NeuraEdge Universal: Complete Line-by-Line Source Reference

Generated from hashed repository source

July 16, 2026

Contents

1 How to read this volume **12**

2 rtl/neuraedge_activation_buffer.sv **13**
- 2.1 Beginner architecture map . . . 13
- 2.2 Complete source . . . 13
- 2.3 Line annotations . . . 13

3 rtl/neuraedge_activation_lut8.sv **17**
- 3.1 Beginner architecture map . . . 17
- 3.2 Complete source . . . 17
- 3.3 Line annotations . . . 19

4 rtl/neuraedge_active_index_buffer.sv **37**
- 4.1 Beginner architecture map . . . 37
- 4.2 Complete source . . . 37
- 4.3 Line annotations . . . 37

5 rtl/neuraedge_alpha_xnor.sv **41**
- 5.1 Beginner architecture map . . . 41
- 5.2 Complete source . . . 41
- 5.3 Line annotations . . . 44

6 rtl/neuraedge_buffered_tensor_core.sv **68**
- 6.1 Beginner architecture map . . . 68
- 6.2 Complete source . . . 68
- 6.3 Line annotations . . . 80

7 rtl/neuraedge_command_pkg.sv **177**
- 7.1 Beginner architecture map . . . 177
- 7.2 Complete source . . . 177
- 7.3 Line annotations . . . 177

8 rtl/neuraedge_descriptor_sequencer.sv **181**
- 8.1 Beginner architecture map . . . 181
- 8.2 Complete source . . . 181
- 8.3 Line annotations . . . 185

9 rtl/neuraedge_gradient_accumulator_bank.sv **216**

9.1 Beginner architecture map . . . 216
9.2 Complete source . . . 216
9.3 Line annotations . . . 216

10 rtl/neuraedge_integer_layernorm.sv 219
10.1 Beginner architecture map . . . 219
10.2 Complete source . . . 219
10.3 Line annotations . . . 228

11 rtl/neuraedge_isqrt64.sv 299
11.1 Beginner architecture map . . . 299
11.2 Complete source . . . 299
11.3 Line annotations . . . 300

12 rtl/neuraedge_lif_bank.sv 309
12.1 Beginner architecture map . . . 309
12.2 Complete source . . . 309
12.3 Line annotations . . . 313

101 Coverage statement 3277

1 How to read this volume

Each file begins with its system-level responsibility and a complete numbered source listing. The following annotations explain every nonblank line using its enclosing function, RTL process, or finite-state-machine phase. Blank lines are visible in the listing but have no executable or synthesized behavior. SystemVerilog describes parallel hardware: an if statement controls a multiplexer and a nonblocking assignment updates a register on a clock edge. Python, PowerShell, and Tcl run sequentially on a processor or inside a tool.

2 rtl/neuraedge_activation_buffer.sv

Role in the complete system: stores one local tile of unsigned eight-bit activations for repeated tensor-array reads.

2.1 Beginner architecture map

Dataflow responsibility A load command writes activation bytes into addressed entries. During compute, the scheduler presents reduction indices and this memory returns one activation vector per selected row; keeping the tile local avoids rereading DDR for every output column.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_activation_buffer into physical nets and primitives. The source declares 5 input-port lines, 1 output-port lines, 1 clocked process(es), and 0 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control This block is primarily a datapath or storage primitive rather than a large state machine. Registers still divide combinational work into cycles and hold valid/data stable during downstream stalls.

Connections to other blocks This is a leaf block: parent modules create it and connect its ports. It does not instantiate another project RTL module, so its arithmetic or storage maps directly into FPGA primitives.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

2.2 Complete source

```
1  `timescale 1ns / 1ps
2  `default_nettype none
3
4  module neuraedge_activation_buffer #(
5      parameter int DEPTH = 2048,
6      parameter int ADDRESS_BITS = 11
7  ) (
8      input  wire clk,
9      input  wire write_enable,
10     input  wire [ADDRESS_BITS-1:0] write_address,
11     input  wire [63:0] write_data,
12     input  wire [ADDRESS_BITS-1:0] read_address,
13     output logic [63:0] read_data
14 );
15     (* ram_style = "block" *) logic [63:0] memory [0:DEPTH-1];
16     logic [63:0] memory_read_data_r;
17
18     always_ff @(posedge clk) begin
19         if (write_enable) memory[write_address] <= write_data;
20         memory_read_data_r <= memory[read_address];
21         read_data <= memory_read_data_r;
22     end
23
24     initial begin
25         if (DEPTH != (1 << ADDRESS_BITS)) $fatal(1, "activation buffer depth/address mismatch");
26     end
27 endmodule
28
29 `default_nettype wire
```

2.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_activation_buffer #(` This opens neuraedge_activation_buffer, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that stores one local tile of unsigned eight-bit activations for repeated tensor-array reads.

Line 5: `parameter int DEPTH = 2048,` This statement continues through source line 14; the explanation uses the complete expression rather than only the first visual fragment. This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [63:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 6: `parameter int ADDRESS_BITS = 11` This is continuation line 2 of the 10-line logical statement that begins at source line 5. Its exact fragment is 'parameter int ADDRESS_BITS = 11'. The important operands are parameter: the value named 'parameter' in this block; ADDRESS_BITS: the value named 'address bits' in this block. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [63:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 7: `) (` This is continuation line 3 of the 10-line logical statement that begins at source line 5. Its exact fragment is ') ('. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [63:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 8: `input wire clk,` This is continuation line 4 of the 10-line logical statement that begins at source line 5. Its exact fragment is 'input wire clk,'. The important operands are input: the value named 'input' in this block; clk: the clock that makes all registers advance together. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [63:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 9: `input wire write_enable,` This is continuation line 5 of the 10-line logical statement that begins at source line 5. Its exact fragment is 'input wire write_enable,'. The important operands are input: the value named 'input' in this block; write_enable: a control bit that permits the associated state or storage update. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [63:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 10: `input wire [ADDRESS_BITS-1:0] write_address,` This is continuation line 6 of the 10-line logical statement that begins at source line 5. Its exact fragment is 'input wire [ADDRESS_BITS-1:0] write_address,'. The important operands are input: the value named 'input' in this block; ADDRESS_BITS: the value named 'address bits' in this block; write_address: the value named 'write address' in this block. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [63:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 11: `input wire [63:0] write_data,` This is continuation line 7 of the 10-line logical statement that begins at source line 5. Its exact fragment is 'input wire [63:0] write_data,'. The important operands are input: the value named 'input' in this block; write_data: the payload carried with the surrounding valid/ready handshake. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [63:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 12: `input wire [ADDRESS_BITS-1:0] read_address,` This is continuation line 8 of the 10-line logical statement that begins at source line 5. Its exact fragment is 'input wire [ADDRESS_BITS-1:0] read_address,'. The important

operands are input: the value named 'input' in this block; ADDRESS_BITS: the value named 'address bits' in this block; read_address: the value named 'read address' in this block. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [63:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 13: `output logic [63:0] read_data` This is continuation line 9 of the 10-line logical statement that begins at source line 5. Its exact fragment is 'output logic [63:0] read_data'. The important operands are output: the value named 'output' in this block; read_data: the payload carried with the surrounding valid/ready handshake. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [63:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 14: `);` This is continuation line 10 of the 10-line logical statement that begins at source line 5. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [63:0] write_data, input wire [ADDRESS_BITS-1:0] read_address, output logic [63:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 15: `(* ram_style = "block" *) logic [63:0] memory [0:DEPTH-1];` Within the module's structural declarations, this exact statement contributes to the block that stores one local tile of unsigned eight-bit activations for repeated tensor-array reads. The important operands are ram_style: the value named 'ram style' in this block; block: the value named 'block' in this block; memory: local FPGA storage addressed by surrounding index logic.

Line 16: `logic [63:0] memory_read_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, memory_read_data_r is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 18: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 19: `if (write_enable) memory[write_address] <= write_data;` This condition selects the following hardware branch only when 'write_enable' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are write_enable: a control bit that permits the associated state or storage update. Context: the clocked process that updates registers only on a rising clock edge.

Line 20: `memory_read_data_r <= memory[read_address];` This makes memory_read_data_r, local FPGA storage addressed by surrounding index logic, equal to 'memory[read_address]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are memory: local FPGA storage addressed by surrounding index logic; read_address: the value named 'read address' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 21: `read_data <= memory_read_data_r;` This makes read_data, the payload carried with the surrounding valid/ready handshake, equal to 'memory_read_data_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are memory_read_data_r: local FPGA storage addressed by surrounding index logic. Context: the clocked process that updates registers only on a rising clock edge.

