b1;` This makes exponent_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'exponent_index + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are exponent_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers

only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase..

Line 225: `exponent_remaining_r <= exponent_remaining_r - 1'b1;` This makes exponent_remaining_r, the value named 'exponent remaining r' in this block, equal to 'exponent_remaining_r - 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are exponent_remaining_r: the value named 'exponent remaining r' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase..

Line 226: `state <= ST_EXPONENT_READ;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_EXPONENT_READ'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_EXPONENT_READ: the value named 'st exponent read' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase..

Line 227: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 228: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_EXPONENT_ACCUMULATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 230: `ST_RECIPROCAL_START: begin` This is the ST_RECIPROCAL_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_START, the machine performs the named control phase..

Line 231: `if (divider_input_ready) state <= ST_RECIPROCAL_WAIT;` This condition selects the following hardware branch only when 'divider_input_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are divider_input_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_START, the machine performs the named control phase..

Line 232: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_START, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 234: `ST_RECIPROCAL_WAIT: begin` This is the ST_RECIPROCAL_WAIT case branch, which waits for both command completion and the declared output count. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 235: `if (divider_output_valid) begin` This condition selects the following hardware branch only when 'divider_output_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are divider_output_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 236: `reciprocal_q31_r <= divider_quotient;` This makes reciprocal_q31_r, the value named 'reciprocal q31 r' in this block, equal to 'divider_quotient'. It updates after the active clock edge together with other nonblocking assignments. The important operands are divider_quotient: the value named 'divider quotient' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 237: `output_index_r <= 9'd0;` This makes output_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 238: `output_remaining_r <= item_count_r;` This makes output_remaining_r, the number of command result beats still expected, equal to 'item_count_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are item_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 239: `config_error <= config_error || divider_zero;` This makes config_error, the value named 'config error' in this block, equal to 'config_error || divider_zero'. It updates after the active clock edge together with other nonblocking assignments. The important operands are config_error: the value named 'config error' in this block; divider_zero: the value named 'divider zero' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 240: `state <= ST_OUTPUT_READ;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_READ'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_READ: the value named 'st output read' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 241: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 242: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 244: `ST_OUTPUT_READ: begin` This is the ST_OUTPUT_READ case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_READ, the machine presents computed results under valid/ready backpressure..

Line 245: `output_exponent_ram_r <= exponent_mem[output_index_r[7:0]];` This makes output_exponent_ram_r, the value named 'output exponent ram r' in this block, equal to 'exponent_mem[output_index_r[7:0]]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are exponent_mem: local FPGA storage addressed by surrounding index logic; output_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_READ, the machine presents computed results under valid/ready backpressure..

Line 246: `state <= ST_OUTPUT_LATCH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_LATCH'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_LATCH: the value named 'st output latch' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_READ, the machine presents computed results under valid/ready backpressure..

Line 247: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_READ, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 249: `ST_OUTPUT_LATCH: begin` This is the ST_OUTPUT_LATCH case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_LATCH, the machine presents computed results under valid/ready backpressure..

Line 250: `output_exponent_r <= output_exponent_ram_r;` This makes output_exponent_r, the value named ’output exponent r’ in this block, equal to ‘output_exponent_ram_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_exponent_ram_r: the value named ’output exponent ram r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_LATCH, the machine presents computed results under valid/ready backpressure..

Line 251: `state <= ST_OUTPUT_OPERANDS;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_OPERANDS‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_OPERANDS: the value named ’st output operands’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_LATCH, the machine presents computed results under valid/ready backpressure..

Line 252: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_LATCH, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 254: `ST_OUTPUT_OPERANDS: begin` This is the ST_OUTPUT_OPERANDS case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_OPERANDS, the machine presents computed results under valid/ready backpressure..

Line 255: `multiply_exponent_r <= output_exponent_r;` This makes multiply_exponent_r, the value named ’multiply exponent r’ in this block, equal to ‘output_exponent_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_exponent_r: the value named ’output exponent r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_OPERANDS, the machine presents computed results under valid/ready backpressure..

Line 256: `multiply_reciprocal_r <= reciprocal_q31_r;` This makes multiply_reciprocal_r, the value named ’multiply reciprocal r’ in this block, equal to ‘reciprocal_q31_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are reciprocal_q31_r: the value named ’reciprocal q31 r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_OPERANDS, the machine presents computed results under valid/ready backpressure..

Line 257: `state <= ST_OUTPUT_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_MULTIPLY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_MULTIPLY: the value named ’st output multiply’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_OPERANDS, the machine presents computed results under valid/ready backpressure..

Line 258: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_OPERANDS, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 260: `ST_OUTPUT_MULTIPLY: begin` This is the ST_OUTPUT_MULTIPLY case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_MULTIPLY, the machine presents computed results under valid/ready backpressure..

Line 261: `probability_low_product_r <= probability_low_product;` This makes probability_low_product_r, the value named 'probability low product r' in this block, equal to 'probability_low_product'. It updates after the active clock edge together with other nonblocking assignments. The important operands are probability_low_product: the value named 'probability low product' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_MULTIPLY, the machine presents computed results under valid/ready backpressure..

Line 262: `probability_high_product_r <= probability_high_product;` This makes probability_high_product_r, the value named 'probability high product r' in this block, equal to 'probability_high_product'. It updates after the active clock edge together with other nonblocking assignments. The important operands are probability_high_product: the value named 'probability high product' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_MULTIPLY, the machine presents computed results under valid/ready backpressure..

Line 263: `state <= ST_OUTPUT_PRODUCT_ADD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_PRODUCT_ADD'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_PRODUCT_ADD: the value named 'st output product add' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_MULTIPLY, the machine presents computed results under valid/ready backpressure..

Line 264: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_MULTIPLY, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 266: `ST_OUTPUT_PRODUCT_ADD: begin` This is the ST_OUTPUT_PRODUCT_ADD case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PRODUCT_ADD, the machine presents computed results under valid/ready backpressure..

Line 267: `probability_product_r <= probability_low_product_r` This statement continues through source line 268; the explanation uses the complete expression rather than only the first visual fragment. This makes probability_product_r, the value named 'probability product r' in this block, equal to 'probability_low_product_r + {probability_high_product_r[15:0], 16'd0}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are probability_low_product_r: the value named 'probability low product r' in this block; probability_high_product_r: the value named 'probability high product r' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PRODUCT_ADD, the machine presents computed results under valid/ready backpressure..

Line 268: `+ {probability_high_product_r[15:0], 16'd0};` This is continuation line 2 of the 2-line logical statement that begins at source line 267. Its exact fragment is '+ {probability_high_product_r[15:0], 16'd0};'. The important operands are probability_high_product_r: the value named 'probability high product r' in this block; d0: the value named 'd0' in this block. Read together, the complete operation is: This makes probability_product_r, the value named 'probability product r' in this block, equal to 'probability_low_product_r + {probability_high_product_r[15:0], 16'd0}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are probability_low_product_r: the value named 'probability low product r' in this block; probability_high_product_r: the value named 'probability high product r' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PRODUCT_ADD, the machine presents computed results under valid/ready backpressure..

Line 269: `state <= ST_OUTPUT_ROUND;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_ROUND'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_ROUND: the value named 'st output round' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PRODUCT_ADD, the machine presents computed results under valid/ready backpressure..

Line 270: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PRODUCT_ADD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 272: `ST_OUTPUT_ROUND: begin` This is the ST_OUTPUT_ROUND case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_ROUND, the machine presents computed results under valid/ready backpressure..

Line 273: `probability_q15 <= probability_product_r[31:16]` This statement continues through source line 274; the explanation uses the complete expression rather than only the first visual fragment. This makes probability_q15, the value named ’probability q15’ in this block, equal to ‘probability_product_r[31:16] + 16’(probability_product_r[15])‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are probability_product_r: the value named ’probability product r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_ROUND, the machine presents computed results under valid/ready backpressure..

Line 274: `+ 16'(probability_product_r[15]);` This is continuation line 2 of the 2-line logical statement that begins at source line 273. Its exact fragment is ‘+ 16’(probability_product_r[15]);‘. The important operands are probability_product_r: the value named ’probability product r’ in this block. Read together, the complete operation is: This makes probability_q15, the value named ’probability q15’ in this block, equal to ‘probability_product_r[31:16] + 16’(probability_product_r[15])‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are probability_product_r: the value named ’probability product r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_ROUND, the machine presents computed results under valid/ready backpressure..

Line 275: `probability_last_r <= output_remaining_r == 9'd1;` This makes probability_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘output_remaining_r == 9’d1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_remaining_r: the number of command result beats still expected; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_ROUND, the machine presents computed results under valid/ready backpressure..

Line 276: `state <= ST_OUTPUT_HOLD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_HOLD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_HOLD: the value named ’st output hold’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_ROUND, the machine presents computed results under valid/ready backpressure..

Line 277: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_ROUND, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 279: `ST_OUTPUT_HOLD: begin` This is the ST_OUTPUT_HOLD case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 280: `if (probability_ready) begin` This condition selects the following hardware branch only when ‘probability_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are probability_ready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 281: `if (probability_last) begin` This condition selects the following hardware branch only when ‘probability_last‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are probability_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 282: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 283: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 284: `output_index_r <= output_index_r + 1'b1;` This makes output_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index_r + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_index_r: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 285: `output_remaining_r <= output_remaining_r - 1'b1;` This makes output_remaining_r, the number of command result beats still expected, equal to ‘output_remaining_r - 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_remaining_r: the number of command result beats still expected; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 286: `state <= ST_OUTPUT_READ;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_READ‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_READ: the value named ’st output read’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 287: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 288: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 289: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 291: `default: state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘state <= ST_IDLE;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 292: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 293: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 294: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 296: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 297: `if (MAX_ITEMS < 1 || MAX_ITEMS > 256) $fatal(1, "MAX_ITEMS must be in [1,256]");` This condition selects the following hardware branch only when ‘MAX_ITEMS < 1 || MAX_ITEMS > 256) $fatal(1, "MAX_ITEMS must be in [1,256]"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are MAX_ITEMS: the value named ’max items’ in this block; fatal: the value named ’fatal’ in this block; must: the value named ’must’ in this block. Context: the module’s structural declarations.

Line 298: `if (SCORE_BITS != 24) $fatal(1, "neuraedge_log_softmax currently requires SCORE_BITS=24");` This condition selects the following hardware branch only when ‘SCORE_BITS != 24) $fatal(1, "neuraedge_log_softmax currently requires SCORE_BITS=24"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are SCORE_BITS: the value named ’score bits’ in this block; fatal: the value named ’fatal’ in this block; neuraedge_log_softmax: the value named ’neuraedge log softmax’ in this block. Context: the module’s structural declarations.

Line 299: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 300: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 302: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that implements power-of-two integer softmax normalization without floating-point exponent hardware.

15 rtl/neuraedge_mac2_array_probe.sv

Role in the complete system: instantiates many packed MAC blocks solely to measure their routed FPGA resource and timing behavior.

15.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to instantiates many packed MAC blocks solely to measure their routed FPGA resource and timing behavior.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_mac2_array_probe into physical nets and primitives. The source declares 3 input-port lines, 1 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control This block is primarily a datapath or storage primitive rather than a large state machine. Registers still divide combinational work into cycles and hold valid/data stable during downstream stalls.

Connections to other blocks This source instantiates neuraedge_mac2_u8 as u_mac. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

15.2 Complete source

The important operands are input: the value named 'input' in this block; rst_n: the active-low synchronous reset. Read together, the complete operation is: This fixes PAIRS to 128) (input wire clk, input wire rst_n, input wire step, output logic [31:0] checksum) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; PAIRS denotes the value named 'pairs' in this block.

Line 10: `input wire step,` This is continuation line 5 of the 7-line logical statement that begins at source line 6. Its exact fragment is 'input wire step,'. The important operands are input: the value named 'input' in this block; step: the value named 'step' in this block. Read together, the complete operation is: This fixes PAIRS to 128) (input wire clk, input wire rst_n, input wire step, output logic [31:0] checksum) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; PAIRS denotes the value named 'pairs' in this block.

Line 11: `output logic [31:0] checksum` This is continuation line 6 of the 7-line logical statement that begins at source line 6. Its exact fragment is 'output logic [31:0] checksum'. The important operands are output: the value named 'output' in this block; checksum: the value named 'checksum' in this block. Read together, the complete operation is: This fixes PAIRS to 128) (input wire clk, input wire rst_n, input wire step, output logic [31:0] checksum) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; PAIRS denotes the value named 'pairs' in this block.

Line 12: `);` This is continuation line 7 of the 7-line logical statement that begins at source line 6. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes PAIRS to 128) (input wire clk, input wire rst_n, input wire step, output logic [31:0] checksum) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; PAIRS denotes the value named 'pairs' in this block.

Line 13: `logic [31:0] stimulus [0:PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stimulus is the value named 'stimulus' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 14: `wire [15:0] product_lo [0:PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_lo is the value named 'product lo' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 15: `wire [15:0] product_hi [0:PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_hi is the value named 'product hi' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 16: `wire product_valid [0:PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `for (genvar pair_idx = 0; pair_idx < PAIRS; pair_idx++) begin : g_pair` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 19: `neuraedge_mac2_u8 u_mac (` This instantiates module neuraedge_mac2_u8 as u_mac. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 20: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 21: `.rst_n(rst_n),` This connects the child instance's named port 'rst_n' to parent expression 'rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 22: `.enable(step),` This connects the child instance's named port 'enable' to parent expression 'step'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'step' in this block.

Line 23: `.activation(stimulus[pair_idx][7:0]),` This connects the child instance's named port 'activation' to parent expression 'stimulus[pair_idx][7:0]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'stimulus' in this block.

Line 24: `.weight_lo(stimulus[pair_idx][15:8]),` This connects the child instance's named port 'weight_lo' to parent expression 'stimulus[pair_idx][15:8]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'stimulus' in this block.

Line 25: `.weight_hi(stimulus[pair_idx][23:16]),` This connects the child instance's named port 'weight_hi' to parent expression 'stimulus[pair_idx][23:16]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'stimulus' in this block.

Line 26: `.product_valid(product_valid[pair_idx]),` This connects the child instance's named port 'product_valid' to parent expression 'product_valid[pair_idx]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 27: `.product_lo(product_lo[pair_idx]),` This connects the child instance's named port 'product_lo' to parent expression 'product_lo[pair_idx]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'product lo' in this block.

Line 28: `.product_hi(product_hi[pair_idx])` This connects the child instance's named port 'product_hi' to parent expression 'product_hi[pair_idx]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'product hi' in this block.

Line 29: `);` Within the module's structural declarations, this exact statement contributes to the block that instantiates many packed MAC blocks solely to measure their routed FPGA resource and timing behavior. The expression is a literal or structural operator and has no hidden software state.

Line 31: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 32: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 33: `stimulus[pair_idx] <= 32'h6d2b79f5 ^ (pair_idx * 32'h9e3779b9);` This makes stimulus[pair_idx], the value named 'stimulus' in this block, equal to '32'h6d2b79f5 ^ (pair_idx * 32'h9e3779b9)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are h6d2b79f5: the value named 'h6d2b79f5' in this block; pair_idx: the value named 'pair idx' in this block; h9e3779b9: the value named 'h9e3779b9' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 34: `end else if (step) begin` This condition selects the following hardware branch only when 'step' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are step: the value named 'step' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 35: `stimulus[pair_idx] <= {stimulus[pair_idx][30:0],` This statement continues through source line 37; the explanation uses the complete expression rather than only the first visual fragment. This makes stimulus[pair_idx], the value named 'stimulus' in this block, equal to '{stimulus[pair_idx][30:0], stimulus[pair_idx][31] ^ stimulus[pair_idx][21] ^ stimulus[pair_idx][1] ^ stimulus[pair_idx][0]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stimulus: the value named 'stimulus' in this block; pair_idx: the value named 'pair idx' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 36: `stimulus[pair_idx][31] ^ stimulus[pair_idx][21]` This is continuation line 2 of the 3-line logical statement that begins at source line 35. Its exact fragment is 'stimulus[pair_idx][31] ^ stimulus[pair_idx][21]'. The important operands are stimulus: the value named 'stimulus' in this block; pair_idx: the value named 'pair idx' in this block. Read together, the complete operation is: This makes stimulus[pair_idx], the value named 'stimulus' in this block, equal to '{stimulus[pair_idx][30:0], stimulus[pair_idx][31] ^ stimulus[pair_idx][21] ^ stimulus[pair_idx][1] ^ stimulus[pair_idx][0]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stimulus: the value named 'stimulus' in this block; pair_idx: the value named 'pair idx' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 37: `^ stimulus[pair_idx][1] ^ stimulus[pair_idx][0]};` This is continuation line 3 of the 3-line logical statement that begins at source line 35. Its exact fragment is '^ stimulus[pair_idx][1] ^ stimulus[pair_idx][0]};'. The important operands are stimulus: the value named 'stimulus' in this block; pair_idx: the value named 'pair idx' in

this block. Read together, the complete operation is: This makes stimulus[pair_idx], the value named 'stimulus' in this block, equal to '{stimulus[pair_idx][30:0], stimulus[pair_idx][31] ^ stimulus[pair_idx][21] ^ stimulus[pair_idx][1] ^ stimulus[pair_idx][0]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stimulus: the value named 'stimulus' in this block; pair_idx: the value named 'pair idx' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 38: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 39: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 40: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 42: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 43: `checksum = 32'd0;` This makes checksum, the value named 'checksum' in this block, equal to '32'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 44: `for (int pair_idx = 0; pair_idx < PAIRS; pair_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 45: `checksum = checksum ^ {product_hi[pair_idx], product_lo[pair_idx]};` This makes checksum, the value named 'checksum' in this block, equal to 'checksum ^ {product_hi[pair_idx], product_lo[pair_idx]}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are checksum: the value named 'checksum' in this block; product_hi: the value named 'product hi' in this block; pair_idx: the value named 'pair idx' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 46: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 47: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 48: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 50: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that instantiates many packed MAC blocks solely to measure their routed FPGA resource and timing behavior.

16 rtl/neuraedge_mac2_u8.sv

Role in the complete system: packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

16.1 Beginner architecture map

Dataflow responsibility Two unsigned byte weights are separated by a guard bit and multiplied by one activation in a DSP48E1. Registered correction handles the DSP's signed interpretation, then slices recover two independent exact 16-bit products without cross-field carry.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_mac2_u8 into physical nets and primitives. The source declares 6 input-port lines, 3 output-port lines, 1 clocked process(es), and 0 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control This block is primarily a datapath or storage primitive rather than a large state machine. Registers still divide combinational work into cycles and hold valid/data stable during downstream stalls.

Connections to other blocks This is a leaf block: parent modules create it and connect its ports. It does not instantiate another project RTL module, so its arithmetic or storage maps directly into FPGA primitives.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

            product_lo <= packed_product[15:0];
            product_hi <= packed_product[32:17];
        end
    end
endmodule

`default_nettype wire
```

16.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `// Computes two exact unsigned 8-bit products in one 25 x 18 multiplier.` Design intent: Computes two exact unsigned 8-bit products in one 25 x 18 multiplier. This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 5: `// The upper weight starts at bit 17, leaving bit 16 as a guard between the` Design intent: The upper weight starts at bit 17, leaving bit 16 as a guard between the This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 6: `// two 16-bit products. Since 255 * 255 is smaller than 2^16, the low product` Design intent: two 16-bit products. Since 255 * 255 is smaller than 2^16, the low product This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 7: `// can never carry into the high product field.` Design intent: can never carry into the high product field. This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 8: `module neuraedge_mac2_u8 (` This opens neuraedge_mac2_u8, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 9: `input wire clk,` This declares clk as a input port with width one bit. It carries the clock that makes all registers advance together across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 10: `input wire rst_n,` This declares rst_n as a input port with width one bit. It carries the active-low synchronous reset across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 11: `input wire enable,` This declares enable as a input port with width one bit. It carries the value named 'enable' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 12: `input wire [7:0] activation,` This declares activation as a input port with width [7:0]. It carries an input feature value consumed by a neuron or multiply-accumulate operation across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 13: `input wire [7:0] weight_lo,` This declares weight_lo as a input port with width [7:0]. It carries a learned coefficient multiplied by an activation across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 14: `input wire [7:0] weight_hi,` This declares weight_hi as a input port with width [7:0]. It carries a learned coefficient multiplied by an activation across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 15: `output wire product_valid,` This declares product_valid as a output port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 16: `output logic [15:0] product_lo,` This declares product_lo as a output port with width [15:0]. It carries the value named 'product lo' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 17: `output logic [15:0] product_hi` This declares product_hi as a output port with width [15:0]. It carries the value named 'product hi' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 18: `);` Within the module's structural declarations, this exact statement contributes to the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication. The expression is a literal or structural operator and has no hidden software state.

Line 19: `logic signed [24:0] packed_weight_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, packed_weight_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `logic signed [17:0] extended_activation_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, extended_activation_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 21: `logic signed [47:0] unsigned_correction_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, unsigned_correction_r is the value named 'unsigned correction r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 22: `(* dont_touch = "yes" *) logic input_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; input_valid_r: the producer's statement that its current payload is meaningful.

Line 23: `(* dont_touch = "yes" *) logic dsp_product_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; dsp_product_valid_r: the producer's statement that its current payload is meaningful.

Line 24: `(* dont_touch = "yes" *) logic product_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; product_valid_r: the producer's statement that its current payload is meaningful.

Line 25: `/* verilator lint_off UNUSEDSIGNAL */` Within the module's structural declarations, this exact statement contributes to the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication. The important operands are verilator: the value named 'verilator' in this block; lint_off: the value named 'lint off' in this block; UNUSEDSIGNAL: the value named 'unusedsignal' in this block.

Line 26: `(* use_dsp = "yes" *) logic signed [47:0] packed_product;` Within the module's structural declarations, this exact statement contributes to the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; packed_product: the value named 'packed product' in this block.

Line 27: `/* verilator lint_on UNUSEDSIGNAL */` Within the module's structural declarations, this exact statement contributes to the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication. The important operands are verilator: the value named 'verilator' in this block; lint_on: the value named 'lint on' in this block; UNUSEDSIGNAL: the value named 'unusedsignal' in this block.

Line 29: `assign product_valid = product_valid_r;` This makes product_valid, the producer's statement that its current payload is meaningful, equal to ‘product_valid_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are product_valid_r: the producer's statement that its current payload is meaningful. Context: the module's structural declarations.

Line 31: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with ‘<=‘ inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 32: `if (!rst_n) begin` This is the reset branch for ‘(!rst_n‘. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 33: `packed_weight_r <= '0;` This makes packed_weight_r, a learned coefficient multiplied by an activation, equal to ‘’0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 34: `extended_activation_r <= '0;` This makes extended_activation_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘’0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 35: `unsigned_correction_r <= '0;` This makes unsigned_correction_r, the value named 'unsigned correction r' in this block, equal to ‘’0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 36: `input_valid_r <= 1'b0;` This makes input_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 37: `dsp_product_valid_r <= 1'b0;` This makes dsp_product_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 38: `packed_product <= '0;` This makes packed_product, the value named 'packed product' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 39: `product_valid_r <= 1'b0;` This makes product_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 40: `product_lo <= 16'd0;` This makes product_lo, the value named 'product lo' in this block, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 41: `product_hi <= 16'd0;` This makes product_hi, the value named 'product hi' in this block, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 42: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 43: `input_valid_r <= enable;` This makes input_valid_r, the producer's statement that its current payload is meaningful, equal to 'enable'. It updates after the active clock edge together with other nonblocking assignments. The important operands are enable: the value named 'enable' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 44: `dsp_product_valid_r <= input_valid_r;` This makes dsp_product_valid_r, the producer's statement that its current payload is meaningful, equal to 'input_valid_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 45: `product_valid_r <= dsp_product_valid_r;` This makes product_valid_r, the producer's statement that its current payload is meaningful, equal to 'dsp_product_valid_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are dsp_product_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 46: `// The tile holds operands stable outside a valid issue. Sampling` Design intent: The tile holds operands stable outside a valid issue. Sampling This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 47: `// every cycle keeps the DSP A/B input registers enabled locally;` Design intent: every cycle keeps the DSP A/B input registers enabled locally; This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 48: `// input_valid_r still gates product retirement, so invalid cycles` Design intent: input_valid_r still gates product retirement, so invalid cycles This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 49: `// cannot change any architectural result.` Design intent: cannot change any architectural result. This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 50: `packed_weight_r <= $signed({weight_hi, 9'b0, weight_lo});` This makes packed_weight_r, a learned coefficient multiplied by an activation, equal to '$signed({weight_hi, 9'b0, weight_lo})'. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_hi: a learned coefficient multiplied by an activation; b0: the value named 'b0' in this block; weight_lo: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 51: `extended_activation_r <= $signed({10'b0, activation});` This makes extended_activation_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '$signed({10'b0, activation})'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block; activation: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge.

Line 52: `unsigned_correction_r <= weight_hi[7]` This statement continues through source line 54; the explanation uses the complete expression rather than only the first visual fragment. This makes unsigned_correction_r, the value named 'unsigned correction r' in this block, equal to 'weight_hi[7] ? $signed({15'b0, activation, 25'b0}) : 48'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_hi: a learned coefficient multiplied by an activation; b0: the value named 'b0' in this block; activation: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge.

Line 53: `? $signed({15'b0, activation, 25'b0})` This is continuation line 2 of the 3-line logical statement that begins at source line 52. Its exact fragment is '? $signed({15'b0, activation, 25'b0})'. The important operands are b0: the value named 'b0' in this block; activation: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This makes unsigned_correction_r, the value named 'unsigned correction r' in this block, equal to 'weight_hi[7] ? $signed({15'b0, activation, 25'b0}) : 48'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_hi: a learned coefficient multiplied by an activation; b0: the value named 'b0' in this block; activation: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge.

Line 54: `: 48'sd0;` This is continuation line 3 of the 3-line logical statement that begins at source line 52. Its exact fragment is ': 48'sd0;'. The important operands are sd0: the value named 'sd0' in this block. Read together, the complete operation is: This makes unsigned_correction_r, the value named 'unsigned correction r' in this block, equal to 'weight_hi[7] ? $signed({15'b0, activation, 25'b0}) : 48'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_hi: a learned coefficient multiplied by an activation; b0: the value named 'b0' in this block; activation: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge.

Line 55: `// Invalid products are discarded by the valid pipeline. Updating` Design intent: Invalid products are discarded by the valid pipeline. Updating This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 56: `// the DSP and unpack registers every clock makes all DSP48E1` Design intent: the DSP and unpack registers every clock makes all DSP48E1 This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 57: `// A/B/M/P clock enables local constants instead of a 64-DSP` Design intent: A/B/M/P clock enables local constants instead of a 64-DSP This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 58: `// control tree spanning the tensor tile.` Design intent: control tree spanning the tensor tile. This comment anchors the surrounding logic in the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

Line 59: `packed_product <= (packed_weight_r * extended_activation_r)` This statement continues through source line 60; the explanation uses the complete expression rather than only the first visual fragment. This makes packed_product, the value named 'packed product' in this block, equal to '(packed_weight_r * extended_activation_r) + unsigned_correction_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are packed_weight_r: a learned coefficient multiplied by an activation; extended_activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; unsigned_correction_r: the value named 'unsigned correction r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 60: `+ unsigned_correction_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 59. Its exact fragment is '+ unsigned_correction_r;'. The important operands are unsigned_correction_r: the value named 'unsigned correction r' in this block. Read together, the complete operation is: This makes packed_product, the value named 'packed product' in this block, equal to '(packed_weight_r * extended_activation_r) + unsigned_correction_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are packed_weight_r: a learned coefficient multiplied by an activation; extended_activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; unsigned_correction_r: the value named 'unsigned correction r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 61: `product_lo <= packed_product[15:0];` This makes product_lo, the value named 'product lo' in this block, equal to 'packed_product[15:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are packed_product: the value named 'packed product' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 62: `product_hi <= packed_product[32:17];` This makes product_hi, the value named 'product hi' in this block, equal to 'packed_product[32:17]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are packed_product: the value named 'packed product' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 63: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 64: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 65: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 67: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that packs two exact unsigned eight-bit multiplications into one DSP48E1 multiplication.

17 rtl/neuraedge_pynq_axi_top.sv

Role in the complete system: provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

17.1 Beginner architecture map

Dataflow responsibility This is the software-visible shell. AXI-Lite writes configure command and descriptor registers, AXI-Stream carries DMA data, registered credit boundaries break READY timing paths, and status/interrupt registers expose completion, errors, and telemetry.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_pynq_axi_top into physical nets and primitives. The source declares 19 input-port lines, 14 output-port lines, 3 clocked process(es), and 4 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control This block is primarily a datapath or storage primitive rather than a large state machine. Registers still divide combinational work into cycles and hold valid/data stable during downstream stalls.

Connections to other blocks This source instantiates unique as case, neuraedge_descriptor_sequencer as u_descriptor_sequenc neuraedge_universal_core as u_core, end as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

17.2 Complete source

```

17.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_pynq_axi_top #(` This opens neuraedge_pynq_axi_top, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 5: `parameter int AXI_ADDR_BITS = 8` This fixes AXI_ADDR_BITS to 8 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; AXI_ADDR_BITS denotes the value named 'axi addr bits' in this block.

Line 6: `) (` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The expression is a literal or structural operator and has no hidden software state.

Line 7: `(* X_INTERFACE_INFO = "xilinx.com:signal:clock:1.0 aclk CLK" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 8: `(* X_INTERFACE_PARAMETER = "XIL_INTERFACENAME aclk, ASSOCIATED_BUSIF S_AXI:S_AXIS:M_AXIS, ASSOCIATED_`
`...` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_PARAMETER: the value named 'x interface parameter' in this block; XIL_INTERFACENAME: the value named 'xil interfacename' in this block; aclk: the AXI and accelerator clock.

Line 9: `input wire aclk,` This declares aclk as a input port with width one bit. It carries the AXI and accelerator clock across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 10: `(* X_INTERFACE_INFO = "xilinx.com:signal:reset:1.0 aresetn RST" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 11: `(* X_INTERFACE_PARAMETER = "XIL_INTERFACENAME aresetn, POLARITY ACTIVE_LOW" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_PARAMETE
the value named 'x interface parameter' in this block; XIL_INTERFACENAME: the value named 'xil interfacename' in this block; aresetn: the active-low AXI reset.

Line 12: `input wire aresetn,` This declares aresetn as a input port with width one bit. It carries the active-low AXI reset across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 14: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI AWADDR" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 15: `(* X_INTERFACE_PARAMETER = "XIL_INTERFACENAME S_AXI, PROTOCOL AXI4LITE, DATA_WIDTH 32, ADDR_WIDTH 8, FREQ_H...` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_PARAMETER: the value named 'x interface parameter' in this block; XIL_INTERFACENAME: the value named 'xil interfacename' in this block; S_AXI: the value named 's axi' in this block.

Line 16: `input wire [AXI_ADDR_BITS-1:0] s_axi_awaddr,` This declares s_axi_awaddr as a input port with width [AXI_ADDR_BITS-1:0]. It carries the value named 's axi awaddr' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 17: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI AWVALID" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 18: `input wire s_axi_awvalid,` This declares s_axi_awvalid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 19: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI AWREADY" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 20: `output logic s_axi_awready,` This declares s_axi_awready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 21: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI WDATA" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 22: `input wire [31:0] s_axi_wdata,` This declares s_axi_wdata as a input port with width [31:0]. It carries the value named 's axi wdata' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 23: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI WSTRB" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 24: `input wire [3:0] s_axi_wstrb,` This declares s_axi_wstrb as a input port with width [3:0]. It carries the value named 's axi wstrb' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 25: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI WVALID" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 26: `input wire s_axi_wvalid,` This declares s_axi_wvalid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 27: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI WREADY" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 28: `output logic s_axi_wready,` This declares s_axi_wready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 29: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI BRESP" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 30: `output logic [1:0] s_axi_bresp,` This declares s_axi_bresp as a output port with width [1:0]. It carries the value named 's axi bresp' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 31: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI BVALID" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 32: `output logic s_axi_bvalid,` This declares s_axi_bvalid as a output port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 33: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI BREADY" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 34: `input wire s_axi_bready,` This declares s_axi_bready as a input port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 35: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI ARADDR" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 36: `input wire [AXI_ADDR_BITS-1:0] s_axi_araddr,` This declares s_axi_araddr as a input port with width [AXI_ADDR_BITS-1:0]. It carries the value named 's axi araddr' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 37: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI ARVALID" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 38: `input wire s_axi_arvalid,` This declares s_axi_arvalid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 39: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI ARREADY" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 40: `output logic s_axi_arready,` This declares s_axi_arready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 41: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI RDATA" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 42: `output logic [31:0] s_axi_rdata,` This declares s_axi_rdata as a output port with width [31:0]. It carries the value named 's axi rdata' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 43: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI RRESP" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 44: `output logic [1:0] s_axi_rresp,` This declares s_axi_rresp as a output port with width [1:0]. It carries the value named 's axi rresp' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 45: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI RVALID" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 46: `output logic s_axi_rvalid,` This declares s_axi_rvalid as a output port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 47: `(* X_INTERFACE_INFO = "xilinx.com:interface:aximm:1.0 S_AXI RREADY" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 48: `input wire s_axi_rready,` This declares s_axi_rready as a input port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 50: `(* X_INTERFACE_INFO = "xilinx.com:interface:axis:1.0 S_AXIS TVALID" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 51: `(* X_INTERFACE_PARAMETER = "XIL_INTERFACENAME S_AXIS, TDATA_NUM_BYTES 8, HAS_TKEEP 1, HAS_TLAST 1, FREQ_HZ ...` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_PARAMETER: the value named 'x interface parameter' in this block; XIL_INTERFACENAME the value named 'xil interfacename' in this block; S_AXIS: the value named 's axis' in this block.

Line 52: `input wire s_axis_tvalid,` This declares s_axis_tvalid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 53: `(* X_INTERFACE_INFO = "xilinx.com:interface:axis:1.0 S_AXIS TREADY" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 54: `output logic s_axis_tready,` This declares s_axis_tready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 55: `(* X_INTERFACE_INFO = "xilinx.com:interface:axis:1.0 S_AXIS TDATA" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 56: `input wire [63:0] s_axis_tdata,` This declares s_axis_tdata as a input port with width [63:0]. It carries the value named 's axis tdata' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 57: `(* X_INTERFACE_INFO = "xilinx.com:interface:axis:1.0 S_AXIS TKEEP" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 58: `input wire [7:0] s_axis_tkeep,` This declares s_axis_tkeep as a input port with width [7:0]. It carries the value named 's axis tkeep' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 59: `(* X_INTERFACE_INFO = "xilinx.com:interface:axis:1.0 S_AXIS TLAST" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 60: `input wire s_axis_tlast,` This declares s_axis_tlast as a input port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 61: `(* X_INTERFACE_INFO = "xilinx.com:interface:axis:1.0 M_AXIS TVALID" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 62: `(* X_INTERFACE_PARAMETER = "XIL_INTERFACENAME M_AXIS, TDATA_NUM_BYTES 8, HAS_TKEEP 1, HAS_TLAST 1, FREQ_HZ ...` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_PARAMETER: the value named 'x interface parameter' in this block; XIL_INTERFACENAME the value named 'xil interfacename' in this block; M_AXIS: the value named 'm axis' in this block.

Line 63: `output logic m_axis_tvalid,` This declares m_axis_tvalid as a output port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 64: `(* X_INTERFACE_INFO = "xilinx.com:interface:axis:1.0 M_AXIS TREADY" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 65: `input wire m_axis_tready,` This declares m_axis_tready as a input port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 66: `(* X_INTERFACE_INFO = "xilinx.com:interface:axis:1.0 M_AXIS TDATA" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 67: `output logic [63:0] m_axis_tdata,` This declares m_axis_tdata as a output port with width [63:0]. It carries the value named 'm axis tdata' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 68: `(* X_INTERFACE_INFO = "xilinx.com:interface:axis:1.0 M_AXIS TKEEP" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 69: `output logic [7:0] m_axis_tkeep,` This declares m_axis_tkeep as a output port with width [7:0]. It carries the value named 'm axis tkeep' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 70: `(* X_INTERFACE_INFO = "xilinx.com:interface:axis:1.0 M_AXIS TLAST" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 71: `output logic m_axis_tlast,` This declares m_axis_tlast as a output port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 72: `(* X_INTERFACE_INFO = "xilinx.com:signal:interrupt:1.0 interrupt INTERRUPT" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_INFO: the value named 'x interface info' in this block; xilinx: the value named 'xilinx' in this block; com: the value named 'com' in this block.

Line 73: `(* X_INTERFACE_PARAMETER = "XIL_INTERFACENAME interrupt, SENSITIVITY LEVEL_HIGH" *)` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are X_INTERFACE_PARA the value named 'x interface parameter' in this block; XIL_INTERFACENAME: the value named 'xil interfacename' in this block; interrupt: the hardware notification that wakes software after completion or error.

Line 74: `output logic interrupt` This declares interrupt as a output port with width one bit. It carries the hardware notification that wakes software after completion or error across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 75: `);` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The expression is a literal or structural operator and has no hidden software state.

Line 76: `localparam logic [7:0] ADDR_CONTROL = 8'h00;` This fixes ADDR_CONTROL to 8'h00 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_CONTROL denotes the value named 'addr control' in this block.

Line 77: `localparam logic [7:0] ADDR_STATUS = 8'h04;` This fixes ADDR_STATUS to 8'h04 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_STATUS denotes the value named 'addr status' in this block.

Line 78: `localparam logic [7:0] ADDR_ACTIVE_OPCODE = 8'h08;` This fixes ADDR_ACTIVE_OPCODE to 8'h08 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_ACTIVE_OPCODE denotes the value named 'addr active opcode' in this block.

Line 79: `localparam logic [7:0] ADDR_COMMAND_COUNT = 8'h0c;` This fixes ADDR_COMMAND_COUNT to 8'h0c during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_COMMAND_COUNT denotes the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 80: `localparam logic [7:0] ADDR_COMMAND0 = 8'h10;` This fixes ADDR_COMMAND0 to 8'h10 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_COMMAND0 denotes the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 81: `localparam logic [7:0] ADDR_COMMAND1 = 8'h14;` This fixes ADDR_COMMAND1 to 8'h14 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_COMMAND1 denotes the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 82: `localparam logic [7:0] ADDR_COMMAND2 = 8'h18;` This fixes ADDR_COMMAND2 to 8'h18 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_COMMAND2 denotes the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 83: `localparam logic [7:0] ADDR_COMMAND3 = 8'h1c;` This fixes ADDR_COMMAND3 to 8'h1c during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_COMMAND3 denotes the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 84: `localparam logic [7:0] ADDR_INPUT_BEATS = 8'h20;` This fixes ADDR_INPUT_BEATS to 8'h20 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_INPUT_BEATS denotes the value named 'addr input beats' in this block.

Line 85: `localparam logic [7:0] ADDR_OUTPUT_BEATS = 8'h24;` This fixes ADDR_OUTPUT_BEATS to 8'h24 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_OUTPUT_BEATS denotes the value named 'addr output beats' in this block.

Line 86: `localparam logic [7:0] ADDR_TARGET_CLOCK = 8'h28;` This fixes ADDR_TARGET_CLOCK to 8'h28 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_TARGET_CLOCK denotes the value named 'addr target clock' in this block.

Line 87: `localparam logic [7:0] ADDR_CAPABILITIES = 8'h2c;` This fixes ADDR_CAPABILITIES to 8'h2c during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_CAPABILITIES denotes the value named 'addr capabilities' in this block.

Line 88: `localparam logic [7:0] ADDR_VERSION = 8'h30;` This fixes ADDR_VERSION to 8'h30 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_VERSION denotes the value named 'addr version' in this block.

Line 89: `localparam logic [7:0] ADDR_ID = 8'h34;` This fixes ADDR_ID to 8'h34 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_ID denotes the value named 'addr id' in this block.

Line 90: `localparam logic [7:0] ADDR_TENSOR_LOADED = 8'h38;` This fixes ADDR_TENSOR_LOADED to 8'h38 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_TENSOR_LOADED denotes the value named 'addr tensor loaded' in this block.

Line 91: `localparam logic [7:0] ADDR_TENSOR_ACTIVE = 8'h3c;` This fixes ADDR_TENSOR_ACTIVE to 8'h3c during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_TENSOR_ACTIVE denotes the value named 'addr tensor active' in this block.

Line 92: `localparam logic [7:0] ADDR_TENSOR_CYCLES = 8'h40;` This fixes ADDR_TENSOR_CYCLES to 8'h40 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_TENSOR_CYCLES denotes the value named 'addr tensor cycles' in this block.

Line 93: `localparam logic [7:0] ADDR_TENSOR_SKIPPED = 8'h44;` This fixes ADDR_TENSOR_SKIPPED to 8'h44 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_TENSOR_SKIPPED denotes the value named 'addr tensor skipped' in this block.

Line 94: `localparam logic [7:0] ADDR_DENSE_MACS_LOW = 8'h48;` This fixes ADDR_DENSE_MACS_LOW to 8'h48 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_DENSE_MACS_LOW denotes a count of ordinary activation-times-weight operations actually issued.

Line 95: `localparam logic [7:0] ADDR_DENSE_MACS_HIGH = 8'h4c;` This fixes ADDR_DENSE_MACS_HIGH to 8'h4c during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_DENSE_MACS_HIGH denotes a count of ordinary activation-times-weight operations actually issued.

Line 96: `localparam logic [7:0] ADDR_SPIKE_ADDS_LOW = 8'h50;` This fixes ADDR_SPIKE_ADDS_LOW to 8'h50 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_SPIKE_ADDS_LOW denotes a binary event produced when a neuron crosses its threshold.

Line 97: `localparam logic [7:0] ADDR_SPIKE_ADDS_HIGH = 8'h54;` This fixes ADDR_SPIKE_ADDS_HIGH to 8'h54 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_SPIKE_ADDS_HIGH denotes a binary event produced when a neuron crosses its threshold.

Line 98: `localparam logic [7:0] ADDR_LAYERNORM_CYCLES = 8'h58;` This fixes ADDR_LAYERNORM_CYCLES to 8'h58 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_LAYERNORM_CYCLES denotes the value named 'addr layernorm cycles' in this block.

Line 99: `localparam logic [7:0] ADDR_LAYERNORM_MEAN = 8'h5c;` This fixes ADDR_LAYERNORM_MEAN to 8'h5c during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_LAYERNORM_MEAN denotes the arithmetic average used by normalization.

Line 100: `localparam logic [7:0] ADDR_LAYERNORM_VARIANCE = 8'h60;` This fixes ADDR_LAYERNORM_VARIANCE to 8'h60 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_LAYERNORM_VARIANC denotes the average squared distance from the mean.

Line 101: `localparam logic [7:0] ADDR_LAYERNORM_SIGMA = 8'h64;` This fixes ADDR_LAYERNORM_SIGMA to 8'h64 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_LAYERNORM_SIGMA denotes the value named 'addr layernorm sigma' in this block.

Line 102: `localparam logic [7:0] ADDR_SOFTMAX_CYCLES = 8'h68;` This fixes ADDR_SOFTMAX_CYCLES to 8'h68 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_SOFTMAX_CYCLES denotes the value named 'addr softmax cycles' in this block.

Line 103: `localparam logic [7:0] ADDR_SOFTMAX_MAXIMUM = 8'h6c;` This fixes ADDR_SOFTMAX_MAXIMUM to 8'h6c during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_SOFTMAX_MAXIMUM denotes the value named 'addr softmax maximum' in this block.

Line 104: `localparam logic [7:0] ADDR_SOFTMAX_DENOMINATOR = 8'h70;` This fixes ADDR_SOFTMAX_DENOMINATOR to 8'h70 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_SOFTMAX_DENOMINA denotes the value named 'addr softmax denominator' in this block.

Line 105: `localparam logic [7:0] ADDR_LIF_SPIKES_LOW = 8'h74;` This fixes ADDR_LIF_SPIKES_LOW to 8'h74 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_LIF_SPIKES_LOW denotes a binary event produced when a neuron crosses its threshold.

Line 106: `localparam logic [7:0] ADDR_LIF_SPIKES_HIGH = 8'h78;` This fixes ADDR_LIF_SPIKES_HIGH to 8'h78 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_LIF_SPIKES_HIGH denotes a binary event produced when a neuron crosses its threshold.

Line 107: `localparam logic [7:0] ADDR_OPTIMIZER_UPDATES = 8'h7c;` This fixes ADDR_OPTIMIZER_UPDATES to 8'h7c during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_OPTIMIZER_UPDATES denotes the value named 'addr optimizer updates' in this block.

Line 108: `localparam logic [7:0] ADDR_LUT_ENTRIES = 8'h80;` This fixes ADDR_LUT_ENTRIES to 8'h80 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_LUT_ENTRIES denotes the value named 'addr lut entries' in this block.

Line 109: `localparam logic [7:0] ADDR_LAYERNORM_RECIPROCAL = 8'h84;` This fixes ADDR_LAYERNORM_RECIPROCA to 8'h84 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_LAYERNORM_RECIPRO denotes the value named 'addr layernorm reciprocal' in this block.

Line 110: `localparam logic [7:0] ADDR_SOFTMAX_RECIPROCAL = 8'h88;` This fixes ADDR_SOFTMAX_RECIPROCAL to 8'h88 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_SOFTMAX_RECIPROCA denotes the value named 'addr softmax reciprocal' in this block.

Line 111: `localparam logic [7:0] ADDR_PROGRAM_RECORDS = 8'h8c;` This fixes ADDR_PROGRAM_RECORDS to 8'h8c during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_PROGRAM_RECORDS denotes the number of descriptor records accepted since program start.

Line 112: `localparam logic [7:0] ADDR_PROGRAM_OUTPUT_BEATS = 8'h90;` This fixes ADDR_PROGRAM_OUTPUT_BEA to 8'h90 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_PROGRAM_OUTPUT_B denotes the value named 'addr program output beats' in this block.

Line 113: `localparam logic [7:0] ADDR_TRAINING_TILES = 8'h94;` This fixes ADDR_TRAINING_TILES to 8'h94 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_TRAINING_TILES denotes the value named 'addr training tiles' in this block.

Line 114: `localparam logic [7:0] ADDR_TRAINING_CYCLES = 8'h98;` This fixes ADDR_TRAINING_CYCLES to 8'h98 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ADDR_TRAINING_CYCLES denotes the value named 'addr training cycles' in this block.

Line 116: `logic [31:0] command_register [0:3];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_register is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 117: `logic [127:0] submitted_command;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, submitted_command is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 118: `logic command_pending;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_pending is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 119: `logic interrupt_enable;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, interrupt_enable is the hardware notification that wakes software after completion or error. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 120: `logic done_sticky;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, done_sticky is the value named 'done sticky' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 121: `logic wrapper_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wrapper_error is the value named 'wrapper error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 122: `logic program_start_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_start_r is the value named 'program start r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 123: `logic program_clear_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_clear_r is the value named 'program clear r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 124: `logic [31:0] program_output_beats_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_output_beats_r is the value named 'program output beats r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 125: `wire program_active;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_active is the value named 'program active' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 126: `wire program_done;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_done is the value named 'program done' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 127: `wire program_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_error is the value named 'program error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 128: `wire [31:0] program_records;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_records is the number of descriptor records accepted since program start. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 130: `logic aw_hold;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, aw_hold is the value named 'aw hold' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 131: `logic [AXI_ADDR_BITS-1:0] awaddr_hold;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, awaddr_hold is the value named 'awaddr hold' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 132: `logic w_hold;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, w_hold is the value named 'w hold' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 133: `logic [31:0] wdata_hold;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wdata_hold is the value named 'wdata hold' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 134: `logic [3:0] wstrb_hold;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wstrb_hold is the value named 'wstrb hold' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 136: `wire core_command_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_command_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 137: `wire core_command_done;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_command_done is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 138: `wire sequencer_core_command_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sequencer_core_command_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 139: `wire [127:0] sequencer_core_command_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sequencer_core_command_data is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 140: `wire sequencer_core_s_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sequencer_core_s_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 141: `wire [63:0] sequencer_core_s_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sequencer_core_s_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 142: `wire sequencer_core_s_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sequencer_core_s_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 143: `wire sequencer_core_m_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sequencer_core_m_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 144: `wire core_busy;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_busy is the value named 'core busy' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 145: `wire core_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_error is the value named 'core error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 146: `wire [3:0] core_active_opcode;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_active_opcode is the value named 'core active opcode' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 147: `wire [31:0] core_command_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_command_count is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 148: `wire [31:0] core_input_beats;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_input_beats is the value named 'core input beats' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 149: `wire [31:0] core_output_beats;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_beats is the value named 'core output beats' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 150: `wire [11:0] core_tensor_loaded_activations;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_tensor_loaded_activations is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 151: `wire [11:0] core_tensor_loaded_weights;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_tensor_loaded_weights is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 152: `wire [11:0] core_tensor_active_issues;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_tensor_active_issues is the value named 'core tensor active issues' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 153: `wire [31:0] core_tensor_compute_cycles;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_tensor_compute_cycles is the value named 'core tensor compute cycles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 154: `wire [31:0] core_tensor_skipped_issues;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_tensor_skipped_issues is the value named 'core tensor skipped issues' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 155: `wire [63:0] core_tensor_dense_macs;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_tensor_dense_macs is a count of ordinary activation-times-weight operations actually issued. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 156: `wire [63:0] core_tensor_spike_adds;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_tensor_spike_adds is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 157: `wire [31:0] core_layernorm_cycles;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_layernorm_cycles is the value named 'core layernorm cycles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 158: `wire signed [31:0] core_layernorm_mean;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_layernorm_mean is the arithmetic average used by normalization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 159: `wire [31:0] core_layernorm_variance;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_layernorm_variance is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 160: `wire [31:0] core_layernorm_sigma;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_layernorm_sigma is the value named 'core layernorm sigma' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 161: `wire [31:0] core_layernorm_reciprocal;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_layernorm_reciprocal is the value named 'core layernorm reciprocal' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 162: `wire [31:0] core_softmax_cycles;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_softmax_cycles is the value named 'core softmax cycles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 163: `wire signed [23:0] core_softmax_maximum;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_softmax_maximum is the value named 'core softmax maximum' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 164: `wire [23:0] core_softmax_denominator;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_softmax_denominator is the value named 'core softmax denominator' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 165: `wire [31:0] core_softmax_reciprocal;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_softmax_reciprocal is the value named 'core softmax reciprocal' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 166: `wire [63:0] core_lif_total_spikes;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_lif_total_spikes is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 167: `wire [31:0] core_optimizer_updates;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_optimizer_updates is the value named 'core optimizer updates' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 168: `wire [8:0] core_lut_loaded_entries;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_lut_loaded_entries is the value named 'core lut loaded entries' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 169: `wire [31:0] core_training_tiles;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_training_tiles is the value named 'core training tiles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 170: `wire [31:0] core_training_cycles;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_training_cycles is the value named 'core training cycles' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 171: `logic core_s_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 172: `wire core_s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 173: `wire core_raw_s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_raw_s_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 174: `logic core_s_ready_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_ready_r is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 175: `logic next_core_s_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, next_core_s_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 176: `logic next_core_s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, next_core_s_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 177: `logic [63:0] core_s_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 178: `logic core_s_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 179: `logic [1:0] input_fifo_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 180: `logic input_fifo_write_pointer;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_write_pointer is the value named 'input fifo write pointer' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 181: `logic input_fifo_read_pointer;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_read_pointer is the value named 'input fifo read pointer' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 182: `logic [63:0] input_fifo_data [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 183: `logic input_fifo_last [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 184: `logic core_input_capture_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_input_capture_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 185: `logic [63:0] core_input_capture_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_input_capture_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 186: `logic core_input_capture_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_input_capture_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 187: `wire core_raw_m_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_raw_m_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 188: `wire core_raw_m_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_raw_m_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 189: `logic core_raw_m_ready_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_raw_m_ready_r is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 190: `wire [63:0] core_raw_m_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_raw_m_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 191: `wire core_raw_m_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_raw_m_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 192: `logic core_m_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 193: `logic next_core_m_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, next_core_m_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 194: `logic next_core_raw_m_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, next_core_raw_m_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 195: `wire core_m_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 196: `wire sequencer_s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sequencer_s_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 197: `wire sequencer_m_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sequencer_m_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 198: `wire [63:0] sequencer_m_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sequencer_m_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 199: `wire sequencer_m_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sequencer_m_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 200: `logic core_m_ready_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_ready_r is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 201: `logic [63:0] core_m_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 202: `logic core_m_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 203: `logic core_output_capture_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_capture_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 204: `logic [63:0] core_output_capture_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_capture_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 205: `logic core_output_capture_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_capture_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 206: `logic [1:0] output_fifo_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_fifo_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 207: `logic output_fifo_write_pointer;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_fifo_write_pointer is the value named 'output fifo write pointer' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 208: `logic output_fifo_read_pointer;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_fifo_read_pointer is the value named 'output fifo read pointer' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 209: `logic [63:0] output_fifo_data [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_fifo_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 210: `logic output_fifo_last [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_fifo_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 211: `logic output_register_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_register_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 212: `logic [63:0] output_register_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_register_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 213: `logic output_register_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_register_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 214: `logic [1:0] next_output_fifo_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, next_output_fifo_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 215: `logic next_core_output_capture_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, next_core_output_capture_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 216: `logic next_core_m_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, next_core_m_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 218: `wire input_fifo_push = s_axis_tvalid && s_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_push is the value named 'input fifo push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 219: `wire input_fifo_pop = input_fifo_count != 0 && !core_input_capture_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_pop is the value named 'input fifo pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 220: `wire wrapper_input_ready = program_active ? sequencer_s_ready : core_s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wrapper_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 221: `wire wrapper_output_valid = program_active ? sequencer_m_valid : core_m_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wrapper_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 222: `wire [63:0] wrapper_output_data = program_active` This statement continues through source line 223; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wrapper_output_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 223: `? sequencer_m_data : core_m_data;` This is continuation line 2 of the 2-line logical statement that begins at source line 222. Its exact fragment is '? sequencer_m_data : core_m_data;'. The important operands are sequencer_m_data: the payload carried with the surrounding valid/ready handshake; core_m_data: the payload carried with the surrounding valid/ready handshake. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wrapper_output_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 224: `wire wrapper_output_last = program_active ? sequencer_m_last : core_m_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wrapper_output_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 225: `wire core_output_capture_push = wrapper_output_valid && core_m_ready_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_capture_push is the value named 'core output capture push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 226: `wire core_output_capture_pop = core_output_capture_valid` This statement continues through source line 227; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_capture_pop is the value named 'core output capture pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 227: `&& output_fifo_count != 2;` This is continuation line 2 of the 2-line logical statement that begins at source line 226. Its exact fragment is '&& output_fifo_count != 2;'. The important operands are output_fifo_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_capture_pop is the value named 'core output capture pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 228: `wire output_fifo_push = core_output_capture_pop;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_fifo_push is the value named 'output fifo push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 229: `wire output_register_ready = !output_register_valid_r || m_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_register_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 230: `wire output_fifo_pop = output_fifo_count != 0 && output_register_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_fifo_pop is the value named 'output fifo pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 231: `wire selected_core_s_valid = program_active` This statement continues through source line 232; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, selected_core_s_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 232: `? sequencer_core_s_valid : core_input_capture_valid;` This is continuation line 2 of the 2-line logical statement that begins at source line 231. Its exact fragment is '? sequencer_core_s_valid : core_input_capture_valid;'. The important operands are sequencer_core_s_valid: the producer's statement that its current payload is meaningful; core_input_capture_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, selected_core_s_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 233: `wire [63:0] selected_core_s_data = program_active` This statement continues through source line 234; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, selected_core_s_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 234: `? sequencer_core_s_data : core_input_capture_data;` This is continuation line 2 of the 2-line logical statement that begins at source line 233. Its exact fragment is '? sequencer_core_s_data : core_input_capture_data;'. The important operands are sequencer_core_s_data: the payload carried with the surrounding valid/ready handshake; core_input_capture_data: the payload carried with the surrounding valid/ready handshake. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, selected_core_s_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 235: `wire selected_core_s_last = program_active` This statement continues through source line 236; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, selected_core_s_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 236: `? sequencer_core_s_last : core_input_capture_last;` This is continuation line 2 of the 2-line logical statement that begins at source line 235. Its exact fragment is '? sequencer_core_s_last : core_input_capture_last;'. The important operands are sequencer_core_s_last: the AXI-Stream marker for the final beat of a packet or command payload; core_input_capture_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, selected_core_s_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 237: `wire core_s_boundary_push = selected_core_s_valid && core_s_ready_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_boundary_push is the value named 'core s boundary push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 238: `wire core_s_boundary_pop = core_s_valid && core_raw_s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_s_boundary_pop is the value named 'core s boundary pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 239: `wire core_m_boundary_push = core_raw_m_valid && core_raw_m_ready_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_boundary_push is the value named 'core m boundary push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 240: `wire core_m_boundary_pop = core_m_valid && core_m_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_m_boundary_pop is the value named 'core m boundary pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 241: `assign core_s_ready = core_s_ready_r;` This makes core_s_ready, the consumer's statement that it can accept a payload this cycle, equal to 'core_s_ready_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are core_s_ready_r: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 242: `assign core_m_ready = program_active` This statement continues through source line 243; the explanation uses the complete expression rather than only the first visual fragment. This makes core_m_ready, the consumer's statement that it can accept a payload this cycle, equal to 'program_active ? sequencer_core_m_ready : core_m_ready_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; sequencer_core_m_ready: the consumer's statement that it can accept a payload this cycle; core_m_ready_r: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 243: `? sequencer_core_m_ready : core_m_ready_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 242. Its exact fragment is '? sequencer_core_m_ready : core_m_ready_r;'. The important operands are sequencer_core_m_ready: the consumer's statement that it can accept a payload this cycle; core_m_ready_r: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This makes core_m_ready, the consumer's statement that it can accept a payload this cycle, equal to 'program_active ? sequencer_core_m_ready : core_m_ready_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; sequencer_core_m_ready: the consumer's statement that it can accept a payload this cycle; core_m_ready_r: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 244: `assign core_raw_m_ready = core_raw_m_ready_r;` This makes core_raw_m_ready, the consumer's statement that it can accept a payload this cycle, equal to 'core_raw_m_ready_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are core_raw_m_ready_r: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 246: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 247: `next_core_s_valid = core_s_valid;` This makes next_core_s_valid, the producer's statement that its current payload is meaningful, equal to 'core_s_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are core_s_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 248: `unique case ({core_s_boundary_push, core_s_boundary_pop})` This starts a multiplexer/state decode selected by '{core_s_boundary_push, core_s_boundary_pop}'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 249: `2'b10: next_core_s_valid = 1'b1;` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are b10: the value named 'b10' in this block; next_core_s_valid: the producer's statement that its current payload is meaningful; b1: the value named 'b1' in this block.

Line 250: `2'b01: next_core_s_valid = 1'b0;` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are b01: the value named 'b01' in this block; next_core_s_valid: the producer's statement that its current payload is meaningful; b0: the value named 'b0' in this block.

Line 251: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the combinational process whose outputs respond without waiting for a clock edge.

Line 252: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 253: `next_core_s_ready = !next_core_s_valid || core_raw_s_ready;` This makes next_core_s_ready, the consumer's statement that it can accept a payload this cycle, equal to '!next_core_s_valid || core_raw_s_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are next_core_s_valid: the producer's statement that its current payload is meaningful; core_raw_s_ready: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 254: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 256: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 257: `next_core_m_valid = core_m_valid;` This makes next_core_m_valid, the producer's statement that its current payload is meaningful, equal to 'core_m_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are core_m_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 258: `unique case ({core_m_boundary_push, core_m_boundary_pop})` This starts a multiplexer/state decode selected by ‘{core_m_boundary_push, core_m_boundary_pop}‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 259: `2'b10: next_core_m_valid = 1'b1;` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are b10: the value named ’b10’ in this block; next_core_m_valid: the producer’s statement that its current payload is meaningful; b1: the value named ’b1’ in this block.

Line 260: `2'b01: next_core_m_valid = 1'b0;` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are b01: the value named ’b01’ in this block; next_core_m_valid: the producer’s statement that its current payload is meaningful; b0: the value named ’b0’ in this block.

Line 261: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin end‘; context is the combinational process whose outputs respond without waiting for a clock edge.

Line 262: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 263: `next_core_raw_m_ready = !next_core_m_valid || core_m_ready;` This makes next_core_raw_m_ready, the consumer’s statement that it can accept a payload this cycle, equal to ‘!next_core_m_valid || core_m_ready‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are next_core_m_valid: the producer’s statement that its current payload is meaningful; core_m_ready: the consumer’s statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 264: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 266: `// Registered credit prevents a child engine's READY state from becoming` Design intent: Registered credit prevents a child engine’s READY state from becoming This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 267: `// a payload clock-enable while retaining simultaneous consume/refill.` Design intent: a payload clock-enable while retaining simultaneous consume/refill. This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 268: `always_ff @(posedge aclk) begin` This opens clocked sequential logic. Everything assigned with ‘<=‘ inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator’s notion of cycles and persistent state.

Line 269: `if (!aresetn) begin` This is the reset branch for ‘(!aresetn‘. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 270: `core_s_valid <= 1'b0;` This makes core_s_valid, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 271: `core_s_ready_r <= 1'b1;` This makes core_s_ready_r, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 272: `core_s_data <= 64'd0;` This makes core_s_data, the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 273: `core_s_last <= 1'b0;` This makes core_s_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 274: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 275: `core_s_valid <= next_core_s_valid;` This makes core_s_valid, the producer's statement that its current payload is meaningful, equal to 'next_core_s_valid'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_core_s_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 276: `core_s_ready_r <= next_core_s_ready;` This makes core_s_ready_r, the consumer's statement that it can accept a payload this cycle, equal to 'next_core_s_ready'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_core_s_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 277: `if (core_s_ready_r) begin` This condition selects the following hardware branch only when 'core_s_ready_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are core_s_ready_r: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 278: `core_s_data <= selected_core_s_data;` This makes core_s_data, the payload carried with the surrounding valid/ready handshake, equal to 'selected_core_s_data'. It updates after the active clock edge together with other nonblocking assignments. The important operands are selected_core_s_data: the payload carried with the surrounding valid/ready handshake. Context: the clocked process that updates registers only on a rising clock edge.

Line 279: `core_s_last <= selected_core_s_last;` This makes core_s_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'selected_core_s_last'. It updates after the active clock edge together with other nonblocking assignments. The important operands are selected_core_s_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 280: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 281: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 282: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 284: `// This elastic boundary isolates every child engine's result-valid path` Design intent: This elastic boundary isolates every child engine's result-valid path This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 285: `// from the descriptor and wrapper FIFOs while retaining one beat/cycle.` Design intent: from the descriptor and wrapper FIFOs while retaining one beat/cycle. This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 286: `always_ff @(posedge aclk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 287: `if (!aresetn) begin` This is the reset branch for '(!aresetn'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 288: `core_m_valid <= 1'b0;` This makes core_m_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 289: `core_raw_m_ready_r <= 1'b1;` This makes core_raw_m_ready_r, the consumer's statement that it can accept a payload this cycle, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 290: `core_m_data <= 64'd0;` This makes core_m_data, the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 291: `core_m_last <= 1'b0;` This makes core_m_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 292: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 293: `core_m_valid <= next_core_m_valid;` This makes core_m_valid, the producer's statement that its current payload is meaningful, equal to 'next_core_m_valid'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_core_m_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 294: `core_raw_m_ready_r <= next_core_raw_m_ready;` This makes core_raw_m_ready_r, the consumer's statement that it can accept a payload this cycle, equal to 'next_core_raw_m_ready'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_core_raw_m_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 295: `if (core_raw_m_ready_r) begin` This condition selects the following hardware branch only when 'core_raw_m_read is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are core_raw_m_ready_r: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 296: `core_m_data <= core_raw_m_data;` This makes core_m_data, the payload carried with the surrounding valid/ready handshake, equal to ‘core_raw_m_data‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are core_raw_m_data: the payload carried with the surrounding valid/ready handshake. Context: the clocked process that updates registers only on a rising clock edge.

Line 297: `core_m_last <= core_raw_m_last;` This makes core_m_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘core_raw_m_last‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are core_raw_m_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 298: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 299: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 300: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 302: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 303: `next_output_fifo_count = output_fifo_count;` This makes next_output_fifo_count, an integer count retained for control or measurable telemetry, equal to ‘output_fifo_count‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_fifo_count: an integer count retained for control or measurable telemetry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 304: `unique case ({output_fifo_push, output_fifo_pop})` This starts a multiplexer/state decode selected by ‘{output_fifo_push, output_fifo_pop}‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 305: `2'b10: next_output_fifo_count = output_fifo_count + 1'b1;` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are b10: the value named 'b10' in this block; next_output_fifo_count: an integer count retained for control or measurable telemetry; output_fifo_count: an integer count retained for control or measurable telemetry.

Line 306: `2'b01: next_output_fifo_count = output_fifo_count - 1'b1;` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are b01: the value named 'b01' in this block; next_output_fifo_count: an integer count retained for control or measurable telemetry; output_fifo_count: an integer count retained for control or measurable telemetry.

Line 307: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin end‘; context is the combinational process whose outputs respond without waiting for a clock edge.

Line 308: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 310: `next_core_output_capture_valid = core_output_capture_valid;` This makes next_core_output_capture_valid the producer's statement that its current payload is meaningful, equal to 'core_output_capture_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are core_output_capture_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 311: `unique case ({core_output_capture_push, core_output_capture_pop})` This starts a multiplexer/state decode selected by '{core_output_capture_push, core_output_capture_pop}'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 312: `2'b10: next_core_output_capture_valid = 1'b1;` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are b10: the value named 'b10' in this block; next_core_output_capture_valid: the producer's statement that its current payload is meaningful; b1: the value named 'b1' in this block.

Line 313: `2'b01: next_core_output_capture_valid = 1'b0;` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are b01: the value named 'b01' in this block; next_core_output_capture_valid: the producer's statement that its current payload is meaningful; b0: the value named 'b0' in this block.

Line 314: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the combinational process whose outputs respond without waiting for a clock edge.

Line 315: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 316: `// This next-cycle credit is conservative when a full FIFO pops: the` Design intent: This next-cycle credit is conservative when a full FIFO pops: the This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 317: `// resulting single restart bubble prevents any combinational READY` Design intent: resulting single restart bubble prevents any combinational READY This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 318: `// path while preserving one result per cycle during steady traffic.` Design intent: path while preserving one result per cycle during steady traffic. This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 319: `next_core_m_ready = !next_core_output_capture_valid` This statement continues through source line 320; the explanation uses the complete expression rather than only the first visual fragment. This makes next_core_m_ready, the consumer's statement that it can accept a payload this cycle, equal to '!next_core_output_capture_valid || next_output_fifo_co != 2'. It is driven by combinational or procedural logic in the current evaluation. The important operands are next_core_output_capture_valid: the producer's statement that its current payload is meaningful; next_output_fifo_count: an integer count retained for control or measurable telemetry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 320: `|| next_output_fifo_count != 2;` This is continuation line 2 of the 2-line logical statement that begins at source line 319. Its exact fragment is '|| next_output_fifo_count != 2;'. The important operands are next_output_fifo_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This makes next_core_m_ready, the consumer's statement that it can accept a payload this cycle, equal to '!next_core_output_capture_valid || next_output_fifo_count != 2'. It is driven by combinational or procedural logic in the current evaluation. The important operands are next_core_output_capture_valid: the producer's statement that its current payload is meaningful;

next_output_fifo_count: an integer count retained for control or measurable telemetry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 321: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 323: `// Two entries isolate external backpressure from every internal engine while` Design intent: Two entries isolate external backpressure from every internal engine while This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 324: `// still allowing simultaneous enqueue/dequeue at one result per clock.` Design intent: still allowing simultaneous enqueue/dequeue at one result per clock. This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 325: `function automatic logic [31:0] apply_write_strobes(` Within the combinational helper apply write strobes, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; apply_write_strobes: the value named 'apply write strobes' in this block.

Line 326: `input logic [31:0] old_value,` This declares old_value as a input port with width [31:0]. It carries the value named 'old value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 327: `input logic [31:0] new_value,` This declares new_value as a input port with width [31:0]. It carries the value named 'new value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 328: `input logic [3:0] strobes` This declares strobes as a input port with width [3:0]. It carries the value named 'strobes' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 329: `);` Within the combinational helper apply write strobes, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The expression is a literal or structural operator and has no hidden software state.

Line 330: `logic [31:0] merged;` This declares hardware signal storage or wiring in the combinational helper apply write strobes. Specifically, merged is the value named 'merged' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 331: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper apply write strobes; it has no arithmetic value of its own.

Line 332: `merged = old_value;` This makes merged, the value named 'merged' in this block, equal to ‘old_value‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are old_value: the value named 'old value' in this block. Context: the combinational helper apply write strobes.

Line 333: `for (int byte_index = 0; byte_index < 4; byte_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational helper apply write strobes.

Line 334: `if (strobes[byte_index]) begin` This condition selects the following hardware branch only when ‘strobes[byte_inde is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are strobes: the value named 'strobes' in this block; byte_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational helper apply write strobes.

Line 335: `merged[byte_index*8 +: 8] = new_value[byte_index*8 +: 8];` Within the combinational helper apply write strobes, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are merged: the value named 'merged' in this block; byte_index: an integer selecting one tensor element, lane, bank, or state entry; new_value: the value named 'new value' in this block.

Line 336: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper apply write strobes; it has no arithmetic value of its own.

Line 337: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper apply write strobes; it has no arithmetic value of its own.

Line 338: `apply_write_strobes = merged;` This makes apply_write_strobes, the value named 'apply write strobes' in this block, equal to ‘merged‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are merged: the value named 'merged' in this block. Context: the combinational helper apply write strobes.

Line 339: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper apply write strobes; it has no arithmetic value of its own.

Line 340: `endfunction` Within the combinational helper apply write strobes, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are endfunction: the value named 'endfunction' in this block.

Line 342: `function automatic logic [31:0] register_read(input logic [7:0] address);` Within the combinational helper register read, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; register_read: the value named 'register read' in this block.

Line 343: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper register read; it has no arithmetic value of its own.

Line 344: `unique case (address)` This starts a multiplexer/state decode selected by ‘address‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 345: `ADDR_CONTROL: register_read = {` This statement continues through source line 347; the explanation uses the complete expression rather than only the first visual fragment. This is the ADDR_CONTROL case branch, which performs this explicitly named phase. The same-cycle action begins with ‘register_read = { 23'd0, interrupt_enable, 5'd0, program_active, 1'b0, command_pending};‘; context is the combinational helper register read Within state ADDR_CONTROL, the machine performs the named control phase..