Line 22: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 24: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 25: `if (DEPTH != (1 << ADDRESS_BITS)) $fatal(1, "activation buffer depth/address mismatch");` This condition selects the following hardware branch only when ‘DEPTH != (1 << ADDRESS_BITS)) $fatal(1, "activation buffer depth/address mismatch"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are DEPTH: the value named ’depth’ in this block; ADDRESS_BITS: the value named ’address bits’ in this block; fatal: the value named ’fatal’ in this block. Context: the module’s structural declarations.

Line 26: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 27: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 29: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that stores one local tile of unsigned eight-bit activations for repeated tensor-array reads.

3 rtl/neuraedge_activation_lut8.sv

Role in the complete system: loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

3.1 Beginner architecture map

Dataflow responsibility Software first streams address/value pairs into the 256-entry table. A later execute command reads eight addresses in parallel, returns eight programmed nonlinear values, and counts only newly initialized addresses so duplicate writes cannot falsely report a complete table.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_activation_lut8 into physical nets and primitives. The source declares 9 input-port lines, 6 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control This block is primarily a datapath or storage primitive rather than a large state machine. Registers still divide combinational work into cycles and hold valid/data stable during downstream stalls.

Connections to other blocks This source instantiates end as if, unique as case, endcase as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

`default_nettype wire
```

3.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_activation_lut8 (` This opens neuraedge_activation_lut8, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 5: `input wire clk,` This declares clk as a input port with width one bit. It carries the clock that makes all registers advance together across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 6: `input wire rst_n,` This declares rst_n as a input port with width one bit. It carries the active-low synchronous reset across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 7: `input wire clear_table,` This declares clear_table as a input port with width one bit. It carries the value named 'clear table' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 8: `input wire load_valid,` This declares load_valid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 9: `output logic load_ready,` This declares load_ready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 10: `input wire [7:0] load_address,` This declares load_address as a input port with width [7:0]. It carries the value named 'load address' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 11: `input wire signed [15:0] load_value,` This declares load_value as a input port with width [15:0]. It carries the value named 'load value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 12: `input wire input_valid,` This declares input_valid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 13: `output logic input_ready,` This declares input_ready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 14: `input wire [63:0] input_indices,` This declares input_indices as a input port with width [63:0]. It carries the value named 'input indices' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 15: `output logic output_valid,` This declares output_valid as a output port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 16: `input wire output_ready,` This declares output_ready as a input port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 17: `output logic [127:0] output_values,` This declares output_values as a output port with width [127:0]. It carries the value named 'output values' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 18: `output logic config_error,` This declares config_error as a output port with width one bit. It carries the value named 'config error' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 19: `output logic [8:0] loaded_entries` This declares loaded_entries as a output port with width [8:0]. It carries the value named 'loaded entries' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 20: `);` Within the module's structural declarations, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The expression is a literal or structural operator and has no hidden software state.

Line 21: `// Replication gives eight independent lookup ports. A 256-entry table is` Design intent: Replication gives eight independent lookup ports. A 256-entry table is This comment anchors the surrounding logic in the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 22: `// small enough for distributed RAM and preserves one eight-value vector per` Design intent: small enough for distributed RAM and preserves one eight-value vector per This comment anchors the surrounding logic in the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 23: `// cycle for GELU, SiLU, sigmoid, tanh, or a model-specific quantized curve.` Design intent: cycle for GELU, SiLU, sigmoid, tanh, or a model-specific quantized curve. This comment anchors the surrounding logic in the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 24: `(* ram_style = "distributed" *) logic signed [15:0] lut_mem0 [0:255];` Within the module's structural declarations, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are ram_style: the value named 'ram style' in this block; distributed: the value named 'distributed' in this block; lut_mem0: the value named 'lut mem0' in this block.

Line 25: `(* ram_style = "distributed" *) logic signed [15:0] lut_mem1 [0:255];` Within the module's structural declarations, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are ram_style: the value named 'ram style' in this block; distributed: the value named 'distributed' in this block; lut_mem1: the value named 'lut mem1' in this block.

Line 26: `(* ram_style = "distributed" *) logic signed [15:0] lut_mem2 [0:255];` Within the module's structural declarations, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are ram_style: the value named 'ram style' in this block; distributed: the value named 'distributed' in this block; lut_mem2: the value named 'lut mem2' in this block.

Line 27: `(* ram_style = "distributed" *) logic signed [15:0] lut_mem3 [0:255];` Within the module's structural declarations, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are ram_style: the value named 'ram style' in this block; distributed: the value named 'distributed' in this block; lut_mem3: the value named 'lut mem3' in this block.

Line 28: `(* ram_style = "distributed" *) logic signed [15:0] lut_mem4 [0:255];` Within the module's structural declarations, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are ram_style: the value named 'ram style' in this block; distributed: the value named 'distributed' in this block; lut_mem4: the value named 'lut mem4' in this block.

Line 29: `(* ram_style = "distributed" *) logic signed [15:0] lut_mem5 [0:255];` Within the module's structural declarations, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are ram_style: the value named 'ram style' in this block; distributed: the value named 'distributed' in this block; lut_mem5: the value named 'lut mem5' in this block.

Line 30: `(* ram_style = "distributed" *) logic signed [15:0] lut_mem6 [0:255];` Within the module's structural declarations, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are ram_style: the value named 'ram style' in this block; distributed: the value named 'distributed' in this block; lut_mem6: the value named 'lut mem6' in this block.

Line 31: `(* ram_style = "distributed" *) logic signed [15:0] lut_mem7 [0:255];` Within the module's structural declarations, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are ram_style: the value named 'ram style' in this block; distributed: the value named 'distributed' in this block; lut_mem7: the value named 'lut mem7' in this block.

Line 32: `logic [255:0] loaded_bitmap;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, loaded_bitmap is the value named 'loaded bitmap' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 33: `logic load_count_pending_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_count_pending_r is the value named 'load count pending r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 34: `logic load_count_new_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_count_new_r is the value named 'load count new r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 35: `logic [1:0] result_fifo_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 36: `logic result_fifo_write_pointer;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_write_pointer is the value named 'result fifo write pointer' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 37: `logic result_fifo_read_pointer;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_read_pointer is the value named 'result fifo read pointer' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 38: `logic [127:0] result_fifo_values [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_values is the value named 'result fifo values' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 39: `logic [7:0] result_fifo_loaded_masks [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_loaded_masks is the value named 'result fifo loaded masks' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 40: `logic [63:0] lookup_indices_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_indices_r is the value named 'lookup indices r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 41: `logic lookup_index_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_index_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 42: `logic [127:0] lookup_mid_values_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_mid_values_r is the value named 'lookup mid values r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 43: `logic [127:0] lookup_loaded_candidates_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_loaded_candidates_r is the value named 'lookup loaded candidates r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 44: `logic [31:0] lookup_high_nibbles_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_high_nibbles_r is the value named 'lookup high nibbles r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 45: `logic lookup_mid_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_mid_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 46: `logic [127:0] lookup_result_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_result_r is the value named 'lookup result r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 47: `logic [7:0] lookup_result_loaded_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_result_loaded_r is the value named 'lookup result loaded r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 48: `logic lookup_result_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_result_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 49: `logic [127:0] lookup_values_comb;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_values_comb is the value named 'lookup values comb' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 50: `logic [127:0] lookup_loaded_candidates_comb;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_loaded_candidates_comb is the value named 'lookup loaded candidates comb' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 51: `wire signed [15:0] lookup_value0 = lut_mem0[lookup_indices_r[7:0]];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_value0 is the value named 'lookup value0' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 52: `wire signed [15:0] lookup_value1 = lut_mem1[lookup_indices_r[15:8]];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_value1 is the value named 'lookup value1' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 53: `wire signed [15:0] lookup_value2 = lut_mem2[lookup_indices_r[23:16]];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_value2 is the value named 'lookup value2' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 54: `wire signed [15:0] lookup_value3 = lut_mem3[lookup_indices_r[31:24]];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_value3 is the value named 'lookup value3' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 55: `wire signed [15:0] lookup_value4 = lut_mem4[lookup_indices_r[39:32]];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_value4 is the value named 'lookup value4' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 56: `wire signed [15:0] lookup_value5 = lut_mem5[lookup_indices_r[47:40]];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_value5 is the value named 'lookup value5' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 57: `wire signed [15:0] lookup_value6 = lut_mem6[lookup_indices_r[55:48]];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_value6 is the value named 'lookup value6' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 58: `wire signed [15:0] lookup_value7 = lut_mem7[lookup_indices_r[63:56]];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_value7 is the value named 'lookup value7' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 59: `wire result_fifo_pop = output_valid && output_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_pop is the value named 'result fifo pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 60: `// Occupancy, rather than downstream ready, controls the lookup stages.` Design intent: Occupancy, rather than downstream ready, controls the lookup stages. This comment anchors the surrounding logic in the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 61: `// This deliberately permits one recovery bubble after a completely full` Design intent: This deliberately permits one recovery bubble after a completely full This comment anchors the surrounding logic in the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 62: `// queue and prevents AXI backpressure from becoming a chip-wide data path.` Design intent: queue and prevents AXI backpressure from becoming a chip-wide data path. This comment anchors the surrounding logic in the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 63: `wire result_fifo_space = result_fifo_count != 2;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_space is the value named 'result fifo space' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 64: `wire result_fifo_push = lookup_result_valid_r && result_fifo_space;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_fifo_push is the value named 'result fifo push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 65: `wire lookup_result_ready = !lookup_result_valid_r || result_fifo_space;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_result_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 66: `wire lookup_mid_transfer = lookup_mid_valid_r && lookup_result_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_mid_transfer is the value named 'lookup mid transfer' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 67: `wire lookup_mid_ready = !lookup_mid_valid_r || lookup_result_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_mid_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 68: `wire lookup_index_transfer = lookup_index_valid_r && lookup_mid_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_index_transfer is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 69: `wire lookup_index_ready = !lookup_index_valid_r || lookup_mid_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_index_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 70: `wire lookup_input_accept = input_valid && input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, lookup_input_accept is the value named 'lookup input accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 72: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 73: `// The load and evaluate datapaths are independent at the acceptance` Design intent: The load and evaluate datapaths are independent at the acceptance This comment anchors the surrounding logic in the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 74: `// edge: a just-written entry is visible before a newly captured index` Design intent: edge: a just-written entry is visible before a newly captured index This comment anchors the surrounding logic in the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 75: `// reaches the lookup stage. Keeping ready independent of peer valid` Design intent: reaches the lookup stage. Keeping ready independent of peer valid This comment anchors the surrounding logic in the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 76: `// also prevents a valid->ready->controller combinational loop.` Design intent: also prevents a valid->ready->controller combinational loop. This comment anchors the surrounding logic in the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

Line 77: `load_ready = result_fifo_count == 0 && !lookup_index_valid_r` This statement continues through source line 78; the explanation uses the complete expression rather than only the first visual fragment. This makes load_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_fifo_count == 0 && !lookup_index_valid_r && !lookup_mid_valid_r && !lookup_result_valid_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_fifo_count: an integer count retained for control or measurable telemetry; lookup_index_valid_r: the producer's statement that its current payload is meaningful; lookup_mid_valid_r: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 78: `&& !lookup_mid_valid_r && !lookup_result_valid_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 77. Its exact fragment is '&& !lookup_mid_valid_r && !lookup_result_valid_r;'. The important operands are lookup_mid_valid_r: the producer's statement that its current payload is meaningful; lookup_result_valid_r: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This makes load_ready, the consumer's statement that it can accept a payload this cycle, equal to 'result_fifo_count == 0 && !lookup_index_valid_r && !lookup_mid_valid_r && !lookup_result_valid_r'. It is driven

by combinational or procedural logic in the current evaluation. The important operands are result_fifo_count: an integer count retained for control or measurable telemetry; lookup_index_valid_r: the producer's statement that its current payload is meaningful; lookup_mid_valid_r: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 79: `input_ready = lookup_index_ready;` This makes input_ready, the consumer's statement that it can accept a payload this cycle, equal to 'lookup_index_ready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lookup_index_ready: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 80: `output_valid = result_fifo_count != 0;` This makes output_valid, the producer's statement that its current payload is meaningful, equal to 'result_fifo_count != 0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_fifo_count: an integer count retained for control or measurable telemetry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 81: `output_values = result_fifo_values[result_fifo_read_pointer];` This makes output_values, the value named 'output values' in this block, equal to 'result_fifo_values[result_fifo_read_pointer]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_fifo_values: the value named 'result fifo values' in this block; result_fifo_read_pointer: the value named 'result fifo read pointer' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 82: `config_error = output_valid` This statement continues through source line 83; the explanation uses the complete expression rather than only the first visual fragment. This makes config_error, the value named 'config error' in this block, equal to 'output_valid && !(&result_fifo_loaded_masks[result_fifo_read_pointer])'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_valid: the producer's statement that its current payload is meaningful; result_fifo_loaded_masks: the value named 'result fifo loaded masks' in this block; result_fifo_read_pointer: the value named 'result fifo read pointer' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 83: `&& !(&result_fifo_loaded_masks[result_fifo_read_pointer]);` This is continuation line 2 of the 2-line logical statement that begins at source line 82. Its exact fragment is '&& !(&result_fifo_loaded_masks[result_fifo_read_pointer]);'. The important operands are result_fifo_loaded_masks: the value named 'result fifo loaded masks' in this block; result_fifo_read_pointer: the value named 'result fifo read pointer' in this block. Read together, the complete operation is: This makes config_error, the value named 'config error' in this block, equal to 'output_valid && !(&result_fifo_loaded_masks[result_fifo_read_pointer])'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_valid: the producer's statement that its current payload is meaningful; result_fifo_loaded_masks: the value named 'result fifo loaded masks' in this block; result_fifo_read_pointer: the value named 'result fifo read pointer' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 85: `lookup_values_comb = {lookup_value7, lookup_value6, lookup_value5,` This statement continues through source line 87; the explanation uses the complete expression rather than only the first visual fragment. This makes lookup_values_comb, the value named 'lookup values comb' in this block, equal to '{lookup_value7, lookup_value6, lookup_value5, lookup_value4, lookup_value3, lookup_value2, lookup_value1, lookup_value0}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lookup_value7: the value named 'lookup value7' in this block; lookup_value6: the value named 'lookup value6' in this block; lookup_value5: the value named 'lookup value5' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 86: `lookup_value4, lookup_value3, lookup_value2,` This is continuation line 2 of the 3-line logical statement that begins at source line 85. Its exact fragment is 'lookup_value4, lookup_value3, lookup_value2,'. The important operands are lookup_value4: the value named 'lookup value4' in this block; lookup_value3: the value named 'lookup value3' in this block; lookup_value2: the value named 'lookup value2' in this block. Read together, the complete operation is: This makes lookup_values_comb, the value named 'lookup values comb' in this block, equal to '{lookup_value7, lookup_value6, lookup_value5, lookup_value4, lookup_value3, lookup_value2, lookup_value1, lookup_value0}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lookup_value7: the