Line 346: `23'd0, interrupt_enable, 5'd0, program_active,` This is continuation line 2 of the 3-line logical statement that begins at source line 345. Its exact fragment is ‘23'd0, interrupt_enable, 5'd0, program_active,‘. The important operands are d0: the value named 'd0' in this block; interrupt_enable: the hardware notification that wakes software after completion or error; program_active: the value named 'program active' in this block. Read together, the complete operation is: This is the ADDR_CONTROL case branch, which performs this explicitly named phase. The same-cycle action begins with ‘register_read = { 23'd0, interrupt_enable, 5'd0, program_active, 1'b0, command_pending};‘; context is the combinational helper register read Within state ADDR_CONTROL, the machine performs the named control phase..

Line 347: `1'b0, command_pending};` This is continuation line 3 of the 3-line logical statement that begins at source line 345. Its exact fragment is '1'b0, command_pending};'. The important operands are b0: the value named 'b0' in this block; command_pending: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This is the ADDR_CONTROL case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = { 23'd0, interrupt_enable, 5'd0, program_active, 1'b0, command_pending};'; context is the combinational helper register read Within state ADDR_CONTROL, the machine performs the named control phase..

Line 348: `ADDR_STATUS: register_read = {` This statement continues through source line 351; the explanation uses the complete expression rather than only the first visual fragment. This is the ADDR_STATUS case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = { 26'd0, program_active, interrupt, command_pending, done_sticky, core_error || wrapper_error || program_error, core_busy || command_pending || program_active};'; context is the combinational helper register read Within state ADDR_STATUS, the machine performs the named control phase..

Line 349: `26'd0, program_active, interrupt, command_pending,` This is continuation line 2 of the 4-line logical statement that begins at source line 348. Its exact fragment is '26'd0, program_active, interrupt, command_pending,'. The important operands are d0: the value named 'd0' in this block; program_active: the value named 'program active' in this block; interrupt: the hardware notification that wakes software after completion or error. Read together, the complete operation is: This is the ADDR_STATUS case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = { 26'd0, program_active, interrupt, command_pending, done_sticky, core_error || wrapper_error || program_error, core_busy || command_pending || program_active};'; context is the combinational helper register read Within state ADDR_STATUS, the machine performs the named control phase..

Line 350: `done_sticky, core_error || wrapper_error || program_error,` This is continuation line 3 of the 4-line logical statement that begins at source line 348. Its exact fragment is 'done_sticky, core_error || wrapper_error || program_error,'. The important operands are done_sticky: the value named 'done sticky' in this block; core_error: the value named 'core error' in this block; wrapper_error: the value named 'wrapper error' in this block. Read together, the complete operation is: This is the ADDR_STATUS case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = { 26'd0, program_active, interrupt, command_pending, done_sticky, core_error || wrapper_error || program_error, core_busy || command_pending || program_active};'; context is the combinational helper register read Within state ADDR_STATUS, the machine performs the named control phase..

Line 351: `core_busy || command_pending || program_active};` This is continuation line 4 of the 4-line logical statement that begins at source line 348. Its exact fragment is 'core_busy || command_pending || program_active};'. The important operands are core_busy: the value named 'core busy' in this block; command_pending: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; program_active: the value named 'program active' in this block. Read together, the complete operation is: This is the ADDR_STATUS case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = { 26'd0, program_active, interrupt, command_pending, done_sticky, core_error || wrapper_error || program_error, core_busy || command_pending || program_active};'; context is the combinational helper register read Within state ADDR_STATUS, the machine performs the named control phase..

Line 352: `ADDR_ACTIVE_OPCODE: register_read = {28'd0, core_active_opcode};` This is the ADDR_ACTIVE_OPCODE case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = {28'd0, core_active_opcode};'; context is the combinational helper register read Within state ADDR_ACTIVE_OPCODE, the machine performs the named control phase..

Line 353: `ADDR_COMMAND_COUNT: register_read = core_command_count;` This is the ADDR_COMMAND_COUNT case branch, which updates a segmented telemetry counter without a long carry chain. The same-cycle action begins with 'register_read = core_command_count;'; context is the combinational helper register read Within state ADDR_COMMAND_COUNT, the machine updates a segmented telemetry counter without a long carry chain..

Line 354: `ADDR_COMMAND0: register_read = command_register[0];` This is the ADDR_COMMAND0 case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = command_register[0];';

context is the combinational helper register read Within state ADDR_COMMAND0, the machine performs the named control phase..

Line 355: `ADDR_COMMAND1: register_read = command_register[1];` This is the ADDR_COMMAND1 case branch, which performs this explicitly named phase. The same-cycle action begins with ‘register_read = command_register[1];‘; context is the combinational helper register read Within state ADDR_COMMAND1, the machine performs the named control phase..

Line 356: `ADDR_COMMAND2: register_read = command_register[2];` This is the ADDR_COMMAND2 case branch, which performs this explicitly named phase. The same-cycle action begins with ‘register_read = command_register[2];‘; context is the combinational helper register read Within state ADDR_COMMAND2, the machine performs the named control phase..

Line 357: `ADDR_COMMAND3: register_read = command_register[3];` This is the ADDR_COMMAND3 case branch, which performs this explicitly named phase. The same-cycle action begins with ‘register_read = command_register[3];‘; context is the combinational helper register read Within state ADDR_COMMAND3, the machine performs the named control phase..

Line 358: `ADDR_INPUT_BEATS: register_read = core_input_beats;` This is the ADDR_INPUT_BEATS case branch, which performs this explicitly named phase. The same-cycle action begins with ‘register_read = core_input_beats;‘; context is the combinational helper register read Within state ADDR_INPUT_BEATS, the machine performs the named control phase..

Line 359: `ADDR_OUTPUT_BEATS: register_read = core_output_beats;` This is the ADDR_OUTPUT_BEATS case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘register_read = core_output_beats;‘; context is the combinational helper register read Within state ADDR_OUTPUT_BEATS, the machine presents computed results under valid/ready backpressure..

Line 360: `ADDR_TARGET_CLOCK: register_read = 32'd200000000;` This is the ADDR_TARGET_CLOCK case branch, which performs this explicitly named phase. The same-cycle action begins with ‘register_read = 32'd200000000;‘; context is the combinational helper register read Within state ADDR_TARGET_CLOCK, the machine performs the named control phase..

Line 361: `// Bits correspond to tensor, binary/ternary, alpha-XNOR,` Design intent: Bits correspond to tensor, binary/ternary, alpha-XNOR, This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 362: `// vector/LUT, normalization, LIF, optimizer, and backward tile.` Design intent: vector/LUT, normalization, LIF, optimizer, and backward tile. This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 363: `ADDR_CAPABILITIES: register_read = 32'h000001ff;` This is the ADDR_CAPABILITIES case branch, which performs this explicitly named phase. The same-cycle action begins with ‘register_read = 32'h000001ff;‘; context is the combinational helper register read Within state ADDR_CAPABILITIES, the machine performs the named control phase..

Line 364: `ADDR_VERSION: register_read = 32'h00010007;` This is the ADDR_VERSION case branch, which performs this explicitly named phase. The same-cycle action begins with ‘register_read = 32'h00010007;‘; context is the combinational helper register read Within state ADDR_VERSION, the machine performs the named control phase..

The same-cycle action begins with 'register_read = core_layernorm_cycles context is the combinational helper register read Within state ADDR_LAYERNORM_CYCLES, the machine performs the named control phase..

Line 377: `ADDR_LAYERNORM_MEAN: register_read = core_layernorm_mean;` This is the ADDR_LAYERNORM_MEAN case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_layernorm_mean; context is the combinational helper register read Within state ADDR_LAYERNORM_MEAN, the machine performs the named control phase..

Line 378: `ADDR_LAYERNORM_VARIANCE: register_read = core_layernorm_variance;` This is the ADDR_LAYERNORM_VA case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_layernorm_varian context is the combinational helper register read Within state ADDR_LAYERNORM_VARIANCE, the machine performs the named control phase..

Line 379: `ADDR_LAYERNORM_SIGMA: register_read = core_layernorm_sigma;` This is the ADDR_LAYERNORM_SIGMA case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_layernorm_sigma context is the combinational helper register read Within state ADDR_LAYERNORM_SIGMA, the machine performs the named control phase..

Line 380: `ADDR_SOFTMAX_CYCLES: register_read = core_softmax_cycles;` This is the ADDR_SOFTMAX_CYCLES case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_softmax_cycles;'; context is the combinational helper register read Within state ADDR_SOFTMAX_CYCLES, the machine performs the named control phase..

Line 381: `ADDR_SOFTMAX_MAXIMUM: register_read =` This statement continues through source line 382; the explanation uses the complete expression rather than only the first visual fragment. This is the ADDR_SOFTMAX_MAXIMUM case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = {{8{core_softmax_ma core_softmax_maximum};'; context is the combinational helper register read Within state ADDR_SOFTMAX_MAXIMUM, the machine performs the named control phase..

Line 382: `{{8{core_softmax_maximum[23]}}, core_softmax_maximum};` This is continuation line 2 of the 2-line logical statement that begins at source line 381. Its exact fragment is '{{8{core_softmax_maximum[23]}}, core_softmax_maximum};'. The important operands are core_softmax_maximum: the value named 'core softmax maximum' in this block. Read together, the complete operation is: This is the ADDR_SOFTMAX_MAXIMUM case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = {{8{core_softmax_maximum[23]}}, core_softmax_maximun context is the combinational helper register read Within state ADDR_SOFTMAX_MAXIMUM, the machine performs the named control phase..

Line 383: `ADDR_SOFTMAX_DENOMINATOR: register_read =` This statement continues through source line 384; the explanation uses the complete expression rather than only the first visual fragment. This is the ADDR_SOFTMAX_DENOMINATOR case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = {8'd0, core_softmax_denominator};'; context is the combinational helper register read Within state ADDR_SOFTMAX_DENOMINATO the machine performs the named control phase..

Line 384: `{8'd0, core_softmax_denominator};` This is continuation line 2 of the 2-line logical statement that begins at source line 383. Its exact fragment is '{8'd0, core_softmax_denominator};'. The important operands are d0: the value named 'd0' in this block; core_softmax_denominator: the value named 'core softmax denominator' in this block. Read together, the complete operation is: This is the ADDR_SOFTMAX_DENOMINATOR case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = {8'd0, core_softmax_denominator};';

context is the combinational helper register read Within state ADDR_SOFTMAX_DENOMINATOR, the machine performs the named control phase..

Line 385: `ADDR_LIF_SPIKES_LOW: register_read = core_lif_total_spikes[31:0];` This is the ADDR_LIF_SPIKES_LOW case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_lif_total_spikes[3 context is the combinational helper register read Within state ADDR_LIF_SPIKES_LOW, the machine performs the named control phase..

Line 386: `ADDR_LIF_SPIKES_HIGH: register_read = core_lif_total_spikes[63:32];` This is the ADDR_LIF_SPIKES_H case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_lif_total_spikes[6 context is the combinational helper register read Within state ADDR_LIF_SPIKES_HIGH, the machine performs the named control phase..

Line 387: `ADDR_OPTIMIZER_UPDATES: register_read = core_optimizer_updates;` This is the ADDR_OPTIMIZER_UPDA case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_optimizer_update context is the combinational helper register read Within state ADDR_OPTIMIZER_UPDATES, the machine performs the named control phase..

Line 388: `ADDR_LUT_ENTRIES: register_read = {23'd0, core_lut_loaded_entries};` This is the ADDR_LUT_ENTRIES case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = {23'd0, core_lut_loaded_entries};'; context is the combinational helper register read Within state ADDR_LUT_ENTRIES, the machine performs the named control phase..

Line 389: `ADDR_LAYERNORM_RECIPROCAL: register_read = core_layernorm_reciprocal;` This is the ADDR_LAYERNORM case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_layernorm_recipr context is the combinational helper register read Within state ADDR_LAYERNORM_RECIPROCAL, the machine performs the named control phase..

Line 390: `ADDR_SOFTMAX_RECIPROCAL: register_read = core_softmax_reciprocal;` This is the ADDR_SOFTMAX_RECI case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_softmax_reciproc context is the combinational helper register read Within state ADDR_SOFTMAX_RECIPROCAL, the machine performs the named control phase..

Line 391: `ADDR_PROGRAM_RECORDS: register_read = program_records;` This is the ADDR_PROGRAM_RECORDS case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = program_records;'; context is the combinational helper register read Within state ADDR_PROGRAM_RECORDS, the machine performs the named control phase..

Line 392: `ADDR_PROGRAM_OUTPUT_BEATS: register_read = program_output_beats_r;` This is the ADDR_PROGRAM_OUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'register_read = program_output_beats_r;'; context is the combinational helper register read Within state ADDR_PROGRAM_OUTP the machine presents computed results under valid/ready backpressure..

Line 393: `ADDR_TRAINING_TILES: register_read = core_training_tiles;` This is the ADDR_TRAINING_TILES case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_training_tiles;'; context is the combinational helper register read Within state ADDR_TRAINING_TILES, the machine performs the named control phase..

Line 394: `ADDR_TRAINING_CYCLES: register_read = core_training_cycles;` This is the ADDR_TRAINING_CYCLES case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = core_training_cycles;'; context is the combinational helper register read Within state ADDR_TRAINING_CYCLES, the machine performs the named control phase..

Line 395: `default: register_read = 32'd0;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'register_read = 32'd0;'; context is the combinational helper register read Within state ADDR_TRAINING_CYCLES, the machine performs the named control phase..

Line 396: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational helper register read Within state ADDR_TRAINING_CYCLES, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 397: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper register read; it has no arithmetic value of its own.

Line 398: `endfunction` Within the combinational helper register read, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are endfunction: the value named 'endfunction' in this block.

Line 400: `neuraedge_descriptor_sequencer u_descriptor_sequencer (` This instantiates module neuraedge_descriptor_sec as u_descriptor_sequencer. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 401: `.clk(aclk), .rst_n(aresetn),` This connects the child instance's named port 'clk' to parent expression 'aclk), .rst_n(aresetn'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 402: `.program_start(program_start_r),` This connects the child instance's named port 'program_start' to parent expression 'program_start_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'program start r' in this block.

Line 403: `.clear_status(program_clear_r),` This connects the child instance's named port 'clear_status' to parent expression 'program_clear_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'program clear r' in this block.

Line 404: `.program_output_beats(program_output_beats_r),` This connects the child instance's named port 'program_output_beats' to parent expression 'program_output_beats_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'program output beats r' in this block.

Line 405: `.program_active(program_active), .program_done(program_done),` This connects the child instance's named port 'program_active' to parent expression 'program_active), .program_done(program_done'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'program active), .program done(program done' in this block.

Line 406: `.program_error(program_error), .program_records(program_records),` This connects the child instance's named port 'program_error' to parent expression 'program_error), .program_records(program_records'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the number of descriptor records accepted since program start.

Line 407: `.s_axis_tvalid(core_input_capture_valid),` This connects the child instance's named port 's_axis_tvalid' to parent expression 'core_input_capture_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 408: `.s_axis_tready(sequencer_s_ready),` This connects the child instance's named port 's_axis_tready' to parent expression 'sequencer_s_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 409: `.s_axis_tdata(core_input_capture_data),` This connects the child instance's named port 's_axis_tdata' to parent expression 'core_input_capture_data'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the payload carried with the surrounding valid/ready handshake.

Line 410: `.s_axis_tlast(core_input_capture_last),` This connects the child instance's named port 's_axis_tlast' to parent expression 'core_input_capture_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 411: `.m_axis_tvalid(sequencer_m_valid),` This connects the child instance's named port 'm_axis_tvalid' to parent expression 'sequencer_m_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 412: `.m_axis_tready(core_m_ready_r),` This connects the child instance's named port 'm_axis_tready' to parent expression 'core_m_ready_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 413: `.m_axis_tdata(sequencer_m_data),` This connects the child instance's named port 'm_axis_tdata' to parent expression 'sequencer_m_data'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the payload carried with the surrounding valid/ready handshake.

Line 414: `.m_axis_tlast(sequencer_m_last),` This connects the child instance's named port 'm_axis_tlast' to parent expression 'sequencer_m_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 415: `.core_command_valid(sequencer_core_command_valid),` This connects the child instance's named port 'core_command_valid' to parent expression 'sequencer_core_command_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 416: `.core_command_ready(core_command_ready),` This connects the child instance's named port 'core_command_ready' to parent expression 'core_command_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 417: `.core_command_data(sequencer_core_command_data),` This connects the child instance's named port 'core_command_data' to parent expression 'sequencer_core_command_data'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 418: `.core_command_done(core_command_done),` This connects the child instance's named port 'core_command_done' to parent expression 'core_command_done'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 419: `.core_status_error(core_error),` This connects the child instance's named port 'core_status_error' to parent expression 'core_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core error' in this block.

Line 420: `.core_s_valid(sequencer_core_s_valid), .core_s_ready(core_s_ready),` This connects the child instance's named port 'core_s_valid' to parent expression 'sequencer_core_s_valid), .core_s_ready(core_s_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 421: `.core_s_data(sequencer_core_s_data), .core_s_last(sequencer_core_s_last),` This connects the child instance's named port 'core_s_data' to parent expression 'sequencer_core_s_data), .core_s_last(sequencer_core_s_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 422: `.core_m_valid(core_m_valid), .core_m_ready(sequencer_core_m_ready),` This connects the child instance's named port 'core_m_valid' to parent expression 'core_m_valid), .core_m_ready(sequencer_core_m_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 423: `.core_m_data(core_m_data), .core_m_last(core_m_last)` This connects the child instance's named port 'core_m_data' to parent expression 'core_m_data), .core_m_last(core_m_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 424: `);` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The expression is a literal or structural operator and has no hidden software state.

Line 426: `neuraedge_universal_core u_core (` This instantiates module neuraedge_universal_core as u_core. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 427: `.clk(aclk), .rst_n(aresetn),` This connects the child instance's named port 'clk' to parent expression 'aclk), .rst_n(aresetn'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 428: `.command_valid(program_active` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are command_valid: the producer's statement that its current payload is meaningful; program_active: the value named 'program active' in this block.

Line 429: `? sequencer_core_command_valid : command_pending),` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are sequencer_core_command_valid: the producer's statement that its current payload is meaningful; command_pending: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 430: `.command_ready(core_command_ready),` This connects the child instance's named port 'command_ready' to parent expression 'core_command_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 431: `.command_data(program_active` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are command_data: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; program_active: the value named 'program active' in this block.

Line 432: `? sequencer_core_command_data : submitted_command),` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are sequencer_core_command_data: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; submitted_command: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 433: `.command_done(core_command_done),` This connects the child instance's named port 'command_done' to parent expression 'core_command_done'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 434: `.status_busy(core_busy), .status_error(core_error),` This connects the child instance's named port 'status_busy' to parent expression 'core_busy), .status_error(core_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core busy), .status error(core error' in this block.

Line 435: `.status_active_opcode(core_active_opcode),` This connects the child instance's named port 'status_active_opcode' to parent expression 'core_active_opcode'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core active opcode' in this block.

Line 436: `.status_command_count(core_command_count),` This connects the child instance's named port 'status_command_count' to parent expression 'core_command_count'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 437: `.status_input_beats(core_input_beats), .status_output_beats(core_output_beats),` This connects the child instance's named port 'status_input_beats' to parent expression 'core_input_beats), .status_output_beats(core_ou
The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core input beats), .status output beats(core output beats' in this block.

Line 438: `.debug_tensor_loaded_activations(core_tensor_loaded_activations),` This connects the child instance's named port 'debug_tensor_loaded_activations' to parent expression 'core_tensor_loaded_activations'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 439: `.debug_tensor_loaded_weights(core_tensor_loaded_weights),` This connects the child instance's named port 'debug_tensor_loaded_weights' to parent expression 'core_tensor_loaded_weights'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 440: `.debug_tensor_active_issues(core_tensor_active_issues),` This connects the child instance's named port 'debug_tensor_active_issues' to parent expression 'core_tensor_active_issues'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core tensor active issues' in this block.

Line 441: `.debug_tensor_compute_cycles(core_tensor_compute_cycles),` This connects the child instance's named port 'debug_tensor_compute_cycles' to parent expression 'core_tensor_compute_cycles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core tensor compute cycles' in this block.

Line 442: `.debug_tensor_skipped_issues(core_tensor_skipped_issues),` This connects the child instance's named port 'debug_tensor_skipped_issues' to parent expression 'core_tensor_skipped_issues'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core tensor skipped issues' in this block.

Line 443: `.debug_tensor_dense_macs(core_tensor_dense_macs),` This connects the child instance's named port 'debug_tensor_dense_macs' to parent expression 'core_tensor_dense_macs'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a count of ordinary activation-times-weight operations actually issued.

Line 444: `.debug_tensor_spike_adds(core_tensor_spike_adds),` This connects the child instance's named port 'debug_tensor_spike_adds' to parent expression 'core_tensor_spike_adds'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 445: `.debug_layernorm_cycles(core_layernorm_cycles),` This connects the child instance's named port 'debug_layernorm_cycles' to parent expression 'core_layernorm_cycles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core layernorm cycles' in this block.

Line 446: `.debug_layernorm_mean(core_layernorm_mean),` This connects the child instance's named port 'debug_layernorm_mean' to parent expression 'core_layernorm_mean'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the arithmetic average used by normalization.

Line 447: `.debug_layernorm_variance(core_layernorm_variance),` This connects the child instance's named port 'debug_layernorm_variance' to parent expression 'core_layernorm_variance'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the average squared distance from the mean.

Line 448: `.debug_layernorm_sigma(core_layernorm_sigma),` This connects the child instance's named port 'debug_layernorm_sigma' to parent expression 'core_layernorm_sigma'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core layernorm sigma' in this block.

Line 449: `.debug_layernorm_reciprocal(core_layernorm_reciprocal),` This connects the child instance's named port 'debug_layernorm_reciprocal' to parent expression 'core_layernorm_reciprocal'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core layernorm reciprocal' in this block.

Line 450: `.debug_softmax_cycles(core_softmax_cycles),` This connects the child instance's named port 'debug_softmax_cycles' to parent expression 'core_softmax_cycles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core softmax cycles' in this block.

Line 451: `.debug_softmax_maximum(core_softmax_maximum),` This connects the child instance's named port 'debug_softmax_maximum' to parent expression 'core_softmax_maximum'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core softmax maximum' in this block.

Line 452: `.debug_softmax_denominator(core_softmax_denominator),` This connects the child instance's named port 'debug_softmax_denominator' to parent expression 'core_softmax_denominator'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core softmax denominator' in this block.

Line 453: `.debug_softmax_reciprocal(core_softmax_reciprocal),` This connects the child instance's named port 'debug_softmax_reciprocal' to parent expression 'core_softmax_reciprocal'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core softmax reciprocal' in this block.

Line 454: `.debug_lif_total_spikes(core_lif_total_spikes),` This connects the child instance's named port 'debug_lif_total_spikes' to parent expression 'core_lif_total_spikes'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 455: `.debug_optimizer_updates(core_optimizer_updates),` This connects the child instance's named port 'debug_optimizer_updates' to parent expression 'core_optimizer_updates'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core optimizer updates' in this block.

Line 456: `.debug_lut_loaded_entries(core_lut_loaded_entries),` This connects the child instance's named port 'debug_lut_loaded_entries' to parent expression 'core_lut_loaded_entries'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core lut loaded entries' in this block.

Line 457: `.debug_training_tiles(core_training_tiles),` This connects the child instance's named port 'debug_training_tiles' to parent expression 'core_training_tiles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core training tiles' in this block.

Line 458: `.debug_training_cycles(core_training_cycles),` This connects the child instance's named port 'debug_training_cycles' to parent expression 'core_training_cycles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'core training cycles' in this block.

Line 459: `.s_axis_tvalid(core_s_valid), .s_axis_tready(core_raw_s_ready),` This connects the child instance's named port ‘s_axis_tvalid‘ to parent expression ‘core_s_valid), .s_axis_tready(core_raw_s_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 460: `.s_axis_tdata(core_s_data), .s_axis_tlast(core_s_last),` This connects the child instance's named port ‘s_axis_tdata‘ to parent expression ‘core_s_data), .s_axis_tlast(core_s_last‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 461: `.m_axis_tvalid(core_raw_m_valid), .m_axis_tready(core_raw_m_ready),` This connects the child instance's named port ‘m_axis_tvalid‘ to parent expression ‘core_raw_m_valid), .m_axis_tready(core_raw_m_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 462: `.m_axis_tdata(core_raw_m_data), .m_axis_tlast(core_raw_m_last)` This connects the child instance's named port ‘m_axis_tdata‘ to parent expression ‘core_raw_m_data), .m_axis_tlast(core_raw_m_last‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 463: `);` Within the module's structural declarations, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The expression is a literal or structural operator and has no hidden software state.

Line 465: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 466: `// A two-entry elastic FIFO makes the external ready path local while` Design intent: A two-entry elastic FIFO makes the external ready path local while This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 467: `// still accepting one input beat per clock during simultaneous pop/push.` Design intent: still accepting one input beat per clock during simultaneous pop/push. This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 468: `s_axis_tready = input_fifo_count != 2;` This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to ‘input_fifo_count != 2‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_fifo_count: an integer count retained for control or measurable telemetry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 469: `s_axi_awready = !aw_hold && !s_axi_bvalid;` This makes s_axi_awready, the consumer's statement that it can accept a payload this cycle, equal to ‘!aw_hold && !s_axi_bvalid‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are aw_hold: the value named 'aw hold' in this block; s_axi_bvalid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 470: `s_axi_wready = !w_hold && !s_axi_bvalid;` This makes s_axi_wready, the consumer's statement that it can accept a payload this cycle, equal to ‘!w_hold && !s_axi_bvalid‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are w_hold: the value named 'w hold' in this block; s_axi_bvalid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 471: `s_axi_bresp = 2'b00;` This makes s_axi_bresp, the value named 's axi bresp' in this block, equal to '2'b00'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b00: the value named 'b00' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 472: `s_axi_arready = !s_axi_rvalid;` This makes s_axi_arready, the consumer's statement that it can accept a payload this cycle, equal to '!s_axi_rvalid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are s_axi_rvalid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 473: `s_axi_rresp = 2'b00;` This makes s_axi_rresp, the value named 's axi rresp' in this block, equal to '2'b00'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b00: the value named 'b00' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 474: `m_axis_tvalid = output_register_valid_r;` This makes m_axis_tvalid, the producer's statement that its current payload is meaningful, equal to 'output_register_valid_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_register_valid_r: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 475: `m_axis_tdata = output_register_data_r;` This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to 'output_register_data_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_register_data_r: the payload carried with the surrounding valid/ready handshake. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 476: `m_axis_tkeep = 8'hff;` This makes m_axis_tkeep, the value named 'm axis tkeep' in this block, equal to '8'hff'. It is driven by combinational or procedural logic in the current evaluation. The important operands are hff: the value named 'hff' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 477: `m_axis_tlast = output_register_last_r;` This makes m_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'output_register_last_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_register_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 478: `interrupt = interrupt_enable && done_sticky;` This makes interrupt, the hardware notification that wakes software after completion or error, equal to 'interrupt_enable && done_sticky'. It is driven by combinational or procedural logic in the current evaluation. The important operands are interrupt_enable: the hardware notification that wakes software after completion or error; done_sticky: the value named 'done sticky' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 479: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 481: `always_ff @(posedge aclk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 482: `if (!aresetn) begin` This is the reset branch for '(!aresetn'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 483: `for (int word_index = 0; word_index < 4; word_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 484: `command_register[word_index] <= 32'd0;` This makes command_register[word_index], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 485: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 486: `submitted_command <= 128'd0;` This makes submitted_command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 487: `command_pending <= 1'b0;` This makes command_pending, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 488: `interrupt_enable <= 1'b0;` This makes interrupt_enable, the hardware notification that wakes software after completion or error, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 489: `done_sticky <= 1'b0;` This makes done_sticky, the value named 'done sticky' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 490: `wrapper_error <= 1'b0;` This makes wrapper_error, the value named 'wrapper error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 491: `program_start_r <= 1'b0;` This makes program_start_r, the value named 'program start r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 492: `program_clear_r <= 1'b0;` This makes program_clear_r, the value named 'program clear r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 493: `program_output_beats_r <= 32'd0;` This makes program_output_beats_r, the value named 'program output beats r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 494: `aw_hold <= 1'b0;` This makes aw_hold, the value named 'aw hold' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 495: `awaddr_hold <= '0;` This makes awaddr_hold, the value named 'awaddr hold' in this block, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 496: `w_hold <= 1'b0;` This makes w_hold, the value named 'w hold' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 497: `wdata_hold <= 32'd0;` This makes wdata_hold, the value named 'wdata hold' in this block, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 498: `wstrb_hold <= 4'd0;` This makes wstrb_hold, the value named 'wstrb hold' in this block, equal to ‘4'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 499: `s_axi_bvalid <= 1'b0;` This makes s_axi_bvalid, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 500: `s_axi_rvalid <= 1'b0;` This makes s_axi_rvalid, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 501: `s_axi_rdata <= 32'd0;` This makes s_axi_rdata, the value named 's axi rdata' in this block, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 502: `output_fifo_count <= 2'd0;` This makes output_fifo_count, an integer count retained for control or measurable telemetry, equal to ‘2'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 503: `core_output_capture_valid <= 1'b0;` This makes core_output_capture_valid, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 504: `core_m_ready_r <= 1'b1;` This makes core_m_ready_r, the consumer's statement that it can accept a payload this cycle, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 505: `core_output_capture_data <= 64'd0;` This makes core_output_capture_data, the payload carried with the surrounding valid/ready handshake, equal to ‘64'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 506: `core_output_capture_last <= 1'b0;` This makes core_output_capture_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 507: `output_fifo_write_pointer <= 1'b0;` This makes output_fifo_write_pointer, the value named 'output fifo write pointer' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 508: `output_fifo_read_pointer <= 1'b0;` This makes output_fifo_read_pointer, the value named 'output fifo read pointer' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 509: `output_fifo_data[0] <= 64'd0;` This makes output_fifo_data[0], the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 510: `output_fifo_data[1] <= 64'd0;` This makes output_fifo_data[1], the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 511: `output_fifo_last[0] <= 1'b0;` This makes output_fifo_last[0], the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 512: `output_fifo_last[1] <= 1'b0;` This makes output_fifo_last[1], the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 513: `output_register_valid_r <= 1'b0;` This makes output_register_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 514: `output_register_data_r <= 64'd0;` This makes output_register_data_r, the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 515: `output_register_last_r <= 1'b0;` This makes output_register_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 516: `input_fifo_count <= 2'd0;` This makes input_fifo_count, an integer count retained for control or measurable telemetry, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 517: `input_fifo_write_pointer <= 1'b0;` This makes input_fifo_write_pointer, the value named 'input fifo write pointer' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 518: `input_fifo_read_pointer <= 1'b0;` This makes input_fifo_read_pointer, the value named 'input fifo read pointer' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 519: `input_fifo_data[0] <= 64'd0;` This makes input_fifo_data[0], the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 520: `input_fifo_data[1] <= 64'd0;` This makes input_fifo_data[1], the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 521: `input_fifo_last[0] <= 1'b0;` This makes input_fifo_last[0], the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 522: `input_fifo_last[1] <= 1'b0;` This makes input_fifo_last[1], the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 523: `core_input_capture_valid <= 1'b0;` This makes core_input_capture_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 524: `core_input_capture_data <= 64'd0;` This makes core_input_capture_data, the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 525: `core_input_capture_last <= 1'b0;` This makes core_input_capture_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 526: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 527: `program_start_r <= 1'b0;` This makes program_start_r, the value named 'program start r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 528: `program_clear_r <= 1'b0;` This makes program_clear_r, the value named 'program clear r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 529: `// The prefetch stage decouples payload storage from deep core-ready` Design intent: The prefetch stage decouples payload storage from deep core-ready This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 530: `// logic. At 200 MHz it accepts one 64-bit beat every two cycles.` Design intent: logic. At 200 MHz it accepts one 64-bit beat every two cycles. This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 531: `if (input_fifo_pop) begin` This condition selects the following hardware branch only when ‘input_fifo_pop‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_fifo_pop: the value named 'input fifo pop' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 532: `core_input_capture_data <= input_fifo_data[input_fifo_read_pointer];` This makes core_input_capture_d the payload carried with the surrounding valid/ready handshake, equal to ‘input_fifo_data[input_fifo_read_pointer]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_fifo_data: the payload carried with the surrounding valid/ready handshake; input_fifo_read_pointer: the value named 'input fifo read pointer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 533: `core_input_capture_last <= input_fifo_last[input_fifo_read_pointer];` This makes core_input_capture_la the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘input_fifo_last[input_fifo_read_pointer]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_fifo_last: the AXI-Stream marker for the final beat of a packet or command payload; input_fifo_read_pointer: the value named 'input fifo read pointer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 534: `core_input_capture_valid <= 1'b1;` This makes core_input_capture_valid, the producer's statement that its current payload is meaningful, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 535: `end else if (core_input_capture_valid && wrapper_input_ready) begin` This condition selects the following hardware branch only when ‘core_input_capture_valid && wrapper_input_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are core_input_capture_valid: the producer's statement that its current payload is meaningful; wrapper_input_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 536: `core_input_capture_valid <= 1'b0;` This makes core_input_capture_valid, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 537: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 538: `if (input_fifo_push) begin` This condition selects the following hardware branch only when ‘input_fifo_push‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_fifo_push: the value named 'input fifo push' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 539: `input_fifo_data[input_fifo_write_pointer] <= s_axis_tdata;` This makes input_fifo_data[input_fifo_write_ the payload carried with the surrounding valid/ready handshake, equal to 's_axis_tdata'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 540: `input_fifo_last[input_fifo_write_pointer] <= s_axis_tlast;` This makes input_fifo_last[input_fifo_write_p the AXI-Stream marker for the final beat of a packet or command payload, equal to 's_axis_tlast'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 541: `input_fifo_write_pointer <= !input_fifo_write_pointer;` This makes input_fifo_write_pointer, the value named 'input fifo write pointer' in this block, equal to '!input_fifo_write_pointer'. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_fifo_write_pointer: the value named 'input fifo write pointer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 542: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 543: `if (input_fifo_pop) begin` This condition selects the following hardware branch only when 'input_fifo_pop' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_fifo_pop: the value named 'input fifo pop' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 544: `input_fifo_read_pointer <= !input_fifo_read_pointer;` This makes input_fifo_read_pointer, the value named 'input fifo read pointer' in this block, equal to '!input_fifo_read_pointer'. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_fifo_read_pointer: the value named 'input fifo read pointer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 545: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 546: `unique case ({input_fifo_push, input_fifo_pop})` This starts a multiplexer/state decode selected by '{input_fifo_push, input_fifo_pop}'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 547: `2'b10: input_fifo_count <= input_fifo_count + 1'b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are b10: the value named 'b10' in this block; input_fifo_count: an integer count retained for control or measurable telemetry; b1: the value named 'b1' in this block.

Line 548: `2'b01: input_fifo_count <= input_fifo_count - 1'b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are b01: the value named 'b01' in this block; input_fifo_count: an integer count retained for control or measurable telemetry; b1: the value named 'b1' in this block.

Line 549: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the clocked process that updates registers only on a rising clock edge.

Line 550: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 551: `// Sampling an invalid payload is harmless because the separate` Design intent: Sampling an invalid payload is harmless because the separate This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 552: `// valid bit qualifies it. Enabling on local registered credit,` Design intent: valid bit qualifies it. Enabling on local registered credit, This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 553: `// rather than deep VALID && READY logic, keeps all 65 payload` Design intent: rather than deep VALID && READY logic, keeps all 65 payload This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 554: `// clock-enables local to this wrapper.` Design intent: clock-enables local to this wrapper. This comment anchors the surrounding logic in the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

Line 555: `if (core_m_ready_r) begin` This condition selects the following hardware branch only when ‘core_m_ready_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are core_m_ready_r: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 556: `core_output_capture_data <= wrapper_output_data;` This makes core_output_capture_data, the payload carried with the surrounding valid/ready handshake, equal to ‘wrapper_output_data‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are wrapper_output_data: the payload carried with the surrounding valid/ready handshake. Context: the clocked process that updates registers only on a rising clock edge.

Line 557: `core_output_capture_last <= wrapper_output_last;` This makes core_output_capture_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘wrapper_output_last‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are wrapper_output_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 558: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 559: `core_output_capture_valid <= next_core_output_capture_valid;` This makes core_output_capture_valid, the producer's statement that its current payload is meaningful, equal to ‘next_core_output_capture_valid‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_core_output_capture_va the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 560: `core_m_ready_r <= next_core_m_ready;` This makes core_m_ready_r, the consumer's statement that it can accept a payload this cycle, equal to ‘next_core_m_ready‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_core_m_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 561: `if (output_fifo_push) begin` This condition selects the following hardware branch only when ‘output_fifo_push‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_fifo_push: the value named 'output fifo push' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 562: `output_fifo_data[output_fifo_write_pointer]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are output_fifo_data: the payload carried with the surrounding valid/ready handshake; output_fifo_write_pointer: the value named 'output fifo write pointer' in this block.

Line 563: `<= core_output_capture_data;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are core_output_capture_data: the payload carried with the surrounding valid/ready handshake.

Line 564: `output_fifo_last[output_fifo_write_pointer]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are output_fifo_last: the AXI-Stream marker for the final beat of a packet or command payload; output_fifo_write_pointer: the value named 'output fifo write pointer' in this block.

Line 565: `<= core_output_capture_last;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are core_output_capture_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 566: `output_fifo_write_pointer <= !output_fifo_write_pointer;` This makes output_fifo_write_pointer, the value named 'output fifo write pointer' in this block, equal to '!output_fifo_write_pointer'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_fifo_write_pointer: the value named 'output fifo write pointer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 567: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 568: `if (output_fifo_pop) begin` This condition selects the following hardware branch only when 'output_fifo_pop' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_fifo_pop: the value named 'output fifo pop' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 569: `output_fifo_read_pointer <= !output_fifo_read_pointer;` This makes output_fifo_read_pointer, the value named 'output fifo read pointer' in this block, equal to '!output_fifo_read_pointer'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_fifo_read_pointer: the value named 'output fifo read pointer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 570: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 571: `output_fifo_count <= next_output_fifo_count;` This makes output_fifo_count, an integer count retained for control or measurable telemetry, equal to 'next_output_fifo_count'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_output_fifo_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge.

Line 572: `if (output_register_ready) begin` This condition selects the following hardware branch only when 'output_register_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_register_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 573: `output_register_valid_r <= output_fifo_count != 0;` This makes output_register_valid_r, the producer's statement that its current payload is meaningful, equal to 'output_fifo_count != 0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_fifo_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge.

Line 574: `if (output_fifo_count != 0) begin` This condition selects the following hardware branch only when 'output_fifo_count != 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_fifo_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge.

Line 575: `output_register_data_r` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are output_register_data_r: the payload carried with the surrounding valid/ready handshake.

Line 576: `<= output_fifo_data[output_fifo_read_pointer];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are output_fifo_data: the payload carried with the surrounding valid/ready handshake; output_fifo_read_pointer: the value named 'output fifo read pointer' in this block.

Line 577: `output_register_last_r` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are output_register_last_r: the AXI-Stream marker for the final beat of a packet or command payload.

Line 578: `<= output_fifo_last[output_fifo_read_pointer];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are output_fifo_last: the AXI-Stream marker for the final beat of a packet or command payload; output_fifo_read_pointer: the value named 'output fifo read pointer' in this block.

Line 579: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 580: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 581: `if (command_pending && !program_active && core_command_ready) begin` This condition selects the following hardware branch only when 'command_pending && !program_active && core_command_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are command_pending: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; program_active: the value named 'program active' in this block; core_command_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 582: `command_pending <= 1'b0;` This makes command_pending, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 583: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 584: `if ((!program_active && core_command_done) || program_done) begin` This condition selects the following hardware branch only when ‘(!program_active && core_command_done) || program_done‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are program_active: the value named 'program active' in this block; core_command_done: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; program_done: the value named 'program done' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 585: `done_sticky <= 1'b1;` This makes done_sticky, the value named 'done sticky' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 586: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 587: `if (input_fifo_push && s_axis_tkeep != 8'hff) begin` This condition selects the following hardware branch only when ‘input_fifo_push && s_axis_tkeep != 8'hff‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_fifo_push: the value named 'input fifo push' in this block; s_axis_tkeep: the value named 's axis tkeep' in this block; hff: the value named 'hff' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 588: `wrapper_error <= 1'b1;` This makes wrapper_error, the value named 'wrapper error' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 589: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 591: `if (s_axi_awvalid && s_axi_awready) begin` This condition selects the following hardware branch only when ‘s_axi_awvalid && s_axi_awready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axi_awvalid: the producer's statement that its current payload is meaningful; s_axi_awready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 592: `aw_hold <= 1'b1;` This makes aw_hold, the value named 'aw hold' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 593: `awaddr_hold <= s_axi_awaddr;` This makes awaddr_hold, the value named 'awaddr hold' in this block, equal to ‘s_axi_awaddr‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axi_awaddr: the value named 's axi awaddr' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 594: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 595: `if (s_axi_wvalid && s_axi_wready) begin` This condition selects the following hardware branch only when ‘s_axi_wvalid && s_axi_wready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axi_wvalid: the producer's statement that its current payload is meaningful; s_axi_wready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 596: `w_hold <= 1'b1;` This makes w_hold, the value named 'w hold' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 597: `wdata_hold <= s_axi_wdata;` This makes wdata_hold, the value named 'wdata hold' in this block, equal to 's_axi_wdata'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axi_wdata: the value named 's axi wdata' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 598: `wstrb_hold <= s_axi_wstrb;` This makes wstrb_hold, the value named 'wstrb hold' in this block, equal to 's_axi_wstrb'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axi_wstrb: the value named 's axi wstrb' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 599: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 601: `if (aw_hold && w_hold && !s_axi_bvalid) begin` This condition selects the following hardware branch only when 'aw_hold && w_hold && !s_axi_bvalid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are aw_hold: the value named 'aw hold' in this block; w_hold: the value named 'w hold' in this block; s_axi_bvalid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 602: `unique case (awaddr_hold[7:0])` This starts a multiplexer/state decode selected by 'awaddr_hold[7:0]'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 603: `ADDR_CONTROL: begin` This is the ADDR_CONTROL case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 604: `if (wstrb_hold[1]) interrupt_enable <= wdata_hold[8];` This condition selects the following hardware branch only when 'wstrb_hold[1]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are wstrb_hold: the value named 'wstrb hold' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 605: `if (wstrb_hold[0] && wdata_hold[1]) begin` This condition selects the following hardware branch only when 'wstrb_hold[0] && wdata_hold[1]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are wstrb_hold: the value named 'wstrb hold' in this block; wdata_hold: the value named 'wdata hold' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 606: `done_sticky <= 1'b0;` This makes done_sticky, the value named 'done sticky' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 607: `wrapper_error <= 1'b0;` This makes wrapper_error, the value named 'wrapper error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 608: `program_clear_r <= 1'b1;` This makes program_clear_r, the value named 'program clear r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 609: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 610: `if (wstrb_hold[0] && wdata_hold[0]) begin` This condition selects the following hardware branch only when ‘wstrb_hold[0] && wdata_hold[0]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are wstrb_hold: the value named ’wstrb hold’ in this block; wdata_hold: the value named ’wdata hold’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 611: `if (command_pending || program_active) begin` This condition selects the following hardware branch only when ‘command_pending || program_active‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are command_pending: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; program_active: the value named ’program active’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 612: `wrapper_error <= 1'b1;` This makes wrapper_error, the value named ’wrapper error’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 613: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 614: `submitted_command <= {command_register[3], command_register[2],` This statement continues through source line 615; the explanation uses the complete expression rather than only the first visual fragment. This makes submitted_command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘{command_register[3], command_register[2], command_register[1], command_register[0]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_register: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 615: `command_register[1], command_register[0]};` This is continuation line 2 of the 2-line logical statement that begins at source line 614. Its exact fragment is ‘command_register[1], command_register[0]};‘. The important operands are command_register: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Read together, the complete operation is: This makes submitted_command, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘{command_register[3], command_register[2], command_register[1], command_register[0]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_register: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 616: `command_pending <= 1'b1;` This makes command_pending, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 617: `done_sticky <= 1'b0;` This makes done_sticky, the value named ’done sticky’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 618: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 619: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 620: `if (wstrb_hold[0] && wdata_hold[2]) begin` This condition selects the following hardware branch only when ‘wstrb_hold[0] && wdata_hold[2]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are wstrb_hold: the value named 'wstrb hold' in this block; wdata_hold: the value named 'wdata hold' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 621: `if (command_pending || program_active) begin` This condition selects the following hardware branch only when ‘command_pending || program_active‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are command_pending: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; program_active: the value named 'program active' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 622: `wrapper_error <= 1'b1;` This makes wrapper_error, the value named 'wrapper error' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ADDR_CONTROL, the machine performs the named control phase..

Line 637: `ADDR_PROGRAM_OUTPUT_BEATS: program_output_beats_r` This is the ADDR_PROGRAM_OUTPUT_BEATS case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'program_output_beats_r'; context is the clocked process that updates registers only on a rising clock edge Within state ADDR_PROGRAM_OUTPUT_BEATS, the machine presents computed results under valid/ready backpressure..

Line 638: `<= apply_write_strobes(` Within the clocked process that updates registers only on a rising clock edge Within state ADDR_PROGRAM_OUTPUT_BEATS, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are apply_write_strobes: the value named 'apply write strobes' in this block.

Line 639: `program_output_beats_r, wdata_hold, wstrb_hold);` Within the clocked process that updates registers only on a rising clock edge Within state ADDR_PROGRAM_OUTPUT_BEATS, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ. The important operands are program_output_beats_r: the value named 'program output beats r' in this block; wdata_hold: the value named 'wdata hold' in this block; wstrb_hold: the value named 'wstrb hold' in this block.

Line 640: `default: wrapper_error <= 1'b1;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'wrapper_error <= 1'b1;'; context is the clocked process that updates registers only on a rising clock edge Within state ADDR_PROGRAM_OUTPUT_BEATS, the machine presents computed results under valid/ready backpressure..

Line 641: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ADDR_PROGRAM_OUTPUT_BEATS, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 642: `aw_hold <= 1'b0;` This makes aw_hold, the value named 'aw hold' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 643: `w_hold <= 1'b0;` This makes w_hold, the value named 'w hold' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 644: `s_axi_bvalid <= 1'b1;` This makes s_axi_bvalid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 645: `end else if (s_axi_bvalid && s_axi_bready) begin` This condition selects the following hardware branch only when 's_axi_bvalid && s_axi_bready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axi_bvalid: the producer's statement that its current payload is meaningful; s_axi_bready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 646: `s_axi_bvalid <= 1'b0;` This makes s_axi_bvalid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 647: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 649: `if (s_axi_arvalid && s_axi_arready) begin` This condition selects the following hardware branch only when 's_axi_arvalid && s_axi_arready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axi_arvalid: the producer's statement that its current payload is meaningful; s_axi_arready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 650: `s_axi_rdata <= register_read(s_axi_araddr[7:0]);` This makes s_axi_rdata, the value named 's axi rdata' in this block, equal to 'register_read(s_axi_araddr[7:0])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are register_read: the value named 'register read' in this block; s_axi_araddr: the value named 's axi araddr' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 651: `s_axi_rvalid <= 1'b1;` This makes s_axi_rvalid, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 652: `end else if (s_axi_rvalid && s_axi_rready) begin` This condition selects the following hardware branch only when 's_axi_rvalid && s_axi_rready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axi_rvalid: the producer's statement that its current payload is meaningful; s_axi_rready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 653: `s_axi_rvalid <= 1'b0;` This makes s_axi_rvalid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 654: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 655: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 656: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 658: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 659: `if (AXI_ADDR_BITS < 8) $fatal(1, "AXI_ADDR_BITS must be at least 8");` This condition selects the following hardware branch only when 'AXI_ADDR_BITS < 8) $fatal(1, "AXI_ADDR_BITS must be at least 8"' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are AXI_ADDR_BITS: the value named 'axi addr bits' in this block; fatal: the value named 'fatal' in this block; must: the value named 'must' in this block. Context: the module's structural declarations.

Line 660: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 661: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 663: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that provides AXI-Lite control, AXI-Stream DMA, interrupts, descriptor mode, and hardware telemetry for PYNQ.

18 rtl/neuraedge_sgd_optimizer8.sv

Role in the complete system: applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state.

18.1 Beginner architecture map

Dataflow responsibility For eight lanes, the engine reads weight, gradient, and momentum velocity, computes the fixed-point momentum update, rounds the learning-rate product symmetrically, saturates the new signed weight, stores new velocity/weight state, and streams the result.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_sgd_optimizer8 into physical nets and primitives. The source declares 12 input-port lines, 6 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_DECAY_ABSOLUTE, ST_DECAY_BIAS, ST_DECAY_MULTIPL ST_DECAY_PRODUCT, ST_DECAY_PRODUCT_RELAY, ST_DECAY_ROUND, ST_DECAY_SATURATE, ST_DECAY_SIGN, ST_IDLE, ST_MOMENTUM_ABSOLUTE, ST_MOMENTUM_BIAS, ST_MOMENTUM_MULTIP ST_MOMENTUM_PRODUCT, ST_MOMENTUM_PRODUCT_RELAY, ST_MOMENTUM_ROUND, ST_MOMENTU ST_MOMENTUM_SIGN, ST_OUTPUT and additional states. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates begin as if, else as if, endfunction as for, unique as case, endcase as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

18.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_sgd_optimizer8 #(` This opens neuraedge_sgd_optimizer8, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state.

Line 5: `parameter int LANES = 8` This statement continues through source line 25; the explanation uses the complete expression rather than only the first visual fragment. This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*16-1:0] weight_vector, input wire [LANES*24-1:0] gradient_vector, input wire [LANES*24-1:0] velocity_vector, input wire [17:0] learning_rate_q16, input wire [16:0] momentum_q16, input wire [16:0] weight_decay_q16, input wire [4:0] update_right_shift, output logic output_valid, input wire output_ready, output logic [LANES*16-1:0] updated_weight_vector, output logic [LANES*24-1:0] updated_velocity_vector, output logic config_error, output logic [31:0] update_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 6: `) (` This is continuation line 2 of the 21-line logical statement that begins at source line 5. Its exact fragment is ‘) (‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*16-1:0] weight_vector, input wire [LANES*24-1:0] gradient_vector, input wire [LANES*24-1:0] velocity_vector, input wire [17:0] learning_rate_q16, input wire [16:0] momentum_q16, input wire [16:0] weight_decay_q16, input wire [4:0] update_right_shift, output logic output_valid, input wire output_ready, output logic [LANES*16-1:0] updated_weight_vector, output logic [LANES*24-1:0] updated_velocity_vector, output logic config_error, output logic [31:0] update_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 7: `input wire clk,` This is continuation line 3 of the 21-line logical statement that begins at source line 5. Its exact fragment is ‘input wire clk,‘. The important operands are input: the value named ’input’ in this block; clk: the clock that makes all registers advance together. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*16-1:0] weight_vector, input wire [LANES*24-1:0] gradient_vector, input wire [LANES*24-1:0] velocity_vector, input wire [17:0] learning_rate_q16, input wire [16:0] momentum_q16, input wire [16:0] weight_decay_q16, input wire [4:0] update_right_shift, output logic output_valid, input wire output_ready, output logic [LANES*16-1:0] updated_weight_vector, output logic [LANES*24-1:0] updated_velocity_vector, output logic config_error, output logic [31:0] update_count) during elaboration. Its exact fragment is 'output logic [LANES*24-1:0] updated_velocity_vector,'. The important operands are output: the value named 'output' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; updated_velocity_vector: the momentum history retained by the SGD optimizer. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*16-1:0] weight_vector, input wire [LANES*24-1:0] gradient_vector, input wire [LANES*24-1:0] velocity_vector, input wire [17:0] learning_rate_q16, input wire [16:0] momentum_q16, input wire [16:0] weight_decay_q16, input wire [4:0] update_right_shift, output logic output_valid, input wire output_ready, output logic [LANES*16-1:0] updated_weight_vector, output logic [LANES*24-1:0] updated_velocity_vector, output logic config_error, output logic [31:0] update_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 23: `output logic config_error,` This is continuation line 19 of the 21-line logical statement that begins at source line 5. Its exact fragment is 'output logic config_error,'. The important operands are output: the value named 'output' in this block; config_error: the value named 'config error' in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*16-1:0] weight_vector, input wire [LANES*24-1:0] gradient_vector, input wire [LANES*24-1:0] velocity_vector, input wire [17:0] learning_rate_q16, input wire [16:0] momentum_q16, input wire [16:0] weight_decay_q16, input wire [4:0] update_right_shift, output logic output_valid, input wire output_ready, output logic [LANES*16-1:0] updated_weight_vector, output logic [LANES*24-1:0] updated_velocity_vector, output logic config_error, output logic [31:0] update_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 24: `output logic [31:0] update_count` This is continuation line 20 of the 21-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] update_count'. The important operands are output:

the value named 'output' in this block; update_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*16-1:0] weight_vector, input wire [LANES*24-1:0] gradient_vector, input wire [LANES*24-1:0] velocity_vector, input wire [17:0] learning_rate_q16, input wire [16:0] momentum_q16, input wire [16:0] weight_decay_q16, input wire [4:0] update_right_shift, output logic output_valid, input wire output_ready, output logic [LANES*16-1:0] updated_weight_vector, output logic [LANES*24-1:0] updated_velocity_vector, output logic config_error, output logic [31:0] update_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 25: `);` This is continuation line 21 of the 21-line logical statement that begins at source line 5. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*16-1:0] weight_vector, input wire [LANES*24-1:0] gradient_vector, input wire [LANES*24-1:0] velocity_vector, input wire [17:0] learning_rate_q16, input wire [16:0] momentum_q16, input wire [16:0] weight_decay_q16, input wire [4:0] update_right_shift, output logic output_valid, input wire output_ready, output logic [LANES*16-1:0] updated_weight_vector, output logic [LANES*24-1:0] updated_velocity_vector, output logic config_error, output logic [31:0] update_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 26: `typedef enum logic [4:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 27: `ST_IDLE = 5'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 28: `ST_MOMENTUM_MULTIPLY = 5'd1,` This assigns a fixed binary encoding to state ST_MOMENTUM_MULTIPLY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 29: `ST_MOMENTUM_ABSOLUTE = 5'd2,` This assigns a fixed binary encoding to state ST_MOMENTUM_ABSOLUTE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 30: `ST_MOMENTUM_ROUND = 5'd3,` This assigns a fixed binary encoding to state ST_MOMENTUM_ROUND, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 31: `ST_MOMENTUM_SIGN = 5'd4,` This assigns a fixed binary encoding to state ST_MOMENTUM_SIGN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 32: `ST_DECAY_MULTIPLY = 5'd5,` This assigns a fixed binary encoding to state ST_DECAY_MULTIPLY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 33: `ST_DECAY_ABSOLUTE = 5'd6,` This assigns a fixed binary encoding to state ST_DECAY_ABSOLUTE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 34: `ST_DECAY_ROUND = 5'd7,` This assigns a fixed binary encoding to state ST_DECAY_ROUND, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 35: `ST_DECAY_SIGN = 5'd8,` This assigns a fixed binary encoding to state ST_DECAY_SIGN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 36: `ST_VELOCITY = 5'd9,` This assigns a fixed binary encoding to state ST_VELOCITY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 37: `ST_UPDATE_MULTIPLY = 5'd10,` This assigns a fixed binary encoding to state ST_UPDATE_MULTIPLY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 38: `ST_UPDATE_ABSOLUTE = 5'd11,` This assigns a fixed binary encoding to state ST_UPDATE_ABSOLUTE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 39: `ST_UPDATE_ROUND = 5'd12,` This assigns a fixed binary encoding to state ST_UPDATE_ROUND, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 40: `ST_UPDATE_SIGN = 5'd13,` This assigns a fixed binary encoding to state ST_UPDATE_SIGN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 41: `ST_UPDATE_SUBTRACT = 5'd14,` This assigns a fixed binary encoding to state ST_UPDATE_SUBTRACT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 42: `ST_OUTPUT = 5'd15,` This assigns a fixed binary encoding to state ST_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 43: `ST_MOMENTUM_PRODUCT = 5'd16,` This assigns a fixed binary encoding to state ST_MOMENTUM_PRODUCT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 44: `ST_DECAY_PRODUCT = 5'd17,` This assigns a fixed binary encoding to state ST_DECAY_PRODUCT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 45: `ST_UPDATE_PRODUCT = 5'd18,` This assigns a fixed binary encoding to state ST_UPDATE_PRODUCT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 46: `ST_VELOCITY_SUM = 5'd19,` This assigns a fixed binary encoding to state ST_VELOCITY_SUM, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 47: `ST_VELOCITY_SATURATE = 5'd20,` This assigns a fixed binary encoding to state ST_VELOCITY_SATURATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 48: `ST_MOMENTUM_SATURATE = 5'd21,` This assigns a fixed binary encoding to state ST_MOMENTUM_SATURATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 49: `ST_DECAY_SATURATE = 5'd22,` This assigns a fixed binary encoding to state ST_DECAY_SATURATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 50: `ST_UPDATE_SATURATE = 5'd23,` This assigns a fixed binary encoding to state ST_UPDATE_SATURATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 51: `ST_MOMENTUM_BIAS = 5'd24,` This assigns a fixed binary encoding to state ST_MOMENTUM_BIAS, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 52: `ST_DECAY_BIAS = 5'd25,` This assigns a fixed binary encoding to state ST_DECAY_BIAS, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 53: `ST_UPDATE_BIAS = 5'd26,` This assigns a fixed binary encoding to state ST_UPDATE_BIAS, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 54: `ST_UPDATE_DIRECTION = 5'd27,` This assigns a fixed binary encoding to state ST_UPDATE_DIRECTION, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 55: `ST_UPDATE_DIRECTION_SATURATE = 5'd28,` This assigns a fixed binary encoding to state ST_UPDATE_DIRECTION_ which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 56: `ST_MOMENTUM_PRODUCT_RELAY = 5'd29,` This assigns a fixed binary encoding to state ST_MOMENTUM_PRODUCT_ which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 57: `ST_DECAY_PRODUCT_RELAY = 5'd30,` This assigns a fixed binary encoding to state ST_DECAY_PRODUCT_RELAY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 58: `ST_UPDATE_PRODUCT_RELAY = 5'd31` This statement continues through source line 59; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_UPDATE_PRODUCT_RELAY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 59: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 58. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_UPDATE_PRODUCT_RELAY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 61: `state_t state;` Within the module's structural declarations, this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are state_t: the finite-state-machine phase retained in flip-flops; state: the finite-state-machine phase retained in flip-flops.

Line 62: `logic signed [15:0] weight_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 63: `logic signed [23:0] gradient_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gradient_r is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 64: `logic signed [23:0] velocity_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, velocity_r is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 65: `logic signed [23:0] next_velocity_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, next_velocity_r is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 66: `logic signed [23:0] momentum_term_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, momentum_term_r is the value named 'momentum term r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 67: `logic signed [23:0] decay_term_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, decay_term_r is the value named 'decay term r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 68: `logic signed [24:0] two_term_sum_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, two_term_sum_r is the value named 'two term sum r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 69: `logic signed [25:0] velocity_sum_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, velocity_sum_r is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 70: `logic signed [41:0] product_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_r is the value named 'product r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 71: `logic product_negative_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_negative_r is the value named 'product negative r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 72: `logic [41:0] product_magnitude_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_magnitude_r is the value named 'product magnitude r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 73: `logic [41:0] rounded_magnitude_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rounded_magnitude_r is the value named 'rounded magnitude r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 74: `logic signed [41:0] signed_rounded_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, signed_rounded_r is the value named 'signed rounded r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 75: `logic signed [41:0] update_value_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, update_value_r is the value named 'update value r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 76: `logic signed [41:0] weight_difference_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_difference_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 77: `logic [17:0] learning_rate_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, learning_rate_r is the fixed-point multiplier controlling update magnitude. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 78: `logic [16:0] momentum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, momentum_r is the value named 'momentum r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 79: `logic [16:0] weight_decay_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_decay_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 80: `logic [4:0] update_right_shift_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, update_right_shift_r is the value named 'update right shift r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 81: `logic [4:0] round_shift_counter_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, round_shift_counter_r is a hardware telemetry register that accumulates measured events. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 82: `logic [41:0] update_rounding_bias_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, update_rounding_bias_r is an additive learned offset applied after accumulation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 84: `logic signed [23:0] multiplier_left [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_left is the value named 'multiplier left' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 85: `logic signed [17:0] multiplier_right [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_right is the value named 'multiplier right' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 86: `logic signed [23:0] multiplier_operand_left_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_operand_left_r is the value named 'multiplier operand left r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 87: `logic signed [17:0] multiplier_operand_right_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_operand_right_r is the value named 'multiplier operand right r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 88: `(* use_dsp = "yes" *) wire signed [41:0] multiplier_product [0:LANES-1];` Within the module's structural declarations, this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; multiplier_product: the value named 'multiplier product' in this block.

Line 89: `(* use_dsp = "yes" *) logic signed [41:0]` Within the module's structural declarations, this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block.

Line 90: `multiplier_product_pipeline_r [0:LANES-1];` Within the module's structural declarations, this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are multiplier_product_pipeline_r: the value named 'multiplier product pipeline r' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath.

Line 92: `function automatic logic signed [23:0] saturate_s24(input logic signed [41:0] value);` Within the combinational helper saturate s24, this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; saturate_s24: the value named 'saturate s24' in this block.

Line 93: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s24; it has no arithmetic value of its own.

Line 94: `if (value > 42'sd8388607) saturate_s24 = 24'sh7fffff;` This condition selects the following hardware branch only when 'value > 42'sd8388607' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; sd8388607: the value named 'sd8388607' in this block. Context: the combinational helper saturate s24.

Line 95: `else if (value < -42'sd8388608) saturate_s24 = 24'sh800000;` This condition selects the following hardware branch only when 'value < -42'sd8388608' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; sd8388608: the value named 'sd8388608' in this block. Context: the combinational helper saturate s24.

Line 96: `else saturate_s24 = value[23:0];` Within the combinational helper saturate s24, this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are saturate_s24: the value named 'saturate s24' in this block; value: the value named 'value' in this block.

Line 97: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s24; it has no arithmetic value of its own.

Line 98: `endfunction` Within the combinational helper saturate s24, this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are endfunction: the value named 'endfunction' in this block.

Line 100: `function automatic logic signed [15:0] saturate_s16(input logic signed [41:0] value);` Within the combinational helper saturate s16, this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; saturate_s16: the value named 'saturate s16' in this block.

Line 101: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s16; it has no arithmetic value of its own.

Line 102: `if (value > 42'sd32767) saturate_s16 = 16'sh7fff;` This condition selects the following hardware branch only when 'value > 42'sd32767' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; sd32767: the value named 'sd32767' in this block. Context: the combinational helper saturate s16.

Line 103: `else if (value < -42'sd32768) saturate_s16 = 16'sh8000;` This condition selects the following hardware branch only when 'value < -42'sd32768' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block; sd32768: the value named 'sd32768' in this block. Context: the combinational helper saturate s16.

Line 104: `else saturate_s16 = value[15:0];` Within the combinational helper saturate s16, this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are saturate_s16: the value named 'saturate s16' in this block; value: the value named 'value' in this block.

Line 105: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s16; it has no arithmetic value of its own.

Line 106: `endfunction` Within the combinational helper saturate s16, this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are endfunction: the value named 'endfunction' in this block.

Line 108: `for (genvar lane = 0; lane < LANES; lane++) begin : g_optimizer_lane` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 109: `assign multiplier_product[lane] =` This statement continues through source line 110; the explanation uses the complete expression rather than only the first visual fragment. This makes multiplier_product[lane], the value named 'multiplier product' in this block, equal to 'multiplier_operand_left_r[lane] * multiplier_operand_right_r[lane]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are multiplier_operand_left_r: the value named 'multiplier operand left r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; multiplier_operand_right_r: the value named 'multiplier operand right r' in this block. Context: the module's structural declarations.

Line 110: `multiplier_operand_left_r[lane] * multiplier_operand_right_r[lane];` This is continuation line 2 of the 2-line logical statement that begins at source line 109. Its exact fragment is 'multiplier_operand_left_r[lane] * multiplier_operand_right_r[lane];'. The important operands are multiplier_operand_left_r: the value named 'multiplier operand left r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; multiplier_operand_right_r: the value named 'multiplier operand right r' in this block. Read together, the complete operation is: This makes multiplier_product[lane], the value named 'multiplier product' in this block, equal to 'multiplier_operand_left_r[lane] * multiplier_operand_right_r[lane]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are multiplier_operand_left_r: the value named 'multiplier operand left r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; multiplier_operand_right_r: the value named 'multiplier operand right r' in this block. Context: the module's structural declarations.

Line 111: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 113: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 114: `input_ready = state == ST_IDLE;` This makes input_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_IDLE'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 115: `output_valid = state == ST_OUTPUT;` This makes output_valid, the producer's statement that its current payload is meaningful, equal to 'state == ST_OUTPUT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_OUTPUT: the value named 'st output' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 116: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 117: `multiplier_left[lane] = 24'sd0;` This makes multiplier_left[lane], the value named 'multiplier left' in this block, equal to '24'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 118: `multiplier_right[lane] = 18'sd0;` This makes multiplier_right[lane], the value named 'multiplier right' in this block, equal to '18'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 119: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 120: `ST_MOMENTUM_MULTIPLY: begin` This is the ST_MOMENTUM_MULTIPLY case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase..

Line 121: `multiplier_left[lane] = velocity_r[lane];` This makes multiplier_left[lane], the value named 'multiplier left' in this block, equal to 'velocity_r[lane]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are velocity_r: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase..

Line 122: `multiplier_right[lane] = $signed({1'b0, momentum_r});` This makes multiplier_right[lane], the value named 'multiplier right' in this block, equal to '$signed({1'b0, momentum_r})'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block; momentum_r: the value named 'momentum r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase..

Line 123: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 124: `ST_DECAY_MULTIPLY: begin` This is the ST_DECAY_MULTIPLY case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase..

Line 125: `multiplier_left[lane] = {{8{weight_r[lane][15]}}, weight_r[lane]};` This makes multiplier_left[lane], the value named 'multiplier left' in this block, equal to '{{8{weight_r[lane][15]}}, weight_r[lane]}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are weight_r: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase..

Line 126: `multiplier_right[lane] = $signed({1'b0, weight_decay_r});` This makes multiplier_right[lane], the value named 'multiplier right' in this block, equal to '$signed({1'b0, weight_decay_r})'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block; weight_decay_r: a learned coefficient multiplied by an activation. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase..

Line 127: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 128: `ST_UPDATE_MULTIPLY: begin` This is the ST_UPDATE_MULTIPLY case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 129: `multiplier_left[lane] = momentum_term_r[lane];` This makes multiplier_left[lane], the value named 'multiplier left' in this block, equal to 'momentum_term_r[lane]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are momentum_term_r: the value named 'momentum term r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 130: `multiplier_right[lane] = $signed(learning_rate_r);` This makes multiplier_right[lane], the value named 'multiplier right' in this block, equal to '$signed(learning_rate_r)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are learning_rate_r: the fixed-point multiplier controlling update magnitude. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 131: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 132: `default: begin` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 133: `multiplier_left[lane] = 24'sd0;` This makes multiplier_left[lane], the value named 'multiplier left' in this block, equal to '24'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 134: `multiplier_right[lane] = 18'sd0;` This makes multiplier_right[lane], the value named 'multiplier right' in this block, equal to '18'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 135: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 136: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 137: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 138: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 140: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 141: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 142: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 143: `updated_weight_vector <= '0;` This makes updated_weight_vector, a learned coefficient multiplied by an activation, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 144: `updated_velocity_vector <= '0;` This makes updated_velocity_vector, the momentum history retained by the SGD optimizer, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 145: `learning_rate_r <= 18'd0;` This makes learning_rate_r, the fixed-point multiplier controlling update magnitude, equal to '18'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 146: `momentum_r <= 17'd0;` This makes momentum_r, the value named 'momentum r' in this block, equal to '17'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 147: `weight_decay_r <= 17'd0;` This makes weight_decay_r, a learned coefficient multiplied by an activation, equal to '17'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 148: `update_right_shift_r <= 5'd16;` This makes update_right_shift_r, the value named 'update right shift r' in this block, equal to '5'd16'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d16: the value named 'd16' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 149: `round_shift_counter_r <= 5'd0;` This makes round_shift_counter_r, a hardware telemetry register that accumulates measured events, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 150: `update_rounding_bias_r <= 42'd32768;` This makes update_rounding_bias_r, an additive learned offset applied after accumulation, equal to '42'd32768'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d32768: the value named 'd32768' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 151: `config_error <= 1'b0;` This makes config_error, the value named 'config error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 152: `update_count <= 32'd0;` This makes update_count, an integer count retained for control or measurable telemetry, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 153: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 154: `weight_r[lane] <= 16'sd0;` This makes weight_r[lane], a learned coefficient multiplied by an activation, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 155: `gradient_r[lane] <= 24'sd0;` This makes gradient_r[lane], the signed loss derivative used to update a learned parameter, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 156: `velocity_r[lane] <= 24'sd0;` This makes velocity_r[lane], the momentum history retained by the SGD optimizer, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 157: `next_velocity_r[lane] <= 24'sd0;` This makes next_velocity_r[lane], the momentum history retained by the SGD optimizer, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 158: `momentum_term_r[lane] <= 24'sd0;` This makes momentum_term_r[lane], the value named 'momentum term r' in this block, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 159: `decay_term_r[lane] <= 24'sd0;` This makes decay_term_r[lane], the value named 'decay term r' in this block, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 160: `two_term_sum_r[lane] <= 25'sd0;` This makes two_term_sum_r[lane], the value named 'two term sum r' in this block, equal to '25'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 161: `velocity_sum_r[lane] <= 26'sd0;` This makes velocity_sum_r[lane], the momentum history retained by the SGD optimizer, equal to '26'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 162: `product_r[lane] <= 42'sd0;` This makes product_r[lane], the value named 'product r' in this block, equal to '42'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 163: `product_negative_r[lane] <= 1'b0;` This makes product_negative_r[lane], the value named 'product negative r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 164: `product_magnitude_r[lane] <= 42'd0;` This makes product_magnitude_r[lane], the value named 'product magnitude r' in this block, equal to '42'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 165: `rounded_magnitude_r[lane] <= 42'd0;` This makes rounded_magnitude_r[lane], the value named 'rounded magnitude r' in this block, equal to '42'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 166: `signed_rounded_r[lane] <= 42'sd0;` This makes signed_rounded_r[lane], the value named 'signed rounded r' in this block, equal to '42'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 167: `update_value_r[lane] <= 42'sd0;` This makes update_value_r[lane], the value named 'update value r' in this block, equal to '42'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 168: `weight_difference_r[lane] <= 42'sd0;` This makes weight_difference_r[lane], a learned coefficient multiplied by an activation, equal to '42'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 169: `multiplier_operand_left_r[lane] <= 24'sd0;` This makes multiplier_operand_left_r[lane], the value named 'multiplier operand left r' in this block, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 170: `multiplier_operand_right_r[lane] <= 18'sd0;` This makes multiplier_operand_right_r[lane], the value named 'multiplier operand right r' in this block, equal to '18'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 171: `multiplier_product_pipeline_r[lane] <= 42'sd0;` This makes multiplier_product_pipeline_r[lane], the value named 'multiplier product pipeline r' in this block, equal to '42'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 172: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 173: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 174: `unique case (state)` This starts a multiplexer/state decode selected by ‘state‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 175: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 176: `if (input_valid) begin` This condition selects the following hardware branch only when ‘input_valid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_valid: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 177: `config_error <= learning_rate_q16 > 18'd131071` This statement continues through source line 179; the explanation uses the complete expression rather than only the first visual fragment. This makes config_error, the value named ’config error’ in this block, equal to ‘learning_rate_q16 > 18’d131071 || momentum_q16 > 17’d65536 || weight_decay_q16 > 17’d65536‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude; d131071: the value named ’d131071’ in this block; momentum_q16: the value named ’momentum q16’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 178: `|| momentum_q16 > 17'd65536` This is continuation line 2 of the 3-line logical statement that begins at source line 177. Its exact fragment is ‘|| momentum_q16 > 17’d65536‘. The important operands are momentum_q16: the value named ’momentum q16’ in this block; d65536: the value named ’d65536’ in this block. Read together, the complete operation is: This makes config_error, the value named ’config error’ in this block, equal to ‘learning_rate_q16 > 18’d131071 || momentum_q16 > 17’d65536 || weight_decay_q16 > 17’d65536‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude; d131071: the value named ’d131071’ in this block; momentum_q16: the value named ’momentum q16’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 179: `|| weight_decay_q16 > 17'd65536;` This is continuation line 3 of the 3-line logical statement that begins at source line 177. Its exact fragment is ‘|| weight_decay_q16 > 17’d65536;‘. The important operands are weight_decay_q16: a learned coefficient multiplied by an activation; d65536: the value named ’d65536’ in this block. Read together, the complete operation is: This makes config_error, the value named ’config error’ in this block, equal to ‘learning_rate_q16 > 18’d131071 || momentum_q16 > 17’d65536 || weight_decay_q16 > 17’d65536‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude; d131071: the value named ’d131071’ in this block; momentum_q16: the value named ’momentum q16’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 180: `learning_rate_r <= learning_rate_q16;` This makes learning_rate_r, the fixed-point multiplier controlling update magnitude, equal to ‘learning_rate_q16‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are learning_rate_q16: the fixed-point multiplier controlling update magnitude. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 181: `momentum_r <= momentum_q16;` This makes momentum_r, the value named 'momentum r' in this block, equal to 'momentum_q16'. It updates after the active clock edge together with other nonblocking assignments. The important operands are momentum_q16: the value named 'momentum q16' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 182: `weight_decay_r <= weight_decay_q16;` This makes weight_decay_r, a learned coefficient multiplied by an activation, equal to 'weight_decay_q16'. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_decay_q16: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 183: `update_right_shift_r <= update_right_shift;` This makes update_right_shift_r, the value named 'update right shift r' in this block, equal to 'update_right_shift'. It updates after the active clock edge together with other nonblocking assignments. The important operands are update_right_shift: the value named 'update right shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 184: `update_rounding_bias_r <= update_right_shift == 0` This statement continues through source line 185; the explanation uses the complete expression rather than only the first visual fragment. This makes update_rounding_bias_r, an additive learned offset applied after accumulation, equal to 'update_right_shift == 0 ? 42'd0 : (42'd1 << (update_right_shift - 1'b1))'. It updates after the active clock edge together with other nonblocking assignments. The important operands are update_right_shift: the value named 'update right shift' in this block; d0: the value named 'd0' in this block; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 185: `? 42'd0 : (42'd1 << (update_right_shift - 1'b1));` This is continuation line 2 of the 2-line logical statement that begins at source line 184. Its exact fragment is '? 42'd0 : (42'd1 << (update_right_shift - 1'b1));'. The important operands are d0: the value named 'd0' in this block; d1: the value named 'd1' in this block; update_right_shift: the value named 'update right shift' in this block. Read together, the complete operation is: This makes update_rounding_bias_r, an additive learned offset applied after accumulation, equal to 'update_right_shift == 0 ? 42'd0 : (42'd1 << (update_right_shift - 1'b1))'. It updates after the active clock edge together with other nonblocking assignments. The important operands are update_right_shift: the value named 'update right shift' in this block; d0: the value named 'd0' in this block; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 186: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 187: `weight_r[lane] <= $signed(weight_vector[lane*16 +: 16]);` This makes weight_r[lane], a learned coefficient multiplied by an activation, equal to '$signed(weight_vector[lane*16 +: 16])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_vector: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 188: `gradient_r[lane] <= $signed(gradient_vector[lane*24 +: 24]);` This makes gradient_r[lane], the signed loss derivative used to update a learned parameter, equal to '$signed(gradient_vector[lane*24 +: 24])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are gradient_vector: the signed loss derivative used to update a learned parameter; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 189: `velocity_r[lane] <= $signed(velocity_vector[lane*24 +: 24]);` This makes velocity_r[lane], the momentum history retained by the SGD optimizer, equal to '$signed(velocity_vector[lane*24 +: 24])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are velocity_vector: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 190: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 191: `state <= ST_MOMENTUM_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MOMENTUM_MULTIPLY'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MOMENTUM_MULTIPLY: the value named 'st momentum multiply' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 192: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 193: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 195: `ST_MOMENTUM_MULTIPLY: begin` This is the ST_MOMENTUM_MULTIPLY case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase..

Line 196: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase..

Line 197: `multiplier_operand_left_r[lane] <= multiplier_left[lane];` This makes multiplier_operand_left_r[lane], the value named 'multiplier operand left r' in this block, equal to 'multiplier_left[lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_left: the value named 'multiplier left' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase..

Line 198: `multiplier_operand_right_r[lane] <= multiplier_right[lane];` This makes multiplier_operand_right_r[lane], the value named 'multiplier operand right r' in this block, equal to 'multiplier_right[lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_right: the value named 'multiplier right' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase..

Line 199: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 200: `state <= ST_MOMENTUM_PRODUCT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MOMENTUM_PRODUCT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MOMENTUM_PRODUCT: the value named 'st momentum product' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase..

Line 201: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 203: `ST_MOMENTUM_PRODUCT: begin` This is the ST_MOMENTUM_PRODUCT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT, the machine performs the named control phase..

Line 204: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT, the machine performs the named control phase..

Line 205: `multiplier_product_pipeline_r[lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are multiplier_product_pipeline_r: the value named 'multiplier product pipeline r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 206: `<= multiplier_product[lane];` Within the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are multiplier_product: the value named 'multiplier product' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 207: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 208: `state <= ST_MOMENTUM_PRODUCT_RELAY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MOMENTUM_PRODUCT_RELAY'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MOMENTUM_PRODUCT_RELAY: the value named 'st momentum product relay' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT, the machine performs the named control phase..

Line 209: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 211: `ST_MOMENTUM_PRODUCT_RELAY: begin` This is the ST_MOMENTUM_PRODUCT_RELAY case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT_RELAY, the machine performs the named control phase..

Line 212: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT_RELAY, the machine performs the named control phase..

Line 213: `product_r[lane] <= multiplier_product_pipeline_r[lane];` This makes product_r[lane], the value named 'product r' in this block, equal to 'multiplier_product_pipeline_r[lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_product_pipeline_r: the value named 'multiplier product pipeline r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT_R the machine performs the named control phase..

Line 214: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT_RELAY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 215: `state <= ST_MOMENTUM_ABSOLUTE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MOMENTUM_ABSOLUTE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MOMENTUM_ABSOLUTE: the value named 'st momentum absolute' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT_RELAY, the machine performs the named control phase..

Line 216: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_PRODUCT_RELAY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 218: `ST_MOMENTUM_ABSOLUTE: begin` This is the ST_MOMENTUM_ABSOLUTE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ABSOLUTE, the machine performs the named control phase..

Line 219: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ABSOLUTE, the machine performs the named control phase..

Line 220: `product_negative_r[lane] <= product_r[lane][41];` This makes product_negative_r[lane], the value named 'product negative r' in this block, equal to 'product_r[lane][41]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ABSOLUTE, the machine performs the named control phase..

Line 221: `product_magnitude_r[lane] <= product_r[lane][41]` This statement continues through source line 222; the explanation uses the complete expression rather than only the first visual fragment. This makes product_magnitude_r[lane], the value named 'product magnitude r' in this block, equal to 'product_r[lane][41] ? -product_r[lane] : product_r[lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ABSOLUTE, the machine performs the named control phase..

Line 222: `? -product_r[lane] : product_r[lane];` This is continuation line 2 of the 2-line logical statement that begins at source line 221. Its exact fragment is '? -product_r[lane] : product_r[lane];'. The important operands are product_r: the value named 'product r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes product_magnitude_r[lane], the value named 'product magnitude r' in this block, equal to 'product_r[lane][41] ? -product_r[lane] : product_r[lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ABSOLUTE, the machine performs the named control phase..

Line 223: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ABSOLUTE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 224: `state <= ST_MOMENTUM_BIAS;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MOMENTUM_BIAS'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MOMENTUM_BIAS: an additive learned offset applied after accumulation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ABSOLUTE, the machine performs the named control phase..

Line 225: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ABSOLUTE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 227: `ST_MOMENTUM_BIAS: begin` This is the ST_MOMENTUM_BIAS case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_BIAS, the machine performs the named control phase..

Line 228: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_BIAS, the machine performs the named control phase..

Line 229: `rounded_magnitude_r[lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_BIAS, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are rounded_magnitude_r: the value named 'rounded magnitude r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 230: `<= product_magnitude_r[lane] + 42'd32768;` Within the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_BIAS, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are product_magnitude_r: the value named 'product magnitude r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; d32768: the value named 'd32768' in this block.

Line 231: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_BIAS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 232: `state <= ST_MOMENTUM_ROUND;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MOMENTUM_ROUND'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MOMENTUM_ROUND: the value named 'st momentum round' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_BIAS, the machine performs the named control phase..

Line 233: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_BIAS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 235: `ST_MOMENTUM_ROUND: begin` This is the ST_MOMENTUM_ROUND case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ROUND, the machine performs the named control phase..

Line 236: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ROUND, the machine performs the named control phase..

Line 237: `rounded_magnitude_r[lane] <= rounded_magnitude_r[lane] >> 16;` This makes rounded_magnitude_r[lane], the value named 'rounded magnitude r' in this block, equal to 'rounded_magnitude_r[lane] >> 16'. It updates after the active clock edge together with other nonblocking assignments. The important operands are rounded_magnitude_r: the value named 'rounded magnitude r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ROUND, the machine performs the named control phase..

Line 238: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ROUND, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 239: `state <= ST_MOMENTUM_SIGN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MOMENTUM_SIGN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MOMENTUM_SIGN: the value named 'st momentum sign' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ROUND, the machine performs the named control phase..

Line 240: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_ROUND, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 242: `ST_MOMENTUM_SIGN: begin` This is the ST_MOMENTUM_SIGN case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SIGN, the machine performs the named control phase..

Line 243: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SIGN, the machine performs the named control phase..

Line 244: `signed_rounded_r[lane] <= product_negative_r[lane]` This statement continues through source line 246; the explanation uses the complete expression rather than only the first visual fragment. This makes signed_rounded_r[lane], the value named 'signed rounded r' in this block, equal to 'product_negative_r[lane] ? -$signed(rounded_magnitude_r[lane]) : $signed(rounded_magnitude_r[lane])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_negative_r: the value named 'product negative r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; rounded_magnitude_r: the value named 'rounded magnitude r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SIGN, the machine performs the named control phase..

Line 245: `? -$signed(rounded_magnitude_r[lane])` This is continuation line 2 of the 3-line logical statement that begins at source line 244. Its exact fragment is '? -$signed(rounded_magnitude_r[lane])'. The important operands are rounded_magnitude_r: the value named 'rounded magnitude r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes signed_rounded_r[lane], the value named 'signed rounded r' in this block, equal to 'product_negative_r[lane] ? -$signed(rounded_magnitude_r[lane]) : $signed(rounded_magnitude_r[lane])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_negative_r: the value named 'product negative r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; rounded_magnitude_r: the value named 'rounded magnitude r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SIGN, the machine performs the named control phase..

Line 246: `: $signed(rounded_magnitude_r[lane]);` This is continuation line 3 of the 3-line logical statement that begins at source line 244. Its exact fragment is ': $signed(rounded_magnitude_r[lane]);'. The important operands are rounded_magnitude_r: the value named 'rounded magnitude r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes signed_rounded_r[lane], the value named 'signed rounded r' in this block, equal to 'product_negative_r[lane] ? -$signed(rounded_magnitude_r[lane]) : $signed(rounded_magnitude_r[lane])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_negative_r: the value named 'product negative r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; rounded_magnitude_r: the value named 'rounded magnitude r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SIGN, the machine performs the named control phase..

Line 247: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SIGN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 248: `state <= ST_MOMENTUM_SATURATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MOMENTUM_SATURATE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MOMENTUM_SATURATE: the value named 'st momentum saturate' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SIGN, the machine performs the named control phase..

Line 249: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SIGN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 251: `ST_MOMENTUM_SATURATE: begin` This is the ST_MOMENTUM_SATURATE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SATURATE, the machine performs the named control phase..

Line 252: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SATURATE, the machine performs the named control phase..

Line 253: `momentum_term_r[lane] <= saturate_s24(signed_rounded_r[lane]);` This makes momentum_term_r[lane], the value named 'momentum term r' in this block, equal to 'saturate_s24(signed_rounded_r[lane])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturate_s24: the value named 'saturate s24' in this block; signed_rounded_r: the value named 'signed rounded r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SATURATE, the machine performs the named control phase..

Line 254: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 255: `state <= ST_DECAY_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_DECAY_MULTIPLY'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DECAY_MULTIPLY: the value named 'st decay multiply' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SATURATE, the machine performs the named control phase..

Line 256: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MOMENTUM_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 258: `ST_DECAY_MULTIPLY: begin` This is the ST_DECAY_MULTIPLY case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase..

Line 259: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase..

Line 260: `multiplier_operand_left_r[lane] <= multiplier_left[lane];` This makes multiplier_operand_left_r[lane], the value named 'multiplier operand left r' in this block, equal to ‘multiplier_left[lane]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_left: the value named 'multiplier left' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase..

Line 261: `multiplier_operand_right_r[lane] <= multiplier_right[lane];` This makes multiplier_operand_right_r[lane], the value named 'multiplier operand right r' in this block, equal to ‘multiplier_right[lane]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_right: the value named 'multiplier right' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase..

Line 262: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 263: `state <= ST_DECAY_PRODUCT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_DECAY_PRODUCT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DECAY_PRODUCT: the value named 'st decay product' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase..

Line 264: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 266: `ST_DECAY_PRODUCT: begin` This is the ST_DECAY_PRODUCT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT, the machine performs the named control phase..

Line 267: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT, the machine performs the named control phase..

Line 268: `multiplier_product_pipeline_r[lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are multiplier_product_pipeline_r: the value named 'multiplier product pipeline r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 269: `<= multiplier_product[lane];` Within the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are multiplier_product: the value named 'multiplier product' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 270: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 271: `state <= ST_DECAY_PRODUCT_RELAY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_DECAY_PRODUCT_RELAY'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DECAY_PRODUCT_RELAY: the value named 'st decay product relay' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT, the machine performs the named control phase..

Line 272: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 274: `ST_DECAY_PRODUCT_RELAY: begin` This is the ST_DECAY_PRODUCT_RELAY case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT_RELAY, the machine performs the named control phase..

Line 275: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT_RELAY, the machine performs the named control phase..

Line 276: `product_r[lane] <= multiplier_product_pipeline_r[lane];` This makes product_r[lane], the value named 'product r' in this block, equal to 'multiplier_product_pipeline_r[lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_product_pipeline_r: the value named 'multiplier product pipeline r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT_RELAY, the machine performs the named control phase..

Line 277: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT_RELAY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 278: `state <= ST_DECAY_ABSOLUTE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_DECAY_ABSOLUTE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DECAY_ABSOLUTE: the value named 'st decay absolute' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT_RELAY, the machine performs the named control phase..

Line 279: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_PRODUCT_RELAY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 281: `ST_DECAY_ABSOLUTE: begin` This is the ST_DECAY_ABSOLUTE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ABSOLUTE, the machine performs the named control phase..

Line 282: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ABSOLUTE, the machine performs the named control phase..

Line 283: `product_negative_r[lane] <= product_r[lane][41];` This makes product_negative_r[lane], the value named 'product negative r' in this block, equal to 'product_r[lane][41]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ABSOLUTE, the machine performs the named control phase..

Line 284: `product_magnitude_r[lane] <= product_r[lane][41]` This statement continues through source line 285; the explanation uses the complete expression rather than only the first visual fragment. This makes product_magnitude_r[lane], the value named 'product magnitude r' in this block, equal to 'product_r[lane][41] ? -product_r[lane] : product_r[lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ABSOLUTE, the machine performs the named control phase..

Line 285: `? -product_r[lane] : product_r[lane];` This is continuation line 2 of the 2-line logical statement that begins at source line 284. Its exact fragment is '? -product_r[lane] : product_r[lane];'. The important operands are product_r: the value named 'product r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes product_magnitude_r[lane], the value named 'product magnitude r' in this block, equal to 'product_r[lane][41] ? -product_r[lane] : product_r[lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ABSOLUTE, the machine performs the named control phase..

Line 286: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ABSOLUTE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 287: `state <= ST_DECAY_BIAS;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_DECAY_BIAS'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DECAY_BIAS: an additive learned offset applied after accumulation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ABSOLUTE, the machine performs the named control phase..

Line 288: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ABSOLUTE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 290: `ST_DECAY_BIAS: begin` This is the ST_DECAY_BIAS case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_BIAS, the machine performs the named control phase..

Line 291: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_BIAS, the machine performs the named control phase..

Line 292: `rounded_magnitude_r[lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_BIAS, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are rounded_magnitude_r: the value named 'rounded magnitude r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 293: `<= product_magnitude_r[lane] + 42'd32768;` Within the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_BIAS, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are product_magnitude_r: the value named 'product magnitude r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; d32768: the value named 'd32768' in this block.

Line 294: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_BIAS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 295: `state <= ST_DECAY_ROUND;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_DECAY_ROUND'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DECAY_ROUND: the value named 'st decay round' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_BIAS, the machine performs the named control phase..

Line 296: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_BIAS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 298: `ST_DECAY_ROUND: begin` This is the ST_DECAY_ROUND case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ROUND, the machine performs the named control phase..

Line 299: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ROUND, the machine performs the named control phase..

Line 300: `rounded_magnitude_r[lane] <= rounded_magnitude_r[lane] >> 16;` This makes rounded_magnitude_r[lane], the value named 'rounded magnitude r' in this block, equal to 'rounded_magnitude_r[lane] >> 16'. It updates after the active clock edge together with other nonblocking assignments. The important operands are rounded_magnitude_r: the value named 'rounded magnitude r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ROUND, the machine performs the named control phase..

Line 301: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ROUND, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 302: `state <= ST_DECAY_SIGN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_DECAY_SIGN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DECAY_SIGN: the value named 'st decay sign' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ROUND, the machine performs the named control phase..

Line 303: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_ROUND, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 305: `ST_DECAY_SIGN: begin` This is the ST_DECAY_SIGN case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SIGN, the machine performs the named control phase..

Line 306: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SIGN, the machine performs the named control phase..

Line 307: `signed_rounded_r[lane] <= product_negative_r[lane]` This statement continues through source line 309; the explanation uses the complete expression rather than only the first visual fragment. This makes signed_rounded_r[lane], the value named ’signed rounded r’ in this block, equal to ‘product_negative_r[lane] ? -$signed(rounded_magnitude_r[lane]) : $signed(rounded_magnitude_r[lane])‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_negative_r: the value named ’product negative r’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; rounded_magnitude_r: the value named ’rounded magnitude r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SIGN, the machine performs the named control phase..

Line 308: `? -$signed(rounded_magnitude_r[lane])` This is continuation line 2 of the 3-line logical statement that begins at source line 307. Its exact fragment is ‘? -$signed(rounded_magnitude_r[lane])‘. The important operands are rounded_magnitude_r: the value named ’rounded magnitude r’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes signed_rounded_r[lane], the value named ’signed rounded r’ in this block, equal to ‘product_negative_r[lane] ? -$signed(rounded_magnitude_r[lane]) : $signed(rounded_magnitude_r[lane])‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_negative_r: the value named ’product negative r’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; rounded_magnitude_r: the value named ’rounded magnitude r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SIGN, the machine performs the named control phase..

Line 309: `: $signed(rounded_magnitude_r[lane]);` This is continuation line 3 of the 3-line logical statement that begins at source line 307. Its exact fragment is ‘: $signed(rounded_magnitude_r[lane]);‘. The important operands are rounded_magnitude_r: the value named ’rounded magnitude r’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes signed_rounded_r[lane], the value named ’signed rounded r’ in this block, equal to ‘product_negative_r[lane] ? -$signed(rounded_magnitude_r[lane]) : $signed(rounded_magnitude_r[lane])‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_negative_r: the value named ’product negative r’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath; rounded_magnitude_r: the value named ’rounded magnitude r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SIGN, the machine performs the named control phase..

Line 310: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SIGN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 311: `state <= ST_DECAY_SATURATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_DECAY_SATURATE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DECAY_SATURATE: the value named ’st decay saturate’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SIGN, the machine performs the named control phase..

Line 312: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SIGN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 314: `ST_DECAY_SATURATE: begin` This is the ST_DECAY_SATURATE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SATURATE, the machine performs the named control phase..

Line 315: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SATURATE, the machine performs the named control phase..

Line 316: `decay_term_r[lane] <= saturate_s24(signed_rounded_r[lane]);` This makes decay_term_r[lane], the value named ’decay term r’ in this block, equal to ‘saturate_s24(signed_rounded_r[lane])‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturate_s24: the value named ’saturate s24’ in this block; signed_rounded_r: the value named ’signed rounded r’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SATURATE, the machine performs the named control phase..

Line 317: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 318: `state <= ST_VELOCITY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_VELOCITY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VELOCITY: the momentum history retained by the SGD optimizer. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SATURATE, the machine performs the named control phase..

Line 319: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECAY_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 321: `ST_VELOCITY: begin` This is the ST_VELOCITY case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY, the machine performs the named control phase..

Line 322: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY, the machine performs the named control phase..

Line 323: `two_term_sum_r[lane] <=` This statement continues through source line 325; the explanation uses the complete expression rather than only the first visual fragment. This makes two_term_sum_r[lane], the value named ’two term sum r’ in this block, equal to ‘{gradient_r[lane][23], gradient_r[lane]} + {momentum_term_r[lane][23], momentum_term_r[lane]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are gradient_r: the signed loss derivative used to update a learned parameter; lane: one parallel arithmetic element within a vector or tensor datapath; momentum_term_r: the value named ’momentum term r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY, the machine performs the named control phase..

Line 324: `{gradient_r[lane][23], gradient_r[lane]}` This is continuation line 2 of the 3-line logical statement that begins at source line 323. Its exact fragment is ‘{gradient_r[lane][23], gradient_r[lane]}‘. The important operands are gradient_r: the signed loss derivative used to update a learned parameter; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes two_term_sum_r[lane], the value named ’two term sum r’ in this block, equal to ‘{gradient_r[lane][23], gradient_r[lane]} + {momentum_term_r[lane][23], momentum_term_r[lane]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are gradient_r: the signed loss derivative used to update a learned parameter; lane: one parallel

arithmetic element within a vector or tensor datapath; momentum_term_r: the value named 'momentum term r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY, the machine performs the named control phase..

Line 325: `+ {momentum_term_r[lane][23], momentum_term_r[lane]};` This is continuation line 3 of the 3-line logical statement that begins at source line 323. Its exact fragment is '+ {momentum_term_r[lane][23], momentum_term_r[lane]};'. The important operands are momentum_term_r: the value named 'momentum term r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes two_term_sum_r[lane], the value named 'two term sum r' in this block, equal to '{gradient_r[lane][23], gradient_r[lane]} + {momentum_term_r[lane][23], momentum_term_r[lane]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are gradient_r: the signed loss derivative used to update a learned parameter; lane: one parallel arithmetic element within a vector or tensor datapath; momentum_term_r: the value named 'momentum term r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY, the machine performs the named control phase..

Line 326: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 327: `state <= ST_VELOCITY_SUM;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_VELOCITY_SUM'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VELOCITY_SUM: the momentum history retained by the SGD optimizer. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY, the machine performs the named control phase..

Line 328: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 330: `ST_VELOCITY_SUM: begin` This is the ST_VELOCITY_SUM case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY_SUM, the machine performs the named control phase..

Line 331: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY_SUM, the machine performs the named control phase..

Line 332: `velocity_sum_r[lane] <=` This statement continues through source line 333; the explanation uses the complete expression rather than only the first visual fragment. This makes velocity_sum_r[lane], the momentum history retained by the SGD optimizer, equal to '{two_term_sum_r[lane][24], two_term_sum_r[lane]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are two_term_sum_r: the value named 'two term sum r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY_SUM, the machine performs the named control phase..

Line 333: `{two_term_sum_r[lane][24], two_term_sum_r[lane]};` This is continuation line 2 of the 2-line logical statement that begins at source line 332. Its exact fragment is '{two_term_sum_r[lane][24], two_term_sum_r[lane]};'. The important operands are two_term_sum_r: the value named 'two term sum r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes velocity_sum_r[lane], the momentum history retained by the SGD optimizer, equal to '{two_term_sum_r[lane][24], two_term_sum_r[lane]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are two_term_sum_r: the value named 'two term sum r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VELOCITY_SUM, the machine performs the named control phase..

Line 347: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION, the machine performs the named control phase..

Line 348: `two_term_sum_r[lane] <=` This statement continues through source line 350; the explanation uses the complete expression rather than only the first visual fragment. This makes two_term_sum_r[lane], the value named 'two term sum r' in this block, equal to '{next_velocity_r[lane][23], next_velocity_r[lane]} + {decay_term_r[lane][23], decay_term_r[lane]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_velocity_r: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath; decay_term_r: the value named 'decay term r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION, the machine performs the named control phase..

Line 349: `{next_velocity_r[lane][23], next_velocity_r[lane]}` This is continuation line 2 of the 3-line logical statement that begins at source line 348. Its exact fragment is '{next_velocity_r[lane][23], next_velocity_r[lane]}'. The important operands are next_velocity_r: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes two_term_sum_r[lane], the value named 'two term sum r' in this block, equal to '{next_velocity_r[lane][23], next_velocity_r[lane]} + {decay_term_r[lane][23], decay_term_r[lane]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_velocity_r: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath; decay_term_r: the value named 'decay term r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION, the machine performs the named control phase..

Line 350: `+ {decay_term_r[lane][23], decay_term_r[lane]};` This is continuation line 3 of the 3-line logical statement that begins at source line 348. Its exact fragment is '+ {decay_term_r[lane][23], decay_term_r[lane]};'. The important operands are decay_term_r: the value named 'decay term r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes two_term_sum_r[lane], the value named 'two term sum r' in this block, equal to '{next_velocity_r[lane][23], next_velocity_r[lane]} + {decay_term_r[lane][23], decay_term_r[lane]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_velocity_r: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath; decay_term_r: the value named 'decay term r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION, the machine performs the named control phase..

Line 351: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 352: `state <= ST_UPDATE_DIRECTION_SATURATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_UPDATE_DIRECTION_SATURATE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_UPDATE_DIRECTION_SATURATE: the value named 'st update direction saturate' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION, the machine performs the named control phase..

Line 353: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 355: `ST_UPDATE_DIRECTION_SATURATE: begin` This is the ST_UPDATE_DIRECTION_SATURATE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION_SATURATE, the machine performs the named control phase..

Line 356: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION_SATURATE, the machine performs the named control phase..

Line 357: `// The retained velocity excludes weight decay. This` Design intent: The retained velocity excludes weight decay. This This comment anchors the surrounding logic in the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state.

Line 358: `// scratch register holds only the SGDW update direction.` Design intent: scratch register holds only the SGDW update direction. This comment anchors the surrounding logic in the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state.

Line 359: `momentum_term_r[lane] <= saturate_s24(` This statement continues through source line 360; the explanation uses the complete expression rather than only the first visual fragment. This makes momentum_term_r[lane], the value named 'momentum term r' in this block, equal to 'saturate_s24({{17{two_term_sum_r[lane][24]}}, two_term_sum_r[lane]} It updates after the active clock edge together with other nonblocking assignments. The important operands are saturate_s24: the value named 'saturate s24' in this block; two_term_sum_r: the value named 'two term sum r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION_SATURATE, the machine performs the named control phase..

Line 360: `{{17{two_term_sum_r[lane][24]}}, two_term_sum_r[lane]});` This is continuation line 2 of the 2-line logical statement that begins at source line 359. Its exact fragment is '{{17{two_term_sum_r[lane][24]}}, two_term_sum_r[lane]}) The important operands are two_term_sum_r: the value named 'two term sum r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes momentum_term_r[lane], the value named 'momentum term r' in this block, equal to 'saturate_s24({{17{two_term_sum_r[lane][24]}}, two_term_sum_r[lane]})'. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturate_s24: the value named 'saturate s24' in this block; two_term_sum_r: the value named 'two term sum r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION_SATURATE, the machine performs the named control phase..

Line 361: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 362: `state <= ST_UPDATE_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_UPDATE_MULTIPLY'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_UPDATE_MULTIPLY: the value named 'st update multiply' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION_SATURATE, the machine performs the named control phase..

Line 363: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_DIRECTION_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 365: `ST_UPDATE_MULTIPLY: begin` This is the ST_UPDATE_MULTIPLY case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 366: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 367: `multiplier_operand_left_r[lane] <= multiplier_left[lane];` This makes multiplier_operand_left_r[lane], the value named ’multiplier operand left r’ in this block, equal to ‘multiplier_left[lane]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_left: the value named ’multiplier left’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 368: `multiplier_operand_right_r[lane] <= multiplier_right[lane];` This makes multiplier_operand_right_r[lane], the value named ’multiplier operand right r’ in this block, equal to ‘multiplier_right[lane]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_right: the value named ’multiplier right’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 369: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 370: `state <= ST_UPDATE_PRODUCT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_UPDATE_PRODUCT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_UPDATE_PRODUCT: the value named ’st update product’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase..

Line 371: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 373: `ST_UPDATE_PRODUCT: begin` This is the ST_UPDATE_PRODUCT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_PRODUCT, the machine performs the named control phase..

Line 374: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_PRODUCT, the machine performs the named control phase..

Line 375: `multiplier_product_pipeline_r[lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_PRODUCT, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are multiplier_product_pipeline_r: the value named ’multiplier product pipeline r’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 376: `<= multiplier_product[lane];` Within the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_PRODUCT, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are multiplier_product: the value named 'multiplier product' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 377: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_PRODUCT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 378: `state <= ST_UPDATE_PRODUCT_RELAY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_UPDATE_PRODUCT_RELAY'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_UPDATE_PRODUCT_RELAY: the value named 'st update product relay' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_PRODUCT, the machine performs the named control phase..

Line 379: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_PRODUCT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 381: `ST_UPDATE_PRODUCT_RELAY: begin` This is the ST_UPDATE_PRODUCT_RELAY case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_PRODUCT_RELAY, the machine performs the named control phase..

Line 382: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SIGN, the machine performs the named control phase..

Line 424: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SIGN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 425: `state <= ST_UPDATE_SUBTRACT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_UPDATE_SUBTRACT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_UPDATE_SUBTRACT: the value named 'st update subtract' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SIGN, the machine performs the named control phase..

Line 426: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SIGN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 428: `ST_UPDATE_SUBTRACT: begin` This is the ST_UPDATE_SUBTRACT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SUBTRACT, the machine performs the named control phase..

Line 429: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SUBTRACT, the machine performs the named control phase..

Line 430: `weight_difference_r[lane] <=` This statement continues through source line 432; the explanation uses the complete expression rather than only the first visual fragment. This makes weight_difference_r[lane], a learned coefficient multiplied by an activation, equal to ‘{{26{weight_r[lane][15]}}, weight_r[lane]} - update_value_r[lane]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_r: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath; update_value_r: the value named 'update value r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SUBTRACT, the machine performs the named control phase..

Line 431: `{{26{weight_r[lane][15]}}, weight_r[lane]}` This is continuation line 2 of the 3-line logical statement that begins at source line 430. Its exact fragment is ‘{{26{weight_r[lane][15]}}, weight_r[lane]}‘. The important operands are weight_r: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes weight_difference_r[lane], a learned coefficient multiplied by an activation, equal to ‘{{26{weight_r[lane][15]}}, weight_r[lane]} - update_value_r[lane]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_r: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath; update_value_r: the value named 'update value r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SUBTRACT, the machine performs the named control phase..

Line 432: `- update_value_r[lane];` This is continuation line 3 of the 3-line logical statement that begins at source line 430. Its exact fragment is ‘- update_value_r[lane];‘. The important operands are update_value_r: the value named 'update value r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes weight_difference_r[lane], a learned coefficient multiplied by an activation, equal to ‘{{26{weight_r[lane][15]}}, weight_r[lane]} - update_value_r[lane]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_r: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath; update_value_r: the value named 'update value r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SUBTRACT, the machine performs the named control phase..

Line 433: `updated_velocity_vector[lane*24 +: 24] <= next_velocity_r[lane];` Within the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SUBTRACT, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are updated_velocity_vector: the momentum history retained by the SGD optimizer; lane: one parallel arithmetic element within a vector or tensor datapath; next_velocity_r: the momentum history retained by the SGD optimizer.

Line 434: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SUBTRACT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 435: `state <= ST_UPDATE_SATURATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_UPDATE_SATURATE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_UPDATE_SATURATE: the value named 'st update saturate' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SUBTRACT, the machine performs the named control phase..

Line 436: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SUBTRACT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 438: `ST_UPDATE_SATURATE: begin` This is the ST_UPDATE_SATURATE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SATURATE, the machine performs the named control phase..

Line 439: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware

rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SATURATE, the machine performs the named control phase..

Line 440: `updated_weight_vector[lane*16 +: 16] <=` This statement continues through source line 441; the explanation uses the complete expression rather than only the first visual fragment. Within the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are updated_weight_vector: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath; saturate_s16: the value named 'saturate s16' in this block.

Line 441: `saturate_s16(weight_difference_r[lane]);` This is continuation line 2 of the 2-line logical statement that begins at source line 440. Its exact fragment is 'saturate_s16(weight_difference_r[lane]);'. The important operands are saturate_s16: the value named 'saturate s16' in this block; weight_difference_r: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: Within the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state. The important operands are updated_weight_vector: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath; saturate_s16: the value named 'saturate s16' in this block.

Line 442: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 443: `update_count <= update_count + LANES;` This makes update_count, an integer count retained for control or measurable telemetry, equal to 'update_count + LANES'. It updates after the active clock edge together with other nonblocking assignments. The important operands are update_count: an integer count retained for control or measurable telemetry; LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SATURATE, the machine performs the named control phase..

Line 444: `state <= ST_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT: the value named 'st output' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SATURATE, the machine performs the named control phase..

Line 445: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_UPDATE_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 447: `ST_OUTPUT: begin` This is the ST_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 448: `if (output_ready) state <= ST_IDLE;` This condition selects the following hardware branch only when 'output_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 449: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 451: `default:  state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘state <= ST_IDLE;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 452: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 453: `if (clear_counters) update_count <= 32'd0;` This condition selects the following hardware branch only when ‘clear_counters‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are clear_counters: a hardware telemetry register that accumulates measured events. Context: the clocked process that updates registers only on a rising clock edge.

Line 454: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 455: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 457: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 458: `if (LANES != 8) $fatal(1, "neuraedge_sgd_optimizer8 currently requires LANES=8");` This condition selects the following hardware branch only when ‘LANES != 8) $fatal(1, "neuraedge_sgd_optimizer8 currently requires LANES=8"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are LANES: one parallel arithmetic element within a vector or tensor datapath; fatal: the value named 'fatal' in this block; neuraedge_sgd_optimizer8: the value named 'neuraedge sgd optimizer8' in this block. Context: the module's structural declarations.

Line 459: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 460: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 462: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that applies signed fixed-point SGD with momentum to eight weight lanes and stores updated state.

19 rtl/neuraedge_tensor_tile.sv

Role in the complete system: implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

19.1 Beginner architecture map

Dataflow responsibility The 8-by-16 tile schedules 64 packed DSP blocks as 128 dense byte MAC lanes, or bypasses multipliers for binary/ternary conditional additions. Per-row active masks, registered sparse popcount, issue/result FIFOs, and deterministic row/column output order make backpressure safe.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_tensor_tile into physical nets and primitives. The source declares 22 input-port lines, 13 output-port lines, 1 clocked process(es), and 3 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_ACCUMULATE_OUTPUT_COUNT, ST_CAPTURE_TARGET, ST_COMBINE_ZERO_POINT, ST_DRAIN, ST_IDLE, ST_LATCH_ZERO_POINT, ST_OUTPUT_PIPELINE, ST_PREPARE_OUTPUT_COUNT, ST_PREPARE_ZERO_POINT, ST_RESTORE_ADD, ST_RESTORE_MULTIPL ST_RESTORE_RELAY, ST_RUN, ST_SPARSE_DRAIN. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates end as endfunction, unique as case, end as for, neuraedge_mac2_u8 as u_mac2, end as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

19.2 Complete source

Line 14: `input wire [3:0] active_rows,` This is continuation line 10 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'input wire [3:0] active_rows,'. The important operands are input: the value named 'input' in this block; active_rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 15: `input wire [5:0] active_columns,` This is continuation line 11 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'input wire [5:0] active_columns,'. The important operands are input: the value named 'input' in this block; active_columns: one output-feature position processed in parallel. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 16: `input wire [7:0] activation_zero_point,` This is continuation line 12 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'input wire [7:0] activation_zero_point,'. The important operands are input: the value named 'input' in this block; activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 17: `input wire [7:0] weight_zero_point,` This is continuation line 13 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'input wire [7:0] weight_zero_point,'. The important operands are input: the value named 'input' in this block; weight_zero_point: a learned coefficient multiplied by an activation. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 18: `output logic config_error,` This is continuation line 14 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'output logic config_error,'. The important operands are output: the value named 'output' in this block; config_error: the value named 'config error' in this block. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 20: `input wire issue_valid,` This is continuation line 16 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'input wire issue_valid,'. The important operands are input: the value named 'input' in this block; issue_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant

to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 21: `output logic issue_ready,` This is continuation line 17 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'output logic issue_ready,'. The important operands are output: the value named 'output' in this block; issue_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 22: `input wire [ROW_LANES*8-1:0] activation_vector,` This is continuation line 18 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'input wire [ROW_LANES*8-1:0] activation_vector,'. The important operands are input: the value named 'input' in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; activation_vector: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 23: `input wire [COLUMN_LANES*8-1:0] outer_weight_vector,` This is continuation line 19 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'input wire [COLUMN_LANES*8-1:0] outer_weight_vector,'. The important operands are input: the value named 'input' in this block; COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath; outer_weight_vector: a learned coefficient multiplied by an activation. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 24: `input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector,` This is continuation line 20 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector,'. The important operands are input: the value named 'input' in this block; COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point,

input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 25: `input wire issue_last,` This is continuation line 21 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'input wire issue_last,'. The important operands are input: the value named 'input' in this block; issue_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 27: `output logic busy,` This is continuation line 23 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'output logic busy,'. The important operands are output: the value named 'output' in this block; busy: the value named 'busy' in this block. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 28: `output logic result_valid,` This is continuation line 24 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'output logic result_valid,'. The important operands are output: the value named 'output' in this block; result_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Line 33: `output logic result_last,` This is continuation line 29 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'output logic result_last,'. The important operands are output: the value named 'output' in this block; result_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 35: `output logic [31:0] debug_accepted_issues,` This is continuation line 31 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] debug_accepted_issues,'. The important operands are output: the value named 'output' in this block; debug_accepted_issues: the value named 'debug accepted issues' in this block. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 36: `output logic [31:0] debug_skipped_issues,` This is continuation line 32 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] debug_skipped_issues,'. The important operands are output: the value named 'output' in this block; debug_skipped_issues: the value named 'debug skipped issues' in this block. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 37: `output logic [31:0] debug_retired_issues,` This is continuation line 33 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] debug_retired_issues,'. The important operands are output: the value named 'output' in this block; debug_retired_issues: the value named 'debug retired issues' in this block. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic

[63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 38: `output logic [63:0] debug_dense_macs,` This is continuation line 34 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'output logic [63:0] debug_dense_macs,'. The important operands are output: the value named 'output' in this block; debug_dense_macs: a count of ordinary activation-times-weight operations actually issued. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 39: `output logic [63:0] debug_spike_adds` This is continuation line 35 of the 36-line logical statement that begins at source line 5. Its exact fragment is 'output logic [63:0] debug_spike_adds'. The important operands are output: the value named 'output' in this block; debug_spike_adds: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 40: `);` This is continuation line 36 of the 36-line logical statement that begins at source line 5. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes ROW_LANES to 8, parameter int COLUMN_LANES = 16, parameter int ACC_BITS = 32) (input wire clk, input wire rst_n, input wire start, input wire [1:0] compute_mode, input wire [3:0] active_rows, input wire [5:0] active_columns, input wire [7:0] activation_zero_point, input wire [7:0] weight_zero_point, output logic config_error, input wire issue_valid, output logic issue_ready, input wire [ROW_LANES*8-1:0] activation_vector, input wire [COLUMN_LANES*8-1:0] outer_weight_vector, input wire [COLUMN_LANES*ROW_LANES*8-1:0] dot_weight_vector, input wire issue_last, output logic busy, output logic result_valid, input wire result_ready, output logic signed [47:0] result_value, output logic [3:0] result_row, output logic [5:0] result_column, output logic result_last, output logic [31:0] debug_accepted_issues, output logic [31:0] debug_skipped_issues, output logic [31:0] debug_retired_issues, output logic [63:0] debug_dense_macs, output logic [63:0] debug_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; ROW_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 41: `localparam logic [1:0] MODE_DENSE_OUTER = 2'd0;` This fixes MODE_DENSE_OUTER to 2'd0 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_DENSE_OUTER denotes the value named 'mode dense outer' in this block.

Line 42: `localparam logic [1:0] MODE_DENSE_DOT8 = 2'd1;` This fixes MODE_DENSE_DOT8 to 2'd1 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_DENSE_DOT8 denotes the value named 'mode dense dot8' in this block.

Line 43: `localparam logic [1:0] MODE_BINARY_WEIGHTED = 2'd2;` This fixes MODE_BINARY_WEIGHTED to 2'd2 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_BINARY_WEIGHTED denotes a learned coefficient multiplied by an activation.

Line 44: `localparam logic [1:0] MODE_TERNARY_WEIGHTED = 2'd3;` This fixes MODE_TERNARY_WEIGHTED to 2'd3 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_TERNARY_WEIGHTED denotes a learned coefficient multiplied by an activation.

Line 45: `localparam int COLUMN_PAIRS = COLUMN_LANES / 2;` This fixes COLUMN_PAIRS to COLUMN_LANES / 2 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; COLUMN_PAIRS denotes one output-feature position processed in parallel.

Line 46: `localparam int RESULT_FIFO_DEPTH = ROW_LANES * COLUMN_LANES;` This fixes RESULT_FIFO_DEPTH to ROW_LANES * COLUMN_LANES during elaboration. Vivado uses that constant to shape or simplify the generated circuit; RESULT_FIFO_DEPTH denotes the value named 'result fifo depth' in this block.

Line 47: `localparam int RESULT_FIFO_ADDRESS_BITS = $clog2(RESULT_FIFO_DEPTH);` This fixes RESULT_FIFO_ADDRE to $clog2(RESULT_FIFO_DEPTH) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; RESULT_FIFO_ADDRESS_BITS denotes the value named 'result fifo address bits' in this block.

Line 48: `localparam int RESULT_FIFO_COUNT_BITS = $clog2(RESULT_FIFO_DEPTH + 1);` This fixes RESULT_FIFO_COUN to $clog2(RESULT_FIFO_DEPTH + 1) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; RESULT_FIFO_COUNT_BITS denotes the value named 'result fifo count bits' in this block.

Line 50: `typedef enum logic [3:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 51: `ST_IDLE = 4'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 52: `ST_RUN = 4'd1,` This assigns a fixed binary encoding to state ST_RUN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 53: `ST_DRAIN = 4'd2,` This assigns a fixed binary encoding to state ST_DRAIN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 54: `ST_PREPARE_ZERO_POINT = 4'd3,` This assigns a fixed binary encoding to state ST_PREPARE_ZERO_POINT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 55: `ST_RESTORE_MULTIPLY = 4'd4,` This assigns a fixed binary encoding to state ST_RESTORE_MULTIPLY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 56: `ST_OUTPUT_PIPELINE = 4'd5,` This assigns a fixed binary encoding to state ST_OUTPUT_PIPELINE, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 57: `ST_LATCH_ZERO_POINT = 4'd6,` This assigns a fixed binary encoding to state ST_LATCH_ZERO_POINT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 58: `ST_RESTORE_ADD = 4'd7,` This assigns a fixed binary encoding to state ST_RESTORE_ADD, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 59: `ST_SPARSE_DRAIN = 4'd8,` This assigns a fixed binary encoding to state ST_SPARSE_DRAIN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 60: `ST_CAPTURE_TARGET = 4'd9,` This assigns a fixed binary encoding to state ST_CAPTURE_TARGET, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 61: `ST_COMBINE_ZERO_POINT = 4'd10,` This assigns a fixed binary encoding to state ST_COMBINE_ZERO_POINT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 62: `ST_PREPARE_OUTPUT_COUNT = 4'd11,` This assigns a fixed binary encoding to state ST_PREPARE_OUTPUT_COUN which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 63: `ST_ACCUMULATE_OUTPUT_COUNT = 4'd12,` This assigns a fixed binary encoding to state ST_ACCUMULATE_OUTPUT which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 64: `ST_RESTORE_RELAY = 4'd13` This statement continues through source line 65; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_RESTORE_RELAY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 65: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 64. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_RESTORE_RELAY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 67: `state_t state;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are state_t: the finite-state-machine phase retained in flip-flops; state: the finite-state-machine phase retained in flip-flops.

Line 68: `(* dont_touch = "yes" *) logic [1:0] mode_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; mode_r: the value named 'mode r' in this block.

Line 69: `(* dont_touch = "yes" *) logic [3:0] rows_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; rows_r: one output-row position processed by the tensor tile.

Line 70: `logic [ROW_LANES-1:0] active_row_mask_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_row_mask_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 71: `logic [5:0] columns_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, columns_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 72: `logic [7:0] activation_zp_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_zp_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 73: `logic [7:0] weight_zp_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_zp_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 75: `logic signed [ACC_BITS-1:0] accumulator [0:ROW_LANES-1][0:COLUMN_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulator is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 76: `// Keep one physical clear source per row. A command-start state bit driving` Design intent: Keep one physical clear source per row. A command-start state bit driving This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 77: `// every accumulator bit creates a long, high-fanout control path after` Design intent: every accumulator bit creates a long, high-fanout control path after This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 78: `// placement; these registered row-local pulses perform the same clear one` Design intent: placement; these registered row-local pulses perform the same clear one This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 79: `// cycle after start, before the issue pipeline can produce a delta.` Design intent: cycle after start, before the issue pipeline can produce a delta. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 80: `(* dont_touch = "yes", max_fanout = 96 *)` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; max_fanout: the value named 'max fanout' in this block.

Line 81: `logic accumulator_clear_row_r [0:ROW_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulator_clear_row_r is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 82: `// Column sums use the same delayed-clear scheme. One register per column` Design intent: Column sums use the same delayed-clear scheme. One register per column This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 83: `// keeps the command-start decode out of a 512-bit distributed CE network.` Design intent: keeps the command-start decode out of a 512-bit distributed CE network. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 84: `(* dont_touch = "yes", max_fanout = 48 *)` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; max_fanout: the value named 'max fanout' in this block.

Line 85: `logic column_sum_clear_r [0:COLUMN_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, column_sum_clear_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 86: `(* dont_touch = "yes" *) logic accumulate_delta_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; accumulate_delta_valid_r: the producer's statement that its current payload is meaningful.

Line 87: `logic signed [20:0] accumulate_delta_r [0:ROW_LANES-1][0:COLUMN_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulate_delta_r is the value named 'accumulate delta r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 88: `logic [31:0] row_sum [0:ROW_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, row_sum is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 89: `logic [31:0] column_sum [0:COLUMN_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, column_sum is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 90: `logic sum_update_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sum_update_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 91: `logic [15:0] row_increment_r [0:ROW_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, row_increment_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 92: `logic [15:0] column_increment_r [0:COLUMN_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, column_increment_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 93: `logic [31:0] effective_reduction;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, effective_reduction is the value named 'effective reduction' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 95: `logic [11:0] mac_issue_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mac_issue_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 96: `// The counter is updated in both run and command-boundary states. A local` Design intent: The counter is updated in both run and command-boundary states. A local This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 97: `// D-input hold avoids a long FSM-to-CE route across the MAC array.` Design intent: D-input hold avoids a long FSM-to-CE route across the MAC array. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 98: `(* extract_enable = "no" *) logic [11:0] mac_retire_count;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block; mac_retire_count: an integer count retained for control or measurable telemetry.

Line 99: `logic [11:0] target_mac_retires;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, target_mac_retires is the value named 'target mac retires' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 100: `// One command can execute at most 2048*8*16 = 262144 useful operations,` Design intent: One command can execute at most 2048*8*16 = 262144 useful operations, This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 101: `// so 19 bits represent the exact per-command telemetry range. The` Design intent: so 19 bits represent the exact per-command telemetry range. The This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 102: `// increment is registered before accumulation to keep popcount and lane` Design intent: increment is registered before accumulation to keep popcount and lane This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 103: `// sizing logic out of the counter carry chain at 200 MHz.` Design intent: sizing logic out of the counter carry chain at 200 MHz. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 104: `logic [18:0] debug_dense_macs_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, debug_dense_macs_r is a count of ordinary activation-times-weight operations actually issued. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 105: `logic [18:0] debug_spike_adds_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, debug_spike_adds_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 106: `logic [7:0] metric_increment_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, metric_increment_r is the value named 'metric increment r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 107: `logic metric_increment_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, metric_increment_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 108: `logic [3:0] sparse_active_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sparse_active_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 109: `logic sparse_metric_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sparse_metric_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 110: `logic [7:0] dense_macs_per_issue_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dense_macs_per_issue_r is a count of ordinary activation-times-weight operations actually issued. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 111: `(* dont_touch = "yes" *) logic drain_complete_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; drain_complete_r: the value named 'drain complete r' in this block.

Line 112: `(* use_dsp = "yes" *) logic [15:0] zero_point_product_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; zero_point_product_r: the integer code representing real numeric zero in affine quantization.

Line 113: `logic [31:0] zero_restore_reduction_operand_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_restore_reduction_operand_r is the value named 'zero restore reduction operand r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 114: `logic [15:0] zero_restore_zp_operand_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_restore_zp_operand_r is the value named 'zero restore zp operand r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 115: `(* use_dsp = "yes" *) logic [31:0] zero_restore_low_product_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; zero_restore_low_product_r: the value named 'zero restore low product r' in this block.

Line 116: `(* use_dsp = "yes" *) logic [31:0] zero_restore_high_product_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; zero_restore_high_product_r: the value named 'zero restore high product r' in this block.

Line 117: `logic [31:0] zero_restore_low_relay_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_restore_low_relay_r is the value named 'zero restore low relay r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 118: `logic [31:0] zero_restore_high_relay_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_restore_high_relay_r is the value named 'zero restore high relay r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 119: `logic [47:0] zero_point_restore_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_point_restore_r is the integer code representing real numeric zero in affine quantization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 120: `logic [7:0] launch_total_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, launch_total_r is the value named 'launch total r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 121: `(* extract_enable = "no" *) logic [7:0] launch_remaining_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block; launch_remaining_r: the value named 'launch remaining r' in this block.

Line 122: `logic [3:0] launch_rows_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, launch_rows_remaining_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 123: `(* extract_enable = "no" *) logic [5:0] launch_columns_remaining_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block; launch_columns_remaining_r: one output-feature position processed in parallel.

Line 124: `(* extract_enable = "no" *) logic [3:0] launch_row_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block; launch_row_r: one output-row position processed by the tensor tile.

Line 125: `(* extract_enable = "no" *) logic [5:0] launch_column_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block; launch_column_r: one output-feature position processed in parallel.

Line 126: `logic pread_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pread_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 127: `logic signed [ACC_BITS-1:0] pread_accumulator_by_row_r [0:ROW_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pread_accumulator_by_row_r is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 128: `logic [31:0] pread_row_sum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pread_row_sum_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 129: `logic [31:0] pread_column_sum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pread_column_sum_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 130: `logic [3:0] pread_row_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pread_row_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 131: `logic [5:0] pread_column_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pread_column_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 132: `(* dont_touch = "yes" *) logic p0_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; p0_valid_r: the producer's statement that its current payload is meaningful.

Line 133: `logic signed [63:0] p0_raw_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p0_raw_r is the value named 'p0 raw r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 134: `logic [31:0] p0_row_sum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p0_row_sum_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 135: `logic [31:0] p0_column_sum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p0_column_sum_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 136: `logic [7:0] p0_row_zp_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p0_row_zp_low_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 137: `logic [7:0] p0_row_zp_high_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p0_row_zp_high_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 138: `logic [7:0] p0_column_zp_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p0_column_zp_low_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 139: `logic [7:0] p0_column_zp_high_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p0_column_zp_high_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 140: `logic [3:0] p0_row_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p0_row_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 141: `logic [5:0] p0_column_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p0_column_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 142: `(* dont_touch = "yes" *) logic p1_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; p1_valid_r: the producer's statement that its current payload is meaningful.

Line 143: `logic signed [63:0] p1_raw_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p1_raw_r is the value named 'p1 raw r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 144: `logic [23:0] p1_row_product_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p1_row_product_low_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 145: `logic [23:0] p1_row_product_high_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p1_row_product_high_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 146: `logic [23:0] p1_column_product_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p1_column_product_low_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 147: `logic [23:0] p1_column_product_high_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p1_column_product_high_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 148: `logic [3:0] p1_row_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p1_row_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 149: `logic [5:0] p1_column_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p1_column_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 150: `(* dont_touch = "yes" *) logic p2_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; p2_valid_r: the producer's statement that its current payload is meaningful.

Line 151: `logic signed [63:0] p2_raw_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p2_raw_r is the value named 'p2 raw r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 152: `logic signed [63:0] p2_row_correction_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p2_row_correction_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 153: `logic signed [63:0] p2_column_correction_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p2_column_correction_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 154: `logic [3:0] p2_row_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p2_row_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 155: `logic [5:0] p2_column_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p2_column_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 156: `(* dont_touch = "yes" *) logic p3_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; p3_valid_r: the producer's statement that its current payload is meaningful.

Line 157: `logic signed [63:0] p3_corrected_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p3_corrected_r is the value named 'p3 corrected r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 158: `logic signed [63:0] p3_column_correction_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p3_column_correction_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 159: `logic [3:0] p3_row_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p3_row_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 160: `logic [5:0] p3_column_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p3_column_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 161: `(* dont_touch = "yes" *) logic p4_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; p4_valid_r: the producer's statement that its current payload is meaningful.

Line 162: `logic signed [63:0] p4_corrected_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p4_corrected_r is the value named 'p4 corrected r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 163: `logic [3:0] p4_row_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p4_row_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 164: `logic [5:0] p4_column_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p4_column_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 165: `(* dont_touch = "yes" *) logic p5_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; p5_valid_r: the producer's statement that its current payload is meaningful.

Line 166: `logic signed [47:0] p5_result_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p5_result_r is the value named 'p5 result r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 167: `logic [3:0] p5_row_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p5_row_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 168: `logic [5:0] p5_column_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, p5_column_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 169: `logic output_pipeline_enable;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_pipeline_enable is a control bit that permits the associated state or storage update. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 170: `logic [RESULT_FIFO_COUNT_BITS-1:0] result_fifo_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 171: `(* dont_touch = "yes" *) logic result_fifo_has_space_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; result_fifo_has_space_r: the value named 'result fifo has space r' in this block.

Line 172: `(* dont_touch = "yes" *) logic result_fifo_nonempty_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; result_fifo_nonempty_r: the value named 'result fifo nonempty r' in this block.

Line 173: `logic [RESULT_FIFO_ADDRESS_BITS-1:0] result_fifo_write_pointer_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_write_pointer_r is the value named 'result fifo write pointer r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 174: `logic [RESULT_FIFO_ADDRESS_BITS-1:0] result_fifo_read_pointer_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_read_pointer_r is the value named 'result fifo read pointer r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 175: `logic [RESULT_FIFO_ADDRESS_BITS-1:0] result_fifo_last_address_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_last_address_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 176: `// One command emits at most 8*16 records. Buffering that complete tile` Design intent: One command emits at most 8*16 records. Buffering that complete tile This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 177: `// removes downstream backpressure from every arithmetic pipeline CE while` Design intent: removes downstream backpressure from every arithmetic pipeline CE while This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 178: `// retaining an asynchronous read suitable for a stable AXI-Stream output.` Design intent: retaining an asynchronous read suitable for a stable AXI-Stream output. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 179: `(* ram_style = "distributed" *) logic [57:0] result_fifo_payload_r` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are ram_style: the value named 'ram style' in this block; distributed: the value named 'distributed' in this block; result_fifo_payload_r: stream data belonging to the current command.

Line 180: `[0:RESULT_FIFO_DEPTH-1];` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are RESULT_FIFO_DEPTH: the value named 'result fifo depth' in this block.

Line 181: `logic result_stage_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_stage_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 182: `logic [57:0] result_stage_payload_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_stage_payload_r is stream data belonging to the current command. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 183: `logic result_stage_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_stage_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 184: `wire result_fifo_push = state == ST_OUTPUT_PIPELINE` This statement continues through source line 185; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_push is the value named 'result fifo push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 185: `&& p5_valid_r && result_fifo_has_space_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 184. Its exact fragment is '&& p5_valid_r && result_fifo_has_space_r;'. The important operands are p5_valid_r: the producer's statement that its current payload is meaningful; result_fifo_has_space_r: the value named 'result fifo has space r' in this block. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_push is the value named 'result fifo push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 186: `wire result_fifo_pop = state == ST_OUTPUT_PIPELINE` This statement continues through source line 189; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_pop is the value named 'result fifo pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 187: `&& result_fifo_nonempty_r` This is continuation line 2 of the 4-line logical statement that begins at source line 186. Its exact fragment is '&& result_fifo_nonempty_r'. The important operands are result_fifo_nonempty_r: the value named 'result fifo nonempty r' in this block. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_pop is the value named 'result fifo pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 188: `&& (!result_stage_valid_r` This is continuation line 3 of the 4-line logical statement that begins at source line 186. Its exact fragment is '&& (!result_stage_valid_r'. The important operands are result_stage_valid_r: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_pop is the value named 'result fifo pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 189: `|| (result_stage_valid_r && result_ready));` This is continuation line 4 of the 4-line logical statement that begins at source line 186. Its exact fragment is '|| (result_stage_valid_r && result_ready));'. The important operands are result_stage_valid_r: the producer's statement that its current payload is meaningful; result_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_pop is the value named 'result fifo pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 190: `wire result_stage_pop = state == ST_OUTPUT_PIPELINE` This statement continues through source line 191; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_stage_pop is the value named 'result stage pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 191: `&& result_stage_valid_r && result_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 190. Its exact fragment is '&& result_stage_valid_r && result_ready;'. The important operands are result_stage_valid_r: the producer's statement that its current payload is meaningful; result_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_stage_pop is the value named 'result stage pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 193: `// Zero-point restoration is computed once per tile. Row and column products` Design intent: Zero-point restoration is computed once per tile. Row and column products This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 194: `// are independent and therefore form a throughput-one correction pipeline.` Design intent: are independent and therefore form a throughput-one correction pipeline. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 195: `(* use_dsp = "yes" *) wire [23:0] p0_row_product_low =` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; p0_row_product_low: one output-row position processed by the tensor tile.

Line 196: `p0_row_sum_r[15:0] * p0_row_zp_low_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are p0_row_sum_r: one output-row position processed by the tensor tile; p0_row_zp_low_r: one output-row position processed by the tensor tile.

Line 197: `(* use_dsp = "yes" *) wire [23:0] p0_row_product_high =` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; p0_row_product_high: one output-row position processed by the tensor tile.

Line 198: `p0_row_sum_r[31:16] * p0_row_zp_high_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are p0_row_sum_r: one output-row position processed by the tensor tile; p0_row_zp_high_r: one output-row position processed by the tensor tile.

Line 199: `(* use_dsp = "yes" *) wire [23:0] p0_column_product_low =` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; p0_column_product_low: one output-feature position processed in parallel.

Line 200: `p0_column_sum_r[15:0] * p0_column_zp_low_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are p0_column_sum_r: one output-feature position processed in parallel; p0_column_zp_low_r: one output-feature position processed in parallel.

Line 201: `(* use_dsp = "yes" *) wire [23:0] p0_column_product_high =` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; p0_column_product_high: one output-feature position processed in parallel.

Line 202: `p0_column_sum_r[31:16] * p0_column_zp_high_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are p0_column_sum_r: one output-feature position processed in parallel; p0_column_zp_high_r: one output-feature position processed in parallel.

Line 204: `logic [7:0] mac_activation [0:ROW_LANES-1][0:COLUMN_PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mac_activation is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 205: `logic [7:0] mac_weight_lo [0:ROW_LANES-1][0:COLUMN_PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mac_weight_lo is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 206: `logic [7:0] mac_weight_hi [0:ROW_LANES-1][0:COLUMN_PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mac_weight_hi is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 207: `wire [15:0] mac_product_lo [0:ROW_LANES-1][0:COLUMN_PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mac_product_lo is the value named 'mac product lo' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 208: `wire [15:0] mac_product_hi [0:ROW_LANES-1][0:COLUMN_PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mac_product_hi is the value named 'mac product hi' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 209: `wire mac_product_valid [0:ROW_LANES-1][0:COLUMN_PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mac_product_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 210: `logic dot_pair_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot_pair_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 211: `logic dot_half_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot_half_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 212: `logic dot_sum_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot_sum_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 213: `logic [16:0] dot_pair_lo_r [0:COLUMN_PAIRS-1][0:3];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot_pair_lo_r is the value named 'dot pair lo r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 214: `logic [16:0] dot_pair_hi_r [0:COLUMN_PAIRS-1][0:3];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot_pair_hi_r is the value named 'dot pair hi r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 215: `logic [17:0] dot_half_lo_r [0:COLUMN_PAIRS-1][0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot_half_lo_r is the value named 'dot half lo r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 216: `logic [17:0] dot_half_hi_r [0:COLUMN_PAIRS-1][0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot_half_hi_r is the value named 'dot half hi r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 217: `logic [19:0] dot_sum_lo_r [0:COLUMN_PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot_sum_lo_r is the value named 'dot sum lo r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 218: `logic [19:0] dot_sum_hi_r [0:COLUMN_PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot_sum_hi_r is the value named 'dot sum hi r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 219: `logic dot8_pair_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot8_pair_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 220: `logic [8:0] dot8_row_pair_r [0:3];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot8_row_pair_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 221: `// As with the retire counter, keep the classify-state hold on the data` Design intent: As with the retire counter, keep the classify-state hold on the data This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 222: `// input so each pair register can be implemented near its adder.` Design intent: input so each pair register can be implemented near its adder. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 223: `(* extract_enable = "no" *)` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block.

Line 224: `logic [8:0] dot8_column_pair_r [0:COLUMN_LANES-1][0:3];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot8_column_pair_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 225: `logic dot8_increment_half_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot8_increment_half_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 226: `logic [9:0] dot8_row_half_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot8_row_half_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 227: `logic [9:0] dot8_column_half_r [0:COLUMN_LANES-1][0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dot8_column_half_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 229: `logic issue_accept;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_accept is the value named 'issue accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 230: `logic input_done_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_done_r is the value named 'input done r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 231: `logic issue_match_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_match_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 232: `logic [7:0] issue_zero_matches_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_zero_matches_r is the value named 'issue zero matches r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 233: `logic issue_match_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_match_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 234: `logic [ROW_LANES*8-1:0] issue_match_activation_vector_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_match_activation_vector_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 235: `logic [COLUMN_LANES*8-1:0] issue_match_outer_weight_vector_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_match_outer_weight_vector_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 236: `logic [COLUMN_LANES*ROW_LANES*8-1:0] issue_match_dot_weight_vector_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_match_dot_weight_vector_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 237: `logic [7:0] issue_zero_matches_comb;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_zero_matches_comb is the value named 'issue zero matches comb' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 239: `function automatic logic [3:0] popcount8(input logic [7:0] value);` Within the combinational helper popcount8, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; popcount8: the value named 'popcount8' in this block.

Line 240: `logic [1:0] pair0;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, pair0 is the value named 'pair0' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 241: `logic [1:0] pair1;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, pair1 is the value named 'pair1' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 242: `logic [1:0] pair2;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, pair2 is the value named 'pair2' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 243: `logic [1:0] pair3;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, pair3 is the value named 'pair3' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 244: `logic [2:0] half0;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, half0 is the value named 'half0' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 245: `logic [2:0] half1;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, half1 is the value named 'half1' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 246: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper popcount8; it has no arithmetic value of its own.

Line 247: `pair0 = value[0] + value[1];` This makes pair0, the value named 'pair0' in this block, equal to 'value[0] + value[1]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper popcount8.

Line 248: `pair1 = value[2] + value[3];` This makes pair1, the value named 'pair1' in this block, equal to 'value[2] + value[3]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper popcount8.

Line 249: `pair2 = value[4] + value[5];` This makes pair2, the value named 'pair2' in this block, equal to 'value[4] + value[5]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper popcount8.

Line 250: `pair3 = value[6] + value[7];` This makes pair3, the value named 'pair3' in this block, equal to 'value[6] + value[7]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper popcount8.

Line 251: `half0 = pair0 + pair1;` This makes half0, the value named 'half0' in this block, equal to 'pair0 + pair1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are pair0: the value named 'pair0' in this block; pair1: the value named 'pair1' in this block. Context: the combinational helper popcount8.

Line 252: `half1 = pair2 + pair3;` This makes half1, the value named 'half1' in this block, equal to 'pair2 + pair3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are pair2: the value named 'pair2' in this block; pair3: the value named 'pair3' in this block. Context: the combinational helper popcount8.

Line 253: `popcount8 = half0 + half1;` This makes popcount8, the value named 'popcount8' in this block, equal to 'half0 + half1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are half0: the value named 'half0' in this block; half1: the value named 'half1' in this block. Context: the combinational helper popcount8.

Line 254: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper popcount8; it has no arithmetic value of its own.

Line 255: `endfunction` Within the combinational helper popcount8, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are endfunction: the value named 'endfunction' in this block.

Line 256: `(* dont_touch = "yes" *) logic classify_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; classify_valid_r: the producer's statement that its current payload is meaningful.

Line 257: `(* dont_touch = "yes" *) logic classify_is_zero_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; classify_is_zero_r: the value named 'classify is zero r' in this block.

Line 258: `logic classify_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, classify_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 259: `logic [ROW_LANES*8-1:0] classify_activation_vector_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, classify_activation_vector_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 260: `logic [COLUMN_LANES*8-1:0] classify_outer_weight_vector_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, classify_outer_weight_vector_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 261: `logic [COLUMN_LANES*ROW_LANES*8-1:0] classify_dot_weight_vector_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, classify_dot_weight_vector_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 262: `logic dense_issue_enable;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dense_issue_enable is a control bit that permits the associated state or storage update. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 263: `(* dont_touch = "yes" *) logic dense_issue_enable_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; dense_issue_enable_r: a control bit that permits the associated state or storage update.

Line 264: `logic [ROW_LANES*8-1:0] dense_activation_vector_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dense_activation_vector_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 265: `logic [7:0] dense_weight_lo_r [0:ROW_LANES-1][0:COLUMN_PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dense_weight_lo_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 266: `logic [7:0] dense_weight_hi_r [0:ROW_LANES-1][0:COLUMN_PAIRS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dense_weight_hi_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 267: `logic dense_outer_tag0_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dense_outer_tag0_r is the value named 'dense outer tag0 r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 268: `logic dense_outer_tag1_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dense_outer_tag1_r is the value named 'dense outer tag1 r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 269: `logic dense_outer_tag2_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dense_outer_tag2_r is the value named 'dense outer tag2 r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 270: `logic sparse_prepare_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sparse_prepare_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 271: `logic [ROW_LANES-1:0] sparse_prepare_active_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sparse_prepare_active_r is the value named 'sparse prepare active r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 272: `logic [ROW_LANES-1:0] sparse_prepare_negative_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sparse_prepare_negative_r is the value named 'sparse prepare negative r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 273: `logic [COLUMN_LANES*8-1:0] sparse_prepare_weight_vector_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sparse_prepare_weight_vector_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 274: `(* dont_touch = "yes" *) logic sparse_delta_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; sparse_delta_valid_r: the producer's statement that its current payload is meaningful.

Line 275: `logic signed [8:0] sparse_delta_r [0:ROW_LANES-1][0:COLUMN_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sparse_delta_r is the value named 'sparse delta r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 276: `wire dense_product_valid = mac_product_valid[0][0];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dense_product_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 277: `wire dense_accumulate_valid = dense_outer_tag2_r || dot_sum_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dense_accumulate_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 279: `function automatic logic [15:0] sum_u8x8(input logic [63:0] values);` Within the combinational helper sum u8x8, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; sum_u8x8: the value named 'sum u8x8' in this block.

Line 280: `logic [8:0] pair0;` This declares hardware signal storage or wiring in the combinational helper sum u8x8. Specifically, pair0 is the value named 'pair0' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 281: `logic [8:0] pair1;` This declares hardware signal storage or wiring in the combinational helper sum u8x8. Specifically, pair1 is the value named 'pair1' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 282: `logic [8:0] pair2;` This declares hardware signal storage or wiring in the combinational helper sum u8x8. Specifically, pair2 is the value named 'pair2' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 283: `logic [8:0] pair3;` This declares hardware signal storage or wiring in the combinational helper sum u8x8. Specifically, pair3 is the value named 'pair3' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 284: `logic [9:0] half0;` This declares hardware signal storage or wiring in the combinational helper sum u8x8. Specifically, half0 is the value named 'half0' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 285: `logic [9:0] half1;` This declares hardware signal storage or wiring in the combinational helper sum u8x8. Specifically, half1 is the value named 'half1' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 286: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper sum u8x8; it has no arithmetic value of its own.