value named 'lookup value7' in this block; lookup_value6: the value named 'lookup value6' in this block; lookup_value5: the value named 'lookup value5' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 87: `lookup_value1, lookup_value0};` This is continuation line 3 of the 3-line logical statement that begins at source line 85. Its exact fragment is 'lookup_value1, lookup_value0};'. The important operands are lookup_value1: the value named 'lookup value1' in this block; lookup_value0: the value named 'lookup value0' in this block. Read together, the complete operation is: This makes lookup_values_comb, the value named 'lookup values comb' in this block, equal to '{lookup_value7, lookup_value6, lookup_value5, lookup_value4, lookup_value3, lookup_value2, lookup_value1, lookup_value0}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are lookup_value7: the value named 'lookup value7' in this block; lookup_value6: the value named 'lookup value6' in this block; lookup_value5: the value named 'lookup value5' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 88: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 89: `for (int group = 0; group < 16; group++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 90: `lookup_loaded_candidates_comb[lane*16+group] =` This statement continues through source line 92; the explanation uses the complete expression rather than only the first visual fragment. Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_loaded_candidates_comb: the value named 'lookup loaded candidates comb' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; group: the value named 'group' in this block.

Line 91: `loaded_bitmap[group*16` This is continuation line 2 of the 3-line logical statement that begins at source line 90. Its exact fragment is 'loaded_bitmap[group*16'. The important operands are loaded_bitmap: the value named 'loaded bitmap' in this block; group: the value named 'group' in this block. Read together, the complete operation is: Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_loaded_candidates_comb: the value named 'lookup loaded candidates comb' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; group: the value named 'group' in this block.

Line 92: `+ int'(lookup_indices_r[lane*8 +: 4])];` This is continuation line 3 of the 3-line logical statement that begins at source line 90. Its exact fragment is '+ int'(lookup_indices_r[lane*8 +: 4])];'. The important operands are lookup_indices_r: the value named 'lookup indices r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_loaded_candidates_comb: the value named 'lookup loaded candidates comb' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; group: the value named 'group' in this block.

Line 93: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 94: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 95: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 97: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 98: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 99: `result_fifo_count <= 2'd0;` This makes result_fifo_count, an integer count retained for control or measurable telemetry, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 100: `result_fifo_write_pointer <= 1'b0;` This makes result_fifo_write_pointer, the value named 'result fifo write pointer' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 101: `result_fifo_read_pointer <= 1'b0;` This makes result_fifo_read_pointer, the value named 'result fifo read pointer' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 102: `result_fifo_values[0] <= 128'd0;` This makes result_fifo_values[0], the value named 'result fifo values' in this block, equal to '128'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 103: `result_fifo_values[1] <= 128'd0;` This makes result_fifo_values[1], the value named 'result fifo values' in this block, equal to '128'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 104: `result_fifo_loaded_masks[0] <= 8'd0;` This makes result_fifo_loaded_masks[0], the value named 'result fifo loaded masks' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 105: `result_fifo_loaded_masks[1] <= 8'd0;` This makes result_fifo_loaded_masks[1], the value named 'result fifo loaded masks' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 106: `lookup_indices_r <= 64'd0;` This makes lookup_indices_r, the value named 'lookup indices r' in this block, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 107: `lookup_index_valid_r <= 1'b0;` This makes lookup_index_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 108: `lookup_mid_values_r <= 128'd0;` This makes lookup_mid_values_r, the value named 'lookup mid values r' in this block, equal to '128'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 109: `lookup_loaded_candidates_r <= 128'd0;` This makes lookup_loaded_candidates_r, the value named 'lookup loaded candidates r' in this block, equal to '128'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 110: `lookup_high_nibbles_r <= 32'd0;` This makes lookup_high_nibbles_r, the value named 'lookup high nibbles r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 111: `lookup_mid_valid_r <= 1'b0;` This makes lookup_mid_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 112: `lookup_result_r <= 128'd0;` This makes lookup_result_r, the value named 'lookup result r' in this block, equal to '128'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 113: `lookup_result_loaded_r <= 8'd0;` This makes lookup_result_loaded_r, the value named 'lookup result loaded r' in this block, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 114: `lookup_result_valid_r <= 1'b0;` This makes lookup_result_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 115: `loaded_bitmap <= 256'd0;` This makes loaded_bitmap, the value named 'loaded bitmap' in this block, equal to '256'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 116: `loaded_entries <= 9'd0;` This makes loaded_entries, the value named 'loaded entries' in this block, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 117: `load_count_pending_r <= 1'b0;` This makes load_count_pending_r, the value named 'load count pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 118: `load_count_new_r <= 1'b0;` This makes load_count_new_r, the value named 'load count new r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 119: `end else if (clear_table) begin` This condition selects the following hardware branch only when ‘clear_table‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are clear_table: the value named ’clear table’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 120: `result_fifo_count <= 2'd0;` This makes result_fifo_count, an integer count retained for control or measurable telemetry, equal to ‘2’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 121: `result_fifo_write_pointer <= 1'b0;` This makes result_fifo_write_pointer, the value named ’result fifo write pointer’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 122: `result_fifo_read_pointer <= 1'b0;` This makes result_fifo_read_pointer, the value named ’result fifo read pointer’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 123: `lookup_index_valid_r <= 1'b0;` This makes lookup_index_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 124: `lookup_mid_valid_r <= 1'b0;` This makes lookup_mid_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 125: `lookup_result_valid_r <= 1'b0;` This makes lookup_result_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 126: `loaded_bitmap <= 256'd0;` This makes loaded_bitmap, the value named ’loaded bitmap’ in this block, equal to ‘256’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 127: `loaded_entries <= 9'd0;` This makes loaded_entries, the value named ’loaded entries’ in this block, equal to ‘9’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 128: `load_count_pending_r <= 1'b0;` This makes load_count_pending_r, the value named ’load count pending r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 129: `load_count_new_r <= 1'b0;` This makes load_count_new_r, the value named ’load count new r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 130: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 131: `load_count_pending_r <= 1'b0;` This makes load_count_pending_r, the value named 'load count pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 132: `if (load_count_pending_r && load_count_new_r) begin` This condition selects the following hardware branch only when 'load_count_pending_r && load_count_new_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_count_pending_r: the value named 'load count pending r' in this block; load_count_new_r: the value named 'load count new r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 133: `loaded_entries <= loaded_entries + 1'b1;` This makes loaded_entries, the value named 'loaded entries' in this block, equal to 'loaded_entries + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are loaded_entries: the value named 'loaded entries' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 134: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 135: `if (load_valid && load_ready) begin` This condition selects the following hardware branch only when 'load_valid && load_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_valid: the producer's statement that its current payload is meaningful; load_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 136: `lut_mem0[load_address] <= load_value;` This makes lut_mem0[load_address], the value named 'lut mem0' in this block, equal to 'load_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_value: the value named 'load value' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 137: `lut_mem1[load_address] <= load_value;` This makes lut_mem1[load_address], the value named 'lut mem1' in this block, equal to 'load_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_value: the value named 'load value' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 138: `lut_mem2[load_address] <= load_value;` This makes lut_mem2[load_address], the value named 'lut mem2' in this block, equal to 'load_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_value: the value named 'load value' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 139: `lut_mem3[load_address] <= load_value;` This makes lut_mem3[load_address], the value named 'lut mem3' in this block, equal to 'load_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_value: the value named 'load value' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 140: `lut_mem4[load_address] <= load_value;` This makes lut_mem4[load_address], the value named 'lut mem4' in this block, equal to 'load_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_value: the value named 'load value' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 141: `lut_mem5[load_address] <= load_value;` This makes lut_mem5[load_address], the value named 'lut mem5' in this block, equal to 'load_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_value: the value named 'load value' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 142: `lut_mem6[load_address] <= load_value;` This makes lut_mem6[load_address], the value named 'lut mem6' in this block, equal to 'load_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_value: the value named 'load value' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 143: `lut_mem7[load_address] <= load_value;` This makes lut_mem7[load_address], the value named 'lut mem7' in this block, equal to 'load_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_value: the value named 'load value' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 144: `load_count_pending_r <= 1'b1;` This makes load_count_pending_r, the value named 'load count pending r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 145: `load_count_new_r <= !loaded_bitmap[load_address];` This makes load_count_new_r, the value named 'load count new r' in this block, equal to '!loaded_bitmap[load_address]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are loaded_bitmap: the value named 'loaded bitmap' in this block; load_address: the value named 'load address' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 146: `loaded_bitmap[load_address] <= 1'b1;` This makes loaded_bitmap[load_address], the value named 'loaded bitmap' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 147: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 149: `if (lookup_input_accept) lookup_indices_r <= input_indices;` This condition selects the following hardware branch only when 'lookup_input_accept' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lookup_input_accept: the value named 'lookup input accept' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 150: `unique case ({lookup_input_accept, lookup_index_transfer})` This starts a multiplexer/state decode selected by '{lookup_input_accept, lookup_index_transfer}'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 151: `2'b10: lookup_index_valid_r <= 1'b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are b10: the value named 'b10' in this block; lookup_index_valid_r: the producer's statement that its current payload is meaningful; b1: the value named 'b1' in this block.