Line 287: `pair0 = values[7:0] + values[15:8];` This makes pair0, the value named 'pair0' in this block, equal to 'values[7:0] + values[15:8]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are values: the value named 'values' in this block. Context: the combinational helper sum u8x8.

Line 288: `pair1 = values[23:16] + values[31:24];` This makes pair1, the value named 'pair1' in this block, equal to 'values[23:16] + values[31:24]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are values: the value named 'values' in this block. Context: the combinational helper sum u8x8.

Line 289: `pair2 = values[39:32] + values[47:40];` This makes pair2, the value named 'pair2' in this block, equal to 'values[39:32] + values[47:40]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are values: the value named 'values' in this block. Context: the combinational helper sum u8x8.

Line 290: `pair3 = values[55:48] + values[63:56];` This makes pair3, the value named 'pair3' in this block, equal to 'values[55:48] + values[63:56]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are values: the value named 'values' in this block. Context: the combinational helper sum u8x8.

Line 291: `half0 = pair0 + pair1;` This makes half0, the value named 'half0' in this block, equal to 'pair0 + pair1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are pair0: the value named 'pair0' in this block; pair1: the value named 'pair1' in this block. Context: the combinational helper sum u8x8.

Line 292: `half1 = pair2 + pair3;` This makes half1, the value named 'half1' in this block, equal to 'pair2 + pair3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are pair2: the value named 'pair2' in this block; pair3: the value named 'pair3' in this block. Context: the combinational helper sum u8x8.

Line 293: `sum_u8x8 = {6'd0, half0} + {6'd0, half1};` This makes sum_u8x8, the value named 'sum u8x8' in this block, equal to '{6'd0, half0} + {6'd0, half1}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block; half0: the value named 'half0' in this block; half1: the value named 'half1' in this block. Context: the combinational helper sum u8x8.

Line 294: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper sum u8x8; it has no arithmetic value of its own.

Line 295: `endfunction` Within the combinational helper sum u8x8, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are endfunction: the value named 'endfunction' in this block.

Line 297: `function automatic logic [19:0] sum_u16x8(` Within the combinational helper sum u16x8, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; sum_u16x8: the value named 'sum u16x8' in this block.

Line 298: `input logic [15:0] value0,` This declares value0 as a input port with width [15:0]. It carries the value named 'value0' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 299: `input logic [15:0] value1,` This declares value1 as a input port with width [15:0]. It carries the value named 'value1' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 300: `input logic [15:0] value2,` This declares value2 as a input port with width [15:0]. It carries the value named 'value2' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 301: `input logic [15:0] value3,` This declares value3 as a input port with width [15:0]. It carries the value named 'value3' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 302: `input logic [15:0] value4,` This declares value4 as a input port with width [15:0]. It carries the value named 'value4' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 303: `input logic [15:0] value5,` This declares value5 as a input port with width [15:0]. It carries the value named 'value5' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 304: `input logic [15:0] value6,` This declares value6 as a input port with width [15:0]. It carries the value named 'value6' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 305: `input logic [15:0] value7` This declares value7 as a input port with width [15:0]. It carries the value named 'value7' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 306: `);` Within the combinational helper sum u16x8, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The expression is a literal or structural operator and has no hidden software state.

Line 307: `logic [16:0] pair0;` This declares hardware signal storage or wiring in the combinational helper sum u16x8. Specifically, pair0 is the value named 'pair0' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 308: `logic [16:0] pair1;` This declares hardware signal storage or wiring in the combinational helper sum u16x8. Specifically, pair1 is the value named 'pair1' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 309: `logic [16:0] pair2;` This declares hardware signal storage or wiring in the combinational helper sum u16x8. Specifically, pair2 is the value named 'pair2' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 310: `logic [16:0] pair3;` This declares hardware signal storage or wiring in the combinational helper sum u16x8. Specifically, pair3 is the value named 'pair3' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 311: `logic [17:0] half0;` This declares hardware signal storage or wiring in the combinational helper sum u16x8. Specifically, half0 is the value named 'half0' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 312: `logic [17:0] half1;` This declares hardware signal storage or wiring in the combinational helper sum u16x8. Specifically, half1 is the value named 'half1' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 313: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper sum u16x8; it has no arithmetic value of its own.

Line 314: `pair0 = value0 + value1;` This makes pair0, the value named 'pair0' in this block, equal to 'value0 + value1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value0: the value named 'value0' in this block; value1: the value named 'value1' in this block. Context: the combinational helper sum u16x8.

Line 315: `pair1 = value2 + value3;` This makes pair1, the value named 'pair1' in this block, equal to 'value2 + value3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value2: the value named 'value2' in this block; value3: the value named 'value3' in this block. Context: the combinational helper sum u16x8.

Line 316: `pair2 = value4 + value5;` This makes pair2, the value named 'pair2' in this block, equal to 'value4 + value5'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value4: the value named 'value4' in this block; value5: the value named 'value5' in this block. Context: the combinational helper sum u16x8.

Line 317: `pair3 = value6 + value7;` This makes pair3, the value named 'pair3' in this block, equal to 'value6 + value7'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value6: the value named 'value6' in this block; value7: the value named 'value7' in this block. Context: the combinational helper sum u16x8.

Line 318: `half0 = pair0 + pair1;` This makes half0, the value named 'half0' in this block, equal to 'pair0 + pair1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are pair0: the value named 'pair0' in this block; pair1: the value named 'pair1' in this block. Context: the combinational helper sum u16x8.

Line 319: `half1 = pair2 + pair3;` This makes half1, the value named 'half1' in this block, equal to 'pair2 + pair3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are pair2: the value named 'pair2' in this block; pair3: the value named 'pair3' in this block. Context: the combinational helper sum u16x8.

Line 320: `sum_u16x8 = {2'd0, half0} + {2'd0, half1};` This makes sum_u16x8, the value named 'sum u16x8' in this block, equal to '{2'd0, half0} + {2'd0, half1}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block; half0: the value named 'half0' in this block; half1: the value named 'half1' in this block. Context: the combinational helper sum u16x8.

Line 321: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper sum u16x8; it has no arithmetic value of its own.

Line 322: `endfunction` Within the combinational helper sum u16x8, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are endfunction: the value named 'endfunction' in this block.

Line 324: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 325: `for (int lane = 0; lane < ROW_LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 326: `unique case (mode_r)` This starts a multiplexer/state decode selected by ‘mode_r‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 327: `MODE_DENSE_OUTER,` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are MODE_DENSE_OUTER: the value named ’mode dense outer’ in this block.

Line 328: `MODE_DENSE_DOT8: issue_zero_matches_comb[lane] =` This statement continues through source line 329; the explanation uses the complete expression rather than only the first visual fragment. This is the MODE_DENSE_DOT8 case branch, which performs this explicitly named phase. The same-cycle action begins with ‘issue_zero_matches_comb[lane] = activation_vector[lane*8 +: 8] == activation_zp_r;‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state MODE_DENSE_DOT8, the machine performs the named control phase..

Line 329: `activation_vector[lane*8 +: 8] == activation_zp_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 328. Its exact fragment is ‘activation_vector[lane*8 +: 8] == activation_zp_r;‘. The important operands are activation_vector: an input feature value consumed by a neuron or multiply-accumulate operation; lane: one parallel arithmetic element within a vector or tensor datapath; activation_zp_r: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This is the MODE_DENSE_DOT8 case branch, which performs this explicitly named phase. The same-cycle action begins with ‘issue_zero_matches_comb[lane] = activation_vector[lane*8 +: 8] == activation_zp_r;‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state MODE_DENSE_DOT8, the machine performs the named control phase..

Line 330: `MODE_BINARY_WEIGHTED,` Within the combinational process whose outputs respond without waiting for a clock edge Within state MODE_DENSE_DOT8, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are MODE_BINARY_WEIGHTED: a learned coefficient multiplied by an activation.

Line 331: `MODE_TERNARY_WEIGHTED: issue_zero_matches_comb[lane] =` This statement continues through source line 332; the explanation uses the complete expression rather than only the first visual fragment. This is the MODE_TERNARY_WE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘issue_zero_matches_comb[lane] = activation_vector[lane*8 +: 8] == 8’d0;‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state MODE_TERNARY_WEIGHTED, the machine performs the named control phase..

Line 332: `activation_vector[lane*8 +: 8] == 8’d0;` This is continuation line 2 of the 2-line logical statement that begins at source line 331. Its exact fragment is ‘activation_vector[lane*8 +: 8] == 8’d0;‘. The important operands are activation_vector: an input feature value consumed by a neuron or multiply-accumulate operation; lane: one parallel arithmetic element within a vector or tensor datapath; d0: the value named ’d0’ in this block. Read together, the complete operation is: This is the MODE_TERNARY_WEIGHTED case branch, which performs this explicitly named phase. The same-cycle action begins with ‘issue_zero_matches_comb[lane] = activation_vector[lane*8 +: 8] == 8’d0;‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state MODE_TERNARY_WEIGHTED, the machine performs the named control phase..

Line 333: `default: issue_zero_matches_comb[lane] = 1’b1;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘issue_zero_matches_comb[lane] = 1’b1;‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state MODE_TERNARY_WEIGHTED, the machine performs the named control phase..

Line 334: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state MODE_TERNARY_WEIGHTED, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 335: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 336: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 338: `assign issue_accept = issue_valid && issue_ready;` This makes issue_accept, the value named 'issue accept' in this block, equal to 'issue_valid && issue_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_valid: the producer's statement that its current payload is meaningful; issue_ready: the consumer's statement that it can accept a payload this cycle. Context: the module's structural declarations.

Line 339: `assign dense_issue_enable = dense_issue_enable_r;` This makes dense_issue_enable, a control bit that permits the associated state or storage update, equal to 'dense_issue_enable_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are dense_issue_enable_r: a control bit that permits the associated state or storage update. Context: the module's structural declarations.

Line 341: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 342: `for (int lane = 0; lane < ROW_LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 343: `for (int pair_idx = 0; pair_idx < COLUMN_PAIRS; pair_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 344: `mac_activation[lane][pair_idx] =` This statement continues through source line 345; the explanation uses the complete expression rather than only the first visual fragment. This makes mac_activation[lane][pair_idx], an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'dense_activation_vector_r[lane*8 +: 8]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are dense_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 345: `dense_activation_vector_r[lane*8 +: 8];` This is continuation line 2 of the 2-line logical statement that begins at source line 344. Its exact fragment is 'dense_activation_vector_r[lane*8 +: 8];'. The important operands are dense_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes mac_activation[lane][pair_idx], an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'dense_activation_vector_r[lane*8 +: 8]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are dense_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 346: `mac_weight_lo[lane][pair_idx] = dense_weight_lo_r[lane][pair_idx];` This makes mac_weight_lo[lane][pair_ a learned coefficient multiplied by an activation, equal to 'dense_weight_lo_r[lane][pair_idx]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are dense_weight_lo_r: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath; pair_idx: the value named 'pair idx' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 347: `mac_weight_hi[lane][pair_idx] = dense_weight_hi_r[lane][pair_idx];` This makes mac_weight_hi[lane][pair_ a learned coefficient multiplied by an activation, equal to 'dense_weight_hi_r[lane][pair_idx]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are dense_weight_hi_r: a learned coefficient

multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath; pair_idx: the value named 'pair idx' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 348: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 349: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 350: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 352: `for (genvar lane = 0; lane < ROW_LANES; lane++) begin : g_mac_lane` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 353: `for (genvar pair_idx = 0; pair_idx < COLUMN_PAIRS; pair_idx++) begin : g_mac_pair` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 354: `neuraedge_mac2_u8 u_mac2 (` This instantiates module neuraedge_mac2_u8 as u_mac2. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 355: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 356: `.rst_n(rst_n),` This connects the child instance's named port 'rst_n' to parent expression 'rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 357: `.enable(dense_issue_enable),` This connects the child instance's named port 'enable' to parent expression 'dense_issue_enable'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a control bit that permits the associated state or storage update.

Line 358: `.activation(mac_activation[lane][pair_idx]),` This connects the child instance's named port 'activation' to parent expression 'mac_activation[lane][pair_idx]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 359: `.weight_lo(mac_weight_lo[lane][pair_idx]),` This connects the child instance's named port 'weight_lo' to parent expression 'mac_weight_lo[lane][pair_idx]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 360: `.weight_hi(mac_weight_hi[lane][pair_idx]),` This connects the child instance's named port 'weight_hi' to parent expression 'mac_weight_hi[lane][pair_idx]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 361: `.product_valid(mac_product_valid[lane][pair_idx]),` This connects the child instance's named port 'product_valid' to parent expression 'mac_product_valid[lane][pair_idx]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 362: `.product_lo(mac_product_lo[lane][pair_idx]),` This connects the child instance's named port 'product_lo' to parent expression 'mac_product_lo[lane][pair_idx]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'mac product lo' in this block.

Line 363: `.product_hi(mac_product_hi[lane][pair_idx])` This connects the child instance's named port 'product_hi' to parent expression 'mac_product_hi[lane][pair_idx]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'mac product hi' in this block.

Line 364: `);` Within the module's structural declarations, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The expression is a literal or structural operator and has no hidden software state.

Line 365: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 366: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 368: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 369: `issue_ready = (state == ST_RUN) && !input_done_r;` This makes issue_ready, the consumer's statement that it can accept a payload this cycle, equal to '(state == ST_RUN) && !input_done_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_RUN: the value named 'st run' in this block; input_done_r: the value named 'input done r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 370: `busy = (state != ST_IDLE);` This makes busy, the value named 'busy' in this block, equal to '(state != ST_IDLE)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 371: `result_valid = (state == ST_OUTPUT_PIPELINE) && result_stage_valid_r;` This makes result_valid, the producer's statement that its current payload is meaningful, equal to '(state == ST_OUTPUT_PIPELINE) && result_stage_valid_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_OUTPUT_PIPELINE: the value named 'st output pipeline' in this block; result_stage_valid_r: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 372: `result_row = result_stage_payload_r[51:48];` This makes result_row, one output-row position processed by the tensor tile, equal to 'result_stage_payload_r[51:48]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_stage_payload_r: stream data belonging to the current command. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 373: `result_column = result_stage_payload_r[57:52];` This makes result_column, one output-feature position processed in parallel, equal to 'result_stage_payload_r[57:52]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_stage_payload_r: stream data belonging to the current command. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 374: `result_last = result_stage_last_r;` This makes result_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'result_stage_last_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_stage_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 375: `result_value = result_stage_payload_r[47:0];` This makes result_value, the value named 'result value' in this block, equal to 'result_stage_payload_r[47:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_stage_payload_r: stream data belonging to the current command. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 376: `debug_dense_macs = {45'd0, debug_dense_macs_r};` This makes debug_dense_macs, a count of ordinary activation-times-weight operations actually issued, equal to '{45'd0, debug_dense_macs_r}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block; debug_dense_macs_r: a count of ordinary activation-times-weight operations actually issued. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 377: `debug_spike_adds = {45'd0, debug_spike_adds_r};` This makes debug_spike_adds, a binary event produced when a neuron crosses its threshold, equal to '{45'd0, debug_spike_adds_r}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block; debug_spike_adds_r: a binary event produced when a neuron crosses its threshold. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 378: `// The FIFO holds the largest legal tile, so all arithmetic stages can` Design intent: The FIFO holds the largest legal tile, so all arithmetic stages can This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 379: `// advance every cycle regardless of downstream READY.` Design intent: advance every cycle regardless of downstream READY. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 380: `output_pipeline_enable = 1'b1;` This makes output_pipeline_enable, a control bit that permits the associated state or storage update, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 381: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 383: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 384: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 385: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 386: `mode_r <= MODE_DENSE_OUTER;` This makes mode_r, the value named 'mode r' in this block, equal to 'MODE_DENSE_OUTER'. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_DENSE_OUTER: the value named 'mode dense outer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 387: `rows_r <= 4'd1;` This makes rows_r, one output-row position processed by the tensor tile, equal to '4'd1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 388: `active_row_mask_r <= {{(ROW_LANES-1){1'b0}}, 1'b1};` This makes active_row_mask_r, one output-row position processed by the tensor tile, equal to '{{(ROW_LANES-1){1'b0}}, 1'b1}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; b0: the value named 'b0' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 389: `columns_r <= 6'd1;` This makes columns_r, one output-feature position processed in parallel, equal to '6'd1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 390: `activation_zp_r <= 8'd0;` This makes activation_zp_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 391: `weight_zp_r <= 8'd0;` This makes weight_zp_r, a learned coefficient multiplied by an activation, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 392: `config_error <= 1'b0;` This makes config_error, the value named 'config error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 393: `effective_reduction <= 32'd0;` This makes effective_reduction, the value named 'effective reduction' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 394: `mac_issue_count <= 12'd0;` This makes mac_issue_count, an integer count retained for control or measurable telemetry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 395: `mac_retire_count <= 12'd0;` This makes mac_retire_count, an integer count retained for control or measurable telemetry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 396: `target_mac_retires <= 12'd0;` This makes target_mac_retires, the value named 'target mac retires' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 397: `drain_complete_r <= 1'b0;` This makes drain_complete_r, the value named 'drain complete r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 398: `zero_point_product_r <= 16'd0;` This makes zero_point_product_r, the integer code representing real numeric zero in affine quantization, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 399: `zero_restore_reduction_operand_r <= 32'd0;` This makes zero_restore_reduction_operand_r, the value named 'zero restore reduction operand r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 400: `zero_restore_zp_operand_r <= 16'd0;` This makes zero_restore_zp_operand_r, the value named 'zero restore zp operand r' in this block, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 401: `zero_restore_low_product_r <= 32'd0;` This makes zero_restore_low_product_r, the value named 'zero restore low product r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 402: `zero_restore_high_product_r <= 32'd0;` This makes zero_restore_high_product_r, the value named 'zero restore high product r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 403: `zero_restore_low_relay_r <= 32'd0;` This makes zero_restore_low_relay_r, the value named 'zero restore low relay r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 404: `zero_restore_high_relay_r <= 32'd0;` This makes zero_restore_high_relay_r, the value named 'zero restore high relay r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 405: `zero_point_restore_r <= 48'd0;` This makes zero_point_restore_r, the integer code representing real numeric zero in affine quantization, equal to '48'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 406: `launch_total_r <= 8'd0;` This makes launch_total_r, the value named 'launch total r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 407: `launch_remaining_r <= 8'd0;` This makes launch_remaining_r, the value named 'launch remaining r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 408: `launch_rows_remaining_r <= 4'd0;` This makes launch_rows_remaining_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 409: `launch_columns_remaining_r <= 6'd0;` This makes launch_columns_remaining_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 410: `launch_row_r <= 4'd0;` This makes launch_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 411: `launch_column_r <= 6'd0;` This makes launch_column_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 412: `pread_valid_r <= 1'b0;` This makes pread_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 413: `pread_row_sum_r <= 32'd0;` This makes pread_row_sum_r, one output-row position processed by the tensor tile, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 414: `pread_column_sum_r <= 32'd0;` This makes pread_column_sum_r, one output-feature position processed in parallel, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 415: `pread_row_r <= 4'd0;` This makes pread_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 416: `pread_column_r <= 6'd0;` This makes pread_column_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 417: `p0_valid_r <= 1'b0;` This makes p0_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 418: `p0_raw_r <= 64'sd0;` This makes p0_raw_r, the value named 'p0 raw r' in this block, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 419: `p0_row_sum_r <= 32'd0;` This makes p0_row_sum_r, one output-row position processed by the tensor tile, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 420: `p0_column_sum_r <= 32'd0;` This makes p0_column_sum_r, one output-feature position processed in parallel, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 421: `p0_row_zp_low_r <= 8'd0;` This makes p0_row_zp_low_r, one output-row position processed by the tensor tile, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 422: `p0_row_zp_high_r <= 8'd0;` This makes p0_row_zp_high_r, one output-row position processed by the tensor tile, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 423: `p0_column_zp_low_r <= 8'd0;` This makes p0_column_zp_low_r, one output-feature position processed in parallel, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 424: `p0_column_zp_high_r <= 8'd0;` This makes p0_column_zp_high_r, one output-feature position processed in parallel, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 425: `p0_row_r <= 4'd0;` This makes p0_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 426: `p0_column_r <= 6'd0;` This makes p0_column_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 427: `p1_valid_r <= 1'b0;` This makes p1_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 428: `p1_raw_r <= 64'sd0;` This makes p1_raw_r, the value named 'p1 raw r' in this block, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 429: `p1_row_product_low_r <= 24'd0;` This makes p1_row_product_low_r, one output-row position processed by the tensor tile, equal to '24'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 430: `p1_row_product_high_r <= 24'd0;` This makes p1_row_product_high_r, one output-row position processed by the tensor tile, equal to '24'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 431: `p1_column_product_low_r <= 24'd0;` This makes p1_column_product_low_r, one output-feature position processed in parallel, equal to '24'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 432: `p1_column_product_high_r <= 24'd0;` This makes p1_column_product_high_r, one output-feature position processed in parallel, equal to '24'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 433: `p1_row_r <= 4'd0;` This makes p1_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 434: `p1_column_r <= 6'd0;` This makes p1_column_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 435: `p2_valid_r <= 1'b0;` This makes p2_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 436: `p2_raw_r <= 64'sd0;` This makes p2_raw_r, the value named 'p2 raw r' in this block, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 437: `p2_row_correction_r <= 64'sd0;` This makes p2_row_correction_r, one output-row position processed by the tensor tile, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 438: `p2_column_correction_r <= 64'sd0;` This makes p2_column_correction_r, one output-feature position processed in parallel, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 439: `p2_row_r <= 4'd0;` This makes p2_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 440: `p2_column_r <= 6'd0;` This makes p2_column_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 441: `p3_valid_r <= 1'b0;` This makes p3_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 442: `p3_corrected_r <= 64'sd0;` This makes p3_corrected_r, the value named 'p3 corrected r' in this block, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 443: `p3_column_correction_r <= 64'sd0;` This makes p3_column_correction_r, one output-feature position processed in parallel, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 444: `p3_row_r <= 4'd0;` This makes p3_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 445: `p3_column_r <= 6'd0;` This makes p3_column_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 446: `p4_valid_r <= 1'b0;` This makes p4_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 447: `p4_corrected_r <= 64'sd0;` This makes p4_corrected_r, the value named 'p4 corrected r' in this block, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 448: `p4_row_r <= 4'd0;` This makes p4_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 449: `p4_column_r <= 6'd0;` This makes p4_column_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 450: `p5_valid_r <= 1'b0;` This makes p5_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 451: `p5_result_r <= 48'sd0;` This makes p5_result_r, the value named 'p5 result r' in this block, equal to '48'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 452: `p5_row_r <= 4'd0;` This makes p5_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 453: `p5_column_r <= 6'd0;` This makes p5_column_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 454: `result_fifo_count_r <= '0;` This makes result_fifo_count_r, an integer count retained for control or measurable telemetry, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 455: `result_fifo_has_space_r <= 1'b1;` This makes result_fifo_has_space_r, the value named 'result fifo has space r' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 456: `result_fifo_nonempty_r <= 1'b0;` This makes result_fifo_nonempty_r, the value named 'result fifo nonempty r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 457: `result_fifo_write_pointer_r <= '0;` This makes result_fifo_write_pointer_r, the value named 'result fifo write pointer r' in this block, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 458: `result_fifo_read_pointer_r <= '0;` This makes result_fifo_read_pointer_r, the value named 'result fifo read pointer r' in this block, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 459: `result_fifo_last_address_r <= '0;` This makes result_fifo_last_address_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 460: `result_stage_valid_r <= 1'b0;` This makes result_stage_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 461: `result_stage_payload_r <= '0;` This makes result_stage_payload_r, stream data belonging to the current command, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 462: `result_stage_last_r <= 1'b0;` This makes result_stage_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 463: `accumulate_delta_valid_r <= 1'b0;` This makes accumulate_delta_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 464: `debug_accepted_issues <= 32'd0;` This makes debug_accepted_issues, the value named 'debug accepted issues' in this block, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 465: `debug_skipped_issues <= 32'd0;` This makes debug_skipped_issues, the value named 'debug skipped issues' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 466: `debug_retired_issues <= 32'd0;` This makes debug_retired_issues, the value named 'debug retired issues' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 467: `debug_dense_macs_r <= 19'd0;` This makes debug_dense_macs_r, a count of ordinary activation-times-weight operations actually issued, equal to '19'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 468: `debug_spike_adds_r <= 19'd0;` This makes debug_spike_adds_r, a binary event produced when a neuron crosses its threshold, equal to '19'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 469: `metric_increment_r <= 8'd0;` This makes metric_increment_r, the value named 'metric increment r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 470: `metric_increment_valid_r <= 1'b0;` This makes metric_increment_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 471: `sparse_active_count_r <= 4'd0;` This makes sparse_active_count_r, an integer count retained for control or measurable telemetry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 472: `sparse_metric_valid_r <= 1'b0;` This makes sparse_metric_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 473: `dense_macs_per_issue_r <= 8'd0;` This makes dense_macs_per_issue_r, a count of ordinary activation-times-weight operations actually issued, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 474: `dot_sum_valid_r <= 1'b0;` This makes dot_sum_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 475: `dot_pair_valid_r <= 1'b0;` This makes dot_pair_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 476: `dot_half_valid_r <= 1'b0;` This makes dot_half_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 477: `dot8_pair_valid_r <= 1'b0;` This makes dot8_pair_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 478: `dot8_increment_half_valid_r <= 1'b0;` This makes dot8_increment_half_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 479: `sum_update_valid_r <= 1'b0;` This makes sum_update_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 480: `input_done_r <= 1'b0;` This makes input_done_r, the value named 'input done r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 481: `issue_match_valid_r <= 1'b0;` This makes issue_match_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 482: `issue_zero_matches_r <= 8'd0;` This makes issue_zero_matches_r, the value named 'issue zero matches r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 483: `issue_match_last_r <= 1'b0;` This makes issue_match_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 484: `issue_match_activation_vector_r <= '0;` This makes issue_match_activation_vector_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 485: `issue_match_outer_weight_vector_r <= '0;` This makes issue_match_outer_weight_vector_r, a learned coefficient multiplied by an activation, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 486: `issue_match_dot_weight_vector_r <= '0;` This makes issue_match_dot_weight_vector_r, a learned coefficient multiplied by an activation, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 487: `classify_valid_r <= 1'b0;` This makes classify_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 488: `classify_is_zero_r <= 1'b0;` This makes classify_is_zero_r, the value named 'classify is zero r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 489: `classify_last_r <= 1'b0;` This makes classify_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 490: `classify_activation_vector_r <= '0;` This makes classify_activation_vector_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 491: `classify_outer_weight_vector_r <= '0;` This makes classify_outer_weight_vector_r, a learned coefficient multiplied by an activation, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 492: `classify_dot_weight_vector_r <= '0;` This makes classify_dot_weight_vector_r, a learned coefficient multiplied by an activation, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 493: `dense_issue_enable_r <= 1'b0;` This makes dense_issue_enable_r, a control bit that permits the associated state or storage update, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 494: `dense_activation_vector_r <= '0;` This makes dense_activation_vector_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 495: `dense_outer_tag0_r <= 1'b0;` This makes dense_outer_tag0_r, the value named 'dense outer tag0 r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 496: `dense_outer_tag1_r <= 1'b0;` This makes dense_outer_tag1_r, the value named 'dense outer tag1 r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 497: `dense_outer_tag2_r <= 1'b0;` This makes dense_outer_tag2_r, the value named 'dense outer tag2 r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 498: `sparse_prepare_valid_r <= 1'b0;` This makes sparse_prepare_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 499: `sparse_prepare_active_r <= '0;` This makes sparse_prepare_active_r, the value named 'sparse prepare active r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 500: `sparse_prepare_negative_r <= '0;` This makes sparse_prepare_negative_r, the value named 'sparse prepare negative r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 501: `sparse_prepare_weight_vector_r <= '0;` This makes sparse_prepare_weight_vector_r, a learned coefficient multiplied by an activation, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 502: `sparse_delta_valid_r <= 1'b0;` This makes sparse_delta_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 503: `for (int pair_idx = 0; pair_idx < COLUMN_PAIRS; pair_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 504: `dot_sum_lo_r[pair_idx] <= 20'd0;` This makes dot_sum_lo_r[pair_idx], the value named 'dot sum lo r' in this block, equal to '20'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 505: `dot_sum_hi_r[pair_idx] <= 20'd0;` This makes dot_sum_hi_r[pair_idx], the value named 'dot sum hi r' in this block, equal to '20'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 506: `for (int reduce_pair = 0; reduce_pair < 4; reduce_pair++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 507: `dot_pair_lo_r[pair_idx][reduce_pair] <= 17'd0;` This makes dot_pair_lo_r[pair_idx][reduce_pair], the value named 'dot pair lo r' in this block, equal to '17'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 508: `dot_pair_hi_r[pair_idx][reduce_pair] <= 17'd0;` This makes dot_pair_hi_r[pair_idx][reduce_pair], the value named 'dot pair hi r' in this block, equal to '17'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 509: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 510: `for (int reduce_half = 0; reduce_half < 2; reduce_half++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 511: `dot_half_lo_r[pair_idx][reduce_half] <= 18'd0;` This makes dot_half_lo_r[pair_idx][reduce_half], the value named 'dot half lo r' in this block, equal to '18'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 512: `dot_half_hi_r[pair_idx][reduce_half] <= 18'd0;` This makes dot_half_hi_r[pair_idx][reduce_half], the value named 'dot half hi r' in this block, equal to '18'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 513: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 514: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 515: `for (int pair_idx = 0; pair_idx < 4; pair_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 516: `dot8_row_pair_r[pair_idx] <= 9'd0;` This makes dot8_row_pair_r[pair_idx], one output-row position processed by the tensor tile, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 517: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 518: `dot8_row_half_r[0] <= 10'd0;` This makes dot8_row_half_r[0], one output-row position processed by the tensor tile, equal to '10'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 519: `dot8_row_half_r[1] <= 10'd0;` This makes dot8_row_half_r[1], one output-row position processed by the tensor tile, equal to '10'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 520: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 521: `accumulator_clear_row_r[row_idx] <= 1'b0;` This makes accumulator_clear_row_r[row_idx], a widened running sum that prevents intermediate overflow, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 522: `pread_accumulator_by_row_r[row_idx] <= '0;` This makes pread_accumulator_by_row_r[row_idx], a widened running sum that prevents intermediate overflow, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 523: `row_sum[row_idx] <= 32'd0;` This makes row_sum[row_idx], one output-row position processed by the tensor tile, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 524: `row_increment_r[row_idx] <= 16'd0;` This makes row_increment_r[row_idx], one output-row position processed by the tensor tile, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 525: `for (int pair_idx = 0; pair_idx < COLUMN_PAIRS; pair_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 526: `dense_weight_lo_r[row_idx][pair_idx] <= 8'd0;` This makes dense_weight_lo_r[row_idx][pair_idx], a learned coefficient multiplied by an activation, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 527: `dense_weight_hi_r[row_idx][pair_idx] <= 8'd0;` This makes dense_weight_hi_r[row_idx][pair_idx], a learned coefficient multiplied by an activation, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 528: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 529: `for (int column_idx = 0; column_idx < COLUMN_LANES; column_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 530: `accumulator[row_idx][column_idx] <= '0;` This makes accumulator[row_idx][column_idx], a widened running sum that prevents intermediate overflow, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 531: `accumulate_delta_r[row_idx][column_idx] <= 21'sd0;` This makes accumulate_delta_r[row_idx][column_idx], the value named 'accumulate delta r' in this block, equal to '21'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 532: `sparse_delta_r[row_idx][column_idx] <= 9'sd0;` This makes sparse_delta_r[row_idx][column_idx], the value named 'sparse delta r' in this block, equal to '9'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 533: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 534: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 535: `for (int column_idx = 0; column_idx < COLUMN_LANES; column_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 536: `column_sum_clear_r[column_idx] <= 1'b0;` This makes column_sum_clear_r[column_idx], one output-feature position processed in parallel, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 537: `column_sum[column_idx] <= 32'd0;` This makes column_sum[column_idx], one output-feature position processed in parallel, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 538: `column_increment_r[column_idx] <= 16'd0;` This makes column_increment_r[column_idx], one output-feature position processed in parallel, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 539: `for (int pair_idx = 0; pair_idx < 4; pair_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 540: `dot8_column_pair_r[column_idx][pair_idx] <= 9'd0;` This makes dot8_column_pair_r[column_idx][pair_idx], one output-feature position processed in parallel, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 541: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 542: `dot8_column_half_r[column_idx][0] <= 10'd0;` This makes dot8_column_half_r[column_idx][0], one output-feature position processed in parallel, equal to '10'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 543: `dot8_column_half_r[column_idx][1] <= 10'd0;` This makes dot8_column_half_r[column_idx][1], one output-feature position processed in parallel, equal to '10'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 544: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 545: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 546: `if (result_fifo_push) begin` This condition selects the following hardware branch only when ‘result_fifo_push‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_fifo_push: the value named ’result fifo push’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 547: `result_fifo_payload_r[result_fifo_write_pointer_r]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are result_fifo_payload_r: stream data belonging to the current command; result_fifo_write_pointer_r: the value named ’result fifo write pointer r’ in this block.

Line 548: `<= {p5_column_r, p5_row_r, p5_result_r};` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are p5_column_r: one output-feature position processed in parallel; p5_row_r: one output-row position processed by the tensor tile; p5_result_r: the value named ’p5 result r’ in this block.

Line 549: `result_fifo_write_pointer_r <= result_fifo_write_pointer_r + 1'b1;` This makes result_fifo_write_pointer the value named ’result fifo write pointer r’ in this block, equal to ‘result_fifo_write_pointer_r + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_fifo_write_pointer_r: the value named ’result fifo write pointer r’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 550: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 551: `if (result_fifo_pop) begin` This condition selects the following hardware branch only when ‘result_fifo_pop‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_fifo_pop: the value named ’result fifo pop’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 552: `result_stage_payload_r` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are result_stage_payload_r: stream data belonging to the current command.

Line 553: `<= result_fifo_payload_r[result_fifo_read_pointer_r];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are result_fifo_payload_r: stream data belonging to the current command; result_fifo_read_pointer_r: the value named ’result fifo read pointer r’ in this block.

Line 554: `result_stage_last_r` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are result_stage_last_r: the AXI-Stream marker for the final beat of a packet or command payload.

Line 555: `<= result_fifo_read_pointer_r == result_fifo_last_address_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are result_fifo_read_pointer_r: the value named 'result fifo read pointer r' in this block; result_fifo_last_address_r: the AXI-Stream marker for the final beat of a packet or command payload.

Line 556: `result_stage_valid_r <= 1'b1;` This makes result_stage_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 557: `result_fifo_read_pointer_r <= result_fifo_read_pointer_r + 1'b1;` This makes result_fifo_read_pointer_r, the value named 'result fifo read pointer r' in this block, equal to 'result_fifo_read_pointer_r + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_fifo_read_pointer_r: the value named 'result fifo read pointer r' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 558: `end else if (result_stage_pop) begin` This condition selects the following hardware branch only when 'result_stage_pop' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_stage_pop: the value named 'result stage pop' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 559: `result_stage_valid_r <= 1'b0;` This makes result_stage_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 560: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 561: `unique case ({result_fifo_push, result_fifo_pop})` This starts a multiplexer/state decode selected by '{result_fifo_push, result_fifo_pop}'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 562: `2'b10: begin` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are b10: the value named 'b10' in this block.

Line 563: `result_fifo_count_r <= result_fifo_count_r + 1'b1;` This makes result_fifo_count_r, an integer count retained for control or measurable telemetry, equal to 'result_fifo_count_r + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_fifo_count_r: an integer count retained for control or measurable telemetry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 564: `result_fifo_has_space_r` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are result_fifo_has_space_r: the value named 'result fifo has space r' in this block.

Line 565: `<= result_fifo_count_r` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are result_fifo_count_r: an integer count retained for control or measurable telemetry.

Line 566: `< RESULT_FIFO_COUNT_BITS'(RESULT_FIFO_DEPTH - 1);` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are RESULT_FIFO_COUNT_BITS: the value named 'result fifo count bits' in this block; RESULT_FIFO_DEPTH: the value named 'result fifo depth' in this block.

Line 567: `result_fifo_nonempty_r <= 1'b1;` This makes result_fifo_nonempty_r, the value named 'result fifo nonempty r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 568: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 569: `2'b01: begin` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are b01: the value named 'b01' in this block.

Line 570: `result_fifo_count_r <= result_fifo_count_r - 1'b1;` This makes result_fifo_count_r, an integer count retained for control or measurable telemetry, equal to 'result_fifo_count_r - 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_fifo_count_r: an integer count retained for control or measurable telemetry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 571: `result_fifo_has_space_r <= 1'b1;` This makes result_fifo_has_space_r, the value named 'result fifo has space r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 572: `result_fifo_nonempty_r <= result_fifo_count_r != 1;` This makes result_fifo_nonempty_r, the value named 'result fifo nonempty r' in this block, equal to 'result_fifo_count_r != 1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_fifo_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge.

Line 573: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 574: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the clocked process that updates registers only on a rising clock edge.

Line 575: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 577: `// Unconditional products let Vivado absorb these registers into` Design intent: Unconditional products let Vivado absorb these registers into This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 578: `// the DSP48E1 PREG stage. The FSM presents operands one cycle` Design intent: the DSP48E1 PREG stage. The FSM presents operands one cycle This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 579: `// before ST_RESTORE_ADD consumes the registered products.` Design intent: before ST_RESTORE_ADD consumes the registered products. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 580: `zero_restore_low_product_r <=` This statement continues through source line 581; the explanation uses the complete expression rather than only the first visual fragment. This makes zero_restore_low_product_r, the value named 'zero restore low product r' in this block, equal to 'zero_restore_reduction_operand_r[15:0] * zero_restore_zp_operand_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_restore_reduction_operand_r: the value named 'zero restore reduction operand r' in this block; zero_restore_zp_operand_r: the value named 'zero restore zp operand r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 581: `zero_restore_reduction_operand_r[15:0] * zero_restore_zp_operand_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 580. Its exact fragment is 'zero_restore_reduction_operand_r[15:0] * zero_restore_zp_operand_r;'. The important operands are zero_restore_reduction_operand_r: the value named 'zero restore reduction operand r' in this block; zero_restore_zp_operand_r: the value named 'zero restore zp operand r' in this block. Read together, the complete operation is: This makes zero_restore_low_product_r, the value named 'zero restore low product r' in this block, equal to 'zero_restore_reduction_operand_r[15:0] * zero_restore_zp_operand_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_restore_reduction_operand_r: the value named 'zero restore reduction operand r' in this block; zero_restore_zp_operand_r: the value named 'zero restore zp operand r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 582: `zero_restore_high_product_r <=` This statement continues through source line 583; the explanation uses the complete expression rather than only the first visual fragment. This makes zero_restore_high_product_r, the value named 'zero restore high product r' in this block, equal to 'zero_restore_reduction_operand_r[31:16] * zero_restore_zp_operand_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_restore_reduction_operand_r: the value named 'zero restore reduction operand r' in this block; zero_restore_zp_operand_r: the value named 'zero restore zp operand r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 583: `zero_restore_reduction_operand_r[31:16] * zero_restore_zp_operand_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 582. Its exact fragment is 'zero_restore_reduction_operand_r[31:16] * zero_restore_zp_operand_r;'. The important operands are zero_restore_reduction_operand_r: the value named 'zero restore reduction operand r' in this block; zero_restore_zp_operand_r: the value named 'zero restore zp operand r' in this block. Read together, the complete operation is: This makes zero_restore_high_product_r, the value named 'zero restore high product r' in this block, equal to 'zero_restore_reduction_operand_r[31:16] * zero_restore_zp_operand_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_restore_reduction_operand_r: the value named 'zero restore reduction operand r' in this block; zero_restore_zp_operand_r: the value named 'zero restore zp operand r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 584: `// This exact unsigned 8x8 product maps to one DSP48E1 PREG. It` Design intent: This exact unsigned 8x8 product maps to one DSP48E1 PREG. It This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 585: `// replaces four LUT multipliers plus a reconstruction carry chain.` Design intent: replaces four LUT multipliers plus a reconstruction carry chain. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 586: `zero_point_product_r <= activation_zp_r * weight_zp_r;` This makes zero_point_product_r, the integer code representing real numeric zero in affine quantization, equal to 'activation_zp_r * weight_zp_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are activation_zp_r: an input feature value consumed by a neuron or multiply-accumulate operation; weight_zp_r: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 587: `// Dedicated copies have one DSP load each, allowing Vivado to use` Design intent: Dedicated copies have one DSP load each, allowing Vivado to use This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 588: `// the four BREG input stages instead of routing shared zero points.` Design intent: the four BREG input stages instead of routing shared zero points. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 589: `p0_row_zp_low_r <= weight_zp_r;` This makes p0_row_zp_low_r, one output-row position processed by the tensor tile, equal to 'weight_zp_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_zp_r: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 590: `p0_row_zp_high_r <= weight_zp_r;` This makes p0_row_zp_high_r, one output-row position processed by the tensor tile, equal to 'weight_zp_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_zp_r: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 591: `p0_column_zp_low_r <= activation_zp_r;` This makes p0_column_zp_low_r, one output-feature position processed in parallel, equal to 'activation_zp_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are activation_zp_r: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge.

Line 592: `p0_column_zp_high_r <= activation_zp_r;` This makes p0_column_zp_high_r, one output-feature position processed in parallel, equal to 'activation_zp_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are activation_zp_r: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge.

Line 594: `// The corresponding valid bit is the architectural qualifier, so` Design intent: The corresponding valid bit is the architectural qualifier, so This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 595: `// these pre-read registers may sample continuously. Free-running` Design intent: these pre-read registers may sample continuously. Free-running This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 596: `// them removes a 256-register launch_remaining clock-enable tree;` Design intent: them removes a 256-register launch_remaining clock-enable tree; This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 597: `// samples outside ST_OUTPUT_PIPELINE are never consumed.` Design intent: samples outside ST_OUTPUT_P are never consumed. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 598: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 599: `pread_accumulator_by_row_r[row_idx]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are pread_accumulator_by_row_r: a widened running sum that prevents intermediate overflow; row_idx: one output-row position processed by the tensor tile.

Line 600: `<= accumulator[row_idx][launch_column_r[3:0]];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are accumulator: a widened running sum that prevents intermediate overflow; row_idx: one output-row position processed by the tensor tile; launch_column_r: one output-feature position processed in parallel.

Line 601: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 602: `pread_row_sum_r <= row_sum[launch_row_r[2:0]];` This makes pread_row_sum_r, one output-row position processed by the tensor tile, equal to 'row_sum[launch_row_r[2:0]]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are row_sum: one output-row position processed by the tensor tile; launch_row_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge.

Line 603: `pread_column_sum_r <= column_sum[launch_column_r[3:0]];` This makes pread_column_sum_r, one output-feature position processed in parallel, equal to 'column_sum[launch_column_r[3:0]]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are column_sum: one output-feature position processed in parallel; launch_column_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 604: `pread_row_r <= launch_row_r;` This makes pread_row_r, one output-row position processed by the tensor tile, equal to 'launch_row_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are launch_row_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge.

Line 605: `pread_column_r <= launch_column_r;` This makes pread_column_r, one output-feature position processed in parallel, equal to 'launch_column_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are launch_column_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 607: `dense_issue_enable_r <= 1'b0;` This makes dense_issue_enable_r, a control bit that permits the associated state or storage update, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 608: `dense_outer_tag0_r <= dense_issue_enable_r` This statement continues through source line 609; the explanation uses the complete expression rather than only the first visual fragment. This makes dense_outer_tag0_r, the value named 'dense outer tag0 r' in this block, equal to 'dense_issue_enable_r && mode_r == MODE_DENSE_OUTER'. It updates after the active clock edge together with other nonblocking assignments. The important operands are dense_issue_enable_r: a control bit that permits the associated state or storage update; mode_r: the value named 'mode r' in this block; MODE_DENSE_OUTER: the value named 'mode dense outer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 609: `&& mode_r == MODE_DENSE_OUTER;` This is continuation line 2 of the 2-line logical statement that begins at source line 608. Its exact fragment is '&& mode_r == MODE_DENSE_OUTER;'. The important operands are mode_r: the value named 'mode r' in this block; MODE_DENSE_OUTER: the value named 'mode dense outer' in this block. Read together, the complete operation is: This makes dense_outer_tag0_r, the value named 'dense outer tag0 r' in this block, equal to 'dense_issue_enable_r && mode_r == MODE_DENSE_OUTER'. It updates after the active clock edge together with other nonblocking assignments. The important operands are dense_issue_enable_r: a control bit that permits the associated state or storage update; mode_r: the value named 'mode r' in this block; MODE_DENSE_OUTER: the value named 'mode dense outer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 610: `dense_outer_tag1_r <= dense_outer_tag0_r;` This makes dense_outer_tag1_r, the value named 'dense outer tag1 r' in this block, equal to 'dense_outer_tag0_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are dense_outer_tag0_r: the value named 'dense outer tag0 r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 611: `dense_outer_tag2_r <= dense_outer_tag1_r;` This makes dense_outer_tag2_r, the value named 'dense outer tag2 r' in this block, equal to 'dense_outer_tag1_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are dense_outer_tag1_r: the value named 'dense outer tag1 r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 612: `sparse_prepare_valid_r <= 1'b0;` This makes sparse_prepare_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 613: `sparse_delta_valid_r <= 1'b0;` This makes sparse_delta_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 614: `accumulate_delta_valid_r <= 1'b0;` This makes accumulate_delta_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 615: `metric_increment_valid_r <= 1'b0;` This makes metric_increment_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 616: `sparse_metric_valid_r <= 1'b0;` This makes sparse_metric_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 617: `if (metric_increment_valid_r) begin` This condition selects the following hardware branch only when 'metric_increment_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are metric_increment_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 618: `if (mode_r == MODE_DENSE_OUTER || mode_r == MODE_DENSE_DOT8) begin` This condition selects the following hardware branch only when 'mode_r == MODE_DENSE_OUTER || mode_r == MODE_DENSE_DOT8' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are mode_r: the value named 'mode r' in this block; MODE_DENSE_OUTER: the value named 'mode dense outer' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 619: `debug_dense_macs_r <= debug_dense_macs_r` This statement continues through source line 620; the explanation uses the complete expression rather than only the first visual fragment. This makes debug_dense_macs_r, a count of ordinary activation-times-weight operations actually issued, equal to 'debug_dense_macs_r + {11'd0, metric_increment_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are debug_dense_macs_r: a count of ordinary activation-times-weight operations actually issued; d0: the value named 'd0' in this block; metric_increment_r: the value named 'metric increment r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 620: `+ {11'd0, metric_increment_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 619. Its exact fragment is '+ {11'd0, metric_increment_r};'. The important operands are d0: the value named 'd0' in this block; metric_increment_r: the value named 'metric increment r' in this block. Read together, the complete operation is: This makes debug_dense_macs_r, a count of ordinary activation-times-weight operations actually issued, equal to 'debug_dense_macs_r + {11'd0, metric_increment_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are debug_dense_macs_r: a count of ordinary activation-times-weight operations actually issued; d0: the value named 'd0' in this block; metric_increment_r: the value named 'metric increment r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 621: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 622: `debug_spike_adds_r <= debug_spike_adds_r` This statement continues through source line 623; the explanation uses the complete expression rather than only the first visual fragment. This makes debug_spike_adds_r, a binary event produced when a neuron crosses its threshold, equal to 'debug_spike_adds_r + {11'd0, metric_increment_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are debug_spike_adds_r: a binary event produced when a neuron crosses its threshold; d0: the value named 'd0' in this block; metric_increment_r: the value named 'metric increment r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 623: `+ {11'd0, metric_increment_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 622. Its exact fragment is '+ {11'd0, metric_increment_r};'. The important operands are d0: the value named 'd0' in this block; metric_increment_r: the value named 'metric increment r' in this block. Read together, the complete operation is: This makes debug_spike_adds_r, a binary event produced when a neuron crosses its threshold, equal to 'debug_spike_adds_r + {11'd0, metric_increment_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are debug_spike_adds_r: a binary event produced when a neuron crosses its threshold; d0: the value named 'd0' in this block; metric_increment_r: the value named 'metric increment r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 624: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 625: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 626: `if (sparse_metric_valid_r) begin` This condition selects the following hardware branch only when 'sparse_metric_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sparse_metric_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 627: `metric_increment_r <= sparse_active_count_r * columns_r;` This makes metric_increment_r, the value named 'metric increment r' in this block, equal to 'sparse_active_count_r * columns_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sparse_active_count_r: an integer count retained for control or measurable telemetry; columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 628: `metric_increment_valid_r <= 1'b1;` This makes metric_increment_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 629: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 630: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 631: `accumulator_clear_row_r[row_idx] <= 1'b0;` This makes accumulator_clear_row_r[row_idx], a widened running sum that prevents intermediate overflow, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 632: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 633: `for (int column_idx = 0; column_idx < COLUMN_LANES; column_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 634: `column_sum_clear_r[column_idx] <= 1'b0;` This makes column_sum_clear_r[column_idx], one output-feature position processed in parallel, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 635: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 636: `classify_valid_r <= issue_match_valid_r;` This makes classify_valid_r, the producer's statement that its current payload is meaningful, equal to 'issue_match_valid_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_match_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 637: `issue_match_valid_r <= issue_accept;` This makes issue_match_valid_r, the producer's statement that its current payload is meaningful, equal to 'issue_accept'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_accept: the value named 'issue accept' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 638: `// The queue head is stable whenever it is not accepted, so capture` Design intent: The queue head is stable whenever it is not accepted, so capture This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 639: `// its payload unconditionally and use issue_match_valid_r as the` Design intent: its payload unconditionally and use issue_match_valid_r as the This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 640: `// only validity qualifier. This removes issue_accept from the CE` Design intent: only validity qualifier. This removes issue_accept from the CE This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 641: `// pins of 1,216 payload registers without changing pipeline latency.` Design intent: pins of 1,216 payload registers without changing pipeline latency. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 642: `issue_zero_matches_r <= issue_zero_matches_comb;` This makes issue_zero_matches_r, the value named 'issue zero matches r' in this block, equal to 'issue_zero_matches_comb'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_zero_matches_comb: the value named 'issue zero matches comb' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 643: `issue_match_last_r <= issue_last;` This makes issue_match_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'issue_last'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 644: `issue_match_activation_vector_r <= activation_vector;` This makes issue_match_activation_vector_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'activation_vector'. It updates after the active clock edge together with other nonblocking assignments. The important operands are activation_vector: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge.

Line 645: `issue_match_outer_weight_vector_r <= outer_weight_vector;` This makes issue_match_outer_weight_vector_ a learned coefficient multiplied by an activation, equal to 'outer_weight_vector'. It updates after the active clock edge together with other nonblocking assignments. The important operands are outer_weight_vector: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 646: `issue_match_dot_weight_vector_r <= dot_weight_vector;` This makes issue_match_dot_weight_vector_r, a learned coefficient multiplied by an activation, equal to 'dot_weight_vector'. It updates after the active clock edge together with other nonblocking assignments. The important operands are dot_weight_vector: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 647: `if (issue_match_valid_r) begin` This condition selects the following hardware branch only when 'issue_match_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are issue_match_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 648: `classify_is_zero_r <= &issue_zero_matches_r;` This makes classify_is_zero_r, the value named 'classify is zero r' in this block, equal to '&issue_zero_matches_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_zero_matches_r: the value named 'issue zero matches r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 649: `classify_last_r <= issue_match_last_r;` This makes classify_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'issue_match_last_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_match_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 650: `classify_activation_vector_r <= issue_match_activation_vector_r;` This makes classify_activation_vector_ an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'issue_match_activation_vector_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_match_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge.

Line 651: `classify_outer_weight_vector_r <= issue_match_outer_weight_vector_r;` This makes classify_outer_weight_ a learned coefficient multiplied by an activation, equal to 'issue_match_outer_weight_vector_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_match_outer_weight_vector_r: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 652: `classify_dot_weight_vector_r <= issue_match_dot_weight_vector_r;` This makes classify_dot_weight_vector a learned coefficient multiplied by an activation, equal to ‘issue_match_dot_weight_vector_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_match_dot_weight_vector_r: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 653: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 654: `dot8_pair_valid_r <= 1'b0;` This makes dot8_pair_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 655: `dot8_increment_half_valid_r <= 1'b0;` This makes dot8_increment_half_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 656: `dot_pair_valid_r <= dense_product_valid && mode_r == MODE_DENSE_DOT8;` This makes dot_pair_valid_r, the producer's statement that its current payload is meaningful, equal to ‘dense_product_valid && mode_r == MODE_DENSE_DOT8‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are dense_product_valid: the producer's statement that its current payload is meaningful; mode_r: the value named 'mode r' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 657: `dot_half_valid_r <= dot_pair_valid_r;` This makes dot_half_valid_r, the producer's statement that its current payload is meaningful, equal to ‘dot_pair_valid_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are dot_pair_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 658: `dot_sum_valid_r <= dot_half_valid_r;` This makes dot_sum_valid_r, the producer's statement that its current payload is meaningful, equal to ‘dot_half_valid_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are dot_half_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 659: `sum_update_valid_r <= 1'b0;` This makes sum_update_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 660: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 661: `if (accumulator_clear_row_r[row_idx]) begin` This condition selects the following hardware branch only when ‘accumulator_clear_row_r[row_idx]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are accumulator_clear_row_r: a widened running sum that prevents intermediate overflow; row_idx: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge.

Line 662: `row_sum[row_idx] <= 32'd0;` This makes row_sum[row_idx], one output-row position processed by the tensor tile, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 663: `end else if (sum_update_valid_r) begin` This condition selects the following hardware branch only when 'sum_update_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sum_update_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 664: `row_sum[row_idx] <= row_sum[row_idx]` This statement continues through source line 665; the explanation uses the complete expression rather than only the first visual fragment. This makes row_sum[row_idx], one output-row position processed by the tensor tile, equal to 'row_sum[row_idx] + {16'd0, row_increment_r[row_idx]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are row_sum: one output-row position processed by the tensor tile; row_idx: one output-row position processed by the tensor tile; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 665: `+ {16'd0, row_increment_r[row_idx]};` This is continuation line 2 of the 2-line logical statement that begins at source line 664. Its exact fragment is '+ {16'd0, row_increment_r[row_idx]};'. The important operands are d0: the value named 'd0' in this block; row_increment_r: one output-row position processed by the tensor tile; row_idx: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes row_sum[row_idx], one output-row position processed by the tensor tile, equal to 'row_sum[row_idx] + {16'd0, row_increment_r[row_idx]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are row_sum: one output-row position processed by the tensor tile; row_idx: one output-row position processed by the tensor tile; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 666: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 667: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 668: `for (int column_idx = 0; column_idx < COLUMN_LANES; column_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 669: `if (column_sum_clear_r[column_idx]) begin` This condition selects the following hardware branch only when 'column_sum_clear_r[column_idx]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are column_sum_clear_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 670: `column_sum[column_idx] <= 32'd0;` This makes column_sum[column_idx], one output-feature position processed in parallel, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 671: `end else if (sum_update_valid_r) begin` This condition selects the following hardware branch only when 'sum_update_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sum_update_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 672: `column_sum[column_idx] <= column_sum[column_idx]` This statement continues through source line 673; the explanation uses the complete expression rather than only the first visual fragment. This makes column_sum[column_idx], one output-feature position processed in parallel, equal to ‘column_sum[column_idx] + {16’d0, column_increment_r[column_idx]}‘ It updates after the active clock edge together with other nonblocking assignments. The important operands are column_sum: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel; d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Read together, the complete operation is: This makes dot8_column_half_r[column_idx][0], one output-feature position processed in parallel, equal to ‘dot8_column_pair_r[column_idx][0] + dot8_column_pair_r[column_idx][1
It updates after the active clock edge together with other nonblocking assignments. The important operands are dot8_column_pair_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 683: `+ dot8_column_pair_r[column_idx][1];` This is continuation line 3 of the 3-line logical statement that begins at source line 681. Its exact fragment is ‘+ dot8_column_pair_r[column_idx][1];‘. The important operands are dot8_column_pair_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel. Read together, the complete operation is: This makes dot8_column_half_r[column_idx][0], one output-feature position processed in parallel, equal to ‘dot8_column_pair_r[column_idx][0] + dot8_column_pair_r[column_idx][1
It updates after the active clock edge together with other nonblocking assignments. The important operands are dot8_column_pair_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 684: `dot8_column_half_r[column_idx][1] <=` This statement continues through source line 686; the explanation uses the complete expression rather than only the first visual fragment. This makes dot8_column_half_r[column_idx][1], one output-feature position processed in parallel, equal to ‘dot8_column_pair_r[column_idx][2] + dot8_column_pair_r[column_id
It updates after the active clock edge together with other nonblocking assignments. The important operands are dot8_column_pair_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 685: `dot8_column_pair_r[column_idx][2]` This is continuation line 2 of the 3-line logical statement that begins at source line 684. Its exact fragment is ‘dot8_column_pair_r[column_idx][2]‘. The important operands are dot8_column_pair_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel. Read together, the complete operation is: This makes dot8_column_half_r[column_idx][1], one output-feature position processed in parallel, equal to ‘dot8_column_pair_r[column_idx][2] + dot8_column_pair_r[column_idx][3
It updates after the active clock edge together with other nonblocking assignments. The important operands are dot8_column_pair_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 686: `+ dot8_column_pair_r[column_idx][3];` This is continuation line 3 of the 3-line logical statement that begins at source line 684. Its exact fragment is ‘+ dot8_column_pair_r[column_idx][3];‘. The important operands are dot8_column_pair_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel. Read together, the complete operation is: This makes dot8_column_half_r[column_idx][1], one output-feature position processed in parallel, equal to ‘dot8_column_pair_r[column_idx][2] + dot8_column_pair_r[column_idx][3
It updates after the active clock edge together with other nonblocking assignments. The important operands are dot8_column_pair_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 687: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 688: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 689: `if (dot8_increment_half_valid_r) begin` This condition selects the following hardware branch only when ‘dot8_increment_half_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are dot8_increment_half_valid_r: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 690: `row_increment_r[0] <= {6'd0, dot8_row_half_r[0]}` This statement continues through source line 691; the explanation uses the complete expression rather than only the first visual fragment. This makes row_increment_r[0], one output-row position processed by the tensor tile, equal to '{6'd0, dot8_row_half_r[0]} + {6'd0, dot8_row_half_r[1]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; dot8_row_half_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge.

Line 691: `+ {6'd0, dot8_row_half_r[1]};` This is continuation line 2 of the 2-line logical statement that begins at source line 690. Its exact fragment is '+ {6'd0, dot8_row_half_r[1]};'. The important operands are d0: the value named 'd0' in this block; dot8_row_half_r: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes row_increment_r[0], one output-row position processed by the tensor tile, equal to '{6'd0, dot8_row_half_r[0]} + {6'd0, dot8_row_half_r[1]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; dot8_row_half_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge.

Line 692: `for (int row_idx = 1; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 693: `row_increment_r[row_idx] <= 16'd0;` This makes row_increment_r[row_idx], one output-row position processed by the tensor tile, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 694: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 695: `for (int column_idx = 0; column_idx < COLUMN_LANES; column_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 696: `column_increment_r[column_idx]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are column_increment_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel.

Line 697: `<= {6'd0, dot8_column_half_r[column_idx][0]}` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are d0: the value named 'd0' in this block; dot8_column_half_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel.

Line 698: `+ {6'd0, dot8_column_half_r[column_idx][1]};` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are d0: the value named 'd0' in this block; dot8_column_half_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel.

Line 699: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 700: `sum_update_valid_r <= 1'b1;` This makes sum_update_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 701: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 702: `if (dense_product_valid && mode_r == MODE_DENSE_DOT8) begin` This condition selects the following hardware branch only when 'dense_product_valid && mode_r == MODE_DENSE_DOT8' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are dense_product_valid: the producer's statement that its current payload is meaningful; mode_r: the value named 'mode r' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 703: `for (int pair_idx = 0; pair_idx < COLUMN_PAIRS; pair_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 704: `for (int reduce_pair = 0; reduce_pair < 4; reduce_pair++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 705: `dot_pair_lo_r[pair_idx][reduce_pair] <=` This statement continues through source line 707; the explanation uses the complete expression rather than only the first visual fragment. This makes dot_pair_lo_r[pair_idx][reduce_pair], the value named 'dot pair lo r' in this block, equal to 'mac_product_lo[2*reduce_pair][pair_idx] + mac_product_lo[2*reduce_pair+ It updates after the active clock edge together with other nonblocking assignments. The important operands are mac_product_lo: the value named 'mac product lo' in this block; reduce_pair: the value named 'reduce pair' in this block; pair_idx: the value named 'pair idx' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 706: `mac_product_lo[2*reduce_pair][pair_idx]` This is continuation line 2 of the 3-line logical statement that begins at source line 705. Its exact fragment is 'mac_product_lo[2*reduce_pair][pair_idx]'. The important operands are mac_product_lo: the value named 'mac product lo' in this block; reduce_pair: the value named 'reduce pair' in this block; pair_idx: the value named 'pair idx' in this block. Read together, the complete operation is: This makes dot_pair_lo_r[pair_idx][reduce_pair], the value named 'dot pair lo r' in this block, equal to 'mac_product_lo[2*reduce_pair][pair_idx] + mac_product_lo[2*reduce_pair+1][pair_idx]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are mac_product_lo: the value named 'mac product lo' in this block; reduce_pair: the value named 'reduce pair' in this block; pair_idx: the value named 'pair idx' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 707: `+ mac_product_lo[2*reduce_pair+1][pair_idx];` This is continuation line 3 of the 3-line logical statement that begins at source line 705. Its exact fragment is '+ mac_product_lo[2*reduce_pair+1][pair_idx];'. The important operands are mac_product_lo: the value named 'mac product lo' in this block; reduce_pair: the value named 'reduce pair' in this block; pair_idx: the value named 'pair idx' in this block. Read together, the complete operation is: This makes dot_pair_lo_r[pair_idx][reduce_pair], the value named 'dot pair lo r' in this block, equal to 'mac_product_lo[2*reduce_pair][pair_idx] + mac_product_lo[2*reduce_pair+1][pair_idx]'. It updates after the active clock edge together with other nonblocking assignments. Line 732: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 733: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 735: `if (sparse_prepare_valid_r) begin` This condition selects the following hardware branch only when ‘sparse_prepare_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sparse_prepare_valid_r: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 736: `sparse_delta_valid_r <= 1'b1;` This makes sparse_delta_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 737: `sparse_active_count_r <= popcount8(sparse_prepare_active_r);` This makes sparse_active_count_r, an integer count retained for control or measurable telemetry, equal to ‘popcount8(sparse_prepare_active_r)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are popcount8: the value named ’popcount8’ in this block; sparse_prepare_active_r: the value named ’sparse prepare active r’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 738: `sparse_metric_valid_r <= 1'b1;` This makes sparse_metric_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 739: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 740: `for (int column_idx = 0; column_idx < COLUMN_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 741: `column_idx++) begin` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are column_idx: one output-feature position processed in parallel.

Line 742: `logic signed [7:0] signed_weight;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge. Specifically, signed_weight is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 743: `logic signed [8:0] extended_weight;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge. Specifically, extended_weight is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 744: `signed_weight = $signed(sparse_prepare_weight_vector_r[` This statement continues through source line 745; the explanation uses the complete expression rather than only the first visual fragment. This makes signed_weight, a learned coefficient multiplied by an activation, equal to ‘$signed(sparse_prepare_weight_vector_r[column_idx*8 +: 8])‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are sparse_prepare_weight_vector_r: a learned coefficient multiplied by an activation; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 745: `column_idx*8 +: 8]);` This is continuation line 2 of the 2-line logical statement that begins at source line 744. Its exact fragment is ‘column_idx*8 +: 8]);‘. The important operands are column_idx: one output-feature position processed in parallel. Read together, the complete operation is: This makes signed_weight, a learned coefficient multiplied by an activation, equal to ‘$signed(sparse_prepare_weight_vector_r[column_idx*8 +: 8])‘. It is driven by combinational

or procedural logic in the current evaluation. The important operands are sparse_prepare_weight_vector_r: a learned coefficient multiplied by an activation; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 746: `extended_weight = {signed_weight[7], signed_weight};` This makes extended_weight, a learned coefficient multiplied by an activation, equal to '{signed_weight[7], signed_weight}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are signed_weight: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 747: `if (sparse_prepare_active_r[row_idx]) begin` This condition selects the following hardware branch only when 'sparse_prepare_active_r[row_idx]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sparse_prepare_active_r: the value named 'sparse prepare active r' in this block; row_idx: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge.

Line 748: `sparse_delta_r[row_idx][column_idx] <=` This statement continues through source line 750; the explanation uses the complete expression rather than only the first visual fragment. This makes sparse_delta_r[row_idx][column_idx], the value named 'sparse delta r' in this block, equal to 'sparse_prepare_negative_r[row_idx] ? -extended_weight : extended_weight'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sparse_prepare_negative_r: the value named 'sparse prepare negative r' in this block; row_idx: one output-row position processed by the tensor tile; extended_weight: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 749: `sparse_prepare_negative_r[row_idx]` This is continuation line 2 of the 3-line logical statement that begins at source line 748. Its exact fragment is 'sparse_prepare_negative_r[row_idx]'. The important operands are sparse_prepare_negative_r: the value named 'sparse prepare negative r' in this block; row_idx: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes sparse_delta_r[row_idx][column_idx], the value named 'sparse delta r' in this block, equal to 'sparse_prepare_negative_r[row_idx] ? -extended_weight : extended_weight'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sparse_prepare_negative_r: the value named 'sparse prepare negative r' in this block; row_idx: one output-row position processed by the tensor tile; extended_weight: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 750: `? -extended_weight : extended_weight;` This is continuation line 3 of the 3-line logical statement that begins at source line 748. Its exact fragment is '? -extended_weight : extended_weight;'. The important operands are extended_weight: a learned coefficient multiplied by an activation. Read together, the complete operation is: This makes sparse_delta_r[row_idx][column_idx], the value named 'sparse delta r' in this block, equal to 'sparse_prepare_negative_r[row_idx] ? -extended_weight : extended_weight'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sparse_prepare_negative_r: the value named 'sparse prepare negative r' in this block; row_idx: one output-row position processed by the tensor tile; extended_weight: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 751: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 752: `sparse_delta_r[row_idx][column_idx] <= 9'sd0;` This makes sparse_delta_r[row_idx][column_idx], the value named 'sparse delta r' in this block, equal to '9'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 753: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 754: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 755: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 756: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 758: `if (dense_accumulate_valid) begin` This condition selects the following hardware branch only when ‘dense_accumulate_valid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are dense_accumulate_valid: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 759: `mac_retire_count <= mac_retire_count + 1'b1;` This makes mac_retire_count, an integer count retained for control or measurable telemetry, equal to ‘mac_retire_count + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are mac_retire_count: an integer count retained for control or measurable telemetry; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 760: `debug_retired_issues <= debug_retired_issues + 1'b1;` This makes debug_retired_issues, the value named ’debug retired issues’ in this block, equal to ‘debug_retired_issues + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are debug_retired_issues: the value named ’debug retired issues’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 761: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 762: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 763: `for (int column_idx = 0; column_idx < COLUMN_LANES; column_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 764: `if (accumulator_clear_row_r[row_idx]) begin` This condition selects the following hardware branch only when ‘accumulator_clear_row_r[row_idx]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are accumulator_clear_row_r: a widened running sum that prevents intermediate overflow; row_idx: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge.

Line 765: `accumulator[row_idx][column_idx] <= '0;` This makes accumulator[row_idx][column_idx], a widened running sum that prevents intermediate overflow, equal to ‘’0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 766: `end else if (accumulate_delta_valid_r) begin` This condition selects the following hardware branch only when ‘accumulate_delta_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are accumulate_delta_valid_r: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 767: `accumulator[row_idx][column_idx] <=` This statement continues through source line 770; the explanation uses the complete expression rather than only the first visual fragment. This makes accumulator[row_idx][column_idx], a widened running sum that prevents intermediate overflow, equal to 'accumulator[row_idx][column_idx] + {{(ACC_BITS-21){accumulate_delta_r[row_idx][column_idx][20]}}, accumulate_delta_r[row_idx][column_idx]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are accumulator: a widened running sum that prevents intermediate overflow; row_idx: one output-row position processed by the tensor tile; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 768: `accumulator[row_idx][column_idx]` This is continuation line 2 of the 4-line logical statement that begins at source line 767. Its exact fragment is 'accumulator[row_idx][column_idx]'. The important operands are accumulator: a widened running sum that prevents intermediate overflow; row_idx: one output-row position processed by the tensor tile; column_idx: one output-feature position processed in parallel. Read together, the complete operation is: This makes accumulator[row_idx][column_idx], a widened running sum that prevents intermediate overflow, equal to 'accumulator[row_idx][column_idx] + {{(ACC_BITS-21){accumulate_delta_r[row_idx][column_idx][20]}}, accumulate_delta_r[row_idx][column_idx]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are accumulator: a widened running sum that prevents intermediate overflow; row_idx: one output-row position processed by the tensor tile; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 769: `+ {{(ACC_BITS-21){accumulate_delta_r[row_idx][column_idx][20]}},` This is continuation line 3 of the 4-line logical statement that begins at source line 767. Its exact fragment is '+ {{(ACC_BITS-21){accumulate_delta_r[row_idx] The important operands are ACC_BITS: the value named 'acc bits' in this block; accumulate_delta_r: the value named 'accumulate delta r' in this block; row_idx: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes accumulator[row_idx][column_idx], a widened running sum that prevents intermediate overflow, equal to 'accumulator[row_idx][column_idx] + {{(ACC_BITS-21){accumulate_delta_r[row_idx][column_idx][20]}}, accumulate_delta_r[row_idx][column_idx]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are accumulator: a widened running sum that prevents intermediate overflow; row_idx: one output-row position processed by the tensor tile; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 770: `accumulate_delta_r[row_idx][column_idx]};` This is continuation line 4 of the 4-line logical statement that begins at source line 767. Its exact fragment is 'accumulate_delta_r[row_idx][column_idx]};'. The important operands are accumulate_delta_r: the value named 'accumulate delta r' in this block; row_idx: one output-row position processed by the tensor tile; column_idx: one output-feature position processed in parallel. Read together, the complete operation is: This makes accumulator[row_idx][column_idx], a widened running sum that prevents intermediate overflow, equal to 'accumulator[row_idx][column_idx] + {{(ACC_BITS-21){accumulate_delta_r[row_idx][column_idx][20]}}, accumulate_delta_r[row_idx][column_idx]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are accumulator: a widened running sum that prevents intermediate overflow; row_idx: one output-row position processed by the tensor tile; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 771: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 802: `sparse_delta_r[row_idx][column_idx]};` This is continuation line 3 of the 3-line logical statement that begins at source line 800. Its exact fragment is ‘sparse_delta_r[row_idx][column_idx]};‘. The important operands are sparse_delta_r: the value named ’sparse delta r’ in this block; row_idx: one output-row position processed by the tensor tile; column_idx: one output-feature position processed in parallel. Read together, the complete operation is: This makes accumulate_delta_r[row_idx][column_idx], the value named ’accumulate delta r’ in this block, equal to ‘{{12{sparse_delta_r[row_idx][column_idx][8]}}, sparse_delta_r[row_idx][column_idx]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are sparse_delta_r: the value named ’sparse delta r’ in this block; row_idx: one output-row position processed by the tensor tile; column_idx: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge.

Line 803: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 804: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 805: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 807: `unique case (state)` This starts a multiplexer/state decode selected by ‘state‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 808: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 809: `if (start) begin` This condition selects the following hardware branch only when ‘start‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are start: the value named ’start’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 810: `mode_r <= compute_mode;` This makes mode_r, the value named ’mode r’ in this block, equal to ‘compute_mode‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_mode: the value named ’compute mode’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 811: `rows_r <= active_rows;` This makes rows_r, one output-row position processed by the tensor tile, equal to ‘active_rows‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_rows: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 812: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 813: `active_row_mask_r[row_idx] <= row_idx < active_rows;` This makes active_row_mask_r[row_idx], one output-row position processed by the tensor tile, equal to 'row_idx < active_rows'. It updates after the active clock edge together with other nonblocking assignments. The important operands are row_idx: one output-row position processed by the tensor tile; active_rows: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 814: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 815: `columns_r <= active_columns;` This makes columns_r, one output-feature position processed in parallel, equal to 'active_columns'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_columns: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 816: `dense_macs_per_issue_r <= compute_mode == MODE_DENSE_DOT8` This statement continues through source line 820; the explanation uses the complete expression rather than only the first visual fragment. This makes dense_macs_per_issue_ a count of ordinary activation-times-weight operations actually issued, equal to 'compute_mode == MODE_DENSE_DOT8 ? {2'd0, active_columns} * 8'd8 : {4'd0, active_rows} * {2'd0, active_columns}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_mode: the value named 'compute mode' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 817: `? {2'd0, active_columns}` This is continuation line 2 of the 5-line logical statement that begins at source line 816. Its exact fragment is '? {2'd0, active_columns}'. The important operands are d0: the value named 'd0' in this block; active_columns: one output-feature position processed in parallel. Read together, the complete operation is: This makes dense_macs_per_issue_r, a count of ordinary activation-times-weight operations actually issued, equal to 'compute_mode == MODE_DENSE_DOT8 ? {2'd0, active_columns} * 8'd8 : {4'd0, active_rows} * {2'd0, active_columns}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_mode: the value named 'compute mode' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 818: `* 8'd8` This is continuation line 3 of the 5-line logical statement that begins at source line 816. Its exact fragment is '* 8'd8'. The important operands are d8: the value named 'd8' in this block. Read together, the complete operation is: This makes dense_macs_per_issue_r, a count of ordinary activation-times-weight operations actually issued, equal to 'compute_mode == MODE_DENSE_DOT8 ? {2'd0, active_columns} * 8'd8 : {4'd0, active_rows} * {2'd0, active_columns}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_mode: the value named 'compute mode' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 819: `: {4'd0, active_rows}` This is continuation line 4 of the 5-line logical statement that begins at source line 816. Its exact fragment is ': {4'd0, active_rows}'. The important operands are d0: the value named 'd0' in this block; active_rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes dense_macs_per_issue_r, a count of ordinary activation-times-weight operations actually issued, equal to 'compute_mode == MODE_DENSE_DOT8 ? {2'd0, active_columns} * 8'd8 : {4'd0, active_rows} * {2'd0, active_columns}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_mode: the value named 'compute mode' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates reg-

isters only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 820: `* {2'd0, active_columns};` This is continuation line 5 of the 5-line logical statement that begins at source line 816. Its exact fragment is '* {2'd0, active_columns};'. The important operands are d0: the value named 'd0' in this block; active_columns: one output-feature position processed in parallel. Read together, the complete operation is: This makes dense_macs_per_issue_r, a count of ordinary activation-times-weight operations actually issued, equal to 'compute_mode == MODE_DENSE_DOT8 ? {2'd0, active_columns} * 8'd8 : {4'd0, active_rows} * {2'd0, active_columns}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_mode: the value named 'compute mode' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 821: `activation_zp_r <= activation_zero_point;` This makes activation_zp_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'activation_zero_point'. It updates after the active clock edge together with other nonblocking assignments. The important operands are activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 822: `weight_zp_r <= weight_zero_point;` This makes weight_zp_r, a learned coefficient multiplied by an activation, equal to 'weight_zero_point'. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_zero_point: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 823: `config_error <= active_rows == 0` This statement continues through source line 827; the explanation uses the complete expression rather than only the first visual fragment. This makes config_error, the value named 'config error' in this block, equal to 'active_rows == 0 || active_rows > 4'(ROW_LANES) || active_columns == 0 || active_columns > 6'(COLUMN_LANES) || (compute_mode == MODE_DENSE_DOT8 && active_rows != 1)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_rows: one output-row position processed by the tensor tile; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; active_columns: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 824: `|| active_rows > 4'(ROW_LANES)` This is continuation line 2 of the 5-line logical statement that begins at source line 823. Its exact fragment is '|| active_rows > 4'(ROW_LANES)'. The important operands are active_rows: one output-row position processed by the tensor tile; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes config_error, the value named 'config error' in this block, equal to 'active_rows == 0 || active_rows > 4'(ROW_LANES) || active_columns == 0 || active_columns > 6'(COLUMN_LANES) || (compute_mode == MODE_DENSE_DOT8 && active_rows != 1)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_rows: one output-row position processed by the tensor tile; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; active_columns: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 825: `|| active_columns == 0` This is continuation line 3 of the 5-line logical statement that begins at source line 823. Its exact fragment is '|| active_columns == 0'. The important operands are active_columns: one output-feature position processed in parallel. Read together, the complete operation is: This makes config_error, the value named 'config error' in this block, equal to 'active_rows == 0 || active_rows > 4'(ROW_LANES) || active_columns == 0 || active_columns > 6'(COLUMN_LANES) || (compute_mode == MODE_DENSE_DOT8 && active_rows != 1)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_rows: one output-row position processed by the tensor tile; ROW_LANES: one parallel arithmetic element within

a vector or tensor datapath; active_columns: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 826: `|| active_columns > 6'(COLUMN_LANES)` This is continuation line 4 of the 5-line logical statement that begins at source line 823. Its exact fragment is '|| active_columns > 6'(COLUMN_LANES)'. The important operands are active_columns: one output-feature position processed in parallel; COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes config_error, the value named 'config error' in this block, equal to 'active_rows == 0 || active_rows > 4'(ROW_LANES) || active_columns == 0 || active_columns > 6'(COLUMN_LANES) || (compute_mode == MODE_DENSE_DOT8 && active_rows != 1)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_rows: one output-row position processed by the tensor tile; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; active_columns: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 827: `|| (compute_mode == MODE_DENSE_DOT8 && active_rows != 1);` This is continuation line 5 of the 5-line logical statement that begins at source line 823. Its exact fragment is '|| (compute_mode == MODE_DENSE_DOT8 && active_rows != 1);'. The important operands are compute_mode: the value named 'compute mode' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; active_rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes config_error, the value named 'config error' in this block, equal to 'active_rows == 0 || active_rows > 4'(ROW_LANES) || active_columns == 0 || active_columns > 6'(COLUMN_LANES) || (compute_mode == MODE_DENSE_DOT8 && active_rows != 1)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_rows: one output-row position processed by the tensor tile; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; active_columns: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 828: `effective_reduction <= 32'd0;` This makes effective_reduction, the value named 'effective reduction' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 829: `mac_issue_count <= 12'd0;` This makes mac_issue_count, an integer count retained for control or measurable telemetry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 830: `mac_retire_count <= 12'd0;` This makes mac_retire_count, an integer count retained for control or measurable telemetry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 831: `target_mac_retires <= 12'd0;` This makes target_mac_retires, the value named 'target mac retires' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 832: `drain_complete_r <= 1'b0;` This makes drain_complete_r, the value named 'drain complete r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important

operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 833: `zero_restore_reduction_operand_r <= 32'd0;` This makes zero_restore_reduction_operand_r, the value named 'zero restore reduction operand r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 834: `zero_restore_zp_operand_r <= 16'd0;` This makes zero_restore_zp_operand_r, the value named 'zero restore zp operand r' in this block, equal to '16'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 835: `zero_point_restore_r <= 48'd0;` This makes zero_point_restore_r, the integer code representing real numeric zero in affine quantization, equal to '48'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 836: `launch_total_r <= 8'd0;` This makes launch_total_r, the value named 'launch total r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 837: `launch_remaining_r <= 8'd0;` This makes launch_remaining_r, the value named 'launch remaining r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 838: `launch_rows_remaining_r <= 4'd0;` This makes launch_rows_remaining_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 839: `launch_columns_remaining_r <= 6'd0;` This makes launch_columns_remaining_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 840: `launch_row_r <= 4'd0;` This makes launch_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 841: `launch_column_r <= 6'd0;` This makes launch_column_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 842: `pread_valid_r <= 1'b0;` This makes pread_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 843: `p0_valid_r <= 1'b0;` This makes p0_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 844: `p1_valid_r <= 1'b0;` This makes p1_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 845: `p2_valid_r <= 1'b0;` This makes p2_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 846: `p3_valid_r <= 1'b0;` This makes p3_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 847: `p4_valid_r <= 1'b0;` This makes p4_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 848: `p5_valid_r <= 1'b0;` This makes p5_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 849: `result_fifo_count_r <= '0;` This makes result_fifo_count_r, an integer count retained for control or measurable telemetry, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 850: `result_fifo_has_space_r <= 1'b1;` This makes result_fifo_has_space_r, the value named 'result fifo has space r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 851: `result_fifo_nonempty_r <= 1'b0;` This makes result_fifo_nonempty_r, the value named 'result fifo nonempty r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 852: `result_fifo_write_pointer_r <= '0;` This makes result_fifo_write_pointer_r, the value named 'result fifo write pointer r' in this block, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 853: `result_fifo_read_pointer_r <= '0;` This makes result_fifo_read_pointer_r, the value named 'result fifo read pointer r' in this block, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 854: `result_fifo_last_address_r <= '0;` This makes result_fifo_last_address_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 855: `result_stage_valid_r <= 1'b0;` This makes result_stage_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 856: `result_stage_payload_r <= '0;` This makes result_stage_payload_r, stream data belonging to the current command, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 857: `result_stage_last_r <= 1'b0;` This makes result_stage_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 858: `dot_sum_valid_r <= 1'b0;` This makes dot_sum_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 859: `dot_pair_valid_r <= 1'b0;` This makes dot_pair_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 860: `dot_half_valid_r <= 1'b0;` This makes dot_half_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 861: `dot8_pair_valid_r <= 1'b0;` This makes dot8_pair_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 862: `dot8_increment_half_valid_r <= 1'b0;` This makes dot8_increment_half_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 863: `sum_update_valid_r <= 1'b0;` This makes sum_update_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 864: `input_done_r <= 1'b0;` This makes input_done_r, the value named 'input done r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 865: `issue_match_valid_r <= 1'b0;` This makes issue_match_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 866: `issue_zero_matches_r <= 8'd0;` This makes issue_zero_matches_r, the value named 'issue zero matches r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 867: `issue_match_last_r <= 1'b0;` This makes issue_match_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 868: `classify_valid_r <= 1'b0;` This makes classify_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 869: `classify_is_zero_r <= 1'b0;` This makes classify_is_zero_r, the value named 'classify is zero r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 870: `classify_last_r <= 1'b0;` This makes classify_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that

updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 871: `dense_issue_enable_r <= 1'b0;` This makes dense_issue_enable_r, a control bit that permits the associated state or storage update, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 872: `dense_outer_tag0_r <= 1'b0;` This makes dense_outer_tag0_r, the value named ’dense outer tag0 r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 873: `dense_outer_tag1_r <= 1'b0;` This makes dense_outer_tag1_r, the value named ’dense outer tag1 r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 874: `dense_outer_tag2_r <= 1'b0;` This makes dense_outer_tag2_r, the value named ’dense outer tag2 r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 875: `sparse_prepare_valid_r <= 1'b0;` This makes sparse_prepare_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 876: `sparse_delta_valid_r <= 1'b0;` This makes sparse_delta_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 877: `accumulate_delta_valid_r <= 1'b0;` This makes accumulate_delta_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 878: `debug_accepted_issues <= 32'd0;` This makes debug_accepted_issues, the value named ’debug accepted issues’ in this block, equal to ‘32’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 879: `debug_skipped_issues <= 32'd0;` This makes debug_skipped_issues, the value named ’debug skipped issues’ in this block, equal to ‘32’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers

only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 880: `debug_retired_issues <= 32'd0;` This makes debug_retired_issues, the value named 'debug retired issues' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 881: `debug_dense_macs_r <= 19'd0;` This makes debug_dense_macs_r, a count of ordinary activation-times-weight operations actually issued, equal to '19'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 882: `debug_spike_adds_r <= 19'd0;` This makes debug_spike_adds_r, a binary event produced when a neuron crosses its threshold, equal to '19'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 883: `metric_increment_r <= 8'd0;` This makes metric_increment_r, the value named 'metric increment r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 884: `metric_increment_valid_r <= 1'b0;` This makes metric_increment_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 885: `sparse_active_count_r <= 4'd0;` This makes sparse_active_count_r, an integer count retained for control or measurable telemetry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 886: `sparse_metric_valid_r <= 1'b0;` This makes sparse_metric_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 887: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 888: `accumulator_clear_row_r[row_idx] <= 1'b1;` This makes accumulator_clear_row_r[row_idx], a widened running sum that prevents intermediate overflow, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 889: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 890: `for (int column_idx = 0; column_idx < COLUMN_LANES; column_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 891: `column_sum_clear_r[column_idx] <= 1'b1;` This makes column_sum_clear_r[column_idx], one output-feature position processed in parallel, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 892: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 893: `state <= ST_RUN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_RUN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_RUN: the value named 'st run' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 894: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 895: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 897: `ST_RUN: begin` This is the ST_RUN case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 898: `if (classify_valid_r) begin` This condition selects the following hardware branch only when ‘classify_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are classify_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 899: `debug_accepted_issues <= debug_accepted_issues + 1'b1;` This makes debug_accepted_issues, the value named 'debug accepted issues' in this block, equal to ‘debug_accepted_issues + 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are debug_accepted_issues: the value named 'debug accepted issues' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 900: `if (classify_is_zero_r) begin` This condition selects the following hardware branch only when ‘classify_is_zero_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are classify_is_zero_r: the value named 'classify is zero r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 901: `debug_skipped_issues <= debug_skipped_issues + 1'b1;` This makes debug_skipped_issues, the value named 'debug skipped issues' in this block, equal to 'debug_skipped_issues + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are debug_skipped_issues: the value named 'debug skipped issues' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 902: `end else if (mode_r == MODE_DENSE_OUTER) begin` This condition selects the following hardware branch only when 'mode_r == MODE_DENSE_OUTER' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are mode_r: the value named 'mode r' in this block; MODE_DENSE_OUTER: the value named 'mode dense outer' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 903: `dense_issue_enable_r <= 1'b1;` This makes dense_issue_enable_r, a control bit that permits the associated state or storage update, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 904: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 905: `// Inactive rows are never emitted. Computing` Design intent: Inactive rows are never emitted. Computing This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 906: `// them removes active_rows from every DSP input` Design intent: them removes active_rows from every DSP input This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 907: `// mux and is therefore both safe and faster.` Design intent: mux and is therefore both safe and faster. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 908: `dense_activation_vector_r[row_idx*8 +: 8]` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dense_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; row_idx: one output-row position processed by the tensor tile.

Line 909: `<= classify_activation_vector_r[row_idx*8 +: 8];` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; row_idx: one output-row position processed by the tensor tile.

Line 910: `for (int pair_idx = 0; pair_idx < COLUMN_PAIRS;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 911: `pair_idx++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are pair_idx: the value named 'pair idx' in this block.

Line 912: `// Inactive columns are never retired, so` Design intent: Inactive columns are never retired, so This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 913: `// computing them is harmless. Loading all` Design intent: computing them is harmless. Loading all This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 914: `// lanes removes active_columns from every` Design intent: lanes removes active_columns from every This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 915: `// DSP operand mux and shortens the routed` Design intent: DSP operand mux and shortens the routed This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 916: `// data path without changing any result.` Design intent: data path without changing any result. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 917: `dense_weight_lo_r[row_idx][pair_idx]` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dense_weight_lo_r: a learned coefficient multiplied by an activation; row_idx: one output-row position processed by the tensor tile; pair_idx: the value named 'pair idx' in this block.

Line 918: `<= classify_outer_weight_vector_r[` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are classify_outer_weight_vector_r: a learned coefficient multiplied by an activation.

Line 919: `(2*pair_idx)*8 +: 8];` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are pair_idx: the value named 'pair idx' in this block.

Line 920: `dense_weight_hi_r[row_idx][pair_idx]` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dense_weight_hi_r: a learned coefficient multiplied by an activation; row_idx: one output-row position processed by the tensor tile; pair_idx: the value named 'pair idx' in this block.

Line 921: `<= classify_outer_weight_vector_r[` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are classify_outer_weight_vector_r: a learned coefficient multiplied by an activation.

Line 922: `(2*pair_idx+1)*8 +: 8];` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are pair_idx: the value named 'pair idx' in this block.

Line 923: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 924: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 925: `mac_issue_count <= mac_issue_count + 1'b1;` This makes mac_issue_count, an integer count retained for control or measurable telemetry, equal to 'mac_issue_count + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are mac_issue_count: an integer count retained for control or measurable telemetry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 926: `metric_increment_r <= dense_macs_per_issue_r;` This makes metric_increment_r, the value named 'metric increment r' in this block, equal to 'dense_macs_per_issue_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are dense_macs_per_issue_r: a count of ordinary activation-times-weight operations actually issued. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 927: `metric_increment_valid_r <= 1'b1;` This makes metric_increment_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 928: `sum_update_valid_r <= 1'b1;` This makes sum_update_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 929: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 930: `row_increment_r[row_idx]` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are row_increment_r: one output-row position processed by the tensor tile; row_idx: one output-row position processed by the tensor tile.

Line 931: `<= {8'd0, classify_activation_vector_r[row_idx*8 +: 8]};` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are d0: the value named 'd0' in this block; classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; row_idx: one output-row position processed by the tensor tile.

Line 932: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 933: `for (int column_idx = 0; column_idx < COLUMN_LANES; column_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 934: `column_increment_r[column_idx]` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are column_increment_r: one output-feature position processed in parallel; column_idx: one output-feature position processed in parallel.

Line 935: `<= {8'd0, classify_outer_weight_vector_r[column_idx*8 +: 8]};` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are d0: the value named 'd0' in this block; classify_outer_weight_vector_r: a learned coefficient multiplied by an activation; column_idx: one output-feature position processed in parallel.

Line 936: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 937: `end else if (mode_r == MODE_DENSE_DOT8) begin` This condition selects the following hardware branch only when 'mode_r == MODE_DENSE_DOT8' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are mode_r: the value named 'mode r' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 938: `dense_issue_enable_r <= 1'b1;` This makes dense_issue_enable_r, a control bit that permits the associated state or storage update, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 939: `dense_activation_vector_r <= classify_activation_vector_r;` This makes dense_activation_vector_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'classify_activation_vector_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 940: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 941: `for (int pair_idx = 0; pair_idx < COLUMN_PAIRS;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 942: `pair_idx++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are pair_idx: the value named 'pair idx' in this block.

Line 943: `dense_weight_lo_r[row_idx][pair_idx]` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dense_weight_lo_r: a learned coefficient multiplied by an activation; row_idx: one output-row position processed by the tensor tile; pair_idx: the value named 'pair idx' in this block.

Line 944: `<= classify_dot_weight_vector_r[` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are classify_dot_weight_vector_r: a learned coefficient multiplied by an activation.

Line 945: `((2*pair_idx)*ROW_LANES+row_idx)*8 +: 8];` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are pair_idx: the value named 'pair idx' in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; row_idx: one output-row position processed by the tensor tile.

Line 946: `dense_weight_hi_r[row_idx][pair_idx]` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are dense_weight_hi_r: a learned coefficient multiplied by an activation; row_idx: one output-row position processed by the tensor tile; pair_idx: the value named 'pair idx' in this block.

Line 947: `<= classify_dot_weight_vector_r[` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are classify_dot_weight_vector_r: a learned coefficient multiplied by an activation.

Line 948: `((2*pair_idx+1)*ROW_LANES+row_idx)*8 +: 8];` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are pair_idx: the value named 'pair idx' in this block; ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; row_idx: one output-row position processed by the tensor tile.

Line 949: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 950: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 951: `mac_issue_count <= mac_issue_count + 1'b1;` This makes mac_issue_count, an integer count retained for control or measurable telemetry, equal to 'mac_issue_count + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are mac_issue_count: an integer count retained for control or measurable telemetry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 952: `metric_increment_r <= dense_macs_per_issue_r;` This makes metric_increment_r, the value named 'metric increment r' in this block, equal to 'dense_macs_per_issue_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are dense_macs_per_issue_r: a count of ordinary activation-times-weight operations actually issued. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 953: `metric_increment_valid_r <= 1'b1;` This makes metric_increment_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 954: `dot8_pair_valid_r <= 1'b1;` This makes dot8_pair_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 955: `for (int pair_idx = 0; pair_idx < 4; pair_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 956: `dot8_row_pair_r[pair_idx] <=` This statement continues through source line 958; the explanation uses the complete expression rather than only the first visual fragment. This makes dot8_row_pair_r[pair_idx], one output-row position processed by the tensor tile, equal to 'classify_activation_vector_r[(2*pair_idx)*8 +: 8] + classify_activation_vector_r[(2 +: 8]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; pair_idx: the value named 'pair idx' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 957: `classify_activation_vector_r[(2*pair_idx)*8 +: 8]` This is continuation line 2 of the 3-line logical statement that begins at source line 956. Its exact fragment is 'classify_activation_vector_r[(2*pair_idx)*8 +: 8]'. The important operands are classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; pair_idx: the value named 'pair idx' in this block. Read together, the complete operation is: This makes dot8_row_pair_r[pair_idx], one output-row position processed by the tensor tile, equal to 'classify_activation_vector_r[(2*p +: 8] + classify_activation_vector_r[(2*pair_idx+1)*8 +: 8]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; pair_idx: the value named 'pair idx' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 958: `+ classify_activation_vector_r[(2*pair_idx+1)*8 +: 8];` This is continuation line 3 of the 3-line logical statement that begins at source line 956. Its exact fragment is '+ classify_activation_vector_r[(2*pair_idx+1)*8 +: 8];'. The important operands are classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; pair_idx: the value named 'pair idx' in this block. Read together, the complete operation is: This makes dot8_row_pair_r[pair_idx], one output-row position processed by the tensor tile, equal to 'classify_activation_vector_r[(2*pair_idx)*8 +: 8] + classify_activation_vector_r[(2*pair_idx+1)*8 +: 8]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; pair_idx: the value named 'pair idx' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 959: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 960: `for (int column_idx = 0; column_idx < COLUMN_LANES; column_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 961: `for (int pair_idx = 0; pair_idx < 4; pair_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 962: `dot8_column_pair_r[column_idx][pair_idx] <=` This statement continues through source line 966; the explanation uses the complete expression rather than only the first visual fragment. This makes dot8_column_pair_r[column_idx][p one output-feature position processed in parallel, equal to ‘classify_dot_weight_vector_r[(column_idx*8+2*pair_idx)*8 +: 8] + classify_dot_weight_vector_r[(column_idx*8+2*pair_idx+1)*8 +: 8]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are classify_dot_weight_vector_r: a learned coefficient multiplied by an activation; column_idx: one output-feature position processed in parallel; pair_idx: the value named ’pair idx’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 963: `classify_dot_weight_vector_r[` This is continuation line 2 of the 5-line logical statement that begins at source line 962. Its exact fragment is ‘classify_dot_weight_vector_r[‘. The important operands are classify_dot_weight_vector_r: a learned coefficient multiplied by an activation. Read together, the complete operation is: This makes dot8_column_pair_r[column_idx][pair_idx], one output-feature position processed in parallel, equal to ‘classify_dot_weight_vector_r[(column_idx*8+2*pair_idx)*8 +: 8] + classify_dot_weight_vector_r[(column_idx*8+2*pair_idx+1)*8 +: 8]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are classify_dot_weight_vector_r: a learned coefficient multiplied by an activation; column_idx: one output-feature position processed in parallel; pair_idx: the value named ’pair idx’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 964: `(column_idx*8+2*pair_idx)*8 +: 8]` This is continuation line 3 of the 5-line logical statement that begins at source line 962. Its exact fragment is ‘(column_idx*8+2*pair_idx)*8 +: 8]‘. The important operands are column_idx: one output-feature position processed in parallel; pair_idx: the value named ’pair idx’ in this block. Read together, the complete operation is: This makes dot8_column_pair_r[column_idx][pair_idx], one output-feature position processed in parallel, equal to ‘classify_dot_weight_vector_r[(column_idx*8+2*pair_idx)*8 +: 8] + classify_dot_weight_vector_r[(column_idx*8+2*pair_idx+1)*8 +: 8]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are classify_dot_weight_vector_r: a learned coefficient multiplied by an activation; column_idx: one output-feature position processed in parallel; pair_idx: the value named ’pair idx’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 965: `+ classify_dot_weight_vector_r[` This is continuation line 4 of the 5-line logical statement that begins at source line 962. Its exact fragment is ‘+ classify_dot_weight_vector_r[‘. The important operands are classify_dot_weight_vector_r: a learned coefficient multiplied by an activation. Read together, the complete operation is: This makes dot8_column_pair_r[column_idx][pair_idx], one output-feature position processed in parallel, equal to ‘classify_dot_weight_vector_r[(column_idx*8+2*pair_idx)*8 +: 8] + classify_dot_weight_vector_r[(column_idx*8+2*pair_idx+1)*8 +: 8]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are classify_dot_weight_vector_r: a learned coefficient multiplied by an activation; column_idx: one output-feature position processed in parallel; pair_idx: the value named ’pair idx’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 966: `(column_idx*8+2*pair_idx+1)*8 +: 8];` This is continuation line 5 of the 5-line logical statement that begins at source line 962. Its exact fragment is ‘(column_idx*8+2*pair_idx+1)*8 +: 8];‘. The important operands are column_idx: one output-feature position processed in parallel; pair_idx: the value named ’pair idx’ in this block. Read together, the complete operation is: This makes dot8_column_pair_r[column_idx][pair_idx], one output-feature position processed in parallel, equal to ‘classify_dot_weight_vector_r[(column_idx*8+2*pair_idx)*8 +: 8] + classify_dot_weight_vector_r[(column_idx*8+2*pair_idx+1)*8 +: 8]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are classify_dot_weight_vector_r: a learned coefficient multiplied by an activation; column_idx: one output-feature position processed in parallel; pair_idx: the value named ’pair idx’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 967: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 968: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 969: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 970: `sparse_prepare_valid_r <= 1'b1;` This makes sparse_prepare_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 971: `sparse_prepare_weight_vector_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are sparse_prepare_weight_vector_r: a learned coefficient multiplied by an activation.

Line 972: `<= classify_outer_weight_vector_r;` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are classify_outer_weight_vector_r: a learned coefficient multiplied by an activation.

Line 973: `for (int row_idx = 0; row_idx < ROW_LANES; row_idx++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 974: `logic signed [7:0] spike_value;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.. Specifically, spike_value is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 975: `spike_value = $signed(` This statement continues through source line 976; the explanation uses the complete expression rather than only the first visual fragment. This makes spike_value, a binary event produced when a neuron crosses its threshold, equal to '$signed(classify_activation_vector_r[row_idx*8 +: 8])'. It is driven by combinational or procedural logic in the current evaluation. The important operands are classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; row_idx: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 976: `classify_activation_vector_r[row_idx*8 +: 8]);` This is continuation line 2 of the 2-line logical statement that begins at source line 975. Its exact fragment is 'classify_activation_vector_r[row_idx*8 +: 8]);'. The important operands are classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; row_idx: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes spike_value, a binary event produced when a neuron crosses its threshold, equal to '$signed(classify_activation_vector_r[row_idx*8 +: 8])'. It is driven by combinational or procedural logic in the current evaluation. The important operands are classify_activation_vector_r: an input feature value consumed by a neuron or multiply-accumulate operation; row_idx: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 977: `sparse_prepare_active_r[row_idx]` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important

operands are sparse_prepare_active_r: the value named 'sparse prepare active r' in this block; row_idx: one output-row position processed by the tensor tile.

Line 978: `<= active_row_mask_r[row_idx] && spike_value != 0;` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are active_row_mask_r: one output-row position processed by the tensor tile; row_idx: one output-row position processed by the tensor tile; spike_value: a binary event produced when a neuron crosses its threshold.

Line 979: `sparse_prepare_negative_r[row_idx]` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are sparse_prepare_negative_r: the value named 'sparse prepare negative r' in this block; row_idx: one output-row position processed by the tensor tile.

Line 980: `<= mode_r == MODE_TERNARY_WEIGHTED` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are mode_r: the value named 'mode r' in this block; MODE_TERNARY_WEIGHTED: a learned coefficient multiplied by an activation.

Line 981: `&& spike_value < 0;` Within the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are spike_value: a binary event produced when a neuron crosses its threshold.

Line 982: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 983: `debug_retired_issues <= debug_retired_issues + 1'b1;` This makes debug_retired_issues, the value named 'debug retired issues' in this block, equal to 'debug_retired_issues + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are debug_retired_issues: the value named 'debug retired issues' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 984: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 986: `if (classify_last_r) begin` This condition selects the following hardware branch only when 'classify_last_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are classify_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 987: `launch_row_r <= 4'd0;` This makes launch_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 988: `launch_column_r <= 6'd0;` This makes launch_column_r, one output-feature position processed in parallel, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 989: `pread_valid_r <= 1'b0;` This makes pread_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 990: `p0_valid_r <= 1'b0;` This makes p0_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 991: `p1_valid_r <= 1'b0;` This makes p1_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 992: `p2_valid_r <= 1'b0;` This makes p2_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 993: `p3_valid_r <= 1'b0;` This makes p3_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 994: `p4_valid_r <= 1'b0;` This makes p4_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 995: `p5_valid_r <= 1'b0;` This makes p5_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 996: `if (mode_r == MODE_DENSE_OUTER || mode_r == MODE_DENSE_DOT8) begin` This condition selects the following hardware branch only when 'mode_r == MODE_DENSE_OUTER || mode_r == MODE_DENSE_DOT8' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are mode_r: the value named 'mode r' in this block; MODE_DENSE_OUTER: the value named 'mode dense outer' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 997: `state <= ST_CAPTURE_TARGET;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_CAPTURE_TARGET'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_CAPTURE_TARGET: the value named 'st capture target' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 998: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 999: `state <= ST_SPARSE_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_SPARSE_DRAIN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SPARSE_DRAIN: the value named ’st sparse drain’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 1000: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1001: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1002: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1004: `if (issue_accept) begin` This condition selects the following hardware branch only when ‘issue_accept‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are issue_accept: the value named ’issue accept’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 1005: `if (issue_last) input_done_r <= 1'b1;` This condition selects the following hardware branch only when ‘issue_last‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are issue_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase..

Line 1006: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1007: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1009: `ST_DRAIN: begin` This is the ST_DRAIN case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_DRAIN, the machine performs the named control phase..

Line 1010: `// End the 12-bit equality at one local register before it` Design intent: End the 12-bit equality at one local register before it This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 1011: `// controls the physically replicated state network.` Design intent: controls the physically replicated state network. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 1012: `drain_complete_r <= mac_retire_count == target_mac_retires;` This makes drain_complete_r, the value named 'drain complete r' in this block, equal to 'mac_retire_count == target_mac_retires'. It updates after the active clock edge together with other nonblocking assignments. The important operands are mac_retire_count: an integer count retained for control or measurable telemetry; target_mac_retires: the value named 'target mac retires' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DRAIN, the machine performs the named control phase..

Line 1013: `if (drain_complete_r) begin` This condition selects the following hardware branch only when 'drain_complete_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are drain_complete_r: the value named 'drain complete r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DRAIN, the machine performs the named control phase..

Line 1014: `state <= ST_PREPARE_ZERO_POINT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_PREPARE_ZERO_POINT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PREPARE_ZERO_POINT: the integer code representing real numeric zero in affine quantization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DRAIN, the machine performs the named control phase..

Line 1015: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DRAIN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1016: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DRAIN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1018: `ST_CAPTURE_TARGET: begin` This is the ST_CAPTURE_TARGET case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE_TARGET, the machine performs the named control phase..

Line 1019: `target_mac_retires <= mac_issue_count;` This makes target_mac_retires, the value named 'target mac retires' in this block, equal to 'mac_issue_count'. It updates after the active clock edge together with other nonblocking assignments. The important operands are mac_issue_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE_TARGET, the machine performs the named control phase..

Line 1020: `effective_reduction <= mode_r == MODE_DENSE_DOT8` This statement continues through source line 1022; the explanation uses the complete expression rather than only the first visual fragment. This makes effective_reduction, the value named 'effective reduction' in this block, equal to 'mode_r == MODE_DENSE_DOT8 ? {17'd0, mac_issue_count, 3'd0} : {20'd0, mac_issue_count}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are mode_r: the value named 'mode r' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE_TARGET, the machine performs the named control phase..

Line 1021: `? {17'd0, mac_issue_count, 3'd0}` This is continuation line 2 of the 3-line logical statement that begins at source line 1020. Its exact fragment is '? {17'd0, mac_issue_count, 3'd0}'. The important operands are d0: the value named 'd0' in this block; mac_issue_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This makes effective_reduction, the value named 'effective reduction' in this block, equal to 'mode_r == MODE_DENSE_DOT8 ? {17'd0, mac_issue_count, 3'd0} : {20'd0, mac_issue_count}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are mode_r: the value named 'mode r' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE_TARGET, the machine performs the named control phase..

Line 1022: `: {20'd0, mac_issue_count};` This is continuation line 3 of the 3-line logical statement that begins at source line 1020. Its exact fragment is ': {20'd0, mac_issue_count};'. The important operands are d0: the value named 'd0' in this block; mac_issue_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This makes effective_reduction, the value named 'effective reduction' in this block, equal to 'mode_r == MODE_DENSE_DOT8 ? {17'd0, mac_issue_count, 3'd0} : {20'd0, mac_issue_count}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are mode_r: the value named 'mode r' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE_TARGET, the machine performs the named control phase..

Line 1023: `drain_complete_r <= 1'b0;` This makes drain_complete_r, the value named 'drain complete r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE_TARGET, the machine performs the named control phase..

Line 1024: `state <= ST_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_DRAIN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DRAIN: the value named 'st drain' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE_TARGET, the machine performs the named control phase..

Line 1025: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE_TARGET, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1027: `ST_SPARSE_DRAIN: begin` This is the ST_SPARSE_DRAIN case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SPARSE_DRAIN, the machine performs the named control phase..

Line 1028: `state <= ST_PREPARE_OUTPUT_COUNT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_PREPARE_OUTPUT_COUNT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PREPARE_OUTPUT_COUNT: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SPARSE_DRAIN, the machine performs the named control phase..

Line 1029: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SPARSE_DRAIN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1031: `ST_PREPARE_ZERO_POINT: begin` This is the ST_PREPARE_ZERO_POINT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_PREPARE_ZERO_POINT, the machine performs the named control phase..

Line 1032: `state <= ST_LATCH_ZERO_POINT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LATCH_ZERO_POINT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LATCH_ZERO_POINT: the integer code representing real numeric zero in affine quantization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREPARE_ZERO_POINT, the machine performs the named control phase..

Line 1033: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PREPARE_ZERO_POINT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1035: `ST_LATCH_ZERO_POINT: begin` This is the ST_LATCH_ZERO_POINT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LATCH_ZERO_POINT, the machine performs the named control phase..

Line 1036: `state <= ST_COMBINE_ZERO_POINT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_COMBINE_ZERO_POINT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMBINE_ZERO_POINT: the integer code representing real numeric zero in affine quantization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LATCH_ZERO_POINT, the machine performs the named control phase..

Line 1037: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LATCH_ZERO_POINT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1039: `ST_COMBINE_ZERO_POINT: begin` This is the ST_COMBINE_ZERO_POINT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMBINE_ZERO_POINT, the machine performs the named control phase..

Line 1040: `zero_restore_reduction_operand_r <= effective_reduction;` This makes zero_restore_reduction_operand_r, the value named ’zero restore reduction operand r’ in this block, equal to ‘effective_reduction‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are effective_reduction: the value named ’effective reduction’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMBINE_ZERO_POINT, the machine performs the named control phase..

Line 1041: `zero_restore_zp_operand_r <= zero_point_product_r;` This makes zero_restore_zp_operand_r, the value named ’zero restore zp operand r’ in this block, equal to ‘zero_point_product_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_point_product_r: the integer code representing real numeric zero in affine quantization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMBINE_ZERO_POINT, the machine performs the named control phase..

Line 1042: `state <= ST_RESTORE_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_RESTORE_MULTIPLY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_RESTORE_MULTIPLY: the value named ’st restore multiply’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMBINE_ZERO_POINT, the machine performs the named control phase..

Line 1043: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMBINE_ZERO_POINT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1045: `ST_RESTORE_MULTIPLY: begin` This is the ST_RESTORE_MULTIPLY case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_MULTIPLY, the machine performs the named control phase..

Line 1046: `state <= ST_RESTORE_RELAY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_RESTORE_RELAY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_RESTORE_RELAY: the value named ’st restore relay’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_MULTIPLY, the machine performs the named control phase..

Line 1047: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1049: `ST_RESTORE_RELAY: begin` This is the ST_RESTORE_RELAY case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_RELAY, the machine performs the named control phase..

Line 1050: `// Isolate the two multiplier PREGs from the reconstruction` Design intent: Isolate the two multiplier PREGs from the reconstruction This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 1051: `// adder. Vivado can absorb these registers into the adder's` Design intent: adder. Vivado can absorb these registers into the adder's This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 1052: `// DSP input stage, replacing one DSP-to-DSP combinational` Design intent: DSP input stage, replacing one DSP-to-DSP combinational This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 1053: `// timing path with two independently timed pipeline paths.` Design intent: timing path with two independently timed pipeline paths. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 1054: `zero_restore_low_relay_r <= zero_restore_low_product_r;` This makes zero_restore_low_relay_r, the value named 'zero restore low relay r' in this block, equal to ‘zero_restore_low_product_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_restore_low_product_r: the value named 'zero restore low product r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_RELAY, the machine performs the named control phase..

Line 1055: `zero_restore_high_relay_r <= zero_restore_high_product_r;` This makes zero_restore_high_relay_r, the value named 'zero restore high relay r' in this block, equal to ‘zero_restore_high_product_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_restore_high_product_r: the value named 'zero restore high product r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_RELAY, the machine performs the named control phase..

Line 1056: `state <= ST_RESTORE_ADD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_RESTORE_ADD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_RESTORE_ADD: the value named 'st restore add' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_RELAY, the machine performs the named control phase..

Line 1057: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_RELAY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1059: `ST_RESTORE_ADD: begin` This is the ST_RESTORE_ADD case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_ADD, the machine performs the named control phase..

Line 1060: `zero_point_restore_r <= {16'd0, zero_restore_low_relay_r}` This statement continues through source line 1061; the explanation uses the complete expression rather than only the first visual fragment. This makes zero_point_restore_r, the integer code representing real numeric zero in affine quantization, equal to ‘{16'd0, zero_restore_low_rela + {zero_restore_high_relay_r, 16'd0}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; zero_restore_low_relay_r: the value named 'zero restore low relay r' in this block; zero_restore_high_relay_r: the value named 'zero restore high relay r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_ADD, the machine performs the named control phase..

Line 1061: `+ {zero_restore_high_relay_r, 16'd0};` This is continuation line 2 of the 2-line logical statement that begins at source line 1060. Its exact fragment is '+ {zero_restore_high_relay_r, 16'd0};'. The important operands are zero_restore_high_relay_r: the value named 'zero restore high relay r' in this block; d0: the value named 'd0' in this block. Read together, the complete operation is: This makes zero_point_restore_r, the integer code representing real numeric zero in affine quantization, equal to '{16'd0, zero_restore_low_relay_r} + {zero_restore_high_relay_r, 16'd0}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; zero_restore_low_relay_r: the value named 'zero restore low relay r' in this block; zero_restore_high_relay_r: the value named 'zero restore high relay r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_ADD, the machine performs the named control phase..

Line 1062: `state <= ST_PREPARE_OUTPUT_COUNT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_PREPARE_OUTPUT_COUNT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PREPARE_OUTPUT_COUNT: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_ADD, the machine performs the named control phase..

Line 1063: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_ADD, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1065: `ST_PREPARE_OUTPUT_COUNT: begin` This is the ST_PREPARE_OUTPUT_COUNT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_PREPARE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1066: `launch_total_r <= {2'd0, columns_r};` This makes launch_total_r, the value named 'launch total r' in this block, equal to '{2'd0, columns_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREPARE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1067: `launch_rows_remaining_r <= rows_r;` This makes launch_rows_remaining_r, one output-row position processed by the tensor tile, equal to 'rows_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are rows_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREPARE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1068: `launch_columns_remaining_r <= columns_r;` This makes launch_columns_remaining_r, one output-feature position processed in parallel, equal to 'columns_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREPARE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1069: `state <= ST_ACCUMULATE_OUTPUT_COUNT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_ACCUMULATE_OUTPUT_COUNT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ACCUMULATE_OUTPUT_COUNT: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREPARE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1070: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PREPARE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1072: `ST_ACCUMULATE_OUTPUT_COUNT: begin` This is the ST_ACCUMULATE_OUTPUT_COUNT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1073: `if (launch_rows_remaining_r <= 4'd1) begin` This statement continues through source line 1074; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when 'launch_rows_remaining_r <= 4'd1' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are launch_rows_remaining_r: one output-row position processed by the tensor tile; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1074: `launch_remaining_r <= launch_total_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 1073. Its exact fragment is 'launch_remaining_r <= launch_total_r;'. The important operands are launch_remaining_r: the value named 'launch remaining r' in this block; launch_total_r: the value named 'launch total r' in this block. Read together, the complete operation is: This condition selects the following hardware branch only when 'launch_rows_remaining_r <= 4'd1' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are launch_rows_remaining_r: one output-row position processed by the tensor tile; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1075: `// Output addresses start at zero. Truncation is exact` Design intent: Output addresses start at zero. Truncation is exact This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 1076: `// for the 128-result case: 128 mod 128 minus one is 127.` Design intent: for the 128-result case: 128 mod 128 minus one is 127. This comment anchors the surrounding logic in the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

Line 1077: `result_fifo_last_address_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are result_fifo_last_address_r: the AXI-Stream marker for the final beat of a packet or command payload.

Line 1078: `<= launch_total_r[RESULT_FIFO_ADDRESS_BITS-1:0] - 1'b1;` Within the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array. The important operands are launch_total_r: the value named 'launch total r' in this block; RESULT_FIFO_ADDRESS_BITS: the value named 'result fifo address bits' in this block; b1: the value named 'b1' in this block.

Line 1079: `state <= ST_OUTPUT_PIPELINE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_PIPELINE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_PIPELINE: the value named 'st output pipeline' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1080: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1081: `launch_total_r <= launch_total_r` This statement continues through source line 1082; the explanation uses the complete expression rather than only the first visual fragment. This makes launch_total_r, the value named 'launch total r' in this block, equal to 'launch_total_r + {2'd0, columns_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are launch_total_r: the value named 'launch total r' in this block; d0: the value named 'd0' in this block; columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1082: `+ {2'd0, columns_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 1081. Its exact fragment is '+ {2'd0, columns_r};'. The important operands are d0: the value named 'd0' in this block; columns_r: one output-feature position processed in parallel. Read together, the complete operation is: This makes launch_total_r, the value named 'launch total r' in this block, equal to 'launch_total_r + {2'd0, columns_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are launch_total_r: the value named 'launch total r' in this block; d0: the value named 'd0' in this block; columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1083: `launch_rows_remaining_r <= launch_rows_remaining_r - 1'b1;` This makes launch_rows_remaining_r, one output-row position processed by the tensor tile, equal to 'launch_rows_remaining_r - 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are launch_rows_remaining_r: one output-row position processed by the tensor tile; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure..

Line 1084: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1085: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE_OUTPUT_COUNT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1087: `ST_OUTPUT_PIPELINE: begin` This is the ST_OUTPUT_PIPELINE case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1088: `if (output_pipeline_enable) begin` This condition selects the following hardware branch only when 'output_pipeline_enable' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_pipeline_enable: a control bit that permits the associated state or storage update. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1089: `p5_valid_r <= p4_valid_r;` This makes p5_valid_r, the producer's statement that its current payload is meaningful, equal to 'p4_valid_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p4_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1090: `if (p4_valid_r) begin` This condition selects the following hardware branch only when 'p4_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are p4_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1091: `p5_result_r <= 48'(p4_corrected_r` This statement continues through source line 1092; the explanation uses the complete expression rather than only the first visual fragment. This makes p5_result_r, the value named 'p5 result r' in this block, equal to '48'(p4_corrected_r + $signed({16'd0, zero_point_restore_r}))'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p4_corrected_r: the value named 'p4 corrected r' in this block; d0: the value named 'd0' in this block; zero_point_restore_r: the integer code representing real numeric zero in affine quantization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1092: `+ $signed({16'd0, zero_point_restore_r}));` This is continuation line 2 of the 2-line logical statement that begins at source line 1091. Its exact fragment is '+ $signed({16'd0, zero_point_restore_r}));'. The important operands are d0: the value named 'd0' in this block; zero_point_restore_r: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This makes p5_result_r, the value named 'p5 result r' in this block, equal to '48'(p4_corrected_r + $signed({16'd0, zero_point_restore_r}))'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p4_corrected_r: the value named 'p4 corrected r' in this block; d0: the value named 'd0' in this block; zero_point_restore_r: the integer code representing real numeric zero in affine quantization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1093: `p5_row_r <= p4_row_r;` This makes p5_row_r, one output-row position processed by the tensor tile, equal to 'p4_row_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p4_row_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1094: `p5_column_r <= p4_column_r;` This makes p5_column_r, one output-feature position processed in parallel, equal to 'p4_column_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p4_column_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1095: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1097: `p4_valid_r <= p3_valid_r;` This makes p4_valid_r, the producer's statement that its current payload is meaningful, equal to 'p3_valid_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p3_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1098: `if (p3_valid_r) begin` This condition selects the following hardware branch only when 'p3_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are p3_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1099: `p4_corrected_r <= p3_corrected_r` This statement continues through source line 1100; the explanation uses the complete expression rather than only the first visual fragment. This makes p4_corrected_r, the value named 'p4 corrected r' in this block, equal to 'p3_corrected_r - p3_column_correction_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p3_corrected_r: the value named 'p3 corrected r' in this block; p3_column_correction_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1100: `- p3_column_correction_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 1099. Its exact fragment is '- p3_column_correction_r;'. The important operands are p3_column_correction_r: one output-feature position processed in parallel. Read together, the complete operation is: This makes p4_corrected_r, the value named 'p4 corrected r' in this block, equal to 'p3_corrected_r - p3_column_correction_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p3_corrected_r: the value named 'p3 corrected r' in this block; p3_column_correction_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1101: `p4_row_r <= p3_row_r;` This makes p4_row_r, one output-row position processed by the tensor tile, equal to 'p3_row_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p3_row_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1102: `p4_column_r <= p3_column_r;` This makes p4_column_r, one output-feature position processed in parallel, equal to 'p3_column_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p3_column_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1103: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1105: `p3_valid_r <= p2_valid_r;` This makes p3_valid_r, the producer's statement that its current payload is meaningful, equal to 'p2_valid_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p2_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1106: `if (p2_valid_r) begin` This condition selects the following hardware branch only when 'p2_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are p2_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1107: `p3_corrected_r <= p2_raw_r - p2_row_correction_r;` This makes p3_corrected_r, the value named 'p3 corrected r' in this block, equal to 'p2_raw_r - p2_row_correction_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p2_raw_r: the value named 'p2 raw r' in this block; p2_row_correction_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1108: `p3_column_correction_r <= p2_column_correction_r;` This makes p3_column_correction_r, one output-feature position processed in parallel, equal to 'p2_column_correction_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p2_column_correction_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1109: `p3_row_r <= p2_row_r;` This makes p3_row_r, one output-row position processed by the tensor tile, equal to 'p2_row_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are p2_row_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1110: `p3_column_r <= p2_column_r;` This makes p3_column_r, one output-feature position processed in parallel, equal to ‘p2_column_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are p2_column_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1111: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1113: `p2_valid_r <= p1_valid_r;` This makes p2_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘p1_valid_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are p1_valid_r: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1114: `if (p1_valid_r) begin` This condition selects the following hardware branch only when ‘p1_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are p1_valid_r: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1115: `p2_raw_r <= p1_raw_r;` This makes p2_raw_r, the value named ’p2 raw r’ in this block, equal to ‘p1_raw_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are p1_raw_r: the value named ’p1 raw r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1116: `p2_row_correction_r <= $signed({40'd0,` This statement continues through source line 1118; the explanation uses the complete expression rather than only the first visual fragment. This makes p2_row_correction_r, one output-row position processed by the tensor tile, equal to ‘$signed({40’d0, p1_row_product_low_r}) + $signed({24’d0, p1_row_product_high_r, 16’d0})‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block; p1_row_product_low_r: one output-row position processed by the tensor tile; p1_row_product_high_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1117: `p1_row_product_low_r})` This is continuation line 2 of the 3-line logical statement that begins at source line 1116. Its exact fragment is ‘p1_row_product_low_r})‘. The important operands are p1_row_product_low_r: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes p2_row_correction_r, one output-row position processed by the tensor tile, equal to ‘$signed({40’d0, p1_row_product_low_r}) + $signed({24’d0, p1_row_product_high_r, 16’d0})‘. It updates after the active clock edge together with other nonblocking assignments. Line 1156: `if (launch_columns_remaining_r == 6'd1) begin` This condition selects the following hardware branch only when ‘launch_columns_remaining_r == 6’d1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are launch_columns_remaining_r: one output-feature position processed in parallel; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1157: `launch_columns_remaining_r <= columns_r;` This makes launch_columns_remaining_r, one output-feature position processed in parallel, equal to ‘columns_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1158: `launch_column_r <= 6'd0;` This makes launch_column_r, one output-feature position processed in parallel, equal to ‘6’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1159: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1160: `launch_columns_remaining_r <=` This statement continues through source line 1161; the explanation uses the complete expression rather than only the first visual fragment. This makes launch_columns_remaining_r, one output-feature position processed in parallel, equal to ‘launch_columns_remaining_r - 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are launch_columns_remaining_r: one output-feature position processed in parallel; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1161: `launch_columns_remaining_r - 1'b1;` This is continuation line 2 of the 2-line logical statement that begins at source line 1160. Its exact fragment is ‘launch_columns_remaining_r - 1’b1;‘. The important operands are launch_columns_remaining_r: one output-feature position processed in parallel; b1: the value named ’b1’ in this block. Read together, the complete operation is: This makes launch_columns_remaining_r, one output-feature position processed in parallel, equal to ‘launch_columns_remaining_r - 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are launch_columns_remaining_r: one output-feature position processed in parallel; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1162: `launch_column_r <= launch_column_r + 1'b1;` This makes launch_column_r, one output-feature position processed in parallel, equal to ‘launch_column_r + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are launch_column_r: one output-feature position processed in parallel; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1163: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1164: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1165: `pread_valid_r <= 1'b0;` This makes pread_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1166: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1167: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1168: `if (result_stage_pop && result_stage_last_r) state <= ST_IDLE;` This condition selects the following hardware branch only when 'result_stage_pop && result_stage_last_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_stage_pop: the value named 'result stage pop' in this block; result_stage_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1169: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1171: `default: state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'state <= ST_IDLE;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure..

Line 1172: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_PIPELINE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1173: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 1174: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 1176: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 1177: `if (ROW_LANES != 8) $fatal(1, "neuraedge_tensor_tile currently requires ROW_LANES=8");` This condition selects the following hardware branch only when ‘ROW_LANES != 8) $fatal(1, "neuraedge_tensor_tile currently requires ROW_LANES=8"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are ROW_LANES: one parallel arithmetic element within a vector or tensor datapath; fatal: the value named ’fatal’ in this block; neuraedge_tensor_tile: the value named ’neuraedge tensor tile’ in this block. Context: the module’s structural declarations.

Line 1178: `if (COLUMN_LANES != 16) $fatal(1, "neuraedge_tensor_tile currently requires COLUMN_LANES=16");` This condition selects the following hardware branch only when ‘COLUMN_LANES != 16) $fatal(1, "neuraedge_tensor_tile currently requires COLUMN_LANES=16"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath; fatal: the value named ’fatal’ in this block; neuraedge_tensor_tile: the value named ’neuraedge tensor tile’ in this block. Context: the module’s structural declarations.

Line 1179: `if (COLUMN_LANES % 2 != 0) $fatal(1, "COLUMN_LANES must be even");` This condition selects the following hardware branch only when ‘COLUMN_LANES % 2 != 0) $fatal(1, "COLUMN_LANES must be even"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath; fatal: the value named ’fatal’ in this block; must: the value named ’must’ in this block. Context: the module’s structural declarations.

Line 1180: `if (ACC_BITS < 32 || ACC_BITS > 48) $fatal(1, "ACC_BITS must be in [32,48]");` This condition selects the following hardware branch only when ‘ACC_BITS $<$ 32 || ACC_BITS $>$ 48) $fatal(1, "ACC_BITS must be in [32,48]"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are ACC_BITS: the value named ’acc bits’ in this block; fatal: the value named ’fatal’ in this block; must: the value named ’must’ in this block. Context: the module’s structural declarations.

Line 1181: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 1182: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 1184: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that implements the eight-row by sixteen-column dense, binary, and ternary arithmetic array.

20 rtl/neuraedge_udivider.sv

Role in the complete system: performs deterministic unsigned integer division one quotient bit per cycle.

20.1 Beginner architecture map

Dataflow responsibility A restoring divider shifts one dividend bit into the remainder each cycle, compares/subtracts the divisor, and writes one quotient bit. Divide-by-zero is reported explicitly instead of producing an accidental numeric value.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_udivider into physical nets and primitives. The source declares 6 input-port lines, 5 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_CAPTURE, ST_IDLE, ST_OUTPUT, ST_SHIFT, ST_SUBTRACT, ST_VALIDATE. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates unique as case, end as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

20.3 Line annotations

Line 1: `timescale 1ns / 1ps This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `default_nettype none This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: module neuraedge_udivider #(This opens neuraedge_udivider, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that performs deterministic unsigned integer division one quotient bit per cycle.

Line 5: parameter int NUMERATOR_BITS = 64, This statement continues through source line 19; the explanation uses the complete expression rather than only the first visual fragment. This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 6: parameter int DENOMINATOR_BITS = 32 This is continuation line 2 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'parameter int DENOMINATOR_BITS = 32'. The important operands are parameter: the value named 'parameter' in this block; DENOMINATOR_BITS: the value named 'denominator bits' in this block. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 7:) (This is continuation line 3 of the 15-line logical statement that begins at source line 5. Its exact fragment is ') ('. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 8: input wire clk, This is continuation line 4 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'input wire clk,'. The important operands are input: the value named 'input' in this block; clk: the clock that makes all registers advance together. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 9: `input wire rst_n,` This is continuation line 5 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'input wire rst_n,'. The important operands are input: the value named 'input' in this block; rst_n: the active-low synchronous reset. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 10: `input wire input_valid,` This is continuation line 6 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'input wire input_valid,'. The important operands are input: the value named 'input' in this block; input_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 11: `output logic input_ready,` This is continuation line 7 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'output logic input_ready,'. The important operands are output: the value named 'output' in this block; input_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 12: `input wire [NUMERATOR_BITS-1:0] numerator,` This is continuation line 8 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'input wire [NUMERATOR_BITS-1:0] numerator,'. The important operands are input: the value named 'input' in this block; NUMERATOR_BITS: the value named 'numerator bits' in this block; numerator: the value named 'numerator' in this block. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 13: `input wire [DENOMINATOR_BITS-1:0] denominator,` This is continuation line 9 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'input wire [DENOMINATOR_BITS-1:0] denominator,'. The important operands are input: the value named 'input' in this block; DENOMINATOR_BITS: the value named 'denominator bits' in this block; denominator: the value named 'denominator' in this block. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 14: `output logic output_valid,` This is continuation line 10 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'output logic output_valid,'. The important operands are output: the value named 'output' in this block; output_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready,

output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 15: `input wire output_ready,` This is continuation line 11 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'input wire output_ready,'. The important operands are input: the value named 'input' in this block; output_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 16: `output logic [NUMERATOR_BITS-1:0] quotient,` This is continuation line 12 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'output logic [NUMERATOR_BITS-1:0] quotient,'. The important operands are output: the value named 'output' in this block; NUMERATOR_BITS: the value named 'numerator bits' in this block; quotient: the value named 'quotient' in this block. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 17: `output logic [DENOMINATOR_BITS-1:0] remainder,` This is continuation line 13 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'output logic [DENOMINATOR_BITS-1:0] remainder,'. The important operands are output: the value named 'output' in this block; DENOMINATOR_BITS: the value named 'denominator bits' in this block; remainder: the value named 'remainder' in this block. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 18: `output logic divide_by_zero` This is continuation line 14 of the 15-line logical statement that begins at source line 5. Its exact fragment is 'output logic divide_by_zero'. The important operands are output: the value named 'output' in this block; divide_by_zero: the value named 'divide by zero' in this block. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 19: `);` This is continuation line 15 of the 15-line logical statement that begins at source line 5. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes NUMERATOR_BITS to 64, parameter int DENOMINATOR_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [NUMERATOR_BITS-1:0] numerator, input wire [DENOMINATOR_BITS-1:0] denominator, output logic output_valid, input wire output_ready, output logic [NUMERATOR_BITS-1:0] quotient, output logic [DENOMINATOR_BITS-1:0] remainder, output logic divide_by_zero) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; NUMERATOR_BITS denotes the value named 'numerator bits' in this block.

Line 20: `localparam int INDEX_BITS = $clog2(NUMERATOR_BITS);` This fixes INDEX_BITS to $clog2(NUMERATOR_BITS during elaboration. Vivado uses that constant to shape or simplify the generated circuit; INDEX_BITS denotes an integer selecting one tensor element, lane, bank, or state entry.

Line 22: `typedef enum logic [2:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 23: `ST_IDLE = 3'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 24: `ST_CAPTURE = 3'd1,` This assigns a fixed binary encoding to state ST_CAPTURE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 25: `ST_SHIFT = 3'd2,` This assigns a fixed binary encoding to state ST_SHIFT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 26: `ST_SUBTRACT = 3'd3,` This assigns a fixed binary encoding to state ST_SUBTRACT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 27: `ST_OUTPUT = 3'd4,` This assigns a fixed binary encoding to state ST_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 28: `ST_VALIDATE = 3'd5` This statement continues through source line 29; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_VALIDATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 29: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 28. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_VALIDATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 31: `state_t state;` Within the module's structural declarations, this exact statement contributes to the block that performs deterministic unsigned integer division one quotient bit per cycle. The important operands are state_t: the finite-state-machine phase retained in flip-flops; state: the finite-state-machine phase retained in flip-flops.

Line 32: `logic [NUMERATOR_BITS-1:0] numerator_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, numerator_r is the value named 'numerator r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `logic [DENOMINATOR_BITS-1:0] denominator_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, denominator_r is the value named 'denominator r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `logic [NUMERATOR_BITS-1:0] quotient_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, quotient_r is the value named 'quotient r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 35: `logic [DENOMINATOR_BITS-1:0] remainder_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, remainder_r is the value named 'remainder r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 36: `logic [DENOMINATOR_BITS:0] shifted_remainder_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, shifted_remainder_r is the value named 'shifted remainder r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 37: `(* extract_enable = "no" *) logic [INDEX_BITS-1:0] bit_index;` Within the module's structural declarations, this exact statement contributes to the block that performs deterministic unsigned integer division one quotient bit per cycle. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block; INDEX_BITS: an integer selecting one tensor element, lane, bank, or state entry.

Line 38: `logic denominator_zero_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, denominator_zero_r is the value named 'denominator zero r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 40: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 41: `input_ready = state == ST_IDLE;` This makes input_ready, the consumer's statement that it can accept a payload this cycle, equal to ‘state == ST_IDLE‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 42: `output_valid = state == ST_OUTPUT;` This makes output_valid, the producer's statement that its current payload is meaningful, equal to ‘state == ST_OUTPUT‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_OUTPUT: the value named 'st output' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 43: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 45: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with ‘<=‘ inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 46: `if (!rst_n) begin` This is the reset branch for ‘(!rst_n‘. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 47: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 48: `numerator_r <= '0;` This makes numerator_r, the value named 'numerator r' in this block, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 49: `denominator_r <= '0;` This makes denominator_r, the value named 'denominator r' in this block, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 50: `quotient_r <= '0;` This makes quotient_r, the value named 'quotient r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 51: `remainder_r <= '0;` This makes remainder_r, the value named 'remainder r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 52: `shifted_remainder_r <= '0;` This makes shifted_remainder_r, the value named 'shifted remainder r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 53: `bit_index <= '0;` This makes bit_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 54: `denominator_zero_r <= 1'b0;` This makes denominator_zero_r, the value named 'denominator zero r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 55: `quotient <= '0;` This makes quotient, the value named 'quotient' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 56: `remainder <= '0;` This makes remainder, the value named 'remainder' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 57: `divide_by_zero <= 1'b0;` This makes divide_by_zero, the value named 'divide by zero' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 58: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 59: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 60: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 61: `if (input_valid) begin` This condition selects the following hardware branch only when 'input_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 62: `numerator_r <= numerator;` This makes numerator_r, the value named 'numerator r' in this block, equal to 'numerator'. It updates after the active clock edge together with other nonblocking assignments. The important operands are numerator: the value named 'numerator' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 63: `denominator_r <= denominator;` This makes denominator_r, the value named 'denominator r' in this block, equal to 'denominator'. It updates after the active clock edge together with other nonblocking assignments. The important operands are denominator: the value named 'denominator' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 64: `state <= ST_CAPTURE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_CAPTURE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_CAPTURE: the value named 'st capture' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 65: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 66: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 68: `ST_CAPTURE: begin` This is the ST_CAPTURE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE, the machine performs the named control phase..

Line 69: `denominator_zero_r <= denominator_r == 0;` This makes denominator_zero_r, the value named 'denominator zero r' in this block, equal to 'denominator_r == 0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are denominator_r: the value named 'denominator r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE, the machine performs the named control phase..

Line 70: `divide_by_zero <= denominator_r == 0;` This makes divide_by_zero, the value named 'divide by zero' in this block, equal to 'denominator_r == 0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are denominator_r: the value named 'denominator r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE, the machine performs the named control phase..

Line 71: `quotient_r <= '0;` This makes quotient_r, the value named 'quotient r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE, the machine performs the named control phase..

Line 72: `remainder_r <= '0;` This makes remainder_r, the value named 'remainder r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE, the machine performs the named control phase..

Line 73: `state <= ST_VALIDATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_VALIDATE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VALIDATE: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE, the machine performs the named control phase..

Line 74: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_CAPTURE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 76: `ST_VALIDATE: begin` This is the ST_VALIDATE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 77: `if (denominator_zero_r) begin` This condition selects the following hardware branch only when ‘denominator_zero_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are denominator_zero_r: the value named ’denominator zero r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 78: `quotient <= {NUMERATOR_BITS{1'b1}};` This makes quotient, the value named ’quotient’ in this block, equal to ‘{NUMERATOR_BITS{1’b1}}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are NUMERATOR_BITS: the value named ’numerator bits’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 79: `remainder <= numerator_r[DENOMINATOR_BITS-1:0];` This makes remainder, the value named ’remainder’ in this block, equal to ‘numerator_r[DENOMINATOR_BITS-1:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are numerator_r: the value named ’numerator r’ in this block; DENOMINATOR_BITS: the value named ’denominator bits’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 80: `state <= ST_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT: the value named ’st output’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 81: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 82: `bit_index <= $clog2(NUMERATOR_BITS)'(NUMERATOR_BITS - 1);` This makes bit_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘$clog2(NUMERATOR_BITS)’(NUMERATOR_BITS - 1)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are clog2: the value named ’clog2’ in this block; NUMERATOR_BITS: the value named ’numerator bits’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 83: `state <= ST_SHIFT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_SHIFT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SHIFT: the value named ’st shift’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 84: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 85: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 87: `ST_SHIFT: begin` This is the ST_SHIFT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase..

Line 88: `shifted_remainder_r <= {` This statement continues through source line 91; the explanation uses the complete expression rather than only the first visual fragment. This makes shifted_remainder_r, the value named ’shifted remainder r’ in this block, equal to ‘{ remainder_r, numerator_r[bit_index] }‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are remainder_r: the value named ’remainder r’ in this block; numerator_r: the value named ’numerator r’ in this block; bit_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase..

Line 89: `remainder_r,` This is continuation line 2 of the 4-line logical statement that begins at source line 88. Its exact fragment is ‘remainder_r,‘. The important operands are remainder_r: the value named ’remainder r’ in this block. Read together, the complete operation is: This makes shifted_remainder_r, the value named ’shifted remainder r’ in this block, equal to ‘{ remainder_r, numerator_r[bit_index] }‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are remainder_r: the value named ’remainder r’ in this block; numerator_r: the value named ’numerator r’ in this block; bit_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase..

Line 90: `numerator_r[bit_index]` This is continuation line 3 of the 4-line logical statement that begins at source line 88. Its exact fragment is ‘numerator_r[bit_index]‘. The important operands are numerator_r: the value named ’numerator r’ in this block; bit_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes shifted_remainder_r, the value named ’shifted remainder r’ in this block, equal to ‘{ remainder_r, numerator_r[bit_index] }‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are remainder_r: the value named ’remainder r’ in this block; numerator_r: the value named ’numerator r’ in this block; bit_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase..

Line 91: `};` This is continuation line 4 of the 4-line logical statement that begins at source line 88. Its exact fragment is ‘};‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This makes shifted_remainder_r, the value named ’shifted remainder r’ in this block, equal to ‘{ remainder_r, numerator_r[bit_index] }‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are remainder_r: the value named ’remainder r’ in this block; numerator_r: the value named ’numerator r’ in this block; bit_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase..

Line 92: `state <= ST_SUBTRACT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_SUBTRACT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SUBTRACT: the value named ’st subtract’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase..

Line 93: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 95: `ST_SUBTRACT: begin` This is the ST_SUBTRACT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 96: `logic [DENOMINATOR_BITS-1:0] next_remainder;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase.. Specifically, next_remainder is the value named ’next remainder’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 97: `logic [NUMERATOR_BITS-1:0] next_quotient;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase.. Specifically, next_quotient is the value named ’next quotient’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 98: `next_quotient = quotient_r;` This makes next_quotient, the value named ’next quotient’ in this block, equal to ‘quotient_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are quotient_r: the value named ’quotient r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 99: `if (shifted_remainder_r >= {1'b0, denominator_r}) begin` This condition selects the following hardware branch only when ‘shifted_remainder_r >= {1’b0, denominator_r}‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are shifted_remainder_r: the value named ’shifted remainder r’ in this block; b0: the value named ’b0’ in this block; denominator_r: the value named ’denominator r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 100: `next_remainder = shifted_remainder_r[DENOMINATOR_BITS-1:0]` This statement continues through source line 101; the explanation uses the complete expression rather than only the first visual fragment. This makes next_remainder, the value named ’next remainder’ in this block, equal to ‘shifted_remainder_r[DENOMINATOR_BITS-1:0] - denominator_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are shifted_remainder_r: the value named ’shifted remainder r’ in this block; DENOMINATOR_BITS: the value named ’denominator bits’ in this block; denominator_r: the value named ’denominator r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 101: `- denominator_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 100. Its exact fragment is ‘- denominator_r;‘. The important operands are denominator_r: the value named ’denominator r’ in this block. Read together, the complete operation is: This makes next_remainder, the value named ’next remainder’ in this block, equal to ‘shifted_remainder_r[DENOMINATOR_BITS-1:0] - denominator_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are shifted_remainder_r: the value named ’shifted remainder r’ in this block; DENOMINATOR_BITS: the value named ’denominator bits’ in this block; denominator_r: the value named ’denominator r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 102: `next_quotient[bit_index] = 1'b1;` This makes next_quotient[bit_index], the value named ’next quotient’ in this block, equal to ‘1’b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 103: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 104: `next_remainder = shifted_remainder_r[DENOMINATOR_BITS-1:0];` This makes next_remainder, the value named 'next remainder' in this block, equal to 'shifted_remainder_r[DENOMINATOR_BITS-1:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are shifted_remainder_r: the value named 'shifted remainder r' in this block; DENOMINATOR_BITS: the value named 'denominator bits' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 105: `next_quotient[bit_index] = 1'b0;` This makes next_quotient[bit_index], the value named 'next quotient' in this block, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 106: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 107: `// A completed subtraction is strictly less than the` Design intent: A completed subtraction is strictly less than the This comment anchors the surrounding logic in the block that performs deterministic unsigned integer division one quotient bit per cycle.

Line 108: `// denominator, so the stored remainder needs no guard bit.` Design intent: denominator, so the stored remainder needs no guard bit. This comment anchors the surrounding logic in the block that performs deterministic unsigned integer division one quotient bit per cycle.

Line 109: `remainder_r <= next_remainder;` This makes remainder_r, the value named 'remainder r' in this block, equal to 'next_remainder'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_remainder: the value named 'next remainder' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 110: `quotient_r <= next_quotient;` This makes quotient_r, the value named 'quotient r' in this block, equal to 'next_quotient'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_quotient: the value named 'next quotient' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 112: `if (bit_index == 0) begin` This condition selects the following hardware branch only when 'bit_index == 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are bit_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 113: `quotient <= next_quotient;` This makes quotient, the value named 'quotient' in this block, equal to 'next_quotient'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_quotient: the value named 'next quotient' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 114: `remainder <= next_remainder;` This makes remainder, the value named 'remainder' in this block, equal to 'next_remainder'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_remainder: the value named 'next remainder' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 115: `state <= ST_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT: the value named 'st output' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 116: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 117: `bit_index <= bit_index - 1'b1;` This makes bit_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'bit_index - 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are bit_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 118: `state <= ST_SHIFT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_SHIFT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SHIFT: the value named 'st shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase..

Line 119: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 120: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SUBTRACT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 122: `ST_OUTPUT: begin` This is the ST_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 123: `if (output_ready) state <= ST_IDLE;` This condition selects the following hardware branch only when 'output_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 124: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 126: `default: state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'state <= ST_IDLE;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 127: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 128: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 129: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 131: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 132: `if (NUMERATOR_BITS < DENOMINATOR_BITS) begin` This condition selects the following hardware branch only when ‘NUMERATOR_BITS < DENOMINATOR_BITS‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are NUMERATOR_BITS: the value named 'numerator bits' in this block; DENOMINATOR_BITS: the value named 'denominator bits' in this block. Context: the module's structural declarations.