Line 152: `2'b01: lookup_index_valid_r <= 1'b0;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are b01: the value named 'b01' in this block; lookup_index_valid_r: the producer's statement that its current payload is meaningful; b0: the value named 'b0' in this block.

Line 153: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin end‘; context is the clocked process that updates registers only on a rising clock edge.

Line 154: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 156: `if (lookup_index_transfer) begin` This condition selects the following hardware branch only when ‘lookup_index_transfer‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lookup_index_transfer: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge.

Line 157: `lookup_mid_values_r <= lookup_values_comb;` This makes lookup_mid_values_r, the value named ’lookup mid values r’ in this block, equal to ‘lookup_values_comb‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are lookup_values_comb: the value named ’lookup values comb’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 158: `lookup_loaded_candidates_r <= lookup_loaded_candidates_comb;` This makes lookup_loaded_candidates_r, the value named ’lookup loaded candidates r’ in this block, equal to ‘lookup_loaded_candidates_comb‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are lookup_loaded_candidates_comb: the value named ’lookup loaded candidates comb’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 159: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 160: `lookup_high_nibbles_r[lane*4 +: 4]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_high_nibbles_r: the value named ’lookup high nibbles r’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 161: `<= lookup_indices_r[lane*8+4 +: 4];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_indices_r: the value named ’lookup indices r’ in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 162: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 163: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 164: `unique case ({lookup_index_transfer, lookup_mid_transfer})` This starts a multiplexer/state decode selected by ‘{lookup_index_transfer, lookup_mid_transfer}‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 165: `2’b10: lookup_mid_valid_r <= 1’b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are b10: the value named ’b10’ in this block; lookup_mid_valid_r: the producer’s statement that its current payload is meaningful; b1: the value named ’b1’ in this block.

Line 166: `2'b01: lookup_mid_valid_r <= 1'b0;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are b01: the value named 'b01' in this block; lookup_mid_valid_r: the producer's statement that its current payload is meaningful; b0: the value named 'b0' in this block.

Line 167: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the clocked process that updates registers only on a rising clock edge.

Line 168: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 170: `if (lookup_mid_transfer) begin` This condition selects the following hardware branch only when 'lookup_mid_tran is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are lookup_mid_transfer: the value named 'lookup mid transfer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 171: `lookup_result_r <= lookup_mid_values_r;` This makes lookup_result_r, the value named 'lookup result r' in this block, equal to 'lookup_mid_values_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are lookup_mid_values_r: the value named 'lookup mid values r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 172: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 173: `lookup_result_loaded_r[lane]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_result_loaded_r: the value named 'lookup result loaded r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 174: `<= lookup_loaded_candidates_r[lane*16` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_loaded_candidates_r: the value named 'lookup loaded candidates r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 175: `+ int'(lookup_high_nibbles_r[lane*4 +: 4])];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_high_nibbles_r: the value named 'lookup high nibbles r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 176: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 177: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 178: `unique case ({lookup_mid_transfer, result_fifo_push})` This starts a multiplexer/state decode selected by '{lookup_mid_transfer, result_fifo_push}'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 179: `2'b10: lookup_result_valid_r <= 1'b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are b10: the value named 'b10' in this block; lookup_result_valid_r: the producer's statement that its current payload is meaningful; b1: the value named 'b1' in this block.

Line 180: `2'b01: lookup_result_valid_r <= 1'b0;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are b01: the value named 'b01' in this block; lookup_result_valid_r: the producer's statement that its current payload is meaningful; b0: the value named 'b0' in this block.

Line 181: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the clocked process that updates registers only on a rising clock edge.

Line 182: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 184: `if (result_fifo_push) begin` This condition selects the following hardware branch only when 'result_fifo_push' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_fifo_push: the value named 'result fifo push' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 185: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 186: `result_fifo_values[result_fifo_write_pointer][lane*16 +: 16]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are result_fifo_values: the value named 'result fifo values' in this block; result_fifo_write_pointer: the value named 'result fifo write pointer' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 187: `<= lookup_result_loaded_r[lane]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_result_loaded_r: the value named 'lookup result loaded r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 188: `? lookup_result_r[lane*16 +: 16] : 16'd0;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_result_r: the value named 'lookup result r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; d0: the value named 'd0' in this block.

Line 189: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 190: `result_fifo_loaded_masks[result_fifo_write_pointer]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are result_fifo_loaded_masks: the value named 'result fifo loaded masks' in this block; result_fifo_write_pointer: the value named 'result fifo write pointer' in this block.

Line 191: `<= lookup_result_loaded_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are lookup_result_loaded_r: the value named 'lookup result loaded r' in this block.

Line 192: `result_fifo_write_pointer <= !result_fifo_write_pointer;` This makes result_fifo_write_pointer, the value named 'result fifo write pointer' in this block, equal to '!result_fifo_write_pointer'. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_fifo_write_pointer: the value named 'result fifo write pointer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 193: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 195: `if (result_fifo_pop) result_fifo_read_pointer <= !result_fifo_read_pointer;` This condition selects the following hardware branch only when 'result_fifo_pop' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_fifo_pop: the value named 'result fifo pop' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 197: `unique case ({result_fifo_push, result_fifo_pop})` This starts a multiplexer/state decode selected by '{result_fifo_push, result_fifo_pop}'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 198: `2'b10: result_fifo_count <= result_fifo_count + 1'b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are b10: the value named 'b10' in this block; result_fifo_count: an integer count retained for control or measurable telemetry; b1: the value named 'b1' in this block.

Line 199: `2'b01: result_fifo_count <= result_fifo_count - 1'b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes. The important operands are b01: the value named 'b01' in this block; result_fifo_count: an integer count retained for control or measurable telemetry; b1: the value named 'b1' in this block.

Line 200: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the clocked process that updates registers only on a rising clock edge.

Line 201: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 202: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 203: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 204: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 206: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that loads and evaluates a programmable 256-entry activation lookup table on eight lanes.

4 rtl/neuraedge_active_index_buffer.sv

Role in the complete system: stores the reduction indices that remain after all-zero activation positions are compacted.

4.1 Beginner architecture map

Dataflow responsibility While activations load, the tensor core tests whether a reduction position is all zero across active rows. Only nonzero positions are written here; compute later walks this compact list, so sparse positions remove issue cycles rather than performing useless zero arithmetic.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_active_index_buffer into physical nets and primitives. The source declares 6 input-port lines, 1 output-port lines, 1 clocked process(es), and 0 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control This block is primarily a datapath or storage primitive rather than a large state machine. Registers still divide combinational work into cycles and hold valid/data stable during downstream stalls.

Connections to other blocks This is a leaf block: parent modules create it and connect its ports. It does not instantiate another project RTL module, so its arithmetic or storage maps directly into FPGA primitives.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

4.2 Complete source