Line 133: `$fatal(1, "NUMERATOR_BITS must be at least DENOMINATOR_BITS");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 134: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 135: `if (NUMERATOR_BITS < 2 || (1 << INDEX_BITS) != NUMERATOR_BITS) begin` This condition selects the following hardware branch only when ‘NUMERATOR_BITS < 2 || (1 << INDEX_BITS) != NUMERATOR_BITS‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are NUMERATOR_BITS: the value named 'numerator bits' in this block; INDEX_BITS: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 136: `$fatal(1, "NUMERATOR_BITS must be a power of two");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 137: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 138: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 139: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 141: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that performs deterministic unsigned integer division one quotient bit per cycle.

21 rtl/neuraedge_universal_core.sv

Role in the complete system: decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

21.1 Beginner architecture map

Dataflow responsibility This command arbiter gives exactly one engine ownership of the shared streams. It stages LUT loads, LIF input, and other multibeat commands, then captures each engine into a source-local result bank before a registered shared output stage. Completion waits for the final AXI transfer, so stalls cannot acknowledge a command early; local accept signals prevent an inactive engine's counters from entering another engine's timing cone.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_universal_core into physical nets and primitives. The source declares 8 input-port lines, 33 output-port lines, 3 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_ALPHA_DRAIN, ST_ALPHA_LOAD, ST_ALPHA_OUTPUT, ST_ALPHA_START, ST_DECODE_COMMAND, ST_IDLE, ST_LAYERNORM_LOAD0, ST_LAYERNORM_LOAD1 ST_LAYERNORM_OUTPUT, ST_LAYERNORM_SEND, ST_LAYERNORM_START, ST_LIF_CLEAR, ST_LIF_LO ST_LIF_OUTPUT, ST_LIF_START, ST_LUT_CLEAR, ST_LUT_EVAL_LOAD, ST_LUT_EVAL_OUTPUT and additional states. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates neuraedge_buffered_tensor_core as u_tensor_core, neuraedge_alpha_x as u_alpha_xnor, neuraedge_vector_alu as u_vector_alu, neuraedge_integer_layernorm as u_layernorm, neuraedge_log_softmax as u_softmax, neuraedge_lif_bank as u_lif_bank, neuraedge_sgd_optimizer8 as u_optimizer, neuraedge_linear_backward8 as u_linear_backward, neuraedge_activation_lut8 as u_activation_lut, unique as case, end as if, else as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

`default_nettype wire
```

21.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_universal_core (` This opens neuraedge_universal_core, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 5: `input wire clk,` This declares clk as a input port with width one bit. It carries the clock that makes all registers advance together across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 6: `input wire rst_n,` This declares rst_n as a input port with width one bit. It carries the active-low synchronous reset across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 7: `input wire command_valid,` This declares command_valid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 8: `output logic command_ready,` This declares command_ready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 9: `input wire [127:0] command_data,` This declares command_data as a input port with width [127:0]. It carries the 128-bit instruction selecting an engine, shape, mode, and numeric parameters across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 10: `output logic command_done,` This declares command_done as a output port with width one bit. It carries the 128-bit instruction selecting an engine, shape, mode, and numeric parameters across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 11: `output logic status_busy,` This declares status_busy as a output port with width one bit. It carries the value named 'status busy' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 12: `output logic status_error,` This declares status_error as a output port with width one bit. It carries the value named 'status error' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 13: `output logic [3:0] status_active_opcode,` This declares status_active_opcode as a output port with width [3:0]. It carries the value named 'status active opcode' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 14: `output logic [31:0] status_command_count,` This declares status_command_count as a output port with width [31:0]. It carries the 128-bit instruction selecting an engine, shape, mode, and numeric parameters across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 15: `output logic [31:0] status_input_beats,` This declares status_input_beats as a output port with width [31:0]. It carries the value named 'status input beats' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 16: `output logic [31:0] status_output_beats,` This declares status_output_beats as a output port with width [31:0]. It carries the value named 'status output beats' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 17: `output wire [11:0] debug_tensor_loaded_activations,` This declares debug_tensor_loaded_activations as a output port with width [11:0]. It carries an input feature value consumed by a neuron or multiply-accumulate operation across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 18: `output wire [11:0] debug_tensor_loaded_weights,` This declares debug_tensor_loaded_weights as a output port with width [11:0]. It carries a learned coefficient multiplied by an activation across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 19: `output wire [11:0] debug_tensor_active_issues,` This declares debug_tensor_active_issues as a output port with width [11:0]. It carries the value named 'debug tensor active issues' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 20: `output wire [31:0] debug_tensor_compute_cycles,` This declares debug_tensor_compute_cycles as a output port with width [31:0]. It carries the value named 'debug tensor compute cycles' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 21: `output wire [31:0] debug_tensor_skipped_issues,` This declares debug_tensor_skipped_issues as a output port with width [31:0]. It carries the value named 'debug tensor skipped issues' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 22: `output wire [63:0] debug_tensor_dense_macs,` This declares debug_tensor_dense_macs as a output port with width [63:0]. It carries a count of ordinary activation-times-weight operations actually issued across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 23: `output wire [63:0] debug_tensor_spike_adds,` This declares debug_tensor_spike_adds as a output port with width [63:0]. It carries a binary event produced when a neuron crosses its threshold across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 24: `output wire [31:0] debug_layernorm_cycles,` This declares debug_layernorm_cycles as a output port with width [31:0]. It carries the value named 'debug layernorm cycles' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 25: `output wire signed [31:0] debug_layernorm_mean,` This declares debug_layernorm_mean as a output port with width [31:0]. It carries the arithmetic average used by normalization across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 26: `output wire [31:0] debug_layernorm_variance,` This declares debug_layernorm_variance as a output port with width [31:0]. It carries the average squared distance from the mean across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 27: `output wire [31:0] debug_layernorm_sigma,` This declares debug_layernorm_sigma as a output port with width [31:0]. It carries the value named 'debug layernorm sigma' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 28: `output wire [31:0] debug_layernorm_reciprocal,` This declares debug_layernorm_reciprocal as a output port with width [31:0]. It carries the value named 'debug layernorm reciprocal' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 29: `output wire [31:0] debug_softmax_cycles,` This declares debug_softmax_cycles as a output port with width [31:0]. It carries the value named 'debug softmax cycles' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 30: `output wire signed [23:0] debug_softmax_maximum,` This declares debug_softmax_maximum as a output port with width [23:0]. It carries the value named 'debug softmax maximum' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 31: `output wire [23:0] debug_softmax_denominator,` This declares debug_softmax_denominator as a output port with width [23:0]. It carries the value named 'debug softmax denominator' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 32: `output wire [31:0] debug_softmax_reciprocal,` This declares debug_softmax_reciprocal as a output port with width [31:0]. It carries the value named 'debug softmax reciprocal' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 33: `output wire [63:0] debug_lif_total_spikes,` This declares debug_lif_total_spikes as a output port with width [63:0]. It carries a binary event produced when a neuron crosses its threshold across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 34: `output wire [31:0] debug_optimizer_updates,` This declares debug_optimizer_updates as a output port with width [31:0]. It carries the value named 'debug optimizer updates' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 35: `output wire [8:0] debug_lut_loaded_entries,` This declares debug_lut_loaded_entries as a output port with width [8:0]. It carries the value named 'debug lut loaded entries' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 36: `output wire [31:0] debug_training_tiles,` This declares debug_training_tiles as a output port with width [31:0]. It carries the value named 'debug training tiles' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 37: `output wire [31:0] debug_training_cycles,` This declares debug_training_cycles as a output port with width [31:0]. It carries the value named 'debug training cycles' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 39: `input wire s_axis_tvalid,` This declares s_axis_tvalid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 40: `output logic s_axis_tready,` This declares s_axis_tready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 41: `input wire [63:0] s_axis_tdata,` This declares s_axis_tdata as a input port with width [63:0]. It carries the value named 's axis tdata' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 42: `input wire s_axis_tlast,` This declares s_axis_tlast as a input port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 43: `output logic m_axis_tvalid,` This declares m_axis_tvalid as a output port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 44: `input wire m_axis_tready,` This declares m_axis_tready as a input port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 45: `output logic [63:0] m_axis_tdata,` This declares m_axis_tdata as a output port with width [63:0]. It carries the value named 'm axis tdata' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 46: `output logic m_axis_tlast` This declares m_axis_tlast as a output port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 47: `);` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The expression is a literal or structural operator and has no hidden software state.

Line 48: `import neuraedge_command_pkg::*;` This imports shared package names into the current module so opcodes and mode constants have exactly one definition. The import changes compile-time name visibility; it does not create registers or consume a clock cycle.

Line 50: `typedef enum logic [5:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 51: `ST_IDLE = 6'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 52: `ST_TENSOR = 6'd1,` This assigns a fixed binary encoding to state ST_TENSOR, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 53: `ST_ALPHA_LOAD = 6'd2,` This assigns a fixed binary encoding to state ST_ALPHA_LOAD, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 54: `ST_ALPHA_START = 6'd3,` This assigns a fixed binary encoding to state ST_ALPHA_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 55: `ST_ALPHA_OUTPUT = 6'd4,` This assigns a fixed binary encoding to state ST_ALPHA_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 56: `ST_VECTOR_LOAD = 6'd5,` This assigns a fixed binary encoding to state ST_VECTOR_LOAD, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 57: `ST_VECTOR_START = 6'd6,` This assigns a fixed binary encoding to state ST_VECTOR_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 58: `ST_VECTOR_OUTPUT = 6'd7,` This assigns a fixed binary encoding to state ST_VECTOR_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 59: `ST_LAYERNORM_START = 6'd8,` This assigns a fixed binary encoding to state ST_LAYERNORM_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 60: `ST_LAYERNORM_LOAD0 = 6'd9,` This assigns a fixed binary encoding to state ST_LAYERNORM_LOAD0, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 61: `ST_LAYERNORM_LOAD1 = 6'd10,` This assigns a fixed binary encoding to state ST_LAYERNORM_LOAD1, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 62: `ST_LAYERNORM_SEND = 6'd11,` This assigns a fixed binary encoding to state ST_LAYERNORM_SEND, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 63: `ST_LAYERNORM_OUTPUT = 6'd12,` This assigns a fixed binary encoding to state ST_LAYERNORM_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 64: `ST_SOFTMAX_START = 6'd13,` This assigns a fixed binary encoding to state ST_SOFTMAX_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 65: `ST_SOFTMAX_LOAD = 6'd14,` This assigns a fixed binary encoding to state ST_SOFTMAX_LOAD, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 66: `ST_SOFTMAX_OUTPUT = 6'd15,` This assigns a fixed binary encoding to state ST_SOFTMAX_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 67: `ST_LIF_LOAD = 6'd16,` This assigns a fixed binary encoding to state ST_LIF_LOAD, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 68: `ST_LIF_CLEAR = 6'd17,` This assigns a fixed binary encoding to state ST_LIF_CLEAR, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 69: `ST_LIF_START = 6'd18,` This assigns a fixed binary encoding to state ST_LIF_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 70: `ST_LIF_OUTPUT = 6'd19,` This assigns a fixed binary encoding to state ST_LIF_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 71: `ST_OPTIMIZER_LOAD = 6'd20,` This assigns a fixed binary encoding to state ST_OPTIMIZER_LOAD, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 72: `ST_OPTIMIZER_START = 6'd21,` This assigns a fixed binary encoding to state ST_OPTIMIZER_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 73: `ST_OPTIMIZER_OUTPUT = 6'd22,` This assigns a fixed binary encoding to state ST_OPTIMIZER_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 74: `ST_LUT_LOAD = 6'd23,` This assigns a fixed binary encoding to state ST_LUT_LOAD, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 75: `ST_LUT_EVAL_LOAD = 6'd24,` This assigns a fixed binary encoding to state ST_LUT_EVAL_LOAD, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 76: `ST_LUT_EVAL_START = 6'd25,` This assigns a fixed binary encoding to state ST_LUT_EVAL_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 77: `ST_LUT_EVAL_OUTPUT = 6'd26,` This assigns a fixed binary encoding to state ST_LUT_EVAL_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 78: `ST_LUT_CLEAR = 6'd27,` This assigns a fixed binary encoding to state ST_LUT_CLEAR, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 79: `ST_ALPHA_DRAIN = 6'd28,` This assigns a fixed binary encoding to state ST_ALPHA_DRAIN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 80: `ST_OPTIMIZER_COMMIT = 6'd29,` This assigns a fixed binary encoding to state ST_OPTIMIZER_COMMIT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 81: `ST_VECTOR_DRAIN = 6'd30,` This assigns a fixed binary encoding to state ST_VECTOR_DRAIN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 82: `ST_DECODE_COMMAND = 6'd31,` This assigns a fixed binary encoding to state ST_DECODE_COMMAND, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 83: `ST_TRAIN_START = 6'd32,` This assigns a fixed binary encoding to state ST_TRAIN_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 84: `ST_TRAIN_RUN = 6'd33,` This assigns a fixed binary encoding to state ST_TRAIN_RUN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 85: `ST_OUTPUT_DRAIN = 6'd34` This statement continues through source line 86; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_OUTPUT_DRAIN, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 86: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 85. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_OUTPUT_DRAIN, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 88: `// One-hot recoding turns every engine-select decision into a single state` Design intent: One-hot recoding turns every engine-select decision into a single state This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 89: `// bit instead of a shared five-bit decode with hundreds of loads.` Design intent: bit instead of a shared five-bit decode with hundreds of loads. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 90: `(* fsm_encoding = "one_hot", extract_enable = "no" *) state_t state;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are fsm_encoding: the value named 'fsm encoding' in this block; one_hot: the value named 'one hot' in this block; extract_enable: a control bit that permits the associated state or storage update.

Line 91: `logic status_error_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, status_error_r is the value named 'status error r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 92: `(* dont_touch = "yes" *) logic error_event_r;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; error_event_r: the value named 'error event r' in this block.

Line 93: `(* dont_touch = "yes" *) logic clear_error_r;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; clear_error_r: the value named 'clear error r' in this block.

Line 94: `(* dont_touch = "yes" *) logic stream_protocol_error_event_r;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; stream_protocol_error_event_r: the value named 'stream protocol error event r' in this block.

Line 95: `(* dont_touch = "yes" *) logic clear_counters_event_r;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; clear_counters_event_r: a hardware telemetry register that accumulates measured events.

Line 96: `(* dont_touch = "yes" *) logic command_done_pending_r;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; command_done_pending_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 97: `(* dont_touch = "yes" *) logic input_beat_accepted_r;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; input_beat_accepted_r: the value named 'input beat accepted r' in this block.

Line 98: `(* dont_touch = "yes" *) logic output_beat_accepted_r;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; output_beat_accepted_r: the value named 'output beat accepted r' in this block.

Line 99: `logic [7:0] stream_beat_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stream_beat_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 100: `logic [11:0] stream_item_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stream_item_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 101: `logic [11:0] stream_items_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stream_items_remaining_r is the value named 'stream items remaining r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 102: `logic stream_last_pending_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, stream_last_pending_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 103: `logic [3:0] output_word_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_word_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 104: `wire [9:0] lif_trace_bit_offset =` This statement continues through source line 105; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_trace_bit_offset is the value named 'lif trace bit offset' in this block; output_word_index} is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 105: `({6'd0, output_word_index} - 10'd1) << 6;` This is continuation line 2 of the 2-line logical statement that begins at source line 104. Its exact fragment is '({6'd0, output_word_index} - 10'd1) << 6;'. The important operands are d0: the value named 'd0' in this block; output_word_index: an integer selecting one tensor element, lane, bank, or state entry; d1: the value named 'd1' in this block. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_trace_bit_offset is the value named 'lif trace bit offset' in this block; output_word_index} is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 106: `logic [108:0] captured_command_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, captured_command_r is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 107: `logic [3:0] train_reserved_partial_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_reserved_partial_r is the value named 'train reserved partial r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 108: `logic train_reserved_nonzero_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_reserved_nonzero_r is the value named 'train reserved nonzero r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 110: `typedef enum logic [3:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 111: `RESULT_TENSOR = 4'd0,` This assigns a fixed binary encoding to state RESULT_TENSOR, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 112: `RESULT_ALPHA = 4'd1,` This assigns a fixed binary encoding to state RESULT_ALPHA, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 113: `RESULT_VECTOR = 4'd2,` This assigns a fixed binary encoding to state RESULT_VECTOR, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 114: `RESULT_LAYERNORM = 4'd3,` This assigns a fixed binary encoding to state RESULT_LAYERNORM, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 115: `RESULT_SOFTMAX = 4'd4,` This assigns a fixed binary encoding to state RESULT_SOFTMAX, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 116: `RESULT_LIF = 4'd5,` This assigns a fixed binary encoding to state RESULT_LIF, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 117: `RESULT_OPTIMIZER = 4'd6,` This assigns a fixed binary encoding to state RESULT_OPTIMIZER, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 118: `RESULT_TRAIN = 4'd7,` This assigns a fixed binary encoding to state RESULT_TRAIN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 119: `RESULT_LUT = 4'd8` This statement continues through source line 120; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state RESULT_LUT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 120: `} result_source_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 119. Its exact fragment is '} result_source_t;'. The important operands are result_source_t: the value named 'result source t' in this block. Read together, the complete operation is: This assigns a fixed binary encoding to state RESULT_LUT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 122: `// Each engine writes a private result register before the shared output` Design intent: Each engine writes a private result register before the shared output This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 123: `// mux. The following elastic register then arbitrates those local banks.` Design intent: mux. The following elastic register then arbitrates those local banks. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 124: `// Splitting formatting and arbitration across clocks removes the former` Design intent: Splitting formatting and arbitration across clocks removes the former This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 125: `// child-to-wrapper nine-way combinational path while preserving one result` Design intent: child-to-wrapper nine-way combinational path while preserving one result This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 126: `// beat per clock after the two stages fill.` Design intent: beat per clock after the two stages fill. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 127: `logic result_input_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 128: `logic result_input_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_input_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 129: `logic result_prestage_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_prestage_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 130: `result_source_t result_prestage_source_r;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are result_source_t: the value named 'result source t' in this block; result_prestage_source_r: the value named 'result prestage source r' in this block.

Line 131: `logic result_prestage_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_prestage_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 132: `logic [63:0] result_tensor_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_tensor_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 133: `logic [63:0] result_alpha_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_alpha_data_r is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 134: `logic [63:0] result_vector_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_vector_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 135: `logic [63:0] result_layernorm_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_layernorm_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 136: `logic [63:0] result_softmax_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_softmax_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 137: `logic [63:0] result_lif_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_lif_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 138: `logic [63:0] result_optimizer_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_optimizer_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 139: `logic [63:0] result_train_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_train_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 140: `logic [63:0] result_lut_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_lut_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 141: `logic result_output_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_output_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 142: `logic [63:0] result_output_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_output_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 143: `logic result_output_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_output_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 144: `logic command_had_output_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_had_output_r is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 145: `logic final_output_accepted_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, final_output_accepted_r is the value named 'final output accepted r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 146: `logic completion_error_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, completion_error_r is the value named 'completion error r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 148: `wire result_output_ready = !result_output_valid_r || m_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 149: `wire result_prestage_ready = !result_prestage_valid_r` This statement continues through source line 150; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_prestage_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 150: `|| result_output_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 149. Its exact fragment is '|| result_output_ready;'. The important operands are result_output_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_prestage_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 151: `wire result_input_accept = result_input_valid && result_prestage_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_input_accept is the value named 'result input accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 152: `wire result_output_accept = result_output_valid_r && m_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_output_accept is the value named 'result output accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 154: `wire command_is_tensor = captured_command_r[3:0] >= CMD_LOAD_ACTIVATIONS` This statement continues through source line 155; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_is_tensor is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 155: `&& captured_command_r[3:0] <= CMD_COMPUTE_TERNARY;` This is continuation line 2 of the 2-line logical statement that begins at source line 154. Its exact fragment is '&& captured_command_r[3:0] <= CMD_COMPUTE_TERNARY;'. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; CMD_COMPUTE_TERNARY: the value named 'cmd compute ternary' in this block. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_is_tensor is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 156: `wire command_routes_tensor = command_is_tensor` This statement continues through source line 157; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_routes_tensor is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 157: `|| captured_command_r[3:0] == CMD_CLEAR_STATUS;` This is continuation line 2 of the 2-line logical statement that begins at source line 156. Its exact fragment is '|| captured_command_r[3:0] == CMD_CLEAR_STATUS;'. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; CMD_CLEAR_STATUS: the value named 'cmd clear status' in this block. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_routes_tensor is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 159: `logic tensor_command_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_command_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 160: `wire tensor_command_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_command_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 161: `wire tensor_command_done;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_command_done is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 162: `wire tensor_status_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_status_error is the value named 'tensor status error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 163: `logic tensor_s_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_s_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 164: `wire tensor_s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_s_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 165: `logic tensor_m_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_m_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 166: `wire tensor_m_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_m_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 167: `wire [63:0] tensor_m_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_m_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 168: `wire tensor_m_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_m_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 170: `neuraedge_buffered_tensor_core u_tensor_core (` This instantiates module neuraedge_buffered_tensor_core as u_tensor_core. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 171: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port ‘clk‘ to parent expression ‘clk), .rst_n(rst_n‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 172: `.command_valid(tensor_command_valid), .command_ready(tensor_command_ready),` This connects the child instance's named port ‘command_valid‘ to parent expression ‘tensor_command_valid), .command_ready(tensor_command_r The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 173: `.command_data(captured_command_r[41:0]), .command_done(tensor_command_done),` This connects the child instance's named port ‘command_data‘ to parent expression ‘captured_command_r[41:0]), .command_done(tensor_comm The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 174: `.status_error(tensor_status_error), .status_busy(),` This connects the child instance's named port ‘status_error‘ to parent expression ‘tensor_status_error), .status_busy(‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'tensor status error), .status busy(' in this block.

Line 175: `.s_axis_tvalid(tensor_s_valid), .s_axis_tready(tensor_s_ready),` This connects the child instance's named port ‘s_axis_tvalid‘ to parent expression ‘tensor_s_valid), .s_axis_tready(tensor_s_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 176: `.s_axis_tdata(s_axis_tdata), .s_axis_tlast(s_axis_tlast),` This connects the child instance's named port ‘s_axis_tdata‘ to parent expression ‘s_axis_tdata), .s_axis_tlast(s_axis_tlast‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 177: `.m_axis_tvalid(tensor_m_valid), .m_axis_tready(tensor_m_ready),` This connects the child instance's named port ‘m_axis_tvalid‘ to parent expression ‘tensor_m_valid), .m_axis_tready(tensor_m_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 178: `.m_axis_tdata(tensor_m_data), .m_axis_tlast(tensor_m_last),` This connects the child instance's named port ‘m_axis_tdata‘ to parent expression ‘tensor_m_data), .m_axis_tlast(tensor_m_last‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 179: `.status_loaded_activations(debug_tensor_loaded_activations),` This connects the child instance's named port 'status_loaded_activations' to parent expression 'debug_tensor_loaded_activations'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 180: `.status_loaded_weights(debug_tensor_loaded_weights),` This connects the child instance's named port 'status_loaded_weights' to parent expression 'debug_tensor_loaded_weights'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 181: `.status_active_issues(debug_tensor_active_issues),` This connects the child instance's named port 'status_active_issues' to parent expression 'debug_tensor_active_issues'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug tensor active issues' in this block.

Line 182: `.status_input_beats(),` This connects the child instance's named port 'status_input_beats' to parent expression ''. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status input beats' in this block.

Line 183: `.status_output_beats(),` This connects the child instance's named port 'status_output_beats' to parent expression ''. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status output beats' in this block.

Line 184: `.status_compute_cycles(debug_tensor_compute_cycles),` This connects the child instance's named port 'status_compute_cycles' to parent expression 'debug_tensor_compute_cycles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug tensor compute cycles' in this block.

Line 185: `.status_skipped_issues(debug_tensor_skipped_issues),` This connects the child instance's named port 'status_skipped_issues' to parent expression 'debug_tensor_skipped_issues'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug tensor skipped issues' in this block.

Line 186: `.status_dense_macs(debug_tensor_dense_macs),` This connects the child instance's named port 'status_dense_macs' to parent expression 'debug_tensor_dense_macs'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a count of ordinary activation-times-weight operations actually issued.

Line 187: `.status_spike_adds(debug_tensor_spike_adds)` This connects the child instance's named port 'status_spike_adds' to parent expression 'debug_tensor_spike_adds'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 188: `);` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The expression is a literal or structural operator and has no hidden software state.

Line 190: `logic [255:0] alpha_query_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_query_r is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 191: `logic [255:0] alpha_key_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_key_r is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 192: `logic [8:0] alpha_active_bits_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_active_bits_r is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 193: `logic [8:0] alpha_q8_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_q8_r is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 194: `logic alpha_load_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_load_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 195: `logic [2:0] alpha_load_index_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_load_index_r is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 196: `logic [63:0] alpha_load_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_load_data_r is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 197: `logic alpha_load_final_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_load_final_r is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 198: `logic alpha_load_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_load_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 199: `logic alpha_input_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 200: `wire alpha_input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 201: `wire alpha_output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 202: `logic alpha_output_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 203: `wire [17:0] alpha_score;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_score is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 204: `wire [8:0] alpha_spike_matches;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_spike_matches is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 205: `wire [8:0] alpha_zero_matches;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_zero_matches is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 206: `wire alpha_config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_config_error is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 208: `neuraedge_alpha_xnor u_alpha_xnor (` This instantiates module neuraedge_alpha_xnor as u_alpha_xnor. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 209: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 210: `.input_valid(alpha_input_valid), .input_ready(alpha_input_ready),` This connects the child instance's named port 'input_valid' to parent expression 'alpha_input_valid), .input_ready(alpha_input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 211: `.query_spikes(alpha_query_r), .key_spikes(alpha_key_r),` This connects the child instance's named port 'query_spikes' to parent expression 'alpha_query_r), .key_spikes(alpha_key_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 212: `.active_bits(alpha_active_bits_r), .alpha_q8(alpha_q8_r),` This connects the child instance's named port 'active_bits' to parent expression 'alpha_active_bits_r), .alpha_q8(alpha_q8_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 213: `.output_valid(alpha_output_valid), .output_ready(alpha_output_ready),` This connects the child instance's named port 'output_valid' to parent expression 'alpha_output_valid), .output_ready(alpha_output_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 214: `.score_q8(alpha_score), .spike_matches(alpha_spike_matches),` This connects the child instance's named port 'score_q8' to parent expression 'alpha_score), .spike_matches(alpha_spike_matches'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 215: `.zero_matches(alpha_zero_matches), .config_error(alpha_config_error)` This connects the child instance's named port 'zero_matches' to parent expression 'alpha_zero_matches), .config_error(alpha_config_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 216: `);` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The expression is a literal or structural operator and has no hidden software state.

Line 218: `logic [3:0] vector_operation_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_operation_r is the value named 'vector operation r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 219: `logic [255:0] vector_operand_a_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_operand_a_r is the value named 'vector operand a r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 220: `logic [255:0] vector_operand_b_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_operand_b_r is the value named 'vector operand b r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 221: `logic signed [15:0] vector_multiplier_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_multiplier_r is the value named 'vector multiplier r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 222: `logic [4:0] vector_shift_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_shift_r is the value named 'vector shift r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 223: `logic signed [15:0] vector_zero_point_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_zero_point_r is the integer code representing real numeric zero in affine quantization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 224: `logic signed [31:0] vector_threshold_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_threshold_r is the membrane level at which a neuron emits a spike. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 225: `logic [31:0] vector_window_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_window_r is the value named 'vector window r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 226: `logic signed [31:0] vector_clamp_min_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_clamp_min_r is the value named 'vector clamp min r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 227: `logic signed [31:0] vector_clamp_max_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_clamp_max_r is the value named 'vector clamp max r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 228: `(* dont_touch = "yes" *) logic vector_load_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; vector_load_valid_r: the producer's statement that its current payload is meaningful.

Line 229: `logic [3:0] vector_load_index_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_load_index_r is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 230: `logic [63:0] vector_load_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_load_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 231: `logic vector_load_final_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_load_final_r is the value named 'vector load final r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 232: `logic vector_load_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_load_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 233: `logic vector_input_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 234: `wire vector_input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 235: `wire vector_output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 236: `logic vector_output_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 237: `wire [255:0] vector_result;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_result is the value named 'vector result' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 238: `wire vector_config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_config_error is the value named 'vector config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 240: `neuraedge_vector_alu u_vector_alu (` This instantiates module neuraedge_vector_alu as u_vector_alu. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 241: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 242: `.input_valid(vector_input_valid), .input_ready(vector_input_ready),` This connects the child instance's named port 'input_valid' to parent expression 'vector_input_valid), .input_ready(vector_input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 243: `.operation(vector_operation_r), .operand_a(vector_operand_a_r),` This connects the child instance's named port 'operation' to parent expression 'vector_operation_r), .operand_a(vector_operand_a_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'vector operation r), .operand a(vector operand a r' in this block.

Line 244: `.operand_b(vector_operand_b_r), .multiplier_q15(vector_multiplier_r),` This connects the child instance's named port 'operand_b' to parent expression 'vector_operand_b_r), .multiplier_q15(vector_multiplier_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'vector operand b r), .multiplier q15(vector multiplier r' in this block.

Line 245: `.right_shift(vector_shift_r), .output_zero_point(vector_zero_point_r),` This connects the child instance's named port ‘right_shift‘ to parent expression ‘vector_shift_r), .output_zero_point(vector_zero_point_r‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the integer code representing real numeric zero in affine quantization.

Line 246: `.threshold(vector_threshold_r), .surrogate_window(vector_window_r),` This connects the child instance's named port ‘threshold‘ to parent expression ‘vector_threshold_r), .surrogate_window(vector_window_r‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the membrane level at which a neuron emits a spike.

Line 247: `.clamp_minimum(vector_clamp_min_r), .clamp_maximum(vector_clamp_max_r),` This connects the child instance's named port ‘clamp_minimum‘ to parent expression ‘vector_clamp_min_r), .clamp_maximum(vector_clamp_max_r‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named ’vector clamp min r), .clamp maximum(vector clamp max r’ in this block.

Line 248: `.output_valid(vector_output_valid), .output_ready(vector_output_ready),` This connects the child instance's named port ‘output_valid‘ to parent expression ‘vector_output_valid), .output_ready(vector_output_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 249: `.result(vector_result), .config_error(vector_config_error)` This connects the child instance's named port ‘result‘ to parent expression ‘vector_result), .config_error(vector_config_error‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named ’vector result), .config error(vector config error’ in this block.

Line 250: `);` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The expression is a literal or structural operator and has no hidden software state.

Line 252: `logic [11:0] ln_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 253: `logic [31:0] ln_epsilon_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_epsilon_r is the value named ’ln epsilon r’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 254: `logic [63:0] ln_sample_word0_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_sample_word0_r is the value named ’ln sample word0 r’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 255: `logic signed [23:0] ln_sample_value_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_sample_value_r is the value named ’ln sample value r’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 256: `logic signed [23:0] ln_sample_gamma_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_sample_gamma_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 257: `logic signed [23:0] ln_sample_beta_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_sample_beta_r is the learned additive LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 258: `logic ln_start_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_start_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 259: `wire ln_start_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_start_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 260: `logic ln_sample_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_sample_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 261: `wire ln_sample_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_sample_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 262: `logic ln_sample_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_sample_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 263: `wire ln_result_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_result_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 264: `logic ln_result_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_result_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 265: `wire signed [31:0] ln_result_value;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_result_value is the value named 'ln result value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 266: `wire [11:0] ln_result_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_result_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 267: `wire ln_result_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_result_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 268: `wire ln_config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_config_error is the value named 'ln config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 269: `logic ln_start_accept_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, ln_start_accept_r is the value named 'ln start accept r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 271: `neuraedge_integer_layernorm u_layernorm (` This instantiates module neuraedge_integer_layernorm as u_layernorm. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 272: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 273: `.start_valid(ln_start_valid), .start_ready(ln_start_ready),` This connects the child instance's named port ‘start_valid‘ to parent expression ‘ln_start_valid), .start_ready(ln_start_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 274: `.feature_count(ln_count_r), .epsilon(ln_epsilon_r),` This connects the child instance's named port ‘feature_count‘ to parent expression ‘ln_count_r), .epsilon(ln_epsilon_r‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'ln count r), .epsilon(ln epsilon r' in this block.

Line 275: `.sample_valid(ln_sample_valid), .sample_ready(ln_sample_ready),` This connects the child instance's named port ‘sample_valid‘ to parent expression ‘ln_sample_valid), .sample_ready(ln_sample_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 276: `.sample_value(ln_sample_value_r), .sample_gamma_q15(ln_sample_gamma_r),` This connects the child instance's named port ‘sample_value‘ to parent expression ‘ln_sample_value_r), .sample_gamma_q15(ln_sample_gamma_r‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the learned multiplicative LayerNorm parameter.

Line 277: `.sample_beta(ln_sample_beta_r), .sample_last(ln_sample_last),` This connects the child instance's named port ‘sample_beta‘ to parent expression ‘ln_sample_beta_r), .sample_last(ln_sample_last‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 278: `.result_valid(ln_result_valid), .result_ready(ln_result_ready),` This connects the child instance's named port ‘result_valid‘ to parent expression ‘ln_result_valid), .result_ready(ln_result_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 279: `.result_value(ln_result_value), .result_index(ln_result_index),` This connects the child instance's named port ‘result_value‘ to parent expression ‘ln_result_value), .result_index(ln_result_index‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an integer selecting one tensor element, lane, bank, or state entry.

Line 280: `.result_last(ln_result_last), .config_error(ln_config_error),` This connects the child instance's named port ‘result_last‘ to parent expression ‘ln_result_last), .config_error(ln_config_error‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 281: `.cycle_count(debug_layernorm_cycles),` This connects the child instance's named port ‘cycle_count‘ to parent expression ‘debug_layernorm_cycles‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug layernorm cycles' in this block.

Line 282: `.debug_mean(debug_layernorm_mean),` This connects the child instance's named port ‘debug_mean‘ to parent expression ‘debug_layernorm_mean‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the arithmetic average used by normalization.

Line 283: `.debug_variance(debug_layernorm_variance),` This connects the child instance's named port ‘debug_variance‘ to parent expression ‘debug_layernorm_variance‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the average squared distance from the mean.

Line 284: `.debug_sigma(debug_layernorm_sigma),` This connects the child instance's named port ‘debug_sigma‘ to parent expression ‘debug_layernorm_sigma‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug layernorm sigma' in this block.

Line 285: `.debug_reciprocal_q31(debug_layernorm_reciprocal)` This connects the child instance's named port 'debug_reciprocal_q31' to parent expression 'debug_layernorm_reciprocal'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug layernorm reciprocal' in this block.

Line 286: `);` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The expression is a literal or structural operator and has no hidden software state.

Line 288: `logic [8:0] softmax_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 289: `logic [4:0] softmax_shift_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_shift_r is the value named 'softmax shift r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 290: `logic softmax_start_accept_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_start_accept_r is the value named 'softmax start accept r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 291: `logic softmax_start_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_start_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 292: `wire softmax_start_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_start_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 293: `logic softmax_score_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_score_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 294: `wire softmax_score_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_score_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 295: `logic signed [23:0] softmax_score_value;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_score_value is the value named 'softmax score value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 296: `logic softmax_score_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_score_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 297: `wire softmax_probability_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_probability_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 298: `logic softmax_probability_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_probability_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 299: `wire [15:0] softmax_probability;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_probability is the value named 'softmax probability' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 300: `wire [8:0] softmax_probability_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_probability_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 301: `wire softmax_probability_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_probability_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 302: `wire softmax_config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_config_error is the value named 'softmax config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 304: `neuraedge_log_softmax u_softmax (` This instantiates module neuraedge_log_softmax as u_softmax. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 305: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 306: `.start_valid(softmax_start_valid), .start_ready(softmax_start_ready),` This connects the child instance's named port 'start_valid' to parent expression 'softmax_start_valid), .start_ready(softmax_start_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 307: `.item_count(softmax_count_r), .difference_shift(softmax_shift_r),` This connects the child instance's named port 'item_count' to parent expression 'softmax_count_r), .difference_shift(softmax_shift_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'softmax count r), .difference shift(softmax shift r' in this block.

Line 308: `.score_valid(softmax_score_valid), .score_ready(softmax_score_ready),` This connects the child instance's named port 'score_valid' to parent expression 'softmax_score_valid), .score_ready(softmax_score_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 309: `.score_value(softmax_score_value), .score_last(softmax_score_last),` This connects the child instance's named port 'score_value' to parent expression 'softmax_score_value), .score_last(softmax_score_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 310: `.probability_valid(softmax_probability_valid),` This connects the child instance's named port 'probability_valid' to parent expression 'softmax_probability_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 311: `.probability_ready(softmax_probability_ready),` This connects the child instance's named port 'probability_ready' to parent expression 'softmax_probability_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 312: `.probability_q15(softmax_probability),` This connects the child instance's named port 'probability_q15' to parent expression 'softmax_probability'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'softmax probability' in this block.

Line 313: `.probability_index(softmax_probability_index),` This connects the child instance's named port 'probability_index' to parent expression 'softmax_probability_index'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an integer selecting one tensor element, lane, bank, or state entry.

Line 314: `.probability_last(softmax_probability_last), .config_error(softmax_config_error),` This connects the child instance's named port 'probability_last' to parent expression 'softmax_probability_last), .config_error(softmax_con The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 315: `.cycle_count(debug_softmax_cycles),` This connects the child instance's named port 'cycle_count' to parent expression 'debug_softmax_cycles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug softmax cycles' in this block.

Line 316: `.debug_maximum_score(debug_softmax_maximum),` This connects the child instance's named port 'debug_maximum_score' to parent expression 'debug_softmax_maximum'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug softmax maximum' in this block.

Line 317: `.debug_denominator(debug_softmax_denominator),` This connects the child instance's named port 'debug_denominator' to parent expression 'debug_softmax_denominator'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug softmax denominator' in this block.

Line 318: `.debug_reciprocal_q31(debug_softmax_reciprocal)` This connects the child instance's named port 'debug_reciprocal_q31' to parent expression 'debug_softmax_reciprocal'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug softmax reciprocal' in this block.

Line 319: `);` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The expression is a literal or structural operator and has no hidden software state.

Line 321: `logic [511:0] lif_current_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_current_r is the value named 'lif current r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 322: `logic [4:0] lif_leak_shift_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_leak_shift_r is the retained fraction of prior membrane state. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 323: `logic signed [23:0] lif_threshold_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_threshold_r is the membrane level at which a neuron emits a spike. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 324: `logic signed [23:0] lif_reset_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_reset_r is the value named 'lif reset r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 325: `logic lif_clear_requested_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_clear_requested_r is the value named 'lif clear requested r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 326: `logic [7:0] lif_load_word_select_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_load_word_select_r is the value named 'lif load word select r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 327: `logic lif_load_pending_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_load_pending_r is the value named 'lif load pending r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 328: `logic [2:0] lif_load_index_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_load_index_r is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 329: `logic [63:0] lif_load_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_load_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 330: `logic lif_load_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_load_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 331: `logic lif_load_final_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_load_final_r is the value named 'lif load final r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 332: `logic lif_clear_state;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_clear_state is the finite-state-machine phase retained in flip-flops. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 333: `logic lif_input_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 334: `wire lif_input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 335: `wire lif_output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 336: `logic lif_output_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 337: `wire [31:0] lif_spikes;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_spikes is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 338: `wire [32*24-1:0] lif_pre_reset_membrane;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_pre_reset_membrane is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 339: `wire [31:0] lif_timesteps;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_timesteps is one discrete SNN update instant. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 340: `logic lif_trace_requested_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_trace_requested_r is the value named 'lif trace requested r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 342: `neuraedge_lif_bank u_lif_bank (` This instantiates module neuraedge_lif_bank as u_lif_bank. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 343: `.clk(clk), .rst_n(rst_n), .clear_state(lif_clear_state),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n), .clear_state(lif_clear_state'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 344: `.clear_counters(clear_counters_event_r),` This connects the child instance's named port 'clear_counters' to parent expression 'clear_counters_event_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a hardware telemetry register that accumulates measured events.

Line 345: `.input_valid(lif_input_valid), .input_ready(lif_input_ready),` This connects the child instance's named port 'input_valid' to parent expression 'lif_input_valid), .input_ready(lif_input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 346: `.current_vector(lif_current_r), .leak_shift(lif_leak_shift_r),` This connects the child instance's named port 'current_vector' to parent expression 'lif_current_r), .leak_shift(lif_leak_shift_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the retained fraction of prior membrane state.

Line 347: `.threshold(lif_threshold_r), .reset_value(lif_reset_r),` This connects the child instance's named port 'threshold' to parent expression 'lif_threshold_r), .reset_value(lif_reset_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the membrane level at which a neuron emits a spike.

Line 348: `.output_valid(lif_output_valid), .output_ready(lif_output_ready),` This connects the child instance's named port 'output_valid' to parent expression 'lif_output_valid), .output_ready(lif_output_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 349: `.spikes(lif_spikes), .membrane_vector(),` This connects the child instance's named port 'spikes' to parent expression 'lif_spikes), .membrane_vector('. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the persistent LIF neuron state carrying charge between timesteps.

Line 350: `.pre_reset_membrane_vector(lif_pre_reset_membrane),` This connects the child instance's named port 'pre_reset_membrane_vector' to parent expression 'lif_pre_reset_membrane'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the persistent LIF neuron state carrying charge between timesteps.

Line 351: `.timestep_count(lif_timesteps),` This connects the child instance's named port 'timestep_count' to parent expression 'lif_timesteps'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one discrete SNN update instant.

Line 352: `.total_spike_count(debug_lif_total_spikes)` This connects the child instance's named port 'total_spike_count' to parent expression 'debug_lif_total_spikes'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 353: `);` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The expression is a literal or structural operator and has no hidden software state.

Line 355: `logic [127:0] optimizer_weight_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_weight_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 356: `logic [191:0] optimizer_gradient_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_gradient_r is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 357: `logic [191:0] optimizer_velocity_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_velocity_r is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 358: `logic [17:0] optimizer_lr_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_lr_r is the value named 'optimizer lr r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 359: `logic [16:0] optimizer_momentum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_momentum_r is the value named 'optimizer momentum r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 360: `logic [16:0] optimizer_decay_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_decay_r is the value named 'optimizer decay r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 361: `logic [4:0] optimizer_update_shift_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_update_shift_r is the value named 'optimizer update shift r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 362: `logic [63:0] optimizer_load_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_load_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 363: `logic optimizer_load_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_load_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 364: `logic [2:0] optimizer_load_index_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_load_index_r is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 365: `logic optimizer_load_final_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_load_final_r is the value named 'optimizer load final r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 366: `(* dont_touch = "yes" *) logic optimizer_commit_valid_r;` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; optimizer_commit_valid_r: the producer's statement that its current payload is meaningful.

Line 367: `logic optimizer_input_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 368: `wire optimizer_input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 369: `wire optimizer_output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 370: `logic optimizer_output_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 371: `wire [127:0] optimizer_updated_weight;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_updated_weight is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 372: `wire [191:0] optimizer_updated_velocity;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_updated_velocity is the momentum history retained by the SGD optimizer. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 373: `wire optimizer_config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_config_error is the value named 'optimizer config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 375: `neuraedge_sgd_optimizer8 u_optimizer (` This instantiates module neuraedge_sgd_optimizer8 as u_optimizer. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 376: `.clk(clk), .rst_n(rst_n), .clear_counters(clear_counters_event_r),` This connects the child instance's named port ‘clk‘ to parent expression ‘clk), .rst_n(rst_n), .clear_counters(clear_counters_event_r‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 377: `.input_valid(optimizer_input_valid), .input_ready(optimizer_input_ready),` This connects the child instance's named port ‘input_valid‘ to parent expression ‘optimizer_input_valid), .input_ready(optimizer_input_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 378: `.weight_vector(optimizer_weight_r), .gradient_vector(optimizer_gradient_r),` This connects the child instance's named port ‘weight_vector‘ to parent expression ‘optimizer_weight_r), .gradient_vector(optimizer_gradient_r‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 379: `.velocity_vector(optimizer_velocity_r), .learning_rate_q16(optimizer_lr_r),` This connects the child instance's named port ‘velocity_vector‘ to parent expression ‘optimizer_velocity_r), .learning_rate_q16(optimizer_lr_r‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the momentum history retained by the SGD optimizer.

Line 380: `.momentum_q16(optimizer_momentum_r), .weight_decay_q16(optimizer_decay_r),` This connects the child instance's named port ‘momentum_q16‘ to parent expression ‘optimizer_momentum_r), .weight_decay_q16(optimizer_decay
The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 381: `.update_right_shift(optimizer_update_shift_r),` This connects the child instance's named port 'update_right_shift' to parent expression 'optimizer_update_shift_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'optimizer update shift r' in this block.

Line 382: `.output_valid(optimizer_output_valid), .output_ready(optimizer_output_ready),` This connects the child instance's named port 'output_valid' to parent expression 'optimizer_output_valid), .output_ready(optimizer_output_re The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 383: `.updated_weight_vector(optimizer_updated_weight),` This connects the child instance's named port 'updated_weight_vector' to parent expression 'optimizer_updated_weight'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 384: `.updated_velocity_vector(optimizer_updated_velocity),` This connects the child instance's named port 'updated_velocity_vector' to parent expression 'optimizer_updated_velocity'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the momentum history retained by the SGD optimizer.

Line 385: `.config_error(optimizer_config_error),` This connects the child instance's named port 'config_error' to parent expression 'optimizer_config_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'optimizer config error' in this block.

Line 386: `.update_count(debug_optimizer_updates)` This connects the child instance's named port 'update_count' to parent expression 'debug_optimizer_updates'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug optimizer updates' in this block.

Line 387: `);` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The expression is a literal or structural operator and has no hidden software state.

Line 389: `logic train_start_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_start_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 390: `wire train_start_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_start_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 391: `logic train_s_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_s_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 392: `wire train_s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_s_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 393: `wire train_m_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_m_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 394: `logic train_m_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_m_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 395: `wire [63:0] train_m_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_m_data is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 396: `wire train_m_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_m_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 397: `wire train_done;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_done is the value named 'train done' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 398: `wire train_config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_config_error is the value named 'train config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 399: `wire train_busy;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_busy is the value named 'train busy' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 401: `neuraedge_linear_backward8 u_linear_backward (` This instantiates module neuraedge_linear_backward8 as u_linear_backward. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 402: `.clk(clk), .rst_n(rst_n), .clear_counters(clear_counters_event_r),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n), .clear_counters(clear_counters_event_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 403: `.start_valid(train_start_valid), .start_ready(train_start_ready),` This connects the child instance's named port 'start_valid' to parent expression 'train_start_valid), .start_ready(train_start_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 404: `.active_rows(captured_command_r[7:4]),` This connects the child instance's named port 'active_rows' to parent expression 'captured_command_r[7:4]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 405: `.active_inputs(captured_command_r[11:8]),` This connects the child instance's named port 'active_inputs' to parent expression 'captured_command_r[11:8]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 406: `.active_outputs(captured_command_r[15:12]),` This connects the child instance's named port 'active_outputs' to parent expression 'captured_command_r[15:12]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 407: `.input_gradient_shift(captured_command_r[20:16]),` This connects the child instance's named port 'input_gradient_shift' to parent expression 'captured_command_r[20:16]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 408: `.weight_gradient_shift(captured_command_r[25:21]),` This connects the child instance's named port 'weight_gradient_shift' to parent expression 'captured_command_r[25:21]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 409: `.gradient_mode(captured_command_r[27:26]),` This connects the child instance's named port 'gradient_mode' to parent expression 'captured_command_r[27:26]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 410: `.accumulate_result(captured_command_r[28]),` This connects the child instance's named port 'accumulate_result' to parent expression 'captured_command_r[28]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 411: `.suppress_output(captured_command_r[29]),` This connects the child instance's named port 'suppress_output' to parent expression 'captured_command_r[29]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 412: `.reserved_nonzero(train_reserved_nonzero_r),` This connects the child instance's named port 'reserved_nonzero' to parent expression 'train_reserved_nonzero_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'train reserved nonzero r' in this block.

Line 413: `.s_axis_tvalid(train_s_valid), .s_axis_tready(train_s_ready),` This connects the child instance's named port 's_axis_tvalid' to parent expression 'train_s_valid), .s_axis_tready(train_s_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 414: `.s_axis_tdata(s_axis_tdata), .s_axis_tlast(s_axis_tlast),` This connects the child instance's named port 's_axis_tdata' to parent expression 's_axis_tdata), .s_axis_tlast(s_axis_tlast'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 415: `.m_axis_tvalid(train_m_valid), .m_axis_tready(train_m_ready),` This connects the child instance's named port 'm_axis_tvalid' to parent expression 'train_m_valid), .m_axis_tready(train_m_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 416: `.m_axis_tdata(train_m_data), .m_axis_tlast(train_m_last),` This connects the child instance's named port 'm_axis_tdata' to parent expression 'train_m_data), .m_axis_tlast(train_m_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 417: `.busy(train_busy), .done(train_done), .config_error(train_config_error),` This connects the child instance's named port 'busy' to parent expression 'train_busy), .done(train_done), .config_error(train_config_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'train busy), .done(train done), .config error(train config error' in this block.

Line 418: `.completed_tiles(debug_training_tiles),` This connects the child instance's named port 'completed_tiles' to parent expression 'debug_training_tiles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug training tiles' in this block.

Line 419: `.active_cycles(debug_training_cycles)` This connects the child instance's named port 'active_cycles' to parent expression 'debug_training_cycles'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug training cycles' in this block.

Line 420: `);` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The expression is a literal or structural operator and has no hidden software state.

Line 422: `logic lut_clear;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_clear is the value named 'lut clear' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 423: `logic lut_load_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_load_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 424: `wire lut_load_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_load_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 425: `logic [7:0] lut_load_address;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_load_address is the value named 'lut load address' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 426: `logic signed [15:0] lut_load_value;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_load_value is the value named 'lut load value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 427: `logic lut_load_pending_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_load_pending_r is the value named 'lut load pending r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 428: `logic [7:0] lut_load_address_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_load_address_r is the value named 'lut load address r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 429: `logic signed [15:0] lut_load_value_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_load_value_r is the value named 'lut load value r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 430: `logic lut_load_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_load_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 431: `logic lut_load_final_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_load_final_r is the value named 'lut load final r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 432: `logic lut_input_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 433: `wire lut_input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 434: `logic [63:0] lut_indices_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_indices_r is the value named 'lut indices r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 435: `wire lut_output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 436: `logic lut_output_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 437: `wire [127:0] lut_output_values;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_output_values is the value named 'lut output values' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 438: `wire lut_config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_config_error is the value named 'lut config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 439: `logic lut_clear_requested_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_clear_requested_r is the value named 'lut clear requested r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 440: `logic decode_error_pending_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, decode_error_pending_r is the value named 'decode error pending r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 442: `neuraedge_activation_lut8 u_activation_lut (` This instantiates module neuraedge_activation_lut8 as u_activation_lut. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 443: `.clk(clk), .rst_n(rst_n), .clear_table(lut_clear),` This connects the child instance's named port ‘clk‘ to parent expression ‘clk), .rst_n(rst_n), .clear_table(lut_clear‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 444: `.load_valid(lut_load_valid), .load_ready(lut_load_ready),` This connects the child instance's named port ‘load_valid‘ to parent expression ‘lut_load_valid), .load_ready(lut_load_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 445: `.load_address(lut_load_address), .load_value(lut_load_value),` This connects the child instance's named port ‘load_address‘ to parent expression ‘lut_load_address), .load_value(lut_load_value‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'lut load address), .load value(lut load value' in this block.

Line 446: `.input_valid(lut_input_valid), .input_ready(lut_input_ready),` This connects the child instance's named port ‘input_valid‘ to parent expression ‘lut_input_valid), .input_ready(lut_input_ready‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 447: `.input_indices(lut_indices_r), .output_valid(lut_output_valid),` This connects the child instance's named port ‘input_indices‘ to parent expression ‘lut_indices_r), .output_valid(lut_output_valid‘. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 448: `.output_ready(lut_output_ready), .output_values(lut_output_values),` This connects the child instance's named port 'output_ready' to parent expression 'lut_output_ready), .output_values(lut_output_values'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 449: `.config_error(lut_config_error),` This connects the child instance's named port 'config_error' to parent expression 'lut_config_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'lut config error' in this block.

Line 450: `.loaded_entries(debug_lut_loaded_entries)` This connects the child instance's named port 'loaded_entries' to parent expression 'debug_lut_loaded_entries'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug lut loaded entries' in this block.

Line 451: `);` Within the module's structural declarations, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The expression is a literal or structural operator and has no hidden software state.

Line 453: `// Keep each engine's transfer event local. A shared OR-of-valids is fine` Design intent: Keep each engine's transfer event local. A shared OR-of-valids is fine This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 454: `// for the single accounting bit, but using it in unrelated FSM branches` Design intent: for the single accounting bit, but using it in unrelated FSM branches This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 455: `// creates false cross-engine control cones after one-hot optimization.` Design intent: creates false cross-engine control cones after one-hot optimization. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 456: `wire tensor_result_accept = state == ST_TENSOR` This statement continues through source line 457; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_result_accept is the value named 'tensor result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 457: `&& tensor_m_valid && result_prestage_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 456. Its exact fragment is '&& tensor_m_valid && result_prestage_ready;'. The important operands are tensor_m_valid: the producer's statement that its current payload is meaningful; result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_result_accept is the value named 'tensor result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 458: `wire alpha_result_accept = state == ST_ALPHA_OUTPUT` This statement continues through source line 459; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_result_accept is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 459: `&& alpha_output_valid && result_prestage_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 458. Its exact fragment is '&& alpha_output_valid && result_prestage_ready;'. The important operands are alpha_output_valid: the producer's statement that its current payload is meaningful; result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_result_accept is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 460: `wire vector_result_accept = state == ST_VECTOR_OUTPUT` This statement continues through source line 461; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_result_accept is the value named 'vector result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 461: `&& vector_output_valid && result_prestage_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 460. Its exact fragment is '&& vector_output_valid && result_prestage_ready;'. The important operands are vector_output_valid: the producer's statement that its current payload is meaningful; result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, vector_result_accept is the value named 'vector result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 462: `wire layernorm_result_accept = state == ST_LAYERNORM_OUTPUT` This statement continues through source line 463; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, layernorm_result_accept is the value named 'layernorm result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 463: `&& ln_result_valid && result_prestage_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 462. Its exact fragment is '&& ln_result_valid && result_prestage_ready;'. The important operands are ln_result_valid: the producer's statement that its current payload is meaningful; result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, layernorm_result_accept is the value named 'layernorm result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 464: `wire softmax_result_accept = state == ST_SOFTMAX_OUTPUT` This statement continues through source line 465; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_result_accept is the value named 'softmax result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 465: `&& softmax_probability_valid && result_prestage_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 464. Its exact fragment is '&& softmax_probability_valid && result_prestage_ready;'. The important operands are softmax_probability_valid: the producer's statement that its current payload is meaningful; result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, softmax_result_accept is the value named 'softmax result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 466: `wire lif_result_accept = state == ST_LIF_OUTPUT` This statement continues through source line 467; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_result_accept is the value named 'lif result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 467: `&& lif_output_valid && result_prestage_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 466. Its exact fragment is '&& lif_output_valid && result_prestage_ready;'. The important operands are lif_output_valid: the producer's statement that its current payload is meaningful; result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lif_result_accept is the value named 'lif result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 468: `wire optimizer_result_accept = state == ST_OPTIMIZER_OUTPUT` This statement continues through source line 469; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_result_accept is the value named 'optimizer result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 469: `&& optimizer_output_valid && result_prestage_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 468. Its exact fragment is '&& optimizer_output_valid && result_prestage_ready;'. The important operands are optimizer_output_valid: the producer's statement that its current payload is meaningful; result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, optimizer_result_accept is the value named 'optimizer result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 470: `wire train_result_accept = state == ST_TRAIN_RUN` This statement continues through source line 471; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_result_accept is the value named 'train result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 471: `&& train_m_valid && result_prestage_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 470. Its exact fragment is '&& train_m_valid && result_prestage_ready;'. The important operands are train_m_valid: the producer's statement that its current payload is meaningful; result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, train_result_accept is the value named 'train result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 472: `wire lut_result_accept = state == ST_LUT_EVAL_OUTPUT` This statement continues through source line 473; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_result_accept is the value named 'lut result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 473: `&& lut_output_valid && result_prestage_ready;` This is continuation line 2 of the 2-line logical statement that begins at source line 472. Its exact fragment is '&& lut_output_valid && result_prestage_ready;'. The important operands are lut_output_valid: the producer's statement that its current payload is meaningful; result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lut_result_accept is the value named 'lut result accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 475: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 476: `command_ready = state == ST_IDLE;` This makes command_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_IDLE'. It is driven by combinational or procedural logic in the current

evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 477: `status_busy = state != ST_IDLE || train_busy;` This makes status_busy, the value named 'status busy' in this block, equal to 'state != ST_IDLE || train_busy'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block; train_busy: the value named 'train busy' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 478: `status_error = status_error_r || tensor_status_error;` This makes status_error, the value named 'status error' in this block, equal to 'status_error_r || tensor_status_error'. It is driven by combinational or procedural logic in the current evaluation. The important operands are status_error_r: the value named 'status error r' in this block; tensor_status_error: the value named 'tensor status error' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 479: `s_axis_tready = 1'b0;` This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 480: `m_axis_tvalid = result_output_valid_r;` This makes m_axis_tvalid, the producer's statement that its current payload is meaningful, equal to 'result_output_valid_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_output_valid_r: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 481: `m_axis_tdata = result_output_data_r;` This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to 'result_output_data_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_output_data_r: the payload carried with the surrounding valid/ready handshake. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 482: `m_axis_tlast = result_output_last_r;` This makes m_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'result_output_last_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_output_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 483: `result_input_valid = 1'b0;` This makes result_input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 484: `result_input_last = 1'b0;` This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 486: `tensor_command_valid = state == ST_DECODE_COMMAND && command_routes_tensor;` This makes tensor_command_valid, the producer's statement that its current payload is meaningful, equal to 'state == ST_DECODE_COMMAN && command_routes_tensor'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_DECODE_COMMAND: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; command_routes_tensor: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 487: `tensor_s_valid = 1'b0;` This makes tensor_s_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 488: `tensor_m_ready = 1'b0;` This makes tensor_m_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 489: `alpha_input_valid = 1'b0;` This makes alpha_input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 490: `alpha_output_ready = 1'b0;` This makes alpha_output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 491: `vector_input_valid = 1'b0;` This makes vector_input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 492: `vector_output_ready = 1'b0;` This makes vector_output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 493: `ln_start_valid = 1'b0;` This makes ln_start_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 494: `ln_sample_valid = 1'b0;` This makes ln_sample_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 495: `ln_sample_last = stream_last_pending_r;` This makes ln_sample_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'stream_last_pending_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are stream_last_pending_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 496: `ln_result_ready = 1'b0;` This makes ln_result_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 497: `softmax_start_valid = 1'b0;` This makes softmax_start_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 498: `softmax_score_valid = 1'b0;` This makes softmax_score_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 499: `softmax_score_value = s_axis_tdata[23:0];` This makes softmax_score_value, the value named 'softmax score value' in this block, equal to 's_axis_tdata[23:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 500: `softmax_score_last = stream_last_pending_r;` This makes softmax_score_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'stream_last_pending_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are stream_last_pending_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 501: `softmax_probability_ready = 1'b0;` This makes softmax_probability_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 502: `lif_clear_state = 1'b0;` This makes lif_clear_state, the finite-state-machine phase retained in flip-flops, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 503: `lif_input_valid = 1'b0;` This makes lif_input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 504: `lif_output_ready = 1'b0;` This makes lif_output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 505: `optimizer_input_valid = 1'b0;` This makes optimizer_input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 506: `optimizer_output_ready = 1'b0;` This makes optimizer_output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 507: `train_start_valid = 1'b0;` This makes train_start_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 508: `train_s_valid = 1'b0;` This makes train_s_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 509: `train_m_ready = 1'b0;` This makes train_m_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 510: `lut_clear = 1'b0;` This makes lut_clear, the value named 'lut clear' in this block, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 511: `lut_load_valid = 1'b0;` This makes lut_load_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 512: `lut_load_address = lut_load_address_r;` This makes lut_load_address, the value named 'lut load address' in this block, equal to 'lut_load_address_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lut_load_address_r: the value named 'lut load address r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 513: `lut_load_value = lut_load_value_r;` This makes lut_load_value, the value named 'lut load value' in this block, equal to 'lut_load_value_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lut_load_value_r: the value named 'lut load value r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 514: `lut_input_valid = 1'b0;` This makes lut_input_valid, the producer's statement that its current payload is meaningful, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 515: `lut_output_ready = 1'b0;` This makes lut_output_ready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 517: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 518: `ST_TENSOR: begin` This is the ST_TENSOR case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 519: `tensor_s_valid = s_axis_tvalid;` This makes tensor_s_valid, the producer's statement that its current payload is meaningful, equal to 's_axis_tvalid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are s_axis_tvalid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 520: `s_axis_tready = tensor_s_ready;` This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to 'tensor_s_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are tensor_s_ready: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 521: `result_input_valid = tensor_m_valid;` This makes result_input_valid, the producer's statement that its current payload is meaningful, equal to 'tensor_m_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are tensor_m_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 522: `result_input_last = tensor_m_last;` This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'tensor_m_last'. It is driven by combinational or procedural logic in the current evaluation. The important operands are tensor_m_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 523: `tensor_m_ready = result_prestage_ready;` This makes tensor_m_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 524: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_TENSOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 525: `ST_ALPHA_LOAD: s_axis_tready = !(alpha_load_valid_r && alpha_load_final_r);` This is the ST_ALPHA_L case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 's_axis_tready = !(alpha_load_valid_r && alpha_load_final_r);'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 526: `ST_VECTOR_LOAD: s_axis_tready = !vector_load_final_r;` This is the ST_VECTOR_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 's_axis_tready = !vector_load_final_r;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 527: `ST_OPTIMIZER_LOAD, ST_LUT_EVAL_LOAD: s_axis_tready = 1'b1;` Within the combinational process whose outputs respond without waiting for a clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are ST_OPTIMIZER_LOAD: the value named 'st optimizer load' in this block; ST_LUT_EVAL_LOAD: the value named 'st lut eval load' in this block; s_axis_tready: the consumer's statement that it can accept a payload this cycle.

Line 528: `ST_LIF_LOAD: s_axis_tready = !lif_load_pending_r;` This is the ST_LIF_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 's_axis_tready = !lif_load_pending_r;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 529: `ST_ALPHA_START: alpha_input_valid = 1'b1;` This is the ST_ALPHA_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'alpha_input_valid = 1'b1;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_ALPHA_START, the machine performs the named control phase..

Line 530: `ST_ALPHA_OUTPUT: begin` This is the ST_ALPHA_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 531: `result_input_valid = alpha_output_valid;` This makes result_input_valid, the producer's statement that its current payload is meaningful, equal to 'alpha_output_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are alpha_output_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 532: `result_input_last = 1'b1;` This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 533: `alpha_output_ready = result_prestage_ready;` This makes alpha_output_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 534: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 535: `ST_VECTOR_START: vector_input_valid = 1'b1;` This is the ST_VECTOR_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'vector_input_valid = 1'b1;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_VECTOR_START, the machine performs the named control phase..

Line 536: `ST_VECTOR_OUTPUT: begin` This is the ST_VECTOR_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 537: `result_input_valid = vector_output_valid;` This makes result_input_valid, the producer's statement that its current payload is meaningful, equal to 'vector_output_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are vector_output_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 538: `result_input_last = output_word_index == 3;` This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'output_word_index == 3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 539: `vector_output_ready = result_prestage_ready` This statement continues through source line 540; the explanation uses the complete expression rather than only the first visual fragment. This makes vector_output_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready && output_word_index == 3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 540: `&& output_word_index == 3;` This is continuation line 2 of the 2-line logical statement that begins at source line 539. Its exact fragment is '&& output_word_index == 3;'. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes vector_output_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready && output_word_index == 3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 541: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 542: `ST_LAYERNORM_START: ln_start_valid = 1'b1;` This is the ST_LAYERNORM_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'ln_start_valid = 1'b1;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LAYERNORM_START, the machine performs the named control phase..

Line 543: `ST_LAYERNORM_LOAD0, ST_LAYERNORM_LOAD1: s_axis_tready = 1'b1;` Within the combinational process whose outputs respond without waiting for a clock edge Within state ST_LAYERNORM_START, the machine performs the named control phase., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are ST_LAYERNORM_LOAD0: the value named 'st layernorm load0' in this block; ST_LAYERNORM_LOAD1: the value named 'st layernorm load1' in this block; s_axis_tready: the consumer's statement that it can accept a payload this cycle.

Line 544: `ST_LAYERNORM_SEND: ln_sample_valid = 1'b1;` This is the ST_LAYERNORM_SEND case branch, which performs this explicitly named phase. The same-cycle action begins with 'ln_sample_valid = 1'b1;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase..

Line 545: `ST_LAYERNORM_OUTPUT: begin` This is the ST_LAYERNORM_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 546: `result_input_valid = ln_result_valid;` This makes result_input_valid, the producer's statement that its current payload is meaningful, equal to 'ln_result_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are ln_result_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 547: `result_input_last = ln_result_last;` This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'ln_result_last'. It is driven by combinational or procedural logic in the current evaluation. The important operands are ln_result_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 548: `ln_result_ready = result_prestage_ready;` This makes ln_result_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 549: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 550: `ST_SOFTMAX_START: softmax_start_valid = 1'b1;` This is the ST_SOFTMAX_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'softmax_start_valid = 1'b1;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_SOFTMAX_START, the machine performs the named control phase..

Line 551: `ST_SOFTMAX_LOAD: begin` This is the ST_SOFTMAX_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 552: `softmax_score_valid = s_axis_tvalid;` This makes softmax_score_valid, the producer's statement that its current payload is meaningful, equal to 's_axis_tvalid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are s_axis_tvalid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 553: `// Entry to this state is delayed until the child accepted its` Design intent: Entry to this state is delayed until the child accepted its This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 554: `// start command, and the child remains ready until score_last.` Design intent: start command, and the child remains ready until score_last. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 555: `// Making that invariant explicit breaks a ready-to-state loop.` Design intent: Making that invariant explicit breaks a ready-to-state loop. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 556: `s_axis_tready = softmax_score_ready;` This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to 'softmax_score_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are softmax_score_ready: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 557: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 558: `ST_SOFTMAX_OUTPUT: begin` This is the ST_SOFTMAX_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 559: `result_input_valid = softmax_probability_valid;` This makes result_input_valid, the producer's statement that its current payload is meaningful, equal to 'softmax_probability_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are softmax_probability_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting

for a clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 560: `result_input_last = softmax_probability_last;` This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'softmax_probability_last'. It is driven by combinational or procedural logic in the current evaluation. The important operands are softmax_probability_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 561: `softmax_probability_ready = result_prestage_ready;` This makes softmax_probability_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 562: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 563: `ST_LIF_CLEAR: lif_clear_state = 1'b1;` This is the ST_LIF_CLEAR case branch, which performs this explicitly named phase. The same-cycle action begins with 'lif_clear_state = 1'b1;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LIF_CLEAR, the machine performs the named control phase..

Line 564: `ST_LIF_START: lif_input_valid = 1'b1;` This is the ST_LIF_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'lif_input_valid = 1'b1;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LIF_START, the machine performs the named control phase..

Line 565: `ST_LIF_OUTPUT: begin` This is the ST_LIF_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 566: `result_input_valid = lif_output_valid;` This makes result_input_valid, the producer's statement that its current payload is meaningful, equal to 'lif_output_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lif_output_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 567: `result_input_last = !lif_trace_requested_r` This statement continues through source line 568; the explanation uses the complete expression rather than only the first visual fragment. This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to '!lif_trace_requested_r || output_word_index == 12'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lif_trace_requested_r: the value named 'lif trace requested r' in this block; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 568: `|| output_word_index == 12;` This is continuation line 2 of the 2-line logical statement that begins at source line 567. Its exact fragment is '|| output_word_index == 12;'. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to '!lif_trace_requested_r

|| output_word_index == 12‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are lif_trace_requested_r: the value named ’lif trace requested r’ in this block; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 569: `lif_output_ready = result_prestage_ready` This statement continues through source line 570; the explanation uses the complete expression rather than only the first visual fragment. This makes lif_output_ready, the consumer’s statement that it can accept a payload this cycle, equal to ‘result_prestage_ready && (!lif_trace_requested_r || output_word_index == 12)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer’s statement that it can accept a payload this cycle; lif_trace_requested_r: the value named ’lif trace requested r’ in this block; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 570: `&& (!lif_trace_requested_r || output_word_index == 12);` This is continuation line 2 of the 2-line logical statement that begins at source line 569. Its exact fragment is ‘&& (!lif_trace_requested_r || output_word_index == 12);‘. The important operands are lif_trace_requested_r: the value named ’lif trace requested r’ in this block; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes lif_output_ready, the consumer’s statement that it can accept a payload this cycle, equal to ‘result_prestage_ready && (!lif_trace_requested_r || output_word_index == 12)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer’s statement that it can accept a payload this cycle; lif_trace_requested_r: the value named ’lif trace requested r’ in this block; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 571: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 572: `ST_OPTIMIZER_START: optimizer_input_valid = 1’b1;` This is the ST_OPTIMIZER_START case branch, which performs this explicitly named phase. The same-cycle action begins with ‘optimizer_input_valid = 1’b1;‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_OPTIMIZER_START, the machine performs the named control phase..

Line 573: `ST_OPTIMIZER_OUTPUT: begin` This is the ST_OPTIMIZER_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 574: `result_input_valid = optimizer_output_valid;` This makes result_input_valid, the producer’s statement that its current payload is meaningful, equal to ‘optimizer_output_valid‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are optimizer_output_valid: the producer’s statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 575: `result_input_last = output_word_index == 4’d7;` This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘output_word_index == 4’d7‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry; d7: the value named ’d7’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 576: `optimizer_output_ready = result_prestage_ready` This statement continues through source line 577; the explanation uses the complete expression rather than only the first visual fragment. This makes optimizer_output_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready && output_word_index == 4'd7'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle; output_word_index: an integer selecting one tensor element, lane, bank, or state entry; d7: the value named 'd7' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 577: `&& output_word_index == 4'd7;` This is continuation line 2 of the 2-line logical statement that begins at source line 576. Its exact fragment is '&& output_word_index == 4'd7;'. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry; d7: the value named 'd7' in this block. Read together, the complete operation is: This makes optimizer_output_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready && output_word_index == 4'd7'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle; output_word_index: an integer selecting one tensor element, lane, bank, or state entry; d7: the value named 'd7' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 578: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 579: `ST_TRAIN_START: train_start_valid = 1'b1;` This is the ST_TRAIN_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'train_start_valid = 1'b1;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_TRAIN_START, the machine performs the named control phase..

Line 580: `ST_TRAIN_RUN: begin` This is the ST_TRAIN_RUN case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 581: `train_s_valid = s_axis_tvalid;` This makes train_s_valid, the producer's statement that its current payload is meaningful, equal to 's_axis_tvalid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are s_axis_tvalid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 582: `s_axis_tready = train_s_ready;` This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to 'train_s_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are train_s_ready: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 583: `result_input_valid = train_m_valid;` This makes result_input_valid, the producer's statement that its current payload is meaningful, equal to 'train_m_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are train_m_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 584: `result_input_last = train_m_last;` This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'train_m_last'. It is driven by combinational or procedural logic in the current evaluation. The important operands are train_m_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 585: `train_m_ready = result_prestage_ready;` This makes train_m_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 586: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 587: `ST_LUT_LOAD: begin` This is the ST_LUT_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 588: `lut_load_valid = lut_load_pending_r;` This makes lut_load_valid, the producer's statement that its current payload is meaningful, equal to 'lut_load_pending_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lut_load_pending_r: the value named 'lut load pending r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 589: `s_axis_tready = !lut_load_pending_r;` This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '!lut_load_pending_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lut_load_pending_r: the value named 'lut load pending r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 590: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 591: `ST_LUT_EVAL_START: lut_input_valid = 1'b1;` This is the ST_LUT_EVAL_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'lut_input_valid = 1'b1;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_EVAL_START, the machine performs the named control phase..

Line 592: `ST_LUT_EVAL_OUTPUT: begin` This is the ST_LUT_EVAL_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 593: `result_input_valid = lut_output_valid;` This makes result_input_valid, the producer's statement that its current payload is meaningful, equal to 'lut_output_valid'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lut_output_valid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 594: `result_input_last = output_word_index == 1;` This makes result_input_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'output_word_index == 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 595: `lut_output_ready = result_prestage_ready` This statement continues through source line 596; the explanation uses the complete expression rather than only the first visual fragment. This makes lut_output_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready && output_word_index == 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 596: `&& output_word_index == 1;` This is continuation line 2 of the 2-line logical statement that begins at source line 595. Its exact fragment is '&& output_word_index == 1;'. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes lut_output_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_prestage_ready && output_word_index == 1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 597: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 598: `ST_LUT_CLEAR: lut_clear = lut_clear_requested_r;` This is the ST_LUT_CLEAR case branch, which performs this explicitly named phase. The same-cycle action begins with 'lut_clear = lut_clear_requested_r;'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase..

Line 599: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase..

Line 600: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 601: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 603: `// A bank samples whenever its source owns an available prestage slot. The` Design intent: A bank samples whenever its source owns an available prestage slot. The This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 604: `// write condition deliberately excludes child VALID: during a downstream` Design intent: write condition deliberately excludes child VALID: during a downstream This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 605: `// stall the full prestage freezes the bank, while an available slot may` Design intent: stall the full prestage freezes the bank, while an available slot may This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 606: `// harmlessly sample an invalid payload. This keeps the wide bank enable` Design intent: harmlessly sample an invalid payload. This keeps the wide bank enable This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 607: `// local to the one-hot core state instead of broadcasting a remote child` Design intent: local to the one-hot core state instead of broadcasting a remote child This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 608: `// FSM bit, and it preserves the payload associated with every valid token.` Design intent: FSM bit, and it preserves the payload associated with every valid token. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 609: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 610: `if (result_prestage_ready) begin` This condition selects the following hardware branch only when 'result_prestage_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_prestage_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 611: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 612: `ST_TENSOR: result_tensor_data_r <= tensor_m_data;` This is the ST_TENSOR case branch, which performs this explicitly named phase. The same-cycle action begins with 'result_tensor_data_r <= tensor_m_data;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 613: `ST_ALPHA_OUTPUT: result_alpha_data_r <= {28'd0,` This statement continues through source line 614; the explanation uses the complete expression rather than only the first visual fragment. This is the ST_ALPHA_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_alpha_data_r <= {28'd0, alpha_zero_matches, alpha_spike_matches, alpha_score};'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 614: `alpha_zero_matches, alpha_spike_matches, alpha_score};` This is continuation line 2 of the 2-line logical statement that begins at source line 613. Its exact fragment is 'alpha_zero_matches, alpha_spike_matches, alpha_score};'. The important operands are alpha_zero_matches: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; alpha_spike_matches: a binary event produced when a neuron crosses its threshold; alpha_score: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Read together, the complete operation is: This is the ST_ALPHA_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_alpha_data_r <= {28'd0, alpha_zero_matches, alpha_spike_matches, alpha_score};'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 615: `ST_VECTOR_OUTPUT: result_vector_data_r` This is the ST_VECTOR_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_vector_data_r'; context is the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 616: `<= vector_result[output_word_index*64 +: 64];` Within the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are vector_result: the value named 'vector result' in this block; output_word_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 617: `ST_LAYERNORM_OUTPUT: result_layernorm_data_r <= {19'd0,` This statement continues through source line 618; the explanation uses the complete expression rather than only the first visual fragment. This is the ST_LAYERNORM_OU case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_layernorm_data_r <= {19'd0, ln_result_last, ln_result_index, ln_result_value};'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 618: `ln_result_last, ln_result_index, ln_result_value};` This is continuation line 2 of the 2-line logical statement that begins at source line 617. Its exact fragment is 'ln_result_last, ln_result_index, ln_result_value};'. The important operands are ln_result_last: the AXI-Stream marker for the final beat of a packet or command payload; ln_result_index: an integer selecting one tensor element, lane, bank, or state entry; ln_result_value: the value named 'ln result value' in this block. Read together, the complete operation is: This is the ST_LAYERNORM_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_layernorm_data_r <= {19'd0, ln_result_last, ln_result_index, ln_result_value};'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 619: `ST_SOFTMAX_OUTPUT: result_softmax_data_r <= {38'd0,` This statement continues through source line 621; the explanation uses the complete expression rather than only the first visual fragment. This is the ST_SOFTMAX_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_softmax_data_r <= {38'd0, softmax_probability_last, softmax_probability_index, softmax_probability};'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 620: `softmax_probability_last, softmax_probability_index,` This is continuation line 2 of the 3-line logical statement that begins at source line 619. Its exact fragment is 'softmax_probability_last, softmax_probability_index,'. The important operands are softmax_probability_last: the AXI-Stream marker for the final beat of a packet or command payload; softmax_probability_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This is the ST_SOFTMAX_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_softmax_data_r <= {38'd0, softmax_probability_last, softmax_probability_index, softmax_probability};'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 621: `softmax_probability};` This is continuation line 3 of the 3-line logical statement that begins at source line 619. Its exact fragment is 'softmax_probability};'. The important operands are softmax_probability: the value named 'softmax probability' in this block. Read together, the complete operation is: This is the ST_SOFTMAX_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_softmax_data_r <= {38'd0, softmax_probability_last, softmax_probability_index, softmax_probability};'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 622: `ST_LIF_OUTPUT: begin` This is the ST_LIF_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 623: `if (output_word_index == 0) begin` This condition selects the following hardware branch only when 'output_word_index == 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than

making software jump. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 624: `result_lif_data_r <= {lif_timesteps, lif_spikes};` This makes result_lif_data_r, the payload carried with the surrounding valid/ready handshake, equal to '{lif_timesteps, lif_spikes}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lif_timesteps: one discrete SNN update instant; lif_spikes: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 625: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 626: `result_lif_data_r <= lif_pre_reset_membrane[` This statement continues through source line 627; the explanation uses the complete expression rather than only the first visual fragment. This makes result_lif_data_r, the payload carried with the surrounding valid/ready handshake, equal to 'lif_pre_reset_membrane[lif_trace_bit_offset +: 64]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lif_pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; lif_trace_bit_offset: the value named 'lif trace bit offset' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 627: `lif_trace_bit_offset +:  64];` This is continuation line 2 of the 2-line logical statement that begins at source line 626. Its exact fragment is 'lif_trace_bit_offset +: 64];'. The important operands are lif_trace_bit_offset: the value named 'lif trace bit offset' in this block. Read together, the complete operation is: This makes result_lif_data_r, the payload carried with the surrounding valid/ready handshake, equal to 'lif_pre_reset_membrane[lif_trace_bit_offset +: 64]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lif_pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; lif_trace_bit_offset: the value named 'lif trace bit offset' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 628: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 629: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 630: `ST_OPTIMIZER_OUTPUT: result_optimizer_data_r <= {24'd0,` This statement continues through source line 632; the explanation uses the complete expression rather than only the first visual fragment. This is the ST_OPTIMIZER_OUTP case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_optimizer_data_r <= {24'd0, optimizer_updated_velocity[output_word_index*24 +: 24], optimizer_updated_weight[outpu +: 16]};'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 631: `optimizer_updated_velocity[output_word_index*24 +:  24],` This is continuation line 2 of the 3-line logical statement that begins at source line 630. Its exact fragment is 'optimizer_updated_velocity[output_word_index*24 +: 24],'. The important operands are optimizer_updated_velocity: the momentum history retained by the SGD optimizer; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This is the ST_OPTIMIZER_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_optimizer_data_r <= {24'd0, optimizer_updated_velocity[ou +: 24], optimizer_updated_weight[output_word_index*16 +: 16]};'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 632: `optimizer_updated_weight[output_word_index*16 +: 16]};` This is continuation line 3 of the 3-line logical statement that begins at source line 630. Its exact fragment is 'optimizer_updated_weight[output_word_index*16 +: 16]};'. The important operands are optimizer_updated_weight: a learned coefficient multiplied by an activation; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This is the ST_OPTIMIZER_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_optimizer_data_r <= {24'd0, optimizer_updated_velocity[output_word_inde +: 24], optimizer_updated_weight[output_word_index*16 +: 16]};'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 633: `ST_TRAIN_RUN: result_train_data_r <= train_m_data;` This is the ST_TRAIN_RUN case branch, which performs this explicitly named phase. The same-cycle action begins with 'result_train_data_r <= train_m_data;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 634: `ST_LUT_EVAL_OUTPUT: result_lut_data_r` This is the ST_LUT_EVAL_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_lut_data_r'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 635: `<= lut_output_values[output_word_index*64 +: 64];` Within the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are lut_output_values: the value named 'lut output values' in this block; output_word_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 636: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 637: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 638: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 639: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 641: `// Two-entry elastic output pipeline. The first stage captures each` Design intent: Two-entry elastic output pipeline. The first stage captures each This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 642: `// engine into a source-local register; the second stage performs only the` Design intent: engine into a source-local register; the second stage performs only the This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 643: `// registered-bank selection. Data and tag registers intentionally have` Design intent: registered-bank selection. Data and tag registers intentionally have This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 644: `// no reset mux because their valid bits are the architectural qualifier.` Design intent: no reset mux because their valid bits are the architectural qualifier. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 645: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 646: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 647: `result_prestage_valid_r <= 1'b0;` This makes result_prestage_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 648: `result_output_valid_r <= 1'b0;` This makes result_output_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 649: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 650: `if (result_output_ready) begin` This condition selects the following hardware branch only when 'result_output_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_output_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 651: `result_output_valid_r <= result_prestage_valid_r;` This makes result_output_valid_r, the producer's statement that its current payload is meaningful, equal to 'result_prestage_valid_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_prestage_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 652: `if (result_prestage_valid_r) begin` This condition selects the following hardware branch only when 'result_prestage_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_prestage_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 653: `result_output_last_r <= result_prestage_last_r;` This makes result_output_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'result_prestage_last_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_prestage_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 654: `unique case (result_prestage_source_r)` This starts a multiplexer/state decode selected by 'result_prestage_sour 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 655: `RESULT_TENSOR: result_output_data_r <= result_tensor_data_r;` This is the RESULT_TENSOR case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_output_data_r <= result_tensor_data_r;‘; context is the clocked process that updates registers only on a rising clock edge Within state RESULT_TENSOR, the machine performs the named control phase..

Line 656: `RESULT_ALPHA: result_output_data_r <= result_alpha_data_r;` This is the RESULT_ALPHA case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_output_data_r <= result_alpha_data_r;‘; context is the clocked process that updates registers only on a rising clock edge Within state RESULT_ALPHA, the machine performs the named control phase..

Line 657: `RESULT_VECTOR: result_output_data_r <= result_vector_data_r;` This is the RESULT_VECTOR case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_output_data_r <= result_vector_data_r;‘; context is the clocked process that updates registers only on a rising clock edge Within state RESULT_VECTOR, the machine performs the named control phase..

Line 658: `RESULT_LAYERNORM: result_output_data_r` This is the RESULT_LAYERNORM case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_output_data_r‘; context is the clocked process that updates registers only on a rising clock edge Within state RESULT_LAYERNORM, the machine performs the named control phase..

Line 659: `<= result_layernorm_data_r;` Within the clocked process that updates registers only on a rising clock edge Within state RESULT_LAYERNORM, the machine performs the named control phase., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are result_layernorm_data_r: the payload carried with the surrounding valid/ready handshake.

Line 660: `RESULT_SOFTMAX: result_output_data_r <= result_softmax_data_r;` This is the RESULT_SOFTMAX case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_output_data_r <= result_softmax_data_r;‘; context is the clocked process that updates registers only on a rising clock edge Within state RESULT_SOFTMAX, the machine performs the named control phase..

Line 661: `RESULT_LIF: result_output_data_r <= result_lif_data_r;` This is the RESULT_LIF case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_output_data_r <= result_lif_data_r;‘; context is the clocked process that updates registers only on a rising clock edge Within state RESULT_LIF, the machine performs the named control phase..

Line 662: `RESULT_OPTIMIZER: result_output_data_r` This is the RESULT_OPTIMIZER case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_output_data_r‘; context is the clocked process that updates registers only on a rising clock edge Within state RESULT_OPTIMIZER, the machine performs the named control phase..

Line 663: `<= result_optimizer_data_r;` Within the clocked process that updates registers only on a rising clock edge Within state RESULT_OPTIMIZER, the machine performs the named control phase., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are result_optimizer_data_r: the payload carried with the surrounding valid/ready handshake.

Line 664: `RESULT_TRAIN: result_output_data_r <= result_train_data_r;` This is the RESULT_TRAIN case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_output_data_r <= result_train_data_r;‘; context is the clocked process that updates registers only on a rising clock edge Within state RESULT_TRAIN, the machine performs the named control phase..

Line 665: `RESULT_LUT: result_output_data_r <= result_lut_data_r;` This is the RESULT_LUT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_output_data_r <= result_lut_data_r;‘; context is the clocked process that updates registers only on a rising clock edge Within state RESULT_LUT, the machine performs the named control phase..

Line 666: `default: result_output_data_r <= 64'd0;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_output_data_r <= 64’d0;‘; context is the clocked process that updates registers only on a rising clock edge Within state RESULT_LUT, the machine performs the named control phase..

Line 667: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state RESULT_LUT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 668: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 669: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 671: `if (result_prestage_ready) begin` This condition selects the following hardware branch only when ‘result_prestage_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_prestage_ready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 672: `result_prestage_valid_r <= result_input_valid;` This makes result_prestage_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘result_input_valid‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_input_valid: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 673: `result_prestage_last_r <= result_input_last;` This makes result_prestage_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘result_input_last‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_input_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 674: `unique case (state)` This starts a multiplexer/state decode selected by ‘state‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 675: `ST_TENSOR: result_prestage_source_r <= RESULT_TENSOR;` This is the ST_TENSOR case branch, which performs this explicitly named phase. The same-cycle action begins with ‘result_prestage_source_r <= RESULT_TENSOR;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 676: `ST_ALPHA_OUTPUT: result_prestage_source_r <= RESULT_ALPHA;` This is the ST_ALPHA_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘result_prestage_source_r <= RESULT_ALPHA;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 677: `ST_VECTOR_OUTPUT: result_prestage_source_r <= RESULT_VECTOR;` This is the ST_VECTOR_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘result_prestage_source_r <= RESULT_VECTOR;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 678: `ST_LAYERNORM_OUTPUT: result_prestage_source_r` This is the ST_LAYERNORM_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_prestage_source_r'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 679: `<= RESULT_LAYERNORM;` Within the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are RESULT_LAYERNORM: the value named 'result layernorm' in this block.

Line 680: `ST_SOFTMAX_OUTPUT: result_prestage_source_r <= RESULT_SOFTMAX;` This is the ST_SOFTMAX_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_prestage_source_r <= RESULT_SOFTMAX;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 681: `ST_LIF_OUTPUT: result_prestage_source_r <= RESULT_LIF;` This is the ST_LIF_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_prestage_source_r <= RESULT_LIF;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 682: `ST_OPTIMIZER_OUTPUT: result_prestage_source_r` This is the ST_OPTIMIZER_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_prestage_source_r'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 683: `<= RESULT_OPTIMIZER;` Within the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are RESULT_OPTIMIZER: the value named 'result optimizer' in this block.

Line 684: `ST_TRAIN_RUN: result_prestage_source_r <= RESULT_TRAIN;` This is the ST_TRAIN_RUN case branch, which performs this explicitly named phase. The same-cycle action begins with 'result_prestage_source_r <= RESULT_TRAIN;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 685: `ST_LUT_EVAL_OUTPUT: result_prestage_source_r <= RESULT_LUT;` This is the ST_LUT_EVAL_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'result_prestage_source_r <= RESULT_LUT;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 686: `default: result_prestage_source_r <= RESULT_TENSOR;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'result_prestage_source_r <= RESULT_TENSOR;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 687: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 688: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 689: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 690: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 692: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 693: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 694: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 695: `command_done <= 1'b0;` This makes command_done, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 696: `command_done_pending_r <= 1'b0;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 697: `input_beat_accepted_r <= 1'b0;` This makes input_beat_accepted_r, the value named 'input beat accepted r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 698: `output_beat_accepted_r <= 1'b0;` This makes output_beat_accepted_r, the value named 'output beat accepted r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 699: `status_error_r <= 1'b0;` This makes status_error_r, the value named 'status error r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 700: `error_event_r <= 1'b0;` This makes error_event_r, the value named 'error event r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 701: `clear_error_r <= 1'b0;` This makes clear_error_r, the value named 'clear error r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 702: `stream_protocol_error_event_r <= 1'b0;` This makes stream_protocol_error_event_r, the value named 'stream protocol error event r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 703: `clear_counters_event_r <= 1'b0;` This makes clear_counters_event_r, a hardware telemetry register that accumulates measured events, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 704: `status_active_opcode <= 4'd0;` This makes status_active_opcode, the value named 'status active opcode' in this block, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 705: `status_command_count <= 32'd0;` This makes status_command_count, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 706: `status_input_beats <= 32'd0;` This makes status_input_beats, the value named 'status input beats' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 707: `status_output_beats <= 32'd0;` This makes status_output_beats, the value named 'status output beats' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 708: `stream_beat_index <= 8'd0;` This makes stream_beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 709: `stream_item_index <= 12'd0;` This makes stream_item_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 710: `stream_items_remaining_r <= 12'd0;` This makes stream_items_remaining_r, the value named 'stream items remaining r' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 711: `stream_last_pending_r <= 1'b0;` This makes stream_last_pending_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 712: `output_word_index <= 4'd0;` This makes output_word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 713: `captured_command_r <= 109'd0;` This makes captured_command_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '109'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 714: `train_reserved_partial_r <= 4'd0;` This makes train_reserved_partial_r, the value named 'train reserved partial r' in this block, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 715: `train_reserved_nonzero_r <= 1'b0;` This makes train_reserved_nonzero_r, the value named 'train reserved nonzero r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 716: `command_had_output_r <= 1'b0;` This makes command_had_output_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 717: `final_output_accepted_r <= 1'b0;` This makes final_output_accepted_r, the value named 'final output accepted r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 718: `completion_error_r <= 1'b0;` This makes completion_error_r, the value named 'completion error r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 719: `alpha_query_r <= '0;` This makes alpha_query_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 720: `alpha_key_r <= '0;` This makes alpha_key_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 721: `alpha_active_bits_r <= 9'd0;` This makes alpha_active_bits_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 722: `alpha_q8_r <= 9'd0;` This makes alpha_q8_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 723: `alpha_load_valid_r <= 1'b0;` This makes alpha_load_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 724: `alpha_load_index_r <= 3'd0;` This makes alpha_load_index_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to '3'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 725: `alpha_load_data_r <= 64'd0;` This makes alpha_load_data_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 726: `alpha_load_final_r <= 1'b0;` This makes alpha_load_final_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 727: `alpha_load_last_r <= 1'b0;` This makes alpha_load_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 728: `vector_operation_r <= 4'd0;` This makes vector_operation_r, the value named 'vector operation r' in this block, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 729: `vector_operand_a_r <= '0;` This makes vector_operand_a_r, the value named 'vector operand a r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 730: `vector_operand_b_r <= '0;` This makes vector_operand_b_r, the value named 'vector operand b r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 731: `vector_multiplier_r <= 16'sd0;` This makes vector_multiplier_r, the value named 'vector multiplier r' in this block, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 732: `vector_shift_r <= 5'd0;` This makes vector_shift_r, the value named 'vector shift r' in this block, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 733: `vector_zero_point_r <= 16'sd0;` This makes vector_zero_point_r, the integer code representing real numeric zero in affine quantization, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 734: `vector_threshold_r <= 32'sd0;` This makes vector_threshold_r, the membrane level at which a neuron emits a spike, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 735: `vector_window_r <= 32'd0;` This makes vector_window_r, the value named 'vector window r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 736: `vector_clamp_min_r <= 32'sh80000000;` This makes vector_clamp_min_r, the value named 'vector clamp min r' in this block, equal to '32'sh80000000'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sh80000000: the value named 'sh80000000' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 737: `vector_clamp_max_r <= 32'sh7fffffff;` This makes vector_clamp_max_r, the value named 'vector clamp max r' in this block, equal to '32'sh7fffffff'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sh7fffffff: the value named 'sh7fffffff' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 738: `vector_load_valid_r <= 1'b0;` This makes vector_load_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 739: `vector_load_index_r <= 4'd0;` This makes vector_load_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 740: `vector_load_data_r <= 64'd0;` This makes vector_load_data_r, the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 741: `vector_load_final_r <= 1'b0;` This makes vector_load_final_r, the value named 'vector load final r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 742: `vector_load_last_r <= 1'b0;` This makes vector_load_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 743: `ln_count_r <= 12'd0;` This makes ln_count_r, an integer count retained for control or measurable telemetry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 744: `ln_epsilon_r <= 32'd0;` This makes ln_epsilon_r, the value named 'ln epsilon r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 745: `ln_sample_word0_r <= 64'd0;` This makes ln_sample_word0_r, the value named 'ln sample word0 r' in this block, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 746: `ln_sample_value_r <= 24'sd0;` This makes ln_sample_value_r, the value named 'ln sample value r' in this block, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 747: `ln_sample_gamma_r <= 24'sd0;` This makes ln_sample_gamma_r, the learned multiplicative LayerNorm parameter, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 748: `ln_sample_beta_r <= 24'sd0;` This makes ln_sample_beta_r, the learned additive LayerNorm parameter, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 749: `ln_start_accept_r <= 1'b0;` This makes ln_start_accept_r, the value named 'ln start accept r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 750: `softmax_count_r <= 9'd0;` This makes softmax_count_r, an integer count retained for control or measurable telemetry, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 751: `softmax_shift_r <= 5'd0;` This makes softmax_shift_r, the value named 'softmax shift r' in this block, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 752: `softmax_start_accept_r <= 1'b0;` This makes softmax_start_accept_r, the value named 'softmax start accept r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 753: `lif_current_r <= '0;` This makes lif_current_r, the value named 'lif current r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 754: `lif_leak_shift_r <= 5'd0;` This makes lif_leak_shift_r, the retained fraction of prior membrane state, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 755: `lif_threshold_r <= 24'sd0;` This makes lif_threshold_r, the membrane level at which a neuron emits a spike, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 756: `lif_reset_r <= 24'sd0;` This makes lif_reset_r, the value named 'lif reset r' in this block, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 757: `lif_clear_requested_r <= 1'b0;` This makes lif_clear_requested_r, the value named 'lif clear requested r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 758: `lif_trace_requested_r <= 1'b0;` This makes lif_trace_requested_r, the value named 'lif trace requested r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 759: `lif_load_word_select_r <= 8'd0;` This makes lif_load_word_select_r, the value named 'lif load word select r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 760: `lif_load_pending_r <= 1'b0;` This makes lif_load_pending_r, the value named 'lif load pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 761: `lif_load_index_r <= 3'd0;` This makes lif_load_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '3'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 762: `lif_load_data_r <= 64'd0;` This makes lif_load_data_r, the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 763: `lif_load_last_r <= 1'b0;` This makes lif_load_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 764: `lif_load_final_r <= 1'b0;` This makes lif_load_final_r, the value named 'lif load final r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 765: `optimizer_weight_r <= '0;` This makes optimizer_weight_r, a learned coefficient multiplied by an activation, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 766: `optimizer_gradient_r <= '0;` This makes optimizer_gradient_r, the signed loss derivative used to update a learned parameter, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 767: `optimizer_velocity_r <= '0;` This makes optimizer_velocity_r, the momentum history retained by the SGD optimizer, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 768: `optimizer_lr_r <= 18'd0;` This makes optimizer_lr_r, the value named 'optimizer lr r' in this block, equal to '18'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 769: `optimizer_momentum_r <= 17'd0;` This makes optimizer_momentum_r, the value named 'optimizer momentum r' in this block, equal to '17'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 770: `optimizer_decay_r <= 17'd0;` This makes optimizer_decay_r, the value named 'optimizer decay r' in this block, equal to '17'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 771: `optimizer_update_shift_r <= 5'd16;` This makes optimizer_update_shift_r, the value named 'optimizer update shift r' in this block, equal to '5'd16'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d16: the value named 'd16' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 772: `optimizer_load_data_r <= 64'd0;` This makes optimizer_load_data_r, the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 773: `optimizer_load_last_r <= 1'b0;` This makes optimizer_load_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 774: `optimizer_load_index_r <= 3'd0;` This makes optimizer_load_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '3'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 775: `optimizer_load_final_r <= 1'b0;` This makes optimizer_load_final_r, the value named 'optimizer load final r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 776: `optimizer_commit_valid_r <= 1'b0;` This makes optimizer_commit_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 777: `lut_load_pending_r <= 1'b0;` This makes lut_load_pending_r, the value named 'lut load pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 778: `lut_load_address_r <= 8'd0;` This makes lut_load_address_r, the value named 'lut load address r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 779: `lut_load_value_r <= 16'sd0;` This makes lut_load_value_r, the value named 'lut load value r' in this block, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 780: `lut_load_last_r <= 1'b0;` This makes lut_load_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 781: `lut_load_final_r <= 1'b0;` This makes lut_load_final_r, the value named 'lut load final r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 782: `lut_indices_r <= 64'd0;` This makes lut_indices_r, the value named 'lut indices r' in this block, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 783: `lut_clear_requested_r <= 1'b0;` This makes lut_clear_requested_r, the value named 'lut clear requested r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 784: `decode_error_pending_r <= 1'b0;` This makes decode_error_pending_r, the value named 'decode error pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 785: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 786: `if (clear_error_r) status_error_r <= 1'b0;` This condition selects the following hardware branch only when 'clear_error_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are clear_error_r: the value named 'clear error r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 787: `else if (error_event_r) status_error_r <= 1'b1;` This condition selects the following hardware branch only when 'error_event_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are error_event_r: the value named 'error event r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 788: `error_event_r <= 1'b0;` This makes error_event_r, the value named 'error event r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 789: `clear_error_r <= 1'b0;` This makes clear_error_r, the value named 'clear error r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 790: `if (stream_protocol_error_event_r) error_event_r <= 1'b1;` This condition selects the following hardware branch only when ‘stream_protocol_error_event_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are stream_protocol_error_event_r: the value named 'stream protocol error event r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 791: `stream_protocol_error_event_r <= 1'b0;` This makes stream_protocol_error_event_r, the value named 'stream protocol error event r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 792: `clear_counters_event_r <= 1'b0;` This makes clear_counters_event_r, a hardware telemetry register that accumulates measured events, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 793: `vector_load_valid_r <= 1'b0;` This makes vector_load_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 794: `command_done <= command_done_pending_r;` This makes command_done, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘command_done_pending_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_done_pending_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge.

Line 795: `command_done_pending_r <= 1'b0;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 796: `optimizer_commit_valid_r <= 1'b0;` This makes optimizer_commit_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 797: `input_beat_accepted_r <= s_axis_tvalid && s_axis_tready;` This makes input_beat_accepted_r, the value named 'input beat accepted r' in this block, equal to ‘s_axis_tvalid && s_axis_tready‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tvalid: the producer's statement that its current payload is meaningful; s_axis_tready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 798: `output_beat_accepted_r <= m_axis_tvalid && m_axis_tready;` This makes output_beat_accepted_r, the value named 'output beat accepted r' in this block, equal to ‘m_axis_tvalid && m_axis_tready‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are m_axis_tvalid: the producer's statement that its current payload is meaningful; m_axis_tready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 799: `softmax_start_accept_r <= softmax_start_valid && softmax_start_ready;` This makes softmax_start_accept the value named 'softmax start accept r' in this block, equal to ‘softmax_start_valid && softmax_start_ready‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are softmax_start_valid: the producer's statement that its current payload is meaningful; softmax_start_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 800: `ln_start_accept_r <= ln_start_valid && ln_start_ready;` This makes ln_start_accept_r, the value named 'ln start accept r' in this block, equal to 'ln_start_valid && ln_start_ready'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ln_start_valid: the producer's statement that its current payload is meaningful; ln_start_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 801: `if (result_input_accept) command_had_output_r <= 1'b1;` This condition selects the following hardware branch only when 'result_input_accept' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_input_accept: the value named 'result input accept' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 802: `if (result_output_accept && result_output_last_r) begin` This condition selects the following hardware branch only when 'result_output_accept && result_output_last_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_output_accept: the value named 'result output accept' in this block; result_output_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 803: `final_output_accepted_r <= 1'b1;` This makes final_output_accepted_r, the value named 'final output accepted r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 804: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 805: `lif_load_word_select_r <= 8'd0;` This makes lif_load_word_select_r, the value named 'lif load word select r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 806: `lif_load_pending_r <= 1'b0;` This makes lif_load_pending_r, the value named 'lif load pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 807: `for (int lif_word = 0; lif_word < 8; lif_word++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 808: `if (lif_load_word_select_r[lif_word]) begin` This condition selects the following hardware branch only when 'lif_load_word_select_r[lif_word]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lif_load_word_select_r: the value named 'lif load word select r' in this block; lif_word: the value named 'lif word' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 809: `lif_current_r[lif_word*64 +:  64] <= lif_load_data_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are lif_current_r: the value named 'lif current r' in this block; lif_word: the value named 'lif word' in this block; lif_load_data_r: the payload carried with the surrounding valid/ready handshake.

Line 810: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 811: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 812: `alpha_load_valid_r <= 1'b0;` This makes alpha_load_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 813: `if (alpha_load_valid_r) begin` This condition selects the following hardware branch only when ‘alpha_load_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are alpha_load_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 814: `if (alpha_load_last_r != alpha_load_final_r) begin` This condition selects the following hardware branch only when ‘alpha_load_last_r != alpha_load_final_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are alpha_load_last_r: the AXI-Stream marker for the final beat of a packet or command payload; alpha_load_final_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the clocked process that updates registers only on a rising clock edge.

Line 815: `stream_protocol_error_event_r <= 1'b1;` This makes stream_protocol_error_event_r, the value named 'stream protocol error event r' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 816: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 817: `if (alpha_load_index_r < 4) begin` This condition selects the following hardware branch only when ‘alpha_load_index_r $<$ 4‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are alpha_load_index_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the clocked process that updates registers only on a rising clock edge.

Line 818: `alpha_query_r[alpha_load_index_r*64 +: 64] <= alpha_load_data_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are alpha_query_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; alpha_load_index_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; alpha_load_data_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 819: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 820: `alpha_key_r[(int'(alpha_load_index_r)-4)*64 +: 64]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are alpha_key_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention; alpha_load_index_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 821: `<= alpha_load_data_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are alpha_load_data_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 822: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 823: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 824: `if (optimizer_commit_valid_r) begin` This condition selects the following hardware branch only when ‘optimizer_commit_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are optimizer_commit_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 825: `optimizer_weight_r[optimizer_load_index_r*16 +: 16]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are optimizer_weight_r: a learned coefficient multiplied by an activation; optimizer_load_index_r: an integer selecting one tensor element, lane, bank, or state entry.

Line 826: `<= optimizer_load_data_r[15:0];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are optimizer_load_data_r: the payload carried with the surrounding valid/ready handshake.

Line 827: `optimizer_gradient_r[optimizer_load_index_r*24 +: 24]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are optimizer_gradient_r: the signed loss derivative used to update a learned parameter; optimizer_load_index_r: an integer selecting one tensor element, lane, bank, or state entry.

Line 828: `<= optimizer_load_data_r[39:16];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are optimizer_load_data_r: the payload carried with the surrounding valid/ready handshake.

Line 829: `optimizer_velocity_r[optimizer_load_index_r*24 +: 24]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are optimizer_velocity_r: the momentum history retained by the SGD optimizer; optimizer_load_index_r: an integer selecting one tensor element, lane, bank, or state entry.

Line 830: `<= optimizer_load_data_r[63:40];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are optimizer_load_data_r: the payload carried with the surrounding valid/ready handshake.

Line 831: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 832: `if (vector_load_valid_r) begin` This condition selects the following hardware branch only when ‘vector_load_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are vector_load_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 833: `if (vector_load_last_r != vector_load_final_r) begin` This condition selects the following hardware branch only when ‘vector_load_last_r != vector_load_final_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are vector_load_last_r: the AXI-Stream marker for the final beat of a packet or command payload; vector_load_final_r: the value named ’vector load final r’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 834: `stream_protocol_error_event_r <= 1'b1;` This makes stream_protocol_error_event_r, the value named ’stream protocol error event r’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 835: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 836: `if (vector_load_index_r == 0) begin` This condition selects the following hardware branch only when ‘vector_load_index_r == 0‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are vector_load_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge.

Line 837: `vector_clamp_min_r <= vector_load_data_r[31:0];` This makes vector_clamp_min_r, the value named ’vector clamp min r’ in this block, equal to ‘vector_load_data_r[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are vector_load_data_r: the payload carried with the surrounding valid/ready handshake. Context: the clocked process that updates registers only on a rising clock edge.

Line 838: `vector_clamp_max_r <= vector_load_data_r[63:32];` This makes vector_clamp_max_r, the value named ’vector clamp max r’ in this block, equal to ‘vector_load_data_r[63:32]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are vector_load_data_r: the payload carried with the surrounding valid/ready handshake. Context: the clocked process that updates registers only on a rising clock edge.

Line 839: `end else if (vector_load_index_r <= 4) begin` This statement continues through source line 841; the explanation uses the complete expression rather than only the first visual fragment. This condition selects the following hardware branch only when ‘vector_load_index_r <= 4) begin vector_operand_a_r[(int’(vector_load_index_r)-1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are vector_load_index_r: an integer selecting one tensor element, lane, bank, or state entry; vector_operand_a_r: the value named ’vector operand a r’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 840: `vector_operand_a_r[(int'(vector_load_index_r)-1)*64 +: 64]` This is continuation line 2 of the 3-line logical statement that begins at source line 839. Its exact fragment is ‘vector_operand_a_r[(int’(vector_load_index_r)-1)*64 +: 64]‘. The important operands are vector_operand_a_r: the value named ’vector operand a r’ in this block; vector_load_index_r: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This condition selects the following hardware branch only when ‘vector_load_index_r <= 4) begin vector_operand_a_r[(int’(vector_load_index_r)-1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are vector_load_index_r: an integer selecting one tensor element, lane, bank, or state entry; vector_operand_a_r: the value named ’vector operand a r’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 841: `<= vector_load_data_r;` This is continuation line 3 of the 3-line logical statement that begins at source line 839. Its exact fragment is ‘<= vector_load_data_r;‘. The important operands are vector_load_data_r: the payload carried with the surrounding valid/ready handshake. Read together, the complete operation is: This condition selects the following hardware branch only when ‘vector_load_index_r <= 4) begin vector_operand_a_r[(int’(vector_load_index_r)-1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are vector_load_index_r: an integer selecting one tensor element, lane, bank, or state entry; vector_operand_a_r: the value named ’vector operand a r’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 842: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 843: `vector_operand_b_r[(int'(vector_load_index_r)-5)*64 +: 64]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are vector_operand_b_r: the value named 'vector operand b r' in this block; vector_load_index_r: an integer selecting one tensor element, lane, bank, or state entry.

Line 844: `<= vector_load_data_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are vector_load_data_r: the payload carried with the surrounding valid/ready handshake.

Line 845: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 846: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 847: `if (clear_counters_event_r) begin` This condition selects the following hardware branch only when ‘clear_counters_event_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are clear_counters_event_r: a hardware telemetry register that accumulates measured events. Context: the clocked process that updates registers only on a rising clock edge.

Line 848: `status_input_beats <= 32'd0;` This makes status_input_beats, the value named 'status input beats' in this block, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 849: `status_output_beats <= 32'd0;` This makes status_output_beats, the value named 'status output beats' in this block, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 850: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 851: `if (input_beat_accepted_r) begin` This condition selects the following hardware branch only when ‘input_beat_accepted_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_beat_accepted_r: the value named 'input beat accepted r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 852: `status_input_beats <= status_input_beats + 1'b1;` This makes status_input_beats, the value named 'status input beats' in this block, equal to ‘status_input_beats + 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_input_beats: the value named 'status input beats' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 853: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 854: `if (output_beat_accepted_r) begin` This condition selects the following hardware branch only when ‘output_beat_accepted_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_beat_accepted_r: the value named ’output beat accepted r’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 855: `status_output_beats <= status_output_beats + 1'b1;` This makes status_output_beats, the value named ’status output beats’ in this block, equal to ‘status_output_beats + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_output_beats: the value named ’status output beats’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 856: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 857: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 859: `unique case (state)` This starts a multiplexer/state decode selected by ‘state‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 860: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 861: `if (command_valid && command_ready) begin` This condition selects the following hardware branch only when ‘command_valid && command_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are command_valid: the producer’s statement that its current payload is meaningful; command_ready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 862: `captured_command_r <= command_data[108:0];` This makes captured_command_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘command_data[108:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_data: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 863: `// Stage the wide reserved-field reduction across the` Design intent: Stage the wide reserved-field reduction across the This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 864: `// existing capture/decode clocks for 200 MHz timing.` Design intent: existing capture/decode clocks for 200 MHz timing. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 865: `train_reserved_partial_r[0] <= |command_data[61:30];` This makes train_reserved_partial_r[0], the value named ’train reserved partial r’ in this block, equal to ‘|command_data[61:30]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_data: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 866: `train_reserved_partial_r[1] <= |command_data[93:62];` This makes train_reserved_partial_r[1], the value named 'train reserved partial r' in this block, equal to '|command_data[93:62]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_data: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 867: `train_reserved_partial_r[2] <= |command_data[125:94];` This makes train_reserved_partial_r[2], the value named 'train reserved partial r' in this block, equal to '|command_data[125:94]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_data: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 868: `train_reserved_partial_r[3] <= |command_data[127:126];` This makes train_reserved_partial_r[3], the value named 'train reserved partial r' in this block, equal to '|command_data[127:126]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_data: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 869: `status_active_opcode <= command_data[3:0];` This makes status_active_opcode, the value named 'status active opcode' in this block, equal to 'command_data[3:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_data: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 870: `status_command_count <= status_command_count + 1'b1;` This makes status_command_count, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'status_command_count + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_command_count: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 871: `stream_beat_index <= 8'd0;` This makes stream_beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 872: `stream_item_index <= 12'd0;` This makes stream_item_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 873: `stream_items_remaining_r <= 12'd0;` This makes stream_items_remaining_r, the value named 'stream items remaining r' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 874: `stream_last_pending_r <= 1'b0;` This makes stream_last_pending_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 875: `output_word_index <= 4'd0;` This makes output_word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘4'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 876: `command_had_output_r <= 1'b0;` This makes command_had_output_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 877: `final_output_accepted_r <= 1'b0;` This makes final_output_accepted_r, the value named 'final output accepted r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 878: `completion_error_r <= 1'b0;` This makes completion_error_r, the value named 'completion error r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 879: `state <= ST_DECODE_COMMAND;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_DECODE_COMMAND‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DECODE_COMMAND: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 880: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 881: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 883: `ST_DECODE_COMMAND: begin` This is the ST_DECODE_COMMAND case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_DECODE_COMMAND, the machine performs the named control phase..

Line 884: `unique case (captured_command_r[3:0])` This starts a multiplexer/state decode selected by ‘captured_command_r ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 885: `CMD_TRAIN_LINEAR_BACKWARD: begin` This is the CMD_TRAIN_LINEAR_BACKWARD case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state CMD_TRAIN_LINEAR_BACKWARD, the machine performs the named control phase..

Line 886: `train_reserved_nonzero_r <= |train_reserved_partial_r;` This makes train_reserved_nonzero_r, the value named 'train reserved nonzero r' in this block, equal to ‘|train_reserved_partial_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are train_reserved_partial_r: the

value named 'train reserved partial r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_TRAIN_LINEAR_BACKWARD, the machine performs the named control phase..

Line 887: `state <= ST_TRAIN_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_TRAIN_START'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_TRAIN_START: the value named 'st train start' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_TRAIN_LINEAR_BACKWARD, the machine performs the named control phase..

Line 888: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_TRAIN_LINEAR_BACKWARD, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 889: `CMD_LOAD_ACTIVATIONS, CMD_LOAD_WEIGHTS_OUTER,` Within the clocked process that updates registers only on a rising clock edge Within state CMD_TRAIN_LINEAR_BACKWARD, the machine performs the named control phase., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are CMD_LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; CMD_LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation.

Line 890: `CMD_LOAD_WEIGHTS_DOT8, CMD_COMPUTE_DENSE_OUTER,` Within the clocked process that updates registers only on a rising clock edge Within state CMD_TRAIN_LINEAR_BACKWARD, the machine performs the named control phase., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are CMD_LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation; CMD_COMPUTE_DENSE_OUTER: the value named 'cmd compute dense outer' in this block.

Line 891: `CMD_COMPUTE_DENSE_DOT8, CMD_COMPUTE_BINARY,` Within the clocked process that updates registers only on a rising clock edge Within state CMD_TRAIN_LINEAR_BACKWARD, the machine performs the named control phase., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are CMD_COMPUTE_DENSE_DOT8: the value named 'cmd compute dense dot8' in this block; CMD_COMPUTE_BINARY: the value named 'cmd compute binary' in this block.

Line 892: `CMD_COMPUTE_TERNARY: begin` This is the CMD_COMPUTE_TERNARY case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_TERNARY, the machine issues arithmetic work using values already held on chip..

Line 893: `if (tensor_command_ready) state <= ST_TENSOR;` This condition selects the following hardware branch only when 'tensor_command_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are tensor_command_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_TERNARY, the machine issues arithmetic work using values already held on chip..

Line 894: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_TERNARY, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 895: `CMD_ALPHA_XNOR: begin` This is the CMD_ALPHA_XNOR case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_ALPHA_XNOR, the machine performs the named control phase..

Line 896: `alpha_active_bits_r <= captured_command_r[50:42];` This makes alpha_active_bits_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to ‘captured_command_r[50:42]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ALPHA_XNOR, the machine performs the named control phase..

Line 897: `alpha_q8_r <= captured_command_r[59:51];` This makes alpha_q8_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to ‘captured_command_r[59:51]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ALPHA_XNOR, the machine performs the named control phase..

Line 898: `// ST_ALPHA_LOAD commits all four query words and all` Design intent: ST_ALPHA_LOAD commits all four query words and all This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 899: `// four key words before start, so retaining the prior` Design intent: four key words before start, so retaining the prior This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 900: `// command here cannot expose stale operand bits.` Design intent: command here cannot expose stale operand bits. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 901: `state <= ST_ALPHA_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_ALPHA_LOAD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ALPHA_LOAD: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ALPHA_XNOR, the machine performs the named control phase..

Line 902: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_ALPHA_XNOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 903: `CMD_VECTOR_ALU: begin` This is the CMD_VECTOR_ALU case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state CMD_VECTOR_ALU, the machine performs the named control phase..

Line 904: `vector_operation_r <= captured_command_r[7:4];` This makes vector_operation_r, the value named 'vector operation r' in this block, equal to ‘captured_command_r[7:4]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_VECTOR_ALU, the machine performs the named control phase..

Line 905: `vector_multiplier_r <= captured_command_r[23:8];` This makes vector_multiplier_r, the value named 'vector multiplier r' in this block, equal to ‘captured_command_r[23:8]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_VECTOR_ALU, the machine performs the named control phase..

Line 906: `vector_shift_r <= captured_command_r[28:24];` This makes vector_shift_r, the value named 'vector shift r' in this block, equal to 'captured_command_r[28:24]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_VECTOR_ALU, the machine performs the named control phase..

Line 907: `vector_zero_point_r <= captured_command_r[44:29];` This makes vector_zero_point_r, the integer code representing real numeric zero in affine quantization, equal to 'captured_command_r[44:29]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_VECTOR_ALU, the machine performs the named control phase..

Line 908: `vector_threshold_r <= captured_command_r[76:45];` This makes vector_threshold_r, the membrane level at which a neuron emits a spike, equal to 'captured_command_r[76:45]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_VECTOR_ALU, the machine performs the named control phase..

Line 909: `vector_window_r <= captured_command_r[108:77];` This makes vector_window_r, the value named 'vector window r' in this block, equal to 'captured_command_r[108:77]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_VECTOR_ALU, the machine performs the named control phase..

Line 910: `state <= ST_VECTOR_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_VECTOR_LOAD'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VECTOR_LOAD: the value named 'st vector load' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_VECTOR_ALU, the machine performs the named control phase..

Line 911: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_VECTOR_ALU, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 912: `CMD_LAYERNORM: begin` This is the CMD_LAYERNORM case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_LAYERNORM, the machine performs the named control phase..

Line 913: `ln_count_r <= captured_command_r[15:4];` This makes ln_count_r, an integer count retained for control or measurable telemetry, equal to 'captured_command_r[15:4]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LAYERNORM, the machine performs the named control phase..

Line 914: `stream_items_remaining_r <= captured_command_r[15:4];` This makes stream_items_remaining_r, the value named 'stream items remaining r' in this block, equal to 'captured_command_r[15:4]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LAYERNORM, the machine performs the named control phase..

Line 915: `stream_last_pending_r <= captured_command_r[15:4] == 1;` This makes stream_last_pending_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'captured_command_r[15:4] == 1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context:

the clocked process that updates registers only on a rising clock edge Within state CMD_LAYERNORM, the machine performs the named control phase..

Line 916: `ln_epsilon_r <= captured_command_r[47:16];` This makes ln_epsilon_r, the value named 'ln epsilon r' in this block, equal to 'captured_command_r[47:16]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LAYERNORM, the machine performs the named control phase..

Line 917: `state <= ST_LAYERNORM_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LAYERNORM_START'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LAYERNORM_START: the value named 'st layernorm start' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LAYERNORM, the machine performs the named control phase..

Line 918: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LAYERNORM, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 919: `CMD_LOG_SOFTMAX: begin` This is the CMD_LOG_SOFTMAX case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_LOG_SOFTMAX, the machine performs the named control phase..

Line 920: `softmax_count_r <= captured_command_r[12:4];` This makes softmax_count_r, an integer count retained for control or measurable telemetry, equal to 'captured_command_r[12:4]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOG_SOFTMAX, the machine performs the named control phase..

Line 921: `stream_items_remaining_r <= {3'd0, captured_command_r[12:4]};` This makes stream_items_remaining_r, the value named 'stream items remaining r' in this block, equal to '{3'd0, captured_command_r[12:4]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOG_SOFTMAX, the machine performs the named control phase..

Line 922: `stream_last_pending_r <= captured_command_r[12:4] == 1;` This makes stream_last_pending_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'captured_command_r[12:4] == 1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOG_SOFTMAX, the machine performs the named control phase..

Line 923: `softmax_shift_r <= captured_command_r[17:13];` This makes softmax_shift_r, the value named 'softmax shift r' in this block, equal to 'captured_command_r[17:13]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOG_SOFTMAX, the machine performs the named control phase..

Line 924: `state <= ST_SOFTMAX_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_SOFTMAX_START'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SOFTMAX_START: the value named 'st softmax start' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOG_SOFTMAX, the machine performs the named control phase..

Line 925: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOG_SOFTMAX, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 926: `CMD_LIF_STEP: begin` This is the CMD_LIF_STEP case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 927: `lif_leak_shift_r <= captured_command_r[8:4];` This makes lif_leak_shift_r, the retained fraction of prior membrane state, equal to 'captured_command_r[8:4]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 928: `lif_threshold_r <= captured_command_r[32:9];` This makes lif_threshold_r, the membrane level at which a neuron emits a spike, equal to 'captured_command_r[32:9]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 929: `lif_reset_r <= captured_command_r[56:33];` This makes lif_reset_r, the value named 'lif reset r' in this block, equal to 'captured_command_r[56:33]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 930: `lif_clear_requested_r <= captured_command_r[57];` This makes lif_clear_requested_r, the value named 'lif clear requested r' in this block, equal to 'captured_command_r[57]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 931: `lif_trace_requested_r <= captured_command_r[58];` This makes lif_trace_requested_r, the value named 'lif trace requested r' in this block, equal to 'captured_command_r[58]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 932: `// The protocol always loads all eight words before` Design intent: The protocol always loads all eight words before This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 933: `// starting the child, so a 512-bit command-time clear` Design intent: starting the child, so a 512-bit command-time clear This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 934: `// would only add a global mux to every current bit.` Design intent: would only add a global mux to every current bit. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 935: `lif_load_word_select_r <= 8'd0;` This makes lif_load_word_select_r, the value named 'lif load word select r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 936: `lif_load_pending_r <= 1'b0;` This makes lif_load_pending_r, the value named 'lif load pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 937: `lif_load_index_r <= 3'd0;` This makes lif_load_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '3'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 938: `lif_load_final_r <= 1'b0;` This makes lif_load_final_r, the value named 'lif load final r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 939: `state <= ST_LIF_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LIF_LOAD'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LIF_LOAD: the value named 'st lif load' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase..

Line 940: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LIF_STEP, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 941: `CMD_SGD_UPDATE: begin` This is the CMD_SGD_UPDATE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_SGD_UPDATE, the machine performs the named control phase..

Line 942: `optimizer_lr_r <= captured_command_r[21:4];` This makes optimizer_lr_r, the value named 'optimizer lr r' in this block, equal to 'captured_command_r[21:4]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_SGD_UPDATE, the machine performs the named control phase..

Line 943: `optimizer_momentum_r <= captured_command_r[38:22];` This makes optimizer_momentum_r, the value named 'optimizer momentum r' in this block, equal to 'captured_command_r[38:22]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_SGD_UPDATE, the machine performs the named control phase..

Line 944: `optimizer_decay_r <= captured_command_r[55:39];` This makes optimizer_decay_r, the value named 'optimizer decay r' in this block, equal to 'captured_command_r[55:39]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_SGD_UPDATE, the machine performs the named control phase..

Line 945: `optimizer_update_shift_r <= captured_command_r[60:56];` This makes optimizer_update_shift_r, the value named 'optimizer update shift r' in this block, equal to 'captured_command_r[60:56]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_SGD_UPDATE, the machine performs the named control phase..

Line 946: `state <= ST_OPTIMIZER_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OPTIMIZER_LOAD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OPTIMIZER_LOAD: the value named ’st optimizer load’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_SGD_UPDATE, the machine performs the named control phase..

Line 947: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_SGD_UPDATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 948: `CMD_ACTIVATION_LUT: begin` This is the CMD_ACTIVATION_LUT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 949: `stream_items_remaining_r <= captured_command_r[19:8];` This makes stream_items_remaining_r, the value named ’stream items remaining r’ in this block, equal to ‘captured_command_r[19:8]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 950: `stream_last_pending_r <= captured_command_r[19:8] == 1;` This makes stream_last_pending_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘captured_command_r[19:8] == 1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 951: `if (captured_command_r[7:4] == 0) begin` This condition selects the following hardware branch only when ‘captured_command_r[7:4] == 0‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 952: `lut_clear_requested_r <= 1’b1;` This makes lut_clear_requested_r, the value named ’lut clear requested r’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 953: `decode_error_pending_r <= 1’b0;` This makes decode_error_pending_r, the value named ’decode error pending r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 954: `state <= ST_LUT_CLEAR;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LUT_CLEAR‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LUT_CLEAR: the value named ’st lut clear’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 955: `end else if (captured_command_r[7:4] == 1` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 956: `&& captured_command_r[19:8] != 0) begin` Within the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 957: `lut_load_pending_r <= 1'b0;` This makes lut_load_pending_r, the value named 'lut load pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 958: `state <= ST_LUT_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LUT_LOAD'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LUT_LOAD: the value named 'st lut load' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 959: `end else if (captured_command_r[7:4] == 2) begin` This condition selects the following hardware branch only when 'captured_command_r[7:4] == 2' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 960: `state <= ST_LUT_EVAL_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LUT_EVAL_LOAD'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LUT_EVAL_LOAD: the value named 'st lut eval load' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 961: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 962: `lut_clear_requested_r <= 1'b0;` This makes lut_clear_requested_r, the value named 'lut clear requested r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 963: `decode_error_pending_r <= 1'b1;` This makes decode_error_pending_r, the value named 'decode error pending r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 964: `state <= ST_LUT_CLEAR;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LUT_CLEAR'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LUT_CLEAR: the value named 'st lut clear' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase..

Line 965: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 966: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_ACTIVATION_LUT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 967: `CMD_CLEAR_STATUS: begin` This is the CMD_CLEAR_STATUS case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 968: `if (tensor_command_ready) begin` This condition selects the following hardware branch only when ‘tensor_command_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are tensor_command_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 969: `clear_error_r <= 1'b1;` This makes clear_error_r, the value named 'clear error r' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 970: `clear_counters_event_r <= 1'b1;` This makes clear_counters_event_r, a hardware telemetry register that accumulates measured events, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 971: `state <= ST_TENSOR;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_TENSOR‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_TENSOR: the value named 'st tensor' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 972: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 973: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 974: `default: begin` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 975: `lut_clear_requested_r <= 1'b0;` This makes lut_clear_requested_r, the value named 'lut clear requested r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 976: `decode_error_pending_r <= 1'b1;` This makes decode_error_pending_r, the value named 'decode error pending r' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 977: `state <= ST_LUT_CLEAR;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LUT_CLEAR‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LUT_CLEAR: the value named ’st lut clear’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 978: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 979: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 980: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 982: `ST_TENSOR: begin` This is the ST_TENSOR case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 983: `if (tensor_command_done) begin` This condition selects the following hardware branch only when ‘tensor_command_done‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are tensor_command_done: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 984: `if (command_had_output_r || tensor_result_accept) begin` This condition selects the following hardware branch only when ‘command_had_output_r || tensor_result_accept‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are command_had_output_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; tensor_result_accept: the value named ’tensor result accept’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 985: `completion_error_r <= tensor_status_error;` This makes completion_error_r, the value named ’completion error r’ in this block, equal to ‘tensor_status_error‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are tensor_status_error: the value named ’tensor status error’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 986: `state <= ST_OUTPUT_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_DRAIN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DRAIN: the value named ’st output drain’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 987: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 988: `if (tensor_status_error) error_event_r <= 1'b1;` This condition selects the following hardware branch only when ‘tensor_status_error‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are tensor_status_error: the value named ’tensor status error’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 989: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 990: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase..

Line 991: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 992: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 993: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_TENSOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 994: `ST_ALPHA_LOAD: begin` This is the ST_ALPHA_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 995: `if (alpha_load_valid_r && alpha_load_final_r) begin` This condition selects the following hardware branch only when ‘alpha_load_valid_r && alpha_load_final_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are alpha_load_valid_r: the producer's statement that its current payload is meaningful; alpha_load_final_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 996: `alpha_load_final_r <= 1'b0;` This makes alpha_load_final_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 997: `state <= ST_ALPHA_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_ALPHA_DRAIN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ALPHA_DRAIN: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 998: `end else if (s_axis_tvalid) begin` This condition selects the following hardware branch only when ‘s_axis_tvalid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tvalid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 999: `alpha_load_valid_r <= 1'b1;` This makes alpha_load_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1000: `alpha_load_index_r <= stream_beat_index[2:0];` This makes alpha_load_index_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to 'stream_beat_index[2:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1001: `alpha_load_data_r <= s_axis_tdata;` This makes alpha_load_data_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to 's_axis_tdata'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1002: `alpha_load_final_r <= stream_beat_index == 7;` This makes alpha_load_final_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to 'stream_beat_index == 7'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1003: `alpha_load_last_r <= s_axis_tlast;` This makes alpha_load_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 's_axis_tlast'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1004: `if (stream_beat_index != 7) begin` This condition selects the following hardware branch only when 'stream_beat_index != 7' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1005: `stream_beat_index <= stream_beat_index + 1'b1;` This makes stream_beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'stream_beat_index + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1006: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1007: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1008: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1009: `ST_ALPHA_DRAIN: if (!alpha_load_valid_r) state <= ST_ALPHA_START;` This is the ST_ALPHA_DRAIN case branch, which performs this explicitly named phase. The same-cycle action begins with ‘if (!alpha_load_valid_r) state <= ST_ALPHA_START;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_DRAIN, the machine performs the named control phase..

Line 1010: `ST_ALPHA_START: if (alpha_input_ready) state <= ST_ALPHA_OUTPUT;` This is the ST_ALPHA_START case branch, which performs this explicitly named phase. The same-cycle action begins with ‘if (alpha_input_ready) state <= ST_ALPHA_OUTPUT;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_START, the machine performs the named control phase..

Line 1011: `ST_ALPHA_OUTPUT: if (alpha_result_accept) begin` This is the ST_ALPHA_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘if (alpha_result_accept) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1012: `completion_error_r <= alpha_config_error;` This makes completion_error_r, the value named ’completion error r’ in this block, equal to ‘alpha_config_error‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are alpha_config_error: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1013: `state <= ST_OUTPUT_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_DRAIN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DRAIN: the value named ’st output drain’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1014: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ALPHA_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1015: `ST_VECTOR_LOAD: begin` This is the ST_VECTOR_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1016: `if (vector_load_final_r) begin` This condition selects the following hardware branch only when ‘vector_load_final_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are vector_load_final_r: the value named ’vector load final r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1017: `vector_load_final_r <= 1'b0;` This makes vector_load_final_r, the value named ’vector load final r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1018: `state <= ST_VECTOR_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_VECTOR_DRAIN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VECTOR_DRAIN: the value named ’st vector drain’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1019: `end else if (s_axis_tvalid) begin` This condition selects the following hardware branch only when ‘s_axis_tvalid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tvalid: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1020: `vector_load_valid_r <= 1'b1;` This makes vector_load_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1021: `vector_load_index_r <= stream_beat_index[3:0];` This makes vector_load_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘stream_beat_index[3:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1022: `vector_load_data_r <= s_axis_tdata;` This makes vector_load_data_r, the payload carried with the surrounding valid/ready handshake, equal to ‘s_axis_tdata‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named ’s axis tdata’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1023: `vector_load_final_r <= stream_beat_index == 8;` This makes vector_load_final_r, the value named ’vector load final r’ in this block, equal to ‘stream_beat_index == 8‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1024: `vector_load_last_r <= s_axis_tlast;` This makes vector_load_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘s_axis_tlast‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1025: `if (stream_beat_index != 8) begin` This condition selects the following hardware branch only when ‘stream_beat_index != 8‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1026: `stream_beat_index <= stream_beat_index + 1'b1;` This makes stream_beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘stream_beat_index + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1027: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1028: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1029: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1030: `// The registered final payload commits at this edge.` Design intent: The registered final payload commits at this edge. This comment anchors the surrounding logic in the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

Line 1031: `ST_VECTOR_DRAIN: state <= ST_VECTOR_START;` This is the ST_VECTOR_DRAIN case branch, which performs this explicitly named phase. The same-cycle action begins with 'state <= ST_VECTOR_START;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_DRAIN, the machine performs the named control phase..

Line 1032: `ST_VECTOR_START: if (vector_input_ready) begin` This is the ST_VECTOR_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'if (vector_input_ready) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_START, the machine performs the named control phase..

Line 1033: `output_word_index <= 4'd0;` This makes output_word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_START, the machine performs the named control phase..

Line 1034: `state <= ST_VECTOR_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_VECTOR_OUTPUT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VECTOR_OUTPUT: the value named 'st vector output' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_START, the machine performs the named control phase..

Line 1035: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_START, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1036: `ST_VECTOR_OUTPUT: if (vector_result_accept) begin` This is the ST_VECTOR_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'if (vector_result_accept) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1037: `if (output_word_index == 3) begin` This condition selects the following hardware branch only when 'output_word_index == 3' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1038: `completion_error_r <= vector_config_error;` This makes completion_error_r, the value named 'completion error r' in this block, equal to 'vector_config_error'. It updates after the active clock edge together with other nonblocking assignments. The important operands are vector_config_error: the value named 'vector config error' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1039: `state <= ST_OUTPUT_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_DRAIN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DRAIN: the value named 'st output drain' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1040: `end else output_word_index <= output_word_index + 1'b1;` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1041: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VECTOR_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1042: `ST_LAYERNORM_START: if (ln_start_accept_r) state <= ST_LAYERNORM_LOAD0;` This is the ST_LAYERNORM case branch, which performs this explicitly named phase. The same-cycle action begins with 'if (ln_start_accept_r) state <= ST_LAYERNORM_LOAD0;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_START, the machine performs the named control phase..

Line 1043: `ST_LAYERNORM_LOAD0: if (s_axis_tvalid) begin` This is the ST_LAYERNORM_LOAD0 case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'if (s_axis_tvalid) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD0, the machine stores incoming operands into local FPGA memory..

Line 1044: `ln_sample_word0_r <= s_axis_tdata;` This makes ln_sample_word0_r, the value named 'ln sample word0 r' in this block, equal to 's_axis_tdata'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD0, the machine stores incoming operands into local FPGA memory..

Line 1045: `state <= ST_LAYERNORM_LOAD1;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LAYERNORM_LOAD1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LAYERNORM_LOAD1: the value named 'st layernorm load1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD0, the machine stores incoming operands into local FPGA memory..

Line 1046: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD0, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1047: `ST_LAYERNORM_LOAD1: if (s_axis_tvalid) begin` This is the ST_LAYERNORM_LOAD1 case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'if (s_axis_tvalid) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD1, the machine stores incoming operands into local FPGA memory..

Line 1048: `ln_sample_value_r <= ln_sample_word0_r[23:0];` This makes ln_sample_value_r, the value named 'ln sample value r' in this block, equal to 'ln_sample_word0_r[23:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ln_sample_word0_r: the value named 'ln sample word0 r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD1, the machine stores incoming operands into local FPGA memory..

Line 1049: `ln_sample_gamma_r <= ln_sample_word0_r[47:24];` This makes ln_sample_gamma_r, the learned multiplicative LayerNorm parameter, equal to 'ln_sample_word0_r[47:24]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ln_sample_word0_r: the value named 'ln sample word0 r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD1, the machine stores incoming operands into local FPGA memory..

Line 1050: `ln_sample_beta_r <= {s_axis_tdata[7:0], ln_sample_word0_r[63:48]};` This makes ln_sample_beta_r, the learned additive LayerNorm parameter, equal to '{s_axis_tdata[7:0], ln_sample_word0_r[63:48]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block; ln_sample_word0_r: the value named 'ln sample word0 r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD1, the machine stores incoming operands into local FPGA memory..

Line 1051: `if (s_axis_tlast != stream_last_pending_r) begin` This condition selects the following hardware branch only when 's_axis_tlast != stream_last_pending_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; stream_last_pending_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD1, the machine stores incoming operands into local FPGA memory..

Line 1052: `error_event_r <= 1'b1;` This makes error_event_r, the value named 'error event r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD1, the machine stores incoming operands into local FPGA memory..

Line 1053: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD1, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1054: `state <= ST_LAYERNORM_SEND;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LAYERNORM_SEND'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LAYERNORM_SEND: the value named 'st layernorm send' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD1, the machine stores incoming operands into local FPGA memory..

Line 1055: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_LOAD1, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1056: `ST_LAYERNORM_SEND: if (ln_sample_ready) begin` This is the ST_LAYERNORM_SEND case branch, which performs this explicitly named phase. The same-cycle action begins with 'if (ln_sample_ready) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase..

Line 1057: `if (stream_last_pending_r) begin` This condition selects the following hardware branch only when 'stream_last_pending_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are stream_last_pending_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase..

Line 1058: `state <= ST_LAYERNORM_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LAYERNORM_OUTPUT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LAYERNORM_OUTPUT: the value named ’st layernorm output’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase..

Line 1059: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1060: `stream_item_index <= stream_item_index + 1’b1;` This makes stream_item_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘stream_item_index + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_item_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase..

Line 1061: `stream_items_remaining_r <= stream_items_remaining_r - 1’b1;` This makes stream_items_remaining_r, the value named ’stream items remaining r’ in this block, equal to ‘stream_items_remaining_r - 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_items_remaining_r: the value named ’stream items remaining r’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase..

Line 1062: `stream_last_pending_r <= stream_items_remaining_r == 12’d2;` This makes stream_last_pending_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘stream_items_remaining_r == 12’d2‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_items_remaining_r: the value named ’stream items remaining r’ in this block; d2: the value named ’d2’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase..

Line 1063: `state <= ST_LAYERNORM_LOAD0;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LAYERNORM_LOAD0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LAYERNORM_LOAD0: the value named ’st layernorm load0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase..

Line 1064: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1065: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_SEND, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1066: `ST_LAYERNORM_OUTPUT: if (layernorm_result_accept` This is the ST_LAYERNORM_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘if (layernorm_result_accept‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1067: `&& ln_result_last) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are ln_result_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 1068: `completion_error_r <= ln_config_error;` This makes completion_error_r, the value named 'completion error r' in this block, equal to 'ln_config_error'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ln_config_error: the value named 'ln config error' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1069: `state <= ST_OUTPUT_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_DRAIN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DRAIN: the value named 'st output drain' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1070: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LAYERNORM_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1071: `ST_SOFTMAX_START: if (softmax_start_accept_r) state <= ST_SOFTMAX_LOAD;` This is the ST_SOFTMAX_S case branch, which performs this explicitly named phase. The same-cycle action begins with 'if (softmax_start_accept_r) state <= ST_SOFTMAX_LOAD;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_START, the machine performs the named control phase..

Line 1072: `ST_SOFTMAX_LOAD: if (s_axis_tvalid) begin` This is the ST_SOFTMAX_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'if (s_axis_tvalid) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1073: `if (s_axis_tlast != stream_last_pending_r) begin` This condition selects the following hardware branch only when 's_axis_tlast != stream_last_pending_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; stream_last_pending_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1074: `error_event_r <= 1'b1;` This makes error_event_r, the value named 'error event r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1075: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1076: `if (stream_last_pending_r) begin` This condition selects the following hardware branch only when 'stream_last_pending_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are stream_last_pending_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1077: `state <= ST_SOFTMAX_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_SOFTMAX_OUTPUT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SOFTMAX_OUTPUT: the value named 'st softmax output' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1078: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1079: `stream_item_index <= stream_item_index + 1'b1;` This makes stream_item_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'stream_item_index + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_item_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1080: `stream_items_remaining_r <= stream_items_remaining_r - 1'b1;` This makes stream_items_remaining_r, the value named 'stream items remaining r' in this block, equal to 'stream_items_remaining_r - 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_items_remaining_r: the value named 'stream items remaining r' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1081: `stream_last_pending_r <= stream_items_remaining_r == 12'd2;` This makes stream_last_pending_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'stream_items_remaining_r == 12'd2'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_items_remaining_r: the value named 'stream items remaining r' in this block; d2: the value named 'd2' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1082: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1083: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1084: `ST_SOFTMAX_OUTPUT: if (softmax_result_accept` This is the ST_SOFTMAX_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'if (softmax_result_accept'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1085: `&& softmax_probability_last) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are softmax_probability_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 1086: `completion_error_r <= softmax_config_error;` This makes completion_error_r, the value named 'completion error r' in this block, equal to 'softmax_config_error'. It updates after the active clock edge together with other nonblocking assignments. The important operands are softmax_config_error: the value named 'softmax config error' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1087: `state <= ST_OUTPUT_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_DRAIN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DRAIN: the value named 'st output drain' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1088: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SOFTMAX_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1089: `ST_LIF_LOAD: begin` This is the ST_LIF_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1090: `if (lif_load_pending_r) begin` This condition selects the following hardware branch only when 'lif_load_pending is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lif_load_pending_r: the value named 'lif load pending r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1091: `if (lif_load_last_r != lif_load_final_r) begin` This condition selects the following hardware branch only when 'lif_load_last_r != lif_load_final_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lif_load_last_r: the AXI-Stream marker for the final beat of a packet or command payload; lif_load_final_r: the value named 'lif load final r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1092: `error_event_r <= 1'b1;` This makes error_event_r, the value named 'error event r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1093: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1094: `if (lif_load_final_r) begin` This condition selects the following hardware branch only when 'lif_load_final_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lif_load_final_r: the value named 'lif load final r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1095: `if (lif_clear_requested_r) state <= ST_LIF_CLEAR;` This condition selects the following hardware branch only when 'lif_clear_requested_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lif_clear_requested_r: the value named 'lif clear requested r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1096: `else state <= ST_LIF_START;` Within the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LIF_START: the value named 'st lif start' in this block.

Line 1097: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1098: `lif_load_index_r <= lif_load_index_r + 1'b1;` This makes lif_load_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘lif_load_index_r + 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are lif_load_index_r: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1099: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1100: `end else if (s_axis_tvalid) begin` This condition selects the following hardware branch only when ‘s_axis_tvalid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tvalid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1101: `lif_load_pending_r <= 1'b1;` This makes lif_load_pending_r, the value named 'lif load pending r' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1102: `lif_load_word_select_r <= 8'b1 << lif_load_index_r;` This makes lif_load_word_select_r, the value named 'lif load word select r' in this block, equal to ‘8'b1 << lif_load_index_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block; lif_load_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1103: `lif_load_data_r <= s_axis_tdata;` This makes lif_load_data_r, the payload carried with the surrounding valid/ready handshake, equal to ‘s_axis_tdata‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1104: `lif_load_last_r <= s_axis_tlast;` This makes lif_load_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘s_axis_tlast‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1105: `lif_load_final_r <= lif_load_index_r == 7;` This makes lif_load_final_r, the value named 'lif load final r' in this block, equal to ‘lif_load_index_r == 7‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are lif_load_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1106: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1107: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1108: `ST_LIF_CLEAR: state <= ST_LIF_START;` This is the ST_LIF_CLEAR case branch, which performs this explicitly named phase. The same-cycle action begins with ‘state <= ST_LIF_START;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LIF_CLEAR, the machine performs the named control phase..

Line 1109: `ST_LIF_START: if (lif_input_ready) begin` This is the ST_LIF_START case branch, which performs this explicitly named phase. The same-cycle action begins with ‘if (lif_input_ready) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LIF_START, the machine performs the named control phase..

Line 1110: `output_word_index <= 4'd0;` This makes output_word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘4'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_START, the machine performs the named control phase..

Line 1111: `state <= ST_LIF_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LIF_OUTPUT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LIF_OUTPUT: the value named 'st lif output' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_START, the machine performs the named control phase..

Line 1112: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_START, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1113: `ST_LIF_OUTPUT: if (lif_result_accept) begin` This is the ST_LIF_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘if (lif_result_accept) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1114: `if (!lif_trace_requested_r || output_word_index == 12) begin` This condition selects the following hardware branch only when ‘!lif_trace_requested_r || output_word_index == 12‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lif_trace_requested_r: the value named 'lif trace requested r' in this block; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1115: `completion_error_r <= 1'b0;` This makes completion_error_r, the value named 'completion error r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1116: `state <= ST_OUTPUT_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_DRAIN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DRAIN: the value named 'st output drain' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1117: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1118: `output_word_index <= output_word_index + 1'b1;` This makes output_word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_word_index + 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1119: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1120: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LIF_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1121: `ST_OPTIMIZER_LOAD: if (s_axis_tvalid) begin` This is the ST_OPTIMIZER_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘if (s_axis_tvalid) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1122: `optimizer_load_data_r <= s_axis_tdata;` This makes optimizer_load_data_r, the payload carried with the surrounding valid/ready handshake, equal to ‘s_axis_tdata‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1123: `optimizer_load_last_r <= s_axis_tlast;` This makes optimizer_load_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘s_axis_tlast‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1124: `optimizer_load_index_r <= stream_beat_index[2:0];` This makes optimizer_load_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘stream_beat_index[2:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1125: `optimizer_load_final_r <= stream_beat_index == 7;` This makes optimizer_load_final_r, the value named 'optimizer load final r' in this block, equal to ‘stream_beat_index == 7‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1126: `optimizer_commit_valid_r <= 1'b1;` This makes optimizer_commit_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1127: `state <= ST_OPTIMIZER_COMMIT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OPTIMIZER_COMMIT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OPTIMIZER_COMMIT: the value named 'st optimizer commit' in this block.

Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1128: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1129: `ST_OPTIMIZER_COMMIT: begin` This is the ST_OPTIMIZER_COMMIT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase..

Line 1130: `if (optimizer_load_last_r != optimizer_load_final_r) begin` This condition selects the following hardware branch only when 'optimizer_load_last_r != optimizer_load_final_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are optimizer_load_last_r: the AXI-Stream marker for the final beat of a packet or command payload; optimizer_load_final_r: the value named 'optimizer load final r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase..

Line 1131: `error_event_r <= 1'b1;` This makes error_event_r, the value named 'error event r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase..

Line 1132: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1133: `if (optimizer_load_final_r) begin` This condition selects the following hardware branch only when 'optimizer_load_final_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are optimizer_load_final_r: the value named 'optimizer load final r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase..

Line 1134: `state <= ST_OPTIMIZER_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OPTIMIZER_START'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OPTIMIZER_START: the value named 'st optimizer start' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase..

Line 1135: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1136: `stream_beat_index <= stream_beat_index + 1'b1;` This makes stream_beat_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'stream_beat_index + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_beat_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase..

Line 1137: `state <= ST_OPTIMIZER_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OPTIMIZER_LOAD'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OPTIMIZER_LOAD: the value named 'st optimizer load' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase..

Line 1138: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1139: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1140: `ST_OPTIMIZER_START: if (optimizer_input_ready) begin` This is the ST_OPTIMIZER_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'if (optimizer_input_ready) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_START, the machine performs the named control phase..

Line 1141: `output_word_index <= 4'd0;` This makes output_word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_START, the machine performs the named control phase..

Line 1142: `state <= ST_OPTIMIZER_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OPTIMIZER_OUTPUT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OPTIMIZER_OUTPUT: the value named 'st optimizer output' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_START, the machine performs the named control phase..

Line 1143: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_START, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1144: `ST_OPTIMIZER_OUTPUT: if (optimizer_result_accept) begin` This is the ST_OPTIMIZER_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'if (optimizer_result_accept) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1145: `if (output_word_index == 4'd7) begin` This condition selects the following hardware branch only when 'output_word_index == 4'd7' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry; d7: the value named 'd7' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1146: `completion_error_r <= optimizer_config_error;` This makes completion_error_r, the value named 'completion error r' in this block, equal to 'optimizer_config_error'. It updates after the active clock edge together with other nonblocking assignments. The important operands are optimizer_config_error: the value named 'optimizer config error' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1147: `state <= ST_OUTPUT_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_DRAIN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DRAIN: the value named 'st output drain' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1148: `end else output_word_index <= output_word_index + 1'b1;` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1149: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OPTIMIZER_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1150: `ST_TRAIN_START: if (train_start_ready) state <= ST_TRAIN_RUN;` This is the ST_TRAIN_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'if (train_start_ready) state <= ST_TRAIN_RUN;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_START, the machine performs the named control phase..

Line 1151: `ST_TRAIN_RUN: if (train_done) begin` This is the ST_TRAIN_RUN case branch, which performs this explicitly named phase. The same-cycle action begins with 'if (train_done) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 1152: `if (command_had_output_r || train_result_accept) begin` This condition selects the following hardware branch only when 'command_had_output_r || train_result_accept' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are command_had_output_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; train_result_accept: the value named 'train result accept' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 1153: `completion_error_r <= train_config_error;` This makes completion_error_r, the value named 'completion error r' in this block, equal to 'train_config_error'. It updates after the active clock edge together with other nonblocking assignments. The important operands are train_config_error: the value named 'train config error' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 1154: `state <= ST_OUTPUT_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_DRAIN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DRAIN: the value named 'st output drain' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 1155: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1156: `if (train_config_error) error_event_r <= 1'b1;` This condition selects the following hardware branch only when 'train_config_error' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are train_config_error: the value named 'train config error' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 1157: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 1158: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase..

Line 1159: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1160: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_TRAIN_RUN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1161: `ST_LUT_LOAD: begin` This is the ST_LUT_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1162: `if (lut_load_pending_r && lut_load_ready) begin` This condition selects the following hardware branch only when ‘lut_load_pending_r && lut_load_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lut_load_pending_r: the value named ’lut load pending r’ in this block; lut_load_ready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1163: `lut_load_pending_r <= 1’b0;` This makes lut_load_pending_r, the value named ’lut load pending r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1164: `if (lut_load_last_r != lut_load_final_r) begin` This condition selects the following hardware branch only when ‘lut_load_last_r != lut_load_final_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lut_load_last_r: the AXI-Stream marker for the final beat of a packet or command payload; lut_load_final_r: the value named ’lut load final r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1165: `error_event_r <= 1’b1;` This makes error_event_r, the value named ’error event r’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1166: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1167: `if (lut_load_final_r) begin` This condition selects the following hardware branch only when ‘lut_load_final_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lut_load_final_r: the value named ’lut load final r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1168: `command_done_pending_r <= 1’b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the

clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1169: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1170: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1171: `stream_item_index <= stream_item_index + 1'b1;` This makes stream_item_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘stream_item_index + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_item_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1172: `stream_items_remaining_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are stream_items_remaining_r: the value named ’stream items remaining r’ in this block.

Line 1173: `<= stream_items_remaining_r - 1'b1;` Within the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are stream_items_remaining_r: the value named ’stream items remaining r’ in this block; b1: the value named ’b1’ in this block.

Line 1174: `stream_last_pending_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are stream_last_pending_r: the AXI-Stream marker for the final beat of a packet or command payload.

Line 1175: `<= stream_items_remaining_r == 12'd2;` Within the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path. The important operands are stream_items_remaining_r: the value named ’stream items remaining r’ in this block; d2: the value named ’d2’ in this block.

Line 1176: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1177: `end else if (!lut_load_pending_r && s_axis_tvalid) begin` This condition selects the following hardware branch only when ‘!lut_load_pending_r && s_axis_tvalid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lut_load_pending_r: the value named ’lut load pending r’ in this block; s_axis_tvalid: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1178: `lut_load_pending_r <= 1'b1;` This makes lut_load_pending_r, the value named 'lut load pending r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1179: `lut_load_address_r <= s_axis_tdata[7:0];` This makes lut_load_address_r, the value named 'lut load address r' in this block, equal to 's_axis_tdata[7:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1180: `lut_load_value_r <= s_axis_tdata[23:8];` This makes lut_load_value_r, the value named 'lut load value r' in this block, equal to 's_axis_tdata[23:8]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1181: `lut_load_last_r <= s_axis_tlast;` This makes lut_load_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 's_axis_tlast'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1182: `lut_load_final_r <= stream_last_pending_r;` This makes lut_load_final_r, the value named 'lut load final r' in this block, equal to 'stream_last_pending_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are stream_last_pending_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1183: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1184: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1185: `ST_LUT_EVAL_LOAD: if (s_axis_tvalid) begin` This is the ST_LUT_EVAL_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'if (s_axis_tvalid) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1186: `lut_indices_r <= s_axis_tdata;` This makes lut_indices_r, the value named 'lut indices r' in this block, equal to 's_axis_tdata'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1187: `if (!s_axis_tlast) error_event_r <= 1'b1;` This condition selects the following hardware branch only when '!s_axis_tlast' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1188: `state <= ST_LUT_EVAL_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LUT_EVAL_START‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LUT_EVAL_START: the value named ’st lut eval start’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_LOAD, the machine stores incoming operands into local FPGA memory..

Line 1189: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 1190: `ST_LUT_EVAL_START: if (lut_input_ready) begin` This is the ST_LUT_EVAL_START case branch, which performs this explicitly named phase. The same-cycle action begins with ‘if (lut_input_ready) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_START, the machine performs the named control phase..

Line 1191: `output_word_index <= 4'd0;` This makes output_word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘4’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_START, the machine performs the named control phase..

Line 1192: `state <= ST_LUT_EVAL_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LUT_EVAL_OUTPUT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LUT_EVAL_OUTPUT: the value named ’st lut eval output’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_START, the machine performs the named control phase..

Line 1193: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_START, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1194: `ST_LUT_EVAL_OUTPUT: begin` This is the ST_LUT_EVAL_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1195: `if (lut_result_accept && output_word_index == 1) begin` This condition selects the following hardware branch only when ‘lut_result_accept && output_word_index == 1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lut_result_accept: the value named ’lut result accept’ in this block; output_word_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1196: `completion_error_r <= lut_config_error;` This makes completion_error_r, the value named ’completion error r’ in this block, equal to ‘lut_config_error‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are lut_config_error: the value named ’lut config error’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1197: `state <= ST_OUTPUT_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_DRAIN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DRAIN: the value named ’st output drain’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1198: `end else if (lut_result_accept) begin` This condition selects the following hardware branch only when ‘lut_result_accept‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lut_result_accept: the value named ’lut result accept’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1199: `output_word_index <= output_word_index + 1'b1;` This makes output_word_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_word_index + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_word_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 1200: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1201: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_EVAL_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1202: `ST_OUTPUT_DRAIN: if (final_output_accepted_r) begin` This is the ST_OUTPUT_DRAIN case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘if (final_output_accepted_r) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DRAIN, the machine presents computed results under valid/ready backpressure..

Line 1203: `if (completion_error_r) error_event_r <= 1'b1;` This condition selects the following hardware branch only when ‘completion_error_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are completion_error_r: the value named ’completion error r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DRAIN, the machine presents computed results under valid/ready backpressure..

Line 1204: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DRAIN, the machine presents computed results under valid/ready backpressure..

Line 1205: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DRAIN, the machine presents computed results under valid/ready backpressure..

Line 1206: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DRAIN, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 1207: `ST_LUT_CLEAR: begin` This is the ST_LUT_CLEAR case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase..

Line 1208: `if (decode_error_pending_r) error_event_r <= 1'b1;` This condition selects the following hardware branch only when ‘decode_error_pending_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are decode_error_pending_r: the value named ’decode

error pending r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase..

Line 1209: `lut_clear_requested_r <= 1'b0;` This makes lut_clear_requested_r, the value named 'lut clear requested r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase..

Line 1210: `decode_error_pending_r <= 1'b0;` This makes decode_error_pending_r, the value named 'decode error pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase..

Line 1211: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase..

Line 1212: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase..

Line 1213: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1214: `default: state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'state <= ST_IDLE;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase..

Line 1215: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LUT_CLEAR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 1216: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 1217: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 1218: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 1220: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that decodes commands and arbitrates the tensor, vector, normalization, LIF, LUT, attention, backward, and optimizer engines through a staged result path.

22 rtl/neuraedge_vector_alu.sv

Role in the complete system: executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

22.1 Beginner architecture map

Dataflow responsibility Eight signed lanes execute residual add, ReLU, requantization, spike conversion, surrogate-gradient gating, maximum, Q15 multiply, or clamp. Wide intermediate products are registered before rounding and saturation so fixed-point behavior is deterministic.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_vector_alu into physical nets and primitives. The source declares 15 input-port lines, 4 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_ABSOLUTE, ST_COMPARE, ST_DISTANCE_ABSOLUTE, ST_IDLE, ST_LOAD_LANE, ST_MULTIPLIER_LATCH, ST_MULTIPLY, ST_OFFSET, ST_OFFSET_ADD, ST_OFFSET_EXTEND, ST_OUTPUT, ST_PRECOMPUTE, ST_PRODUCT_CROSS, ST_PRODUCT_LATCH, ST_PRODUCT_LOW, ST_RESTORE_SIGN, ST_RESULT, ST_ROUND_BIAS and additional states. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates else as if, unique as case. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

`default_nettype wire
```