```
1  `timescale 1ns / 1ps
2  `default_nettype none
3
4  // Simple-dual-port storage for the compacted list of nonzero activation tiles.
5  // Both ports are synchronous, matching the canonical Vivado BRAM template.
6  module neuraedge_active_index_buffer #(
7      parameter int DEPTH = 2048,
8      parameter int ADDRESS_BITS = 11
9  ) (
10     input  wire clk,
11     input  wire write_enable,
12     input  wire [ADDRESS_BITS-1:0] write_address,
13     input  wire [ADDRESS_BITS-1:0] write_data,
14     input  wire read_enable,
15     input  wire [ADDRESS_BITS-1:0] read_address,
16     output logic [ADDRESS_BITS-1:0] read_data
17 );
18     (* ram_style = "block" *) logic [ADDRESS_BITS-1:0] memory [0:DEPTH-1];
19
20     always_ff @(posedge clk) begin
21         if (write_enable) memory[write_address] <= write_data;
22         if (read_enable) read_data <= memory[read_address];
23     end
24
25     initial begin
26         if (DEPTH != (1 << ADDRESS_BITS)) begin
27             $fatal(1, "active-index depth must equal 2^ADDRESS_BITS");
28         end
29     end
30 endmodule
31
32 `default_nettype wire
```

4.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `// Simple-dual-port storage for the compacted list of nonzero activation tiles.` Design intent: Simple-dual-port storage for the compacted list of nonzero activation tiles. This comment anchors the surrounding logic in the block that stores the reduction indices that remain after all-zero activation positions are compacted.

Line 5: `// Both ports are synchronous, matching the canonical Vivado BRAM template.` Design intent: Both ports are synchronous, matching the canonical Vivado BRAM template. This comment anchors the surrounding logic in the block that stores the reduction indices that remain after all-zero activation positions are compacted.

Line 6: `module neuraedge_active_index_buffer #(` This opens neuraedge_active_index_buffer, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that stores the reduction indices that remain after all-zero activation positions are compacted.

Line 7: `parameter int DEPTH = 2048,` This statement continues through source line 17; the explanation uses the complete expression rather than only the first visual fragment. This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 8: `parameter int ADDRESS_BITS = 11` This is continuation line 2 of the 11-line logical statement that begins at source line 7. Its exact fragment is 'parameter int ADDRESS_BITS = 11'. The important operands are parameter: the value named 'parameter' in this block; ADDRESS_BITS: the value named 'address bits' in this block. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 9: `) (` This is continuation line 3 of the 11-line logical statement that begins at source line 7. Its exact fragment is ') ('. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 10: `input wire clk,` This is continuation line 4 of the 11-line logical statement that begins at source line 7. Its exact fragment is 'input wire clk,'. The important operands are input: the value named 'input' in this block; clk: the clock that makes all registers advance together. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 11: `input wire write_enable,` This is continuation line 5 of the 11-line logical statement that begins at source line 7. Its exact fragment is 'input wire write_enable,'. The important operands are input: the value named 'input' in this block; write_enable: a control bit that permits the associated state or storage update. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 12: `input wire [ADDRESS_BITS-1:0] write_address,` This is continuation line 6 of the 11-line logical statement that begins at source line 7. Its exact fragment is 'input wire [ADDRESS_BITS-1:0] write_address,'. The important operands are input: the value named 'input' in this block; ADDRESS_BITS: the value named 'address bits'

in this block; write_address: the value named 'write address' in this block. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 13: `input wire [ADDRESS_BITS-1:0] write_data,` This is continuation line 7 of the 11-line logical statement that begins at source line 7. Its exact fragment is 'input wire [ADDRESS_BITS-1:0] write_data,'. The important operands are input: the value named 'input' in this block; ADDRESS_BITS: the value named 'address bits' in this block; write_data: the payload carried with the surrounding valid/ready handshake. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 14: `input wire read_enable,` This is continuation line 8 of the 11-line logical statement that begins at source line 7. Its exact fragment is 'input wire read_enable,'. The important operands are input: the value named 'input' in this block; read_enable: a control bit that permits the associated state or storage update. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 15: `input wire [ADDRESS_BITS-1:0] read_address,` This is continuation line 9 of the 11-line logical statement that begins at source line 7. Its exact fragment is 'input wire [ADDRESS_BITS-1:0] read_address,'. The important operands are input: the value named 'input' in this block; ADDRESS_BITS: the value named 'address bits' in this block; read_address: the value named 'read address' in this block. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 16: `output logic [ADDRESS_BITS-1:0] read_data` This is continuation line 10 of the 11-line logical statement that begins at source line 7. Its exact fragment is 'output logic [ADDRESS_BITS-1:0] read_data'. The important operands are output: the value named 'output' in this block; ADDRESS_BITS: the value named 'address bits' in this block; read_data: the payload carried with the surrounding valid/ready handshake. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 17: `);` This is continuation line 11 of the 11-line logical statement that begins at source line 7. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes DEPTH to 2048, parameter int ADDRESS_BITS = 11) (input wire clk, input wire write_enable, input wire [ADDRESS_BITS-1:0] write_address, input wire [ADDRESS_BITS-1:0] write_data, input wire read_enable, input wire [ADDRESS_BITS-1:0] read_address, output logic [ADDRESS_BITS-1:0] read_data) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; DEPTH denotes the value named 'depth' in this block.

Line 18: `(* ram_style = "block" *) logic [ADDRESS_BITS-1:0] memory [0:DEPTH-1];` Within the module's structural declarations, this exact statement contributes to the block that stores the reduction indices that remain after all-zero activation positions are compacted. The important operands are ram_style: the value named 'ram style' in this block; block: the value named 'block' in this block; ADDRESS_BITS: the value named 'address bits' in this block.

Line 20: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 21: `if (write_enable) memory[write_address] <= write_data;` This condition selects the following hardware branch only when 'write_enable' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are write_enable: a control bit that permits the associated state or storage update. Context: the clocked process that updates registers only on a rising clock edge.

Line 22: `if (read_enable) read_data <= memory[read_address];` This condition selects the following hardware branch only when 'read_enable' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_enable: a control bit that permits the associated state or storage update. Context: the clocked process that updates registers only on a rising clock edge.

Line 23: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 25: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 26: `if (DEPTH != (1 << ADDRESS_BITS)) begin` This condition selects the following hardware branch only when 'DEPTH != (1 << ADDRESS_BITS)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are DEPTH: the value named 'depth' in this block; ADDRESS_BITS: the value named 'address bits' in this block. Context: the module's structural declarations.

Line 27: `$fatal(1, "active-index depth must equal 2^ADDRESS_BITS");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 28: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 29: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 30: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 32: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that stores the reduction indices that remain after all-zero activation positions are compacted.

5 rtl/neuraedge_alpha_xnor.sv

Role in the complete system: computes alpha-weighted XNOR spiking similarity and streams its accumulated scores.

5.1 Beginner architecture map

Dataflow responsibility The input stream supplies packed query and key spike masks. The block counts matching one bits and matching zero bits, weights zero matches by programmable alpha, accumulates across chunks, and emits one fixed-point attention score under valid/ready backpressure.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_alpha_xnor into physical nets and primitives. The source declares 8 input-port lines, 6 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_ACCUMULATE, ST_IDLE, ST_MASK_CHUNK, ST_OUTPUT, ST_POPCOUNT, ST_POPCOUNT_FINAL, ST_POPCOUNT_HALF, ST_POPCOUNT_PARTIAL, ST_SCORE_ADD ST_SCORE_LATCH, ST_SCORE_MULTIPLY, ST_VALIDATE. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates end as for, unique as case. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

5.2 Complete source

Read together, the complete operation is: This fixes VECTOR_BITS to 256) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [VECTOR_BITS-1:0] query_spikes, input wire [VECTOR_BITS-1:0] key_spikes, input wire [8:0] active_bits, input wire [8:0] alpha_q8, output logic output_valid, input wire output_ready, output logic [17:0] score_q8, output logic [8:0] spike_matches, output logic [8:0] zero_matches, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; VECTOR_BITS denotes the value named 'vector bits' in this block.

Line 16: `input wire output_ready,` This is continuation line 12 of the 17-line logical statement that begins at source line 5. Its exact fragment is 'input wire output_ready,'. The important operands are input: the value named 'input' in this block; output_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes VECTOR_BITS to 256) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [VECTOR_BITS-1:0] query_spikes, input wire [VECTOR_BITS-1:0] key_spikes, input wire [8:0] active_bits, input wire [8:0] alpha_q8, output logic output_valid, input wire output_ready, output logic [17:0] score_q8, output logic [8:0] spike_matches, output logic [8:0] zero_matches, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; VECTOR_BITS denotes the value named 'vector bits' in this block.

Line 17: `output logic [17:0] score_q8,` This is continuation line 13 of the 17-line logical statement that begins at source line 5. Its exact fragment is 'output logic [17:0] score_q8,'. The important operands are output: the value named 'output' in this block; score_q8: the value named 'score q8' in this block. Read together, the complete operation is: This fixes VECTOR_BITS to 256) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [VECTOR_BITS-1:0] query_spikes, input wire [VECTOR_BITS-1:0] key_spikes, input wire [8:0] active_bits, input wire [8:0] alpha_q8, output logic output_valid, input wire output_ready, output logic [17:0] score_q8, output logic [8:0] spike_matches, output logic [8:0] zero_matches, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; VECTOR_BITS denotes the value named 'vector bits' in this block.

Line 18: `output logic [8:0] spike_matches,` This is continuation line 14 of the 17-line logical statement that begins at source line 5. Its exact fragment is 'output logic [8:0] spike_matches,'. The important operands are output: the value named 'output' in this block; spike_matches: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This fixes VECTOR_BITS to 256) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [VECTOR_BITS-1:0] query_spikes, input wire [VECTOR_BITS-1:0] key_spikes, input wire [8:0] active_bits, input wire [8:0] alpha_q8, output logic output_valid, input wire output_ready, output logic [17:0] score_q8, output logic [8:0] spike_matches, output logic [8:0] zero_matches, output logic config_error

) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; VECTOR_BITS denotes the value named 'vector bits' in this block.