22.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_vector_alu #(` This opens neuraedge_vector_alu, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

Line 5: `parameter int LANES = 8,` This statement continues through source line 26; the explanation uses the complete expression rather than only the first visual fragment. This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 6: `parameter int DATA_BITS = 32` This is continuation line 2 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'parameter int DATA_BITS = 32'. The important operands are parameter: the value named 'parameter' in this block; DATA_BITS: the value named 'data bits' in this block. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 7: `) (` This is continuation line 3 of the 22-line logical statement that begins at source line 5. Its exact fragment is ') ('. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 8: `input wire clk,` This is continuation line 4 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire clk,'. The important operands are input: the value named 'input' in this block; clk: the clock that makes all registers advance together. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 9: `input wire rst_n,` This is continuation line 5 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire rst_n,'. The important operands are input: the value named 'input' in this block; rst_n: the active-low synchronous reset. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire

output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 10: `input wire input_valid,` This is continuation line 6 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire input_valid,'. The important operands are input: the value named 'input' in this block; input_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 11: `output logic input_ready,` This is continuation line 7 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'output logic input_ready,'. The important operands are output: the value named 'output' in this block; input_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 12: `input wire [3:0] operation,` This is continuation line 8 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire [3:0] operation,'. The important operands are input: the value named 'input' in this block; operation: the value named 'operation' in this block. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 13: `input wire [LANES*DATA_BITS-1:0] operand_a,` This is continuation line 9 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire [LANES*DATA_BITS-1:0] operand_a,'. The important operands are input: the value named 'input' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; DATA_BITS: the value named 'data bits' in this block. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 14: `input wire [LANES*DATA_BITS-1:0] operand_b,` This is continuation line 10 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire [LANES*DATA_BITS-1:0] operand_b,'. The important operands are input: the value named 'input' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; DATA_BITS: the value named 'data bits' in this block. Read together, the complete

operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 15: `input wire signed [15:0] multiplier_q15,` This is continuation line 11 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [15:0] multiplier_q15,'. The important operands are input: the value named 'input' in this block; multiplier_q15: the value named 'multiplier q15' in this block. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 16: `input wire [4:0] right_shift,` This is continuation line 12 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire [4:0] right_shift,'. The important operands are input: the value named 'input' in this block; right_shift: the value named 'right shift' in this block. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 17: `input wire signed [15:0] output_zero_point,` This is continuation line 13 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [15:0] output_zero_point,'. The important operands are input: the value named 'input' in this block; output_zero_point: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 18: `input wire signed [DATA_BITS-1:0] threshold,` This is continuation line 14 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [DATA_BITS-1:0] threshold,'. The important operands are input: the value named 'input' in this block; DATA_BITS: the value named 'data bits' in this block; threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result,

output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 19: `input wire [DATA_BITS-1:0] surrogate_window,` This is continuation line 15 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire [DATA_BITS-1:0] surrogate_window,'. The important operands are input: the value named 'input' in this block; DATA_BITS: the value named 'data bits' in this block; surrogate_window: the value named 'surrogate window' in this block. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 20: `input wire signed [DATA_BITS-1:0] clamp_minimum,` This is continuation line 16 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [DATA_BITS-1:0] clamp_minimum,'. The important operands are input: the value named 'input' in this block; DATA_BITS: the value named 'data bits' in this block; clamp_minimum: the value named 'clamp minimum' in this block. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 21: `input wire signed [DATA_BITS-1:0] clamp_maximum,` This is continuation line 17 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [DATA_BITS-1:0] clamp_maximum,'. The important operands are input: the value named 'input' in this block; DATA_BITS: the value named 'data bits' in this block; clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 22: `output logic output_valid,` This is continuation line 18 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'output logic output_valid,'. The important operands are output: the value named 'output' in this block; output_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 23: `input wire output_ready,` This is continuation line 19 of the 22-line logical statement that begins at source line 5. Its exact fragment is 'input wire output_ready,'. The important operands are input: the value named 'input' in this block; output_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete

operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 24: `output logic [LANES*DATA_BITS-1:0] result,` This is continuation line 20 of the 22-line logical statement that begins at source line 5. Its exact fragment is ‘output logic [LANES*DATA_BITS-1:0] result,‘. The important operands are output: the value named ’output’ in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; DATA_BITS: the value named ’data bits’ in this block. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 25: `output logic config_error` This is continuation line 21 of the 22-line logical statement that begins at source line 5. Its exact fragment is ‘output logic config_error‘. The important operands are output: the value named ’output’ in this block; config_error: the value named ’config error’ in this block. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 26: `);` This is continuation line 22 of the 22-line logical statement that begins at source line 5. Its exact fragment is ‘);‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes LANES to 8, parameter int DATA_BITS = 32) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [3:0] operation, input wire [LANES*DATA_BITS-1:0] operand_a, input wire [LANES*DATA_BITS-1:0] operand_b, input wire signed [15:0] multiplier_q15, input wire [4:0] right_shift, input wire signed [15:0] output_zero_point, input wire signed [DATA_BITS-1:0] threshold, input wire [DATA_BITS-1:0] surrogate_window, input wire signed [DATA_BITS-1:0] clamp_minimum, input wire signed [DATA_BITS-1:0] clamp_maximum, output logic output_valid, input wire output_ready, output logic [LANES*DATA_BITS-1:0] result, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 27: `localparam logic [3:0] OP_ADD_SAT = 4'd0;` This fixes OP_ADD_SAT to 4’d0 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_ADD_SAT denotes the value named ’op add sat’ in this block.

Line 28: `localparam logic [3:0] OP_RELU = 4'd1;` This fixes OP_RELU to 4’d1 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_RELU denotes the value named ’op relu’ in this block.

Line 29: `localparam logic [3:0] OP_REQUANTIZE = 4'd2;` This fixes OP_REQUANTIZE to 4’d2 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_REQUANTIZE denotes the conversion of a wide accumulated result back into a bounded activation code.

Line 30: `localparam logic [3:0] OP_BINARY_SPIKE = 4'd3;` This fixes OP_BINARY_SPIKE to 4'd3 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_BINARY_SPIKE denotes a binary event produced when a neuron crosses its threshold.

Line 31: `localparam logic [3:0] OP_TERNARY_SPIKE = 4'd4;` This fixes OP_TERNARY_SPIKE to 4'd4 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_TERNARY_SPIKE denotes a binary event produced when a neuron crosses its threshold.

Line 32: `localparam logic [3:0] OP_SURROGATE_GRADIENT = 4'd5;` This fixes OP_SURROGATE_GRADIENT to 4'd5 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_SURROGATE_GRADIENT denotes the signed loss derivative used to update a learned parameter.

Line 33: `localparam logic [3:0] OP_MAXIMUM = 4'd6;` This fixes OP_MAXIMUM to 4'd6 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_MAXIMUM denotes the value named 'op maximum' in this block.

Line 34: `localparam logic [3:0] OP_MULTIPLY_Q15 = 4'd7;` This fixes OP_MULTIPLY_Q15 to 4'd7 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_MULTIPLY_Q15 denotes the value named 'op multiply q15' in this block.

Line 35: `localparam logic [3:0] OP_CLAMP = 4'd8;` This fixes OP_CLAMP to 4'd8 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_CLAMP denotes the value named 'op clamp' in this block.

Line 36: `localparam logic [3:0] OP_FLEX_REQUANTIZE = 4'd9;` This fixes OP_FLEX_REQUANTIZE to 4'd9 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_FLEX_REQUANTIZE denotes the conversion of a wide accumulated result back into a bounded activation code.

Line 37: `localparam logic [3:0] OP_SELECT_ZERO = 4'd10;` This fixes OP_SELECT_ZERO to 4'd10 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_SELECT_ZERO denotes the value named 'op select zero' in this block.

Line 38: `localparam logic [3:0] OP_SELECT_NONZERO = 4'd11;` This fixes OP_SELECT_NONZERO to 4'd11 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_SELECT_NONZERO denotes the value named 'op select nonzero' in this block.

Line 39: `localparam logic [3:0] OP_COMPARE_GE = 4'd12;` This fixes OP_COMPARE_GE to 4'd12 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; OP_COMPARE_GE denotes the value named 'op compare ge' in this block.

Line 41: `// One arithmetic transformation is performed per state. Besides making the` Design intent: One arithmetic transformation is performed per state. Besides making the This comment anchors the surrounding logic in the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

Line 42: `// latency deterministic, these registers prevent a multiply, absolute value,` Design intent: latency deterministic, these registers prevent a multiply, absolute value, This comment anchors the surrounding logic in the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

Line 43: `// rounding add, barrel shift, sign restore, and clamp from becoming one path.` Design intent: rounding add, barrel shift, sign restore, and clamp from becoming one path. This comment anchors the surrounding logic in the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

Line 44: `typedef enum logic [4:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 45: `ST_IDLE = 5'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 46: `ST_LOAD_LANE = 5'd1,` This assigns a fixed binary encoding to state ST_LOAD_LANE, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 47: `ST_MULTIPLY = 5'd2,` This assigns a fixed binary encoding to state ST_MULTIPLY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 48: `ST_ABSOLUTE = 5'd3,` This assigns a fixed binary encoding to state ST_ABSOLUTE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 49: `ST_ROUND_BIAS = 5'd4,` This assigns a fixed binary encoding to state ST_ROUND_BIAS, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 50: `ST_SHIFT = 5'd5,` This assigns a fixed binary encoding to state ST_SHIFT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 51: `ST_RESTORE_SIGN = 5'd6,` This assigns a fixed binary encoding to state ST_RESTORE_SIGN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 52: `ST_OFFSET = 5'd7,` This assigns a fixed binary encoding to state ST_OFFSET, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 53: `ST_PRECOMPUTE = 5'd8,` This assigns a fixed binary encoding to state ST_PRECOMPUTE, which issues arithmetic work using values already held on chip. The encoding is visible in waveforms even though the source uses the readable name.

Line 54: `ST_COMPARE = 5'd9,` This assigns a fixed binary encoding to state ST_COMPARE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 55: `ST_RESULT = 5'd10,` This assigns a fixed binary encoding to state ST_RESULT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 56: `ST_OUTPUT = 5'd11,` This assigns a fixed binary encoding to state ST_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 57: `ST_MULTIPLIER_LATCH = 5'd12,` This assigns a fixed binary encoding to state ST_MULTIPLIER_LATCH, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 58: `ST_PRODUCT_LATCH = 5'd13,` This assigns a fixed binary encoding to state ST_PRODUCT_LATCH, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 59: `ST_PRODUCT_CROSS = 5'd14,` This assigns a fixed binary encoding to state ST_PRODUCT_CROSS, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 60: `ST_PRODUCT_LOW = 5'd15,` This assigns a fixed binary encoding to state ST_PRODUCT_LOW, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 61: `ST_OFFSET_ADD = 5'd16,` This assigns a fixed binary encoding to state ST_OFFSET_ADD, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 62: `ST_OFFSET_EXTEND = 5'd17,` This assigns a fixed binary encoding to state ST_OFFSET_EXTEND, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 63: `ST_DISTANCE_ABSOLUTE = 5'd18,` This assigns a fixed binary encoding to state ST_DISTANCE_ABSOLUTE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 64: `ST_STORE_RESULT = 5'd19` This statement continues through source line 65; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_STORE_RESULT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 65: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 64. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_STORE_RESULT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 67: `state_t state;` Within the module's structural declarations, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are state_t: the finite-state-machine phase retained in flip-flops; state: the finite-state-machine phase retained in flip-flops.

Line 68: `logic [2:0] lane_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 69: `logic [3:0] operation_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, operation_r is the value named 'operation r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 70: `logic [LANES*DATA_BITS-1:0] operand_a_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, operand_a_r is the value named 'operand a r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 71: `logic [LANES*DATA_BITS-1:0] operand_b_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, operand_b_r is the value named 'operand b r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 72: `logic signed [15:0] multiplier_q15_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_q15_r is the value named 'multiplier q15 r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 73: `logic signed [15:0] output_zero_point_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_zero_point_r is the integer code representing real numeric zero in affine quantization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 74: `logic signed [31:0] threshold_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, threshold_r is the membrane level at which a neuron emits a spike. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 75: `logic signed [31:0] negative_threshold_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, negative_threshold_r is the membrane level at which a neuron emits a spike. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 76: `logic [31:0] surrogate_window_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, surrogate_window_r is the value named 'surrogate window r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 77: `logic signed [31:0] clamp_minimum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clamp_minimum_r is the value named 'clamp minimum r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 78: `logic signed [31:0] clamp_maximum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, clamp_maximum_r is the value named 'clamp maximum r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 79: `logic [5:0] shift_amount_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, shift_amount_r is the value named 'shift amount r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 80: `logic [63:0] rounding_bias_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rounding_bias_r is an additive learned offset applied after accumulation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 82: `logic signed [31:0] lane_a_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_a_r is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 83: `logic signed [31:0] lane_b_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_b_r is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 84: `logic signed [31:0] multiplier_left_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_left_r is the value named 'multiplier left r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 85: `logic signed [31:0] multiplier_right_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_right_r is the value named 'multiplier right r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 86: `logic signed [16:0] multiplier_left_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_left_low_r is the value named 'multiplier left low r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 87: `logic signed [16:0] multiplier_right_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_right_low_r is the value named 'multiplier right low r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 88: `logic signed [15:0] multiplier_left_high_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_left_high_r is the value named 'multiplier left high r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 89: `logic signed [15:0] multiplier_right_high_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_right_high_r is the value named 'multiplier right high r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 90: `(* use_dsp = "yes" *) wire signed [33:0] multiplier_product_ll =` Within the module's structural declarations, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; multiplier_product_ll: the value named 'multiplier product ll' in this block.

Line 91: `multiplier_left_low_r * multiplier_right_low_r;` Within the module's structural declarations, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are multiplier_left_low_r: the value named 'multiplier left low r' in this block; multiplier_right_low_r: the value named 'multiplier right low r' in this block.

Line 92: `(* use_dsp = "yes" *) wire signed [32:0] multiplier_product_lh =` Within the module's structural declarations, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; multiplier_product_lh: the value named 'multiplier product lh' in this block.

Line 93: `multiplier_left_low_r * multiplier_right_high_r;` Within the module's structural declarations, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are multiplier_left_low_r: the value named 'multiplier left low r' in this block; multiplier_right_high_r: the value named 'multiplier right high r' in this block.

Line 94: `(* use_dsp = "yes" *) wire signed [32:0] multiplier_product_hl =` Within the module's structural declarations, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; multiplier_product_hl: the value named 'multiplier product hl' in this block.

Line 95: `multiplier_left_high_r * multiplier_right_low_r;` Within the module's structural declarations, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are multiplier_left_high_r: the value named 'multiplier left high r' in this block; multiplier_right_low_r: the value named 'multiplier right low r' in this block.

Line 96: `(* use_dsp = "yes" *) wire signed [31:0] multiplier_product_hh =` Within the module's structural declarations, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; multiplier_product_hh: the value named 'multiplier product hh' in this block.

Line 97: `multiplier_left_high_r * multiplier_right_high_r;` Within the module's structural declarations, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are multiplier_left_high_r: the value named 'multiplier left high r' in this block; multiplier_right_high_r: the value named 'multiplier right high r' in this block.

Line 98: `logic signed [33:0] product_ll_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_ll_r is the value named 'product ll r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 99: `logic signed [32:0] product_lh_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_lh_r is the value named 'product lh r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 100: `logic signed [32:0] product_hl_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_hl_r is the value named 'product hl r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 101: `logic signed [31:0] product_hh_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_hh_r is the value named 'product hh r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 102: `logic signed [33:0] product_cross_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_cross_r is the value named 'product cross r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 103: `logic signed [63:0] product_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_low_r is the value named 'product low r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 104: `logic signed [63:0] product_latched_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_latched_r is the value named 'product latched r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 105: `logic product_negative_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_negative_r is the value named 'product negative r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 106: `logic [63:0] magnitude_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, magnitude_r is the value named 'magnitude r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 107: `logic [63:0] biased_magnitude_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, biased_magnitude_r is an additive learned offset applied after accumulation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 108: `logic [63:0] shifted_magnitude_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, shifted_magnitude_r is the value named 'shifted magnitude r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 109: `logic signed [63:0] rounded_signed_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rounded_signed_r is the value named 'rounded signed r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 110: `logic signed [32:0] offset_left_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, offset_left_r is the value named 'offset left r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 111: `logic signed [32:0] offset_right_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, offset_right_r is the value named 'offset right r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 112: `logic signed [32:0] offset_sum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, offset_sum_r is the value named 'offset sum r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 113: `logic signed [63:0] wide_result_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, wide_result_r is the value named 'wide result r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 114: `logic signed [31:0] saturated_value_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, saturated_value_r is the value named 'saturated value r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 115: `logic [31:0] distance_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, distance_r is the value named 'distance r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 116: `logic signed [32:0] distance_difference_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, distance_difference_r is the value named 'distance difference r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 117: `logic lane_a_negative_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_a_negative_r is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 118: `logic lane_a_ge_threshold_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_a_ge_threshold_r is the membrane level at which a neuron emits a spike. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 119: `logic lane_a_le_negative_threshold_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_a_le_negative_threshold_r is the membrane level at which a neuron emits a spike. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 120: `logic lane_a_ge_b_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_a_ge_b_r is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 121: `logic lane_a_zero_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_a_zero_r is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 122: `logic lane_a_below_clamp_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_a_below_clamp_r is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 123: `logic lane_a_above_clamp_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_a_above_clamp_r is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 124: `logic saturated_below_clamp_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, saturated_below_clamp_r is the value named 'saturated below clamp r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 125: `logic saturated_above_clamp_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, saturated_above_clamp_r is the value named 'saturated above clamp r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 126: `logic inside_surrogate_window_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, inside_surrogate_window_r is the value named 'inside surrogate window r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 127: `logic signed [31:0] lane_result_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lane_result_r is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 129: `function automatic logic signed [31:0] saturate_s32(` Within the combinational helper saturate s32, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; saturate_s32: the value named 'saturate s32' in this block.

Line 130: `input logic signed [63:0] value` This declares value as a input port with width [63:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 131: `);` Within the combinational helper saturate s32, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The expression is a literal or structural operator and has no hidden software state.

Line 132: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s32; it has no arithmetic value of its own.

Line 133: `// A signed 64-bit number fits in 32 bits exactly when every upper bit` Design intent: A signed 64-bit number fits in 32 bits exactly when every upper bit This comment anchors the surrounding logic in the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

Line 134: `// repeats bit 31. This avoids a long pair of 64-bit comparators.` Design intent: repeats bit 31. This avoids a long pair of 64-bit comparators. This comment anchors the surrounding logic in the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives.

Line 135: `if (value[63:32] == {32{value[31]}}) saturate_s32 = value[31:0];` This condition selects the following hardware branch only when 'value[63:32] == {32{value[31]}}' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the combinational helper saturate s32.

Line 136: `else if (value[63]) saturate_s32 = 32'sh80000000;` This condition selects the following hardware branch only when 'value[63]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the combinational helper saturate s32.

Line 137: `else saturate_s32 = 32'sh7fffffff;` Within the combinational helper saturate s32, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are saturate_s32: the value named 'saturate s32' in this block; sh7fffffff: the value named 'sh7fffffff' in this block.

Line 138: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s32; it has no arithmetic value of its own.

Line 139: `endfunction` Within the combinational helper saturate s32, this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are endfunction: the value named 'endfunction' in this block.

Line 141: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 142: `input_ready = state == ST_IDLE;` This makes input_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_IDLE'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 143: `output_valid = state == ST_OUTPUT;` This makes output_valid, the producer's statement that its current payload is meaningful, equal to 'state == ST_OUTPUT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_OUTPUT: the value named 'st output' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 144: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 146: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 147: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 148: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 149: `lane_index <= 3'd0;` This makes lane_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '3'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 150: `operation_r <= OP_ADD_SAT;` This makes operation_r, the value named 'operation r' in this block, equal to 'OP_ADD_SAT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are OP_ADD_SAT: the value named 'op add sat' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 151: `operand_a_r <= '0;` This makes operand_a_r, the value named 'operand a r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 152: `operand_b_r <= '0;` This makes operand_b_r, the value named 'operand b r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 153: `multiplier_q15_r <= 16'sd0;` This makes multiplier_q15_r, the value named 'multiplier q15 r' in this block, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 154: `output_zero_point_r <= 16'sd0;` This makes output_zero_point_r, the integer code representing real numeric zero in affine quantization, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 155: `threshold_r <= 32'sd0;` This makes threshold_r, the membrane level at which a neuron emits a spike, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 156: `negative_threshold_r <= 32'sd0;` This makes negative_threshold_r, the membrane level at which a neuron emits a spike, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 157: `surrogate_window_r <= 32'd0;` This makes surrogate_window_r, the value named 'surrogate window r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 158: `clamp_minimum_r <= 32'sh80000000;` This makes clamp_minimum_r, the value named 'clamp minimum r' in this block, equal to '32'sh80000000'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sh80000000: the value named 'sh80000000' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 159: `clamp_maximum_r <= 32'sh7fffffff;` This makes clamp_maximum_r, the value named 'clamp maximum r' in this block, equal to '32'sh7fffffff'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sh7fffffff: the value named 'sh7fffffff' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 160: `shift_amount_r <= 6'd0;` This makes shift_amount_r, the value named 'shift amount r' in this block, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 161: `rounding_bias_r <= 64'd0;` This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 162: `lane_a_r <= 32'sd0;` This makes lane_a_r, one parallel arithmetic element within a vector or tensor datapath, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 163: `lane_b_r <= 32'sd0;` This makes lane_b_r, one parallel arithmetic element within a vector or tensor datapath, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 164: `multiplier_left_r <= 32'sd0;` This makes multiplier_left_r, the value named 'multiplier left r' in this block, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 165: `multiplier_right_r <= 32'sd0;` This makes multiplier_right_r, the value named 'multiplier right r' in this block, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 166: `multiplier_left_low_r <= 17'sd0;` This makes multiplier_left_low_r, the value named 'multiplier left low r' in this block, equal to '17'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 167: `multiplier_right_low_r <= 17'sd0;` This makes multiplier_right_low_r, the value named 'multiplier right low r' in this block, equal to '17'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 168: `multiplier_left_high_r <= 16'sd0;` This makes multiplier_left_high_r, the value named 'multiplier left high r' in this block, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 169: `multiplier_right_high_r <= 16'sd0;` This makes multiplier_right_high_r, the value named 'multiplier right high r' in this block, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 170: `product_ll_r <= 34'sd0;` This makes product_ll_r, the value named 'product ll r' in this block, equal to '34'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 171: `product_lh_r <= 33'sd0;` This makes product_lh_r, the value named 'product lh r' in this block, equal to '33'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 172: `product_hl_r <= 33'sd0;` This makes product_hl_r, the value named 'product hl r' in this block, equal to '33'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 173: `product_hh_r <= 32'sd0;` This makes product_hh_r, the value named 'product hh r' in this block, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 174: `product_cross_r <= 34'sd0;` This makes product_cross_r, the value named 'product cross r' in this block, equal to '34'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 175: `product_low_r <= 64'sd0;` This makes product_low_r, the value named 'product low r' in this block, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 176: `product_latched_r <= 64'sd0;` This makes product_latched_r, the value named 'product latched r' in this block, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 177: `product_negative_r <= 1'b0;` This makes product_negative_r, the value named 'product negative r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 178: `magnitude_r <= 64'd0;` This makes magnitude_r, the value named 'magnitude r' in this block, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 179: `biased_magnitude_r <= 64'd0;` This makes biased_magnitude_r, an additive learned offset applied after accumulation, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 180: `shifted_magnitude_r <= 64'd0;` This makes shifted_magnitude_r, the value named 'shifted magnitude r' in this block, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 181: `rounded_signed_r <= 64'sd0;` This makes rounded_signed_r, the value named 'rounded signed r' in this block, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 182: `offset_left_r <= 33'sd0;` This makes offset_left_r, the value named 'offset left r' in this block, equal to '33'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 183: `offset_right_r <= 33'sd0;` This makes offset_right_r, the value named 'offset right r' in this block, equal to '33'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 184: `offset_sum_r <= 33'sd0;` This makes offset_sum_r, the value named 'offset sum r' in this block, equal to '33'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 185: `wide_result_r <= 64'sd0;` This makes wide_result_r, the value named 'wide result r' in this block, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 186: `saturated_value_r <= 32'sd0;` This makes saturated_value_r, the value named 'saturated value r' in this block, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 187: `distance_r <= 32'd0;` This makes distance_r, the value named 'distance r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 188: `distance_difference_r <= 33'sd0;` This makes distance_difference_r, the value named 'distance difference r' in this block, equal to '33'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 189: `lane_a_negative_r <= 1'b0;` This makes lane_a_negative_r, one parallel arithmetic element within a vector or tensor datapath, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 190: `lane_a_ge_threshold_r <= 1'b0;` This makes lane_a_ge_threshold_r, the membrane level at which a neuron emits a spike, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 191: `lane_a_le_negative_threshold_r <= 1'b0;` This makes lane_a_le_negative_threshold_r, the membrane level at which a neuron emits a spike, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 192: `lane_a_ge_b_r <= 1'b0;` This makes lane_a_ge_b_r, one parallel arithmetic element within a vector or tensor datapath, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 193: `lane_a_zero_r <= 1'b0;` This makes lane_a_zero_r, one parallel arithmetic element within a vector or tensor datapath, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 194: `lane_a_below_clamp_r <= 1'b0;` This makes lane_a_below_clamp_r, one parallel arithmetic element within a vector or tensor datapath, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 195: `lane_a_above_clamp_r <= 1'b0;` This makes lane_a_above_clamp_r, one parallel arithmetic element within a vector or tensor datapath, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 196: `saturated_below_clamp_r <= 1'b0;` This makes saturated_below_clamp_r, the value named 'saturated below clamp r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 197: `saturated_above_clamp_r <= 1'b0;` This makes saturated_above_clamp_r, the value named 'saturated above clamp r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 198: `inside_surrogate_window_r <= 1'b0;` This makes inside_surrogate_window_r, the value named 'inside surrogate window r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 199: `lane_result_r <= 32'sd0;` This makes lane_result_r, one parallel arithmetic element within a vector or tensor datapath, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 200: `result <= '0;` This makes result, the value named 'result' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 201: `config_error <= 1'b0;` This makes config_error, the value named 'config error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 202: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 203: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 204: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 205: `if (input_valid) begin` This condition selects the following hardware branch only when 'input_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 206: `operation_r <= operation;` This makes operation_r, the value named 'operation r' in this block, equal to 'operation'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operation: the value named 'operation' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 207: `operand_a_r <= operand_a;` This makes operand_a_r, the value named 'operand a r' in this block, equal to 'operand_a'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operand_a: the value named 'operand a' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 208: `operand_b_r <= operand_b;` This makes operand_b_r, the value named 'operand b r' in this block, equal to 'operand_b'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operand_b: the value named 'operand b' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 209: `multiplier_q15_r <= multiplier_q15;` This makes multiplier_q15_r, the value named 'multiplier q15 r' in this block, equal to 'multiplier_q15'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_q15: the value named 'multiplier q15' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 210: `output_zero_point_r <= output_zero_point;` This makes output_zero_point_r, the integer code representing real numeric zero in affine quantization, equal to 'output_zero_point'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_zero_point: the integer code representing real numeric zero in affine quantization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 211: `threshold_r <= threshold;` This makes threshold_r, the membrane level at which a neuron emits a spike, equal to 'threshold'. It updates after the active clock edge together with other nonblocking assignments. The important operands are threshold: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 212: `negative_threshold_r <= -threshold;` This makes negative_threshold_r, the membrane level at which a neuron emits a spike, equal to '-threshold'. It updates after the active clock edge together with other nonblocking assignments. The important operands are threshold: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 213: `surrogate_window_r <= surrogate_window;` This makes surrogate_window_r, the value named 'surrogate window r' in this block, equal to 'surrogate_window'. It updates after the active clock edge together with other nonblocking assignments. The important operands are surrogate_window: the value named 'surrogate window' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 214: `clamp_minimum_r <= clamp_minimum;` This makes clamp_minimum_r, the value named 'clamp minimum r' in this block, equal to 'clamp_minimum'. It updates after the active clock edge together with other nonblocking assignments. The important operands are clamp_minimum: the value named 'clamp minimum' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 215: `clamp_maximum_r <= clamp_maximum;` This makes clamp_maximum_r, the value named 'clamp maximum r' in this block, equal to 'clamp_maximum'. It updates after the active clock edge together with other nonblocking assignments. The important operands are clamp_maximum: the value named 'clamp maximum' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 216: `config_error <= operation > OP_COMPARE_GE` This statement continues through source line 219; the explanation uses the complete expression rather than only the first visual fragment. This makes config_error, the value named 'config error' in this block, equal to 'operation > OP_COMPARE_GE || clamp_minimum > clamp_maximum || (operation == OP_FLEX_REQUANTIZE && right_shift == 5'b10000)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operation: the value named 'operation' in this block; OP_COMPARE_GE: the value named 'op compare ge' in this block; clamp_minimum: the value named 'clamp minimum' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 217: `|| clamp_minimum > clamp_maximum` This is continuation line 2 of the 4-line logical statement that begins at source line 216. Its exact fragment is '|| clamp_minimum > clamp_maximum'. The important operands are clamp_minimum: the value named 'clamp minimum' in this block; clamp_maximum: the value named 'clamp maximum' in this block. Read together, the complete operation is: This makes config_error, the value named 'config

error' in this block, equal to 'operation > OP_COMPARE_GE || clamp_minimum > clamp_maximum || (operation == OP_FLEX_REQUANTIZE && right_shift == 5'b10000)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operation: the value named 'operation' in this block; OP_COMPARE_GE: the value named 'op compare ge' in this block; clamp_minimum: the value named 'clamp minimum' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 218: `|| (operation == OP_FLEX_REQUANTIZE` This is continuation line 3 of the 4-line logical statement that begins at source line 216. Its exact fragment is '|| (operation == OP_FLEX_REQUANTIZE'. The important operands are operation: the value named 'operation' in this block; OP_FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Read together, the complete operation is: This makes config_error, the value named 'config error' in this block, equal to 'operation > OP_COMPARE_GE || clamp_minimum > clamp_maximum || (operation == OP_FLEX_REQUANTIZE && right_shift == 5'b10000)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operation: the value named 'operation' in this block; OP_COMPARE_GE: the value named 'op compare ge' in this block; clamp_minimum: the value named 'clamp minimum' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 219: `&& right_shift == 5'b10000);` This is continuation line 4 of the 4-line logical statement that begins at source line 216. Its exact fragment is '&& right_shift == 5'b10000);'. The important operands are right_shift: the value named 'right shift' in this block; b10000: the value named 'b10000' in this block. Read together, the complete operation is: This makes config_error, the value named 'config error' in this block, equal to 'operation > OP_COMPARE_GE || clamp_minimum > clamp_maximum || (operation == OP_FLEX_REQUANTIZE && right_shift == 5'b10000)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operation: the value named 'operation' in this block; OP_COMPARE_GE: the value named 'op compare ge' in this block; clamp_minimum: the value named 'clamp minimum' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 220: `lane_index <= 3'd0;` This makes lane_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '3'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 221: `if (operation == OP_REQUANTIZE) begin` This condition selects the following hardware branch only when 'operation == OP_REQUANTIZE' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are operation: the value named 'operation' in this block; OP_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 222: `shift_amount_r <= 6'd15 + {1'b0, right_shift};` This makes shift_amount_r, the value named 'shift amount r' in this block, equal to '6'd15 + {1'b0, right_shift}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d15: the value named 'd15' in this block; b0: the value named 'b0' in this block; right_shift: the value named 'right shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 223: `rounding_bias_r <= 64'd16384 << right_shift;` This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to '64'd16384 << right_shift'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d16384: the value named 'd16384' in this block; right_shift: the value named 'right shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 224: `end else if (operation == OP_FLEX_REQUANTIZE) begin` This condition selects the following hardware branch only when 'operation == OP_FLEX_REQUANTIZE' is true. Both branches exist as gates; the condition

controls a multiplexer rather than making software jump. The important operands are operation: the value named 'operation' in this block; OP_FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 225: `logic signed [5:0] effective_shift;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.. Specifically, effective_shift is the value named 'effective shift' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 226: `effective_shift = 6'sd15` This statement continues through source line 227; the explanation uses the complete expression rather than only the first visual fragment. This makes effective_shift, the value named 'effective shift' in this block, equal to '6'sd15 + $signed({right_shift[4], right_shift})'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd15: the value named 'sd15' in this block; right_shift: the value named 'right shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 227: `+ $signed({right_shift[4], right_shift});` This is continuation line 2 of the 2-line logical statement that begins at source line 226. Its exact fragment is '+ $signed({right_shift[4], right_shift});'. The important operands are right_shift: the value named 'right shift' in this block. Read together, the complete operation is: This makes effective_shift, the value named 'effective shift' in this block, equal to '6'sd15 + $signed({right_shift[4], right_shift})'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd15: the value named 'sd15' in this block; right_shift: the value named 'right shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 228: `if (right_shift == 5'b10000) begin` This condition selects the following hardware branch only when 'right_shift == 5'b10000' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are right_shift: the value named 'right shift' in this block; b10000: the value named 'b10000' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 229: `shift_amount_r <= 6'd0;` This makes shift_amount_r, the value named 'shift amount r' in this block, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 230: `rounding_bias_r <= 64'd0;` This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 231: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 232: `shift_amount_r <= effective_shift[5:0];` This makes shift_amount_r, the value named 'shift amount r' in this block, equal to 'effective_shift[5:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are effective_shift: the value named 'effective shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 233: `rounding_bias_r <= effective_shift == 0` This statement continues through source line 235; the explanation uses the complete expression rather than only the first visual fragment. This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to ‘effective_shift == 0 ? 64’d0 : (64’d1 << (effective_shift - 1’b1))‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are effective_shift: the value named ’effective shift’ in this block; d0: the value named ’d0’ in this block; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 234: `? 64’d0` This is continuation line 2 of the 3-line logical statement that begins at source line 233. Its exact fragment is ‘? 64’d0‘. The important operands are d0: the value named ’d0’ in this block. Read together, the complete operation is: This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to ‘effective_shift == 0 ? 64’d0 : (64’d1 << (effective_shift - 1’b1))‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are effective_shift: the value named ’effective shift’ in this block; d0: the value named ’d0’ in this block; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 235: `: (64’d1 << (effective_shift - 1’b1));` This is continuation line 3 of the 3-line logical statement that begins at source line 233. Its exact fragment is ‘: (64’d1 << (effective_shift - 1’b1));‘. The important operands are d1: the value named ’d1’ in this block; effective_shift: the value named ’effective shift’ in this block; b1: the value named ’b1’ in this block. Read together, the complete operation is: This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to ‘effective_shift == 0 ? 64’d0 : (64’d1 << (effective_shift - 1’b1))‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are effective_shift: the value named ’effective shift’ in this block; d0: the value named ’d0’ in this block; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 236: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 237: `end else if (operation == OP_MULTIPLY_Q15) begin` This condition selects the following hardware branch only when ‘operation == OP_MULTIPLY_Q15‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are operation: the value named ’operation’ in this block; OP_MULTIPLY_Q15: the value named ’op multiply q15’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 238: `shift_amount_r <= 6’d15;` This makes shift_amount_r, the value named ’shift amount r’ in this block, equal to ‘6’d15‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d15: the value named ’d15’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 239: `rounding_bias_r <= 64’d16384;` This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to ‘64’d16384‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d16384: the value named ’d16384’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 240: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 241: `shift_amount_r <= 6’d0;` This makes shift_amount_r, the value named ’shift amount r’ in this block, equal to ‘6’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important

operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 242: `rounding_bias_r <= 64'd0;` This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 243: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 244: `state <= ST_LOAD_LANE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LOAD_LANE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_LANE: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 245: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 246: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 248: `ST_LOAD_LANE: begin` This is the ST_LOAD_LANE case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_LANE, the machine stores incoming operands into local FPGA memory..

Line 249: `lane_a_r <= $signed(` This statement continues through source line 250; the explanation uses the complete expression rather than only the first visual fragment. This makes lane_a_r, one parallel arithmetic element within a vector or tensor datapath, equal to '$signed(operand_a_r[lane_index*DATA_BITS +: DATA_BITS])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operand_a_r: the value named 'operand a r' in this block; lane_index: an integer selecting one tensor element, lane, bank, or state entry; DATA_BITS: the value named 'data bits' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_LANE, the machine stores incoming operands into local FPGA memory..

Line 250: `operand_a_r[lane_index*DATA_BITS +: DATA_BITS]);` This is continuation line 2 of the 2-line logical statement that begins at source line 249. Its exact fragment is 'operand_a_r[lane_index*DATA_BITS +: DATA_BITS]);'. The important operands are operand_a_r: the value named 'operand a r' in this block; lane_index: an integer selecting one tensor element, lane, bank, or state entry; DATA_BITS: the value named 'data bits' in this block. Read together, the complete operation is: This makes lane_a_r, one parallel arithmetic element within a vector or tensor datapath, equal to '$signed(operand_a_r[lane_index*DATA_BITS +: DATA_BITS])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operand_a_r: the value named 'operand a r' in this block; lane_index: an integer selecting one tensor element, lane, bank, or state entry; DATA_BITS: the value named 'data bits' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_LANE, the machine stores incoming operands into local FPGA memory..

Line 251: `lane_b_r <= $signed(` This statement continues through source line 252; the explanation uses the complete expression rather than only the first visual fragment. This makes lane_b_r, one parallel arithmetic element within a vector or tensor datapath, equal to '$signed(operand_b_r[lane_index*DATA_BITS +: DATA_BITS])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operand_b_r: the

value named 'operand b r' in this block; lane_index: an integer selecting one tensor element, lane, bank, or state entry; DATA_BITS: the value named 'data bits' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_LANE, the machine stores incoming operands into local FPGA memory..

Line 252: `operand_b_r[lane_index*DATA_BITS +: DATA_BITS]);` This is continuation line 2 of the 2-line logical statement that begins at source line 251. Its exact fragment is 'operand_b_r[lane_index*DATA_BITS +: DATA_BITS]);'. The important operands are operand_b_r: the value named 'operand b r' in this block; lane_index: an integer selecting one tensor element, lane, bank, or state entry; DATA_BITS: the value named 'data bits' in this block. Read together, the complete operation is: This makes lane_b_r, one parallel arithmetic element within a vector or tensor datapath, equal to '$signed(operand_b_r[lane_index*DATA_BITS +: DATA_BITS])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are operand_b_r: the value named 'operand b r' in this block; lane_index: an integer selecting one tensor element, lane, bank, or state entry; DATA_BITS: the value named 'data bits' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_LANE, the machine stores incoming operands into local FPGA memory..

Line 253: `state <= ST_MULTIPLIER_LATCH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MULTIPLIER_LATCH'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MULTIPLIER_LATCH: the value named 'st multiplier latch' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_LANE, the machine stores incoming operands into local FPGA memory..

Line 254: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_LANE, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 256: `ST_MULTIPLIER_LATCH: begin` This is the ST_MULTIPLIER_LATCH case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase..

Line 257: `multiplier_left_r <= lane_a_r;` This makes multiplier_left_r, the value named 'multiplier left r' in this block, equal to 'lane_a_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase..

Line 258: `if (operation_r == OP_REQUANTIZE` Within the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase., this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are operation_r: the value named 'operation r' in this block; OP_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code.

Line 259: `|| operation_r == OP_FLEX_REQUANTIZE) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase., this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are operation_r: the value named 'operation r' in this block; OP_FLEX_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code.

Line 260: `multiplier_right_r <= {` This statement continues through source line 261; the explanation uses the complete expression rather than only the first visual fragment. This makes multiplier_right_r, the value named 'multiplier right r' in this block, equal to '{ {16{multiplier_q15_r[15]}}, multiplier_q15_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_q15_r: the value named 'multiplier q15 r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase..

Line 261: `{16{multiplier_q15_r[15]}}, multiplier_q15_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 260. Its exact fragment is '{16{multiplier_q15_r[15]}}, multiplier_q15_r};'. The important operands are multiplier_q15_r: the value named 'multiplier q15 r' in this block. Read together, the complete operation is: This makes multiplier_right_r, the value named 'multiplier right r' in this block, equal to '{ {16{multiplier_q15_r[15]}}, multiplier_q15_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_q15_r: the value named 'multiplier q15 r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase..

Line 262: `end else if (operation_r == OP_MULTIPLY_Q15) begin` This condition selects the following hardware branch only when 'operation_r == OP_MULTIPLY_Q15' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are operation_r: the value named 'operation r' in this block; OP_MULTIPLY_Q15: the value named 'op multiply q15' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase..

Line 263: `multiplier_right_r <= lane_b_r;` This makes multiplier_right_r, the value named 'multiplier right r' in this block, equal to 'lane_b_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_b_r: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase..

Line 264: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 265: `multiplier_right_r <= 32'sd0;` This makes multiplier_right_r, the value named 'multiplier right r' in this block, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase..

Line 266: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 267: `state <= ST_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MULTIPLY'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MULTIPLY: the value named 'st multiply' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase..

Line 268: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLIER_LATCH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 270: `ST_MULTIPLY: begin` This is the ST_MULTIPLY case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase..

Line 271: `multiplier_left_low_r <= $signed({1'b0, multiplier_left_r[15:0]});` This makes multiplier_left_low_r, the value named 'multiplier left low r' in this block, equal to '$signed({1'b0, multiplier_left_r[15:0]})'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block; multiplier_left_r: the value named 'multiplier left r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase..

Line 272: `multiplier_right_low_r <= $signed({1'b0, multiplier_right_r[15:0]});` This makes multiplier_right_low_r the value named 'multiplier right low r' in this block, equal to '$signed({1'b0, multiplier_right_r[15:0]})'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block; multiplier_right_r: the value named 'multiplier right r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase..

Line 273: `multiplier_left_high_r <= multiplier_left_r[31:16];` This makes multiplier_left_high_r, the value named 'multiplier left high r' in this block, equal to 'multiplier_left_r[31:16]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_left_r: the value named 'multiplier left r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase..

Line 274: `multiplier_right_high_r <= multiplier_right_r[31:16];` This makes multiplier_right_high_r, the value named 'multiplier right high r' in this block, equal to 'multiplier_right_r[31:16]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_right_r: the value named 'multiplier right r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase..

Line 275: `state <= ST_PRODUCT_CROSS;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_PRODUCT_CROSS'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PRODUCT_CROSS: the value named 'st product cross' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase..

Line 276: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 278: `ST_PRODUCT_CROSS: begin` This is the ST_PRODUCT_CROSS case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_CROSS, the machine performs the named control phase..

Line 279: `product_ll_r <= multiplier_product_ll;` This makes product_ll_r, the value named 'product ll r' in this block, equal to 'multiplier_product_ll'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_product_ll: the value named 'multiplier product ll' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_CROSS, the machine performs the named control phase..

Line 280: `product_lh_r <= multiplier_product_lh;` This makes product_lh_r, the value named 'product lh r' in this block, equal to 'multiplier_product_lh'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_product_lh: the value named 'multiplier product lh' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_CROSS, the machine performs the named control phase..

Line 281: `product_hl_r <= multiplier_product_hl;` This makes product_hl_r, the value named 'product hl r' in this block, equal to 'multiplier_product_hl'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_product_hl: the value named 'multiplier product hl' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_CROSS, the machine performs the named control phase..

Line 282: `product_hh_r <= multiplier_product_hh;` This makes product_hh_r, the value named 'product hh r' in this block, equal to 'multiplier_product_hh'. It updates after the active clock edge together with other nonblocking assignments. The important operands are multiplier_product_hh: the value named 'multiplier product hh' in this block.

Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_CROSS, the machine performs the named control phase..

Line 283: `state <= ST_PRODUCT_LOW;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_PRODUCT_LOW‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PRODUCT_LOW: the value named ’st product low’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_CROSS, the machine performs the named control phase..

Line 284: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_CROSS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 286: `ST_PRODUCT_LOW: begin` This is the ST_PRODUCT_LOW case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LOW, the machine performs the named control phase..

Line 287: `product_cross_r <= $signed({product_lh_r[32], product_lh_r})` This statement continues through source line 288; the explanation uses the complete expression rather than only the first visual fragment. This makes product_cross_r, the value named ’product cross r’ in this block, equal to ‘$signed({product_lh_r[32], product_lh_r}) + $signed({product_hl_r[32], product_hl_r})‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_lh_r: the value named ’product lh r’ in this block; product_hl_r: the value named ’product hl r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LOW, the machine performs the named control phase..

Line 288: `+ $signed({product_hl_r[32], product_hl_r});` This is continuation line 2 of the 2-line logical statement that begins at source line 287. Its exact fragment is ‘+ $signed({product_hl_r[32], product_hl_r});‘. The important operands are product_hl_r: the value named ’product hl r’ in this block. Read together, the complete operation is: This makes product_cross_r, the value named ’product cross r’ in this block, equal to ‘$signed({product_lh_r[32], product_lh_r}) + $signed({product_hl_r[32], product_hl_r})‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_lh_r: the value named ’product lh r’ in this block; product_hl_r: the value named ’product hl r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LOW, the machine performs the named control phase..

Line 289: `product_low_r <= $signed({{30{product_ll_r[33]}}, product_ll_r});` This makes product_low_r, the value named ’product low r’ in this block, equal to ‘$signed({{30{product_ll_r[33]}}, product_ll_r})‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_ll_r: the value named ’product ll r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LOW, the machine performs the named control phase..

Line 290: `state <= ST_PRODUCT_LATCH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_PRODUCT_LATCH‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PRODUCT_LATCH: the value named ’st product latch’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LOW, the machine performs the named control phase..

Line 291: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LOW, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 293: `ST_PRODUCT_LATCH: begin` This is the ST_PRODUCT_LATCH case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LATCH, the machine performs the named control phase..

Line 294: `product_latched_r <= product_low_r` This statement continues through source line 296; the explanation uses the complete expression rather than only the first visual fragment. This makes product_latched_r, the value named 'product latched r' in this block, equal to 'product_low_r + ($signed({{30{product_cross_r[33]}}, product_cross_r}) <<< 16) + ($signed({{32{product_hh_r[31]}}, product_hh_r}) <<< 32)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_low_r: the value named 'product low r' in this block; product_cross_r: the value named 'product cross r' in this block; product_hh_r: the value named 'product hh r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LATCH, the machine performs the named control phase..

Line 295: `+ ($signed({{30{product_cross_r[33]}}, product_cross_r}) <<< 16)` This is continuation line 2 of the 3-line logical statement that begins at source line 294. Its exact fragment is '+ ($signed({{30{product_cross_r[33]}}, product_cross_r}) <<< 16)'. The important operands are product_cross_r: the value named 'product cross r' in this block. Read together, the complete operation is: This makes product_latched_r, the value named 'product latched r' in this block, equal to 'product_low_r + ($signed({{30{product_cross_r[33]}}, product_cross_r}) <<< 16) + ($signed({{32{product_hh_r[31]}}, product_hh_r}) <<< 32)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_low_r: the value named 'product low r' in this block; product_cross_r: the value named 'product cross r' in this block; product_hh_r: the value named 'product hh r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LATCH, the machine performs the named control phase..

Line 296: `+ ($signed({{32{product_hh_r[31]}}, product_hh_r}) <<< 32);` This is continuation line 3 of the 3-line logical statement that begins at source line 294. Its exact fragment is '+ ($signed({{32{product_hh_r[31]}}, product_hh_r}) <<< 32);'. The important operands are product_hh_r: the value named 'product hh r' in this block. Read together, the complete operation is: This makes product_latched_r, the value named 'product latched r' in this block, equal to 'product_low_r + ($signed({{30{product_cross_r[33]}}, product_cross_r}) <<< 16) + ($signed({{32{product_hh_r[31]}}, product_hh_r}) <<< 32)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_low_r: the value named 'product low r' in this block; product_cross_r: the value named 'product cross r' in this block; product_hh_r: the value named 'product hh r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LATCH, the machine performs the named control phase..

Line 297: `state <= ST_ABSOLUTE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_ABSOLUTE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ABSOLUTE: the value named 'st absolute' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LATCH, the machine performs the named control phase..

Line 298: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT_LATCH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 300: `ST_ABSOLUTE: begin` This is the ST_ABSOLUTE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ABSOLUTE, the machine performs the named control phase..

Line 301: `product_negative_r <= product_latched_r[63];` This makes product_negative_r, the value named 'product negative r' in this block, equal to 'product_latched_r[63]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_latched_r: the value named 'product latched r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ABSOLUTE, the machine performs the named control phase..

Line 302: `magnitude_r <= product_latched_r[63]` This statement continues through source line 303; the explanation uses the complete expression rather than only the first visual fragment. This makes magnitude_r, the value named 'magnitude r' in this block, equal to 'product_latched_r[63] ? -product_latched_r : product_latched_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_latched_r:

the value named 'product latched r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ABSOLUTE, the machine performs the named control phase..

Line 303: `? -product_latched_r : product_latched_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 302. Its exact fragment is '? -product_latched_r : product_latched_r;'. The important operands are product_latched_r: the value named 'product latched r' in this block. Read together, the complete operation is: This makes magnitude_r, the value named 'magnitude r' in this block, equal to 'product_latched_r[63] ? -product_latched_r : product_latched_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_latched_r: the value named 'product latched r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ABSOLUTE, the machine performs the named control phase..

Line 304: `state <= ST_ROUND_BIAS;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_ROUND_BIAS'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ROUND_BIAS: an additive learned offset applied after accumulation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ABSOLUTE, the machine performs the named control phase..

Line 305: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ABSOLUTE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 307: `ST_ROUND_BIAS: begin` This is the ST_ROUND_BIAS case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase..

Line 308: `biased_magnitude_r <= magnitude_r + rounding_bias_r;` This makes biased_magnitude_r, an additive learned offset applied after accumulation, equal to 'magnitude_r + rounding_bias_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are magnitude_r: the value named 'magnitude r' in this block; rounding_bias_r: an additive learned offset applied after accumulation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase..

Line 309: `state <= ST_SHIFT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_SHIFT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SHIFT: the value named 'st shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase..

Line 310: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 312: `ST_SHIFT: begin` This is the ST_SHIFT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase..

Line 313: `shifted_magnitude_r <= biased_magnitude_r >> shift_amount_r;` This makes shifted_magnitude_r, the value named 'shifted magnitude r' in this block, equal to 'biased_magnitude_r >> shift_amount_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are biased_magnitude_r: an additive learned offset applied after accumulation; shift_amount_r: the value named 'shift amount r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase..

Line 314: `state <= ST_RESTORE_SIGN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_RESTORE_SIGN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_RESTORE_SIGN: the value named ’st restore sign’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase..

Line 315: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SHIFT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 317: `ST_RESTORE_SIGN: begin` This is the ST_RESTORE_SIGN case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_SIGN, the machine performs the named control phase..

Line 318: `rounded_signed_r <= product_negative_r` This statement continues through source line 320; the explanation uses the complete expression rather than only the first visual fragment. This makes rounded_signed_r, the value named ’rounded signed r’ in this block, equal to ‘product_negative_r ? -$signed(shifted_magnitude_r) : $signed(shifted_magnitude_r)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_negative_r: the value named ’product negative r’ in this block; shifted_magnitude_r: the value named ’shifted magnitude r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_SIGN, the machine performs the named control phase..

Line 319: `? -$signed(shifted_magnitude_r)` This is continuation line 2 of the 3-line logical statement that begins at source line 318. Its exact fragment is ‘? -$signed(shifted_magnitude_r)‘. The important operands are shifted_magnitude_r: the value named ’shifted magnitude r’ in this block. Read together, the complete operation is: This makes rounded_signed_r, the value named ’rounded signed r’ in this block, equal to ‘product_negative_r ? -$signed(shifted_magnitude_r) : $signed(shifted_magnitude_r)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_negative_r: the value named ’product negative r’ in this block; shifted_magnitude_r: the value named ’shifted magnitude r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_SIGN, the machine performs the named control phase..

Line 320: `: $signed(shifted_magnitude_r);` This is continuation line 3 of the 3-line logical statement that begins at source line 318. Its exact fragment is ‘: $signed(shifted_magnitude_r);‘. The important operands are shifted_magnitude_r: the value named ’shifted magnitude r’ in this block. Read together, the complete operation is: This makes rounded_signed_r, the value named ’rounded signed r’ in this block, equal to ‘product_negative_r ? -$signed(shifted_magnitude_r) : $signed(shifted_magnitude_r)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_negative_r: the value named ’product negative r’ in this block; shifted_magnitude_r: the value named ’shifted magnitude r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_SIGN, the machine performs the named control phase..

Line 321: `state <= ST_OFFSET;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OFFSET‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OFFSET: the value named ’st offset’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_SIGN, the machine performs the named control phase..

Line 322: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RESTORE_SIGN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 324: `ST_OFFSET: begin` This is the ST_OFFSET case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OFFSET, the machine performs the named control phase..

Line 325: `unique case (operation_r)` This starts a multiplexer/state decode selected by ‘operation_r‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 326: `OP_ADD_SAT: begin` This is the OP_ADD_SAT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state OP_ADD_SAT, the machine performs the named control phase..

Line 327: `offset_left_r <= {lane_a_r[31], lane_a_r};` This makes offset_left_r, the value named ’offset left r’ in this block, equal to ‘{lane_a_r[31], lane_a_r}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state OP_ADD_SAT, the machine performs the named control phase..

Line 328: `offset_right_r <= {lane_b_r[31], lane_b_r};` This makes offset_right_r, the value named ’offset right r’ in this block, equal to ‘{lane_b_r[31], lane_b_r}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_b_r: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state OP_ADD_SAT, the machine performs the named control phase..

Line 329: `state <= ST_OFFSET_ADD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OFFSET_ADD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OFFSET_ADD: the value named ’st offset add’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_ADD_SAT, the machine performs the named control phase..

Line 330: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_ADD_SAT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 331: `OP_REQUANTIZE,` Within the clocked process that updates registers only on a rising clock edge Within state OP_ADD_SAT, the machine performs the named control phase., this exact statement contributes to the block that executes lane-wise residual, activation, comparison, requantization, and pooling primitives. The important operands are OP_REQUANTIZE: the conversion of a wide accumulated result back into a bounded activation code.

Line 332: `OP_FLEX_REQUANTIZE: begin` This is the OP_FLEX_REQUANTIZE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 333: `offset_left_r <= rounded_signed_r[32:0];` This makes offset_left_r, the value named ’offset left r’ in this block, equal to ‘rounded_signed_r[32:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are rounded_signed_r: the value named ’rounded signed r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 334: `offset_right_r <= {{17{output_zero_point_r[15]}},` This statement continues through source line 335; the explanation uses the complete expression rather than only the first visual fragment. This makes offset_right_r, the value named ’offset right r’ in this block, equal to ‘{{17{output_zero_point_r[15]}}, output_zero_point_r}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_zero_point_r: the integer code representing real numeric zero in affine quantization. Context: the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 335: `output_zero_point_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 334. Its exact fragment is ‘output_zero_point_r};‘. The important operands are output_zero_point_r: the integer code representing real numeric zero in affine quantization. Read together, the complete operation is: This makes offset_right_r, the value named ’offset right r’ in this block, equal to ‘{{17{output_zero_point_r[15]}}, output_zero_point_r}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_zero_point_r: the integer code representing real numeric zero in affine quantization. Context: the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 336: `state <= ST_OFFSET_ADD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OFFSET_ADD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OFFSET_ADD: the value named ’st offset add’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase..

Line 337: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_FLEX_REQUANTIZE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 338: `OP_MULTIPLY_Q15: begin` This is the OP_MULTIPLY_Q15 case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state OP_MULTIPLY_Q15, the machine performs the named control phase..

Line 339: `wide_result_r <= rounded_signed_r;` This makes wide_result_r, the value named ’wide result r’ in this block, equal to ‘rounded_signed_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are rounded_signed_r: the value named ’rounded signed r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_MULTIPLY_Q15, the machine performs the named control phase..

Line 340: `state <= ST_PRECOMPUTE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_PRECOMPUTE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PRECOMPUTE: the value named ’st precompute’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_MULTIPLY_Q15, the machine performs the named control phase..

Line 341: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_MULTIPLY_Q15, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 342: `default: begin` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state OP_MULTIPLY_Q15, the machine performs the named control phase..

Line 343: `wide_result_r <= {{32{lane_a_r[31]}}, lane_a_r};` This makes wide_result_r, the value named ’wide result r’ in this block, equal to ‘{{32{lane_a_r[31]}}, lane_a_r}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are lane_a_r: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state OP_MULTIPLY_Q15, the machine performs the named control phase..

Line 344: `state <= ST_PRECOMPUTE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_PRECOMPUTE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PRECOMPUTE: the value named ’st precompute’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state OP_MULTIPLY_Q15, the machine performs the named control phase..

Line 345: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state OP_MULTIPLY_Q15, the machine performs the named control phase.; it has no arithmetic value of its own.