Line 19: `output logic [8:0] zero_matches,` This is continuation line 15 of the 17-line logical statement that begins at source line 5. Its exact fragment is 'output logic [8:0] zero_matches,'. The important operands are output: the value named 'output' in this block; zero_matches: the value named 'zero matches' in this block. Read together, the complete operation is: This fixes VECTOR_BITS to 256) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [VECTOR_BITS-1:0] query_spikes, input wire [VECTOR_BITS-1:0] key_spikes, input wire [8:0] active_bits, input wire [8:0] alpha_q8, output logic output_valid, input wire output_ready, output logic [17:0] score_q8, output logic [8:0] spike_matches, output logic [8:0] zero_matches, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; VECTOR_BITS denotes the value named 'vector bits' in this block.

Line 20: `output logic config_error` This is continuation line 16 of the 17-line logical statement that begins at source line 5. Its exact fragment is 'output logic config_error'. The important operands are output: the value named 'output' in this block; config_error: the value named 'config error' in this block. Read together, the complete operation is: This fixes VECTOR_BITS to 256) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [VECTOR_BITS-1:0] query_spikes, input wire [VECTOR_BITS-1:0] key_spikes, input wire [8:0] active_bits, input wire [8:0] alpha_q8, output logic output_valid, input wire output_ready, output logic [17:0] score_q8, output logic [8:0] spike_matches, output logic [8:0] zero_matches, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; VECTOR_BITS denotes the value named 'vector bits' in this block.

Line 21: `);` This is continuation line 17 of the 17-line logical statement that begins at source line 5. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes VECTOR_BITS to 256) (input wire clk, input wire rst_n, input wire input_valid, output logic input_ready, input wire [VECTOR_BITS-1:0] query_spikes, input wire [VECTOR_BITS-1:0] key_spikes, input wire [8:0] active_bits, input wire [8:0] alpha_q8, output logic output_valid, input wire output_ready, output logic [17:0] score_q8, output logic [8:0] spike_matches, output logic [8:0] zero_matches, output logic config_error) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; VECTOR_BITS denotes the value named 'vector bits' in this block.

Line 22: `localparam int CHUNK_BITS = 32;` This fixes CHUNK_BITS to 32 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CHUNK_BITS denotes the value named 'chunk bits' in this block.

Line 23: `localparam int CHUNKS = VECTOR_BITS / CHUNK_BITS;` This fixes CHUNKS to VECTOR_BITS / CHUNK_BITS during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CHUNKS denotes the value named 'chunks' in this block.

Line 25: `typedef enum logic [3:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 26: `ST_IDLE = 4'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 27: `ST_MASK_CHUNK = 4'd1,` This assigns a fixed binary encoding to state ST_MASK_CHUNK, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 28: `ST_ACCUMULATE = 4'd2,` This assigns a fixed binary encoding to state ST_ACCUMULATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 29: `ST_SCORE_MULTIPLY = 4'd3,` This assigns a fixed binary encoding to state ST_SCORE_MULTIPLY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 30: `ST_SCORE_ADD = 4'd4,` This assigns a fixed binary encoding to state ST_SCORE_ADD, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 31: `ST_OUTPUT = 4'd5,` This assigns a fixed binary encoding to state ST_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 32: `ST_SCORE_LATCH = 4'd6,` This assigns a fixed binary encoding to state ST_SCORE_LATCH, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 33: `ST_POPCOUNT = 4'd7,` This assigns a fixed binary encoding to state ST_POPCOUNT, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 34: `ST_POPCOUNT_PARTIAL = 4'd8,` This assigns a fixed binary encoding to state ST_POPCOUNT_PARTIAL, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 35: `ST_VALIDATE = 4'd9,` This assigns a fixed binary encoding to state ST_VALIDATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 36: `ST_POPCOUNT_HALF = 4'd10,` This assigns a fixed binary encoding to state ST_POPCOUNT_HALF, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 37: `ST_POPCOUNT_FINAL = 4'd11` This statement continues through source line 38; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_POPCOUNT_FINAL, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 38: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 37. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_POPCOUNT_FINAL, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 40: `state_t state;` Within the module's structural declarations, this exact statement contributes to the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores. The important operands are state_t: the finite-state-machine phase retained in flip-flops; state: the finite-state-machine phase retained in flip-flops.

Line 41: `logic [VECTOR_BITS-1:0] query_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, query_r is the value named 'query r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 42: `logic [VECTOR_BITS-1:0] key_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, key_r is the value named 'key r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 43: `logic [8:0] active_bits_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_bits_r is the value named 'active bits r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 44: `logic [8:0] alpha_q8_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_q8_r is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 45: `logic [$clog2(CHUNKS)-1:0] chunk_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, chunk_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 46: `logic [31:0] spike_mask_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, spike_mask_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 47: `logic [31:0] zero_mask_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_mask_r is the value named 'zero mask r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 48: `logic [8:0] spike_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, spike_count_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 49: `logic [8:0] zero_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 50: `logic [5:0] spike_chunk_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, spike_chunk_count_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 51: `logic [5:0] zero_chunk_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_chunk_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 52: `logic [2:0] spike_nibble_count_r [0:7];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, spike_nibble_count_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 53: `logic [2:0] zero_nibble_count_r [0:7];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_nibble_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 54: `logic [3:0] spike_pair_count_r [0:3];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, spike_pair_count_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 55: `logic [3:0] zero_pair_count_r [0:3];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_pair_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 56: `logic [4:0] spike_half_count_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, spike_half_count_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 57: `logic [4:0] zero_half_count_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, zero_half_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 58: `logic [8:0] final_spike_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, final_spike_count_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 59: `logic [8:0] final_zero_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, final_zero_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 60: `(* dont_touch = "yes" *) logic [8:0] score_spike_operand_r;` Within the module's structural declarations, this exact statement contributes to the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; score_spike_operand_r: a binary event produced when a neuron crosses its threshold.

Line 61: `(* dont_touch = "yes" *) logic [8:0] score_zero_operand_r;` Within the module's structural declarations, this exact statement contributes to the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; score_zero_operand_r: the value named 'score zero operand r' in this block.

Line 62: `logic [17:0] alpha_product_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, alpha_product_r is the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 64: `(* use_dsp = "yes" *) wire [17:0] alpha_product =` Within the module's structural declarations, this exact statement contributes to the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; alpha_product: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 65: `score_zero_operand_r * alpha_q8_r;` Within the module's structural declarations, this exact statement contributes to the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores. The important operands are score_zero_operand_r: the value named 'score zero operand r' in this block; alpha_q8_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 67: `function automatic logic [2:0] popcount4(input logic [3:0] value);` Within the combinational helper popcount4, this exact statement contributes to the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; popcount4: the value named 'popcount4' in this block.

Line 68: `logic [1:0] low_pair;` This declares hardware signal storage or wiring in the combinational helper popcount4. Specifically, low_pair is the value named 'low pair' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 69: `logic [1:0] high_pair;` This declares hardware signal storage or wiring in the combinational helper popcount4. Specifically, high_pair is the value named 'high pair' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 70: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper popcount4; it has no arithmetic value of its own.

Line 71: `low_pair = value[0] + value[1];` This makes low_pair, the value named 'low pair' in this block, equal to 'value[0] + value[1]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper popcount4.

Line 72: `high_pair = value[2] + value[3];` This makes high_pair, the value named 'high pair' in this block, equal to 'value[2] + value[3]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper popcount4.

Line 73: `popcount4 = low_pair + high_pair;` This makes popcount4, the value named 'popcount4' in this block, equal to 'low_pair + high_pair'. It is driven by combinational or procedural logic in the current evaluation. The important operands are low_pair: the value named 'low pair' in this block; high_pair: the value named 'high pair' in this block. Context: the combinational helper popcount4.

Line 74: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper popcount4; it has no arithmetic value of its own.

Line 75: `endfunction` Within the combinational helper popcount4, this exact statement contributes to the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores. The important operands are endfunction: the value named 'endfunction' in this block.

Line 77: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 78: `input_ready = state == ST_IDLE;` This makes input_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_IDLE'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 79: `output_valid = state == ST_OUTPUT;` This makes output_valid, the producer's statement that its current payload is meaningful, equal to 'state == ST_OUTPUT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_OUTPUT: the value named 'st output' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 80: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 82: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 83: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 84: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 85: `query_r <= '0;` This makes query_r, the value named 'query r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 86: `key_r <= '0;` This makes key_r, the value named 'key r' in this block, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 87: `active_bits_r <= 9'd0;` This makes active_bits_r, the value named 'active bits r' in this block, equal to ‘9'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 88: `alpha_q8_r <= 9'd0;` This makes alpha_q8_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to ‘9'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 89: `chunk_index <= '0;` This makes chunk_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 90: `spike_mask_r <= 32'd0;` This makes spike_mask_r, a binary event produced when a neuron crosses its threshold, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 91: `zero_mask_r <= 32'd0;` This makes zero_mask_r, the value named 'zero mask r' in this block, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 92: `spike_count_r <= 9'd0;` This makes spike_count_r, a binary event produced when a neuron crosses its threshold, equal to ‘9'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 93: `zero_count_r <= 9'd0;` This makes zero_count_r, an integer count retained for control or measurable telemetry, equal to ‘9'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 94: `spike_chunk_count_r <= 6'd0;` This makes spike_chunk_count_r, a binary event produced when a neuron crosses its threshold, equal to ‘6'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 95: `zero_chunk_count_r <= 6'd0;` This makes zero_chunk_count_r, an integer count retained for control or measurable telemetry, equal to ‘6'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 96: `for (int nibble = 0; nibble < 8; nibble++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 97: `spike_nibble_count_r[nibble] <= 3'd0;` This makes spike_nibble_count_r[nibble], a binary event produced when a neuron crosses its threshold, equal to ‘3'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 98: `zero_nibble_count_r[nibble] <= 3'd0;` This makes zero_nibble_count_r[nibble], an integer count retained for control or measurable telemetry, equal to '3'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 99: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 100: `for (int pair = 0; pair < 4; pair++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 101: `spike_pair_count_r[pair] <= 4'd0;` This makes spike_pair_count_r[pair], a binary event produced when a neuron crosses its threshold, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 102: `zero_pair_count_r[pair] <= 4'd0;` This makes zero_pair_count_r[pair], an integer count retained for control or measurable telemetry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 103: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 104: `for (int half = 0; half < 2; half++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 105: `spike_half_count_r[half] <= 5'd0;` This makes spike_half_count_r[half], a binary event produced when a neuron crosses its threshold, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 106: `zero_half_count_r[half] <= 5'd0;` This makes zero_half_count_r[half], an integer count retained for control or measurable telemetry, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 107: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 108: `final_spike_count_r <= 9'd0;` This makes final_spike_count_r, a binary event produced when a neuron crosses its threshold, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 109: `final_zero_count_r <= 9'd0;` This makes final_zero_count_r, an integer count retained for control or measurable telemetry, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 110: `score_spike_operand_r <= 9'd0;` This makes score_spike_operand_r, a binary event produced when a neuron crosses its threshold, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 111: `score_zero_operand_r <= 9'd0;` This makes score_zero_operand_r, the value named 'score zero operand r' in this block, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 112: `alpha_product_r <= 18'd0;` This makes alpha_product_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to '18'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 113: `score_q8 <= 18'd0;` This makes score_q8, the value named 'score q8' in this block, equal to '18'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 114: `spike_matches <= 9'd0;` This makes spike_matches, a binary event produced when a neuron crosses its threshold, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 115: `zero_matches <= 9'd0;` This makes zero_matches, the value named 'zero matches' in this block, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 116: `config_error <= 1'b0;` This makes config_error, the value named 'config error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 117: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 118: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 119: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 120: `if (input_valid) begin` This condition selects the following hardware branch only when 'input_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 121: `query_r <= query_spikes;` This makes query_r, the value named 'query r' in this block, equal to 'query_spikes'. It updates after the active clock edge together with other nonblocking assignments. The important operands are query_spikes: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 122: `key_r <= key_spikes;` This makes key_r, the value named 'key r' in this block, equal to 'key_spikes'. It updates after the active clock edge together with other nonblocking assignments. The important operands are key_spikes: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 123: `active_bits_r <= active_bits;` This makes active_bits_r, the value named 'active bits r' in this block, equal to 'active_bits'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_bits: the value named 'active bits' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 124: `alpha_q8_r <= alpha_q8;` This makes alpha_q8_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to 'alpha_q8'. It updates after the active clock edge together with other nonblocking assignments. The important operands are alpha_q8: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 125: `state <= ST_VALIDATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_VALIDATE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VALIDATE: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 126: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 127: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 129: `ST_VALIDATE: begin` This is the ST_VALIDATE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 130: `if (active_bits_r == 0` Within the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase., this exact statement contributes to the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores. The important operands are active_bits_r: the value named 'active bits r' in this block.

Line 131: `|| active_bits_r > 9'(VECTOR_BITS)` Within the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase., this exact statement contributes to the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores. The important operands are active_bits_r: the value named 'active bits r' in this block; VECTOR_BITS: the value named 'vector bits' in this block.

Line 132: `|| alpha_q8_r > 256) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase., this exact statement contributes to the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores. The important operands are alpha_q8_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 133: `config_error <= 1'b1;` This makes config_error, the value named 'config error' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 134: `score_q8 <= 18'd0;` This makes score_q8, the value named 'score q8' in this block, equal to '18'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 135: `spike_matches <= 9'd0;` This makes spike_matches, a binary event produced when a neuron crosses its threshold, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 136: `zero_matches <= 9'd0;` This makes zero_matches, the value named 'zero matches' in this block, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 137: `state <= ST_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT: the value named 'st output' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 138: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 139: `config_error <= 1'b0;` This makes config_error, the value named 'config error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 140: `chunk_index <= '0;` This makes chunk_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 141: `spike_count_r <= 9'd0;` This makes spike_count_r, a binary event produced when a neuron crosses its threshold, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 142: `zero_count_r <= 9'd0;` This makes zero_count_r, an integer count retained for control or measurable telemetry, equal to '9'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 143: `state <= ST_MASK_CHUNK;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MASK_CHUNK'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MASK_CHUNK: the value named 'st mask chunk' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase..

Line 144: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 145: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VALIDATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 147: `ST_MASK_CHUNK: begin` This is the ST_MASK_CHUNK case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase..

Line 148: `for (int bit_index = 0; bit_index < CHUNK_BITS; bit_index++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase..

Line 149: `logic [8:0] global_bit;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase.. Specifically, global_bit is the value named 'global bit' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 150: `logic query_bit;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase.. Specifically, query_bit is the value named 'query bit' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 151: `logic key_bit;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase.. Specifically, key_bit is the value named 'key bit' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 152: `global_bit = {chunk_index, 5'd0} + 9'(bit_index);` This makes global_bit, the value named 'global bit' in this block, equal to '{chunk_index, 5'd0} + 9'(bit_index)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are chunk_index: an integer selecting one tensor element, lane, bank, or state entry; d0: the value named 'd0' in this block; bit_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase..

Line 153: `query_bit = query_r[chunk_index*CHUNK_BITS + bit_index];` This makes query_bit, the value named 'query bit' in this block, equal to 'query_r[chunk_index*CHUNK_BITS + bit_index]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are query_r: the value named 'query r' in this block; chunk_index: an integer selecting one tensor element, lane, bank, or state entry; CHUNK_BITS: the value named 'chunk bits' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase..

Line 154: `key_bit = key_r[chunk_index*CHUNK_BITS + bit_index];` This makes key_bit, the value named 'key bit' in this block, equal to 'key_r[chunk_index*CHUNK_BITS + bit_index]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are key_r: the value named 'key r' in this block; chunk_index: an integer selecting one tensor element, lane, bank, or state entry; CHUNK_BITS: the value named 'chunk bits' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase..

Line 155: `spike_mask_r[bit_index] <= global_bit < active_bits_r` This statement continues through source line 156; the explanation uses the complete expression rather than only the first visual fragment. This makes spike_mask_r[bit_index], a binary event produced when a neuron crosses its threshold, equal to ‘global_bit < active_bits_r && query_bit && key_bit‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are global_bit: the value named ’global bit’ in this block; active_bits_r: the value named ’active bits r’ in this block; query_bit: the value named ’query bit’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase..

Line 156: `&& query_bit && key_bit;` This is continuation line 2 of the 2-line logical statement that begins at source line 155. Its exact fragment is ‘&& query_bit && key_bit;‘. The important operands are query_bit: the value named ’query bit’ in this block; key_bit: the value named ’key bit’ in this block. Read together, the complete operation is: This makes spike_mask_r[bit_index], a binary event produced when a neuron crosses its threshold, equal to ‘global_bit < active_bits_r && query_bit && key_bit‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are global_bit: the value named ’global bit’ in this block; active_bits_r: the value named ’active bits r’ in this block; query_bit: the value named ’query bit’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase..

Line 157: `zero_mask_r[bit_index] <= global_bit < active_bits_r` This statement continues through source line 158; the explanation uses the complete expression rather than only the first visual fragment. This makes zero_mask_r[bit_index], the value named ’zero mask r’ in this block, equal to ‘global_bit < active_bits_r && !query_bit && !key_bit‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are global_bit: the value named ’global bit’ in this block; active_bits_r: the value named ’active bits r’ in this block; query_bit: the value named ’query bit’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase..

Line 158: `&& !query_bit && !key_bit;` This is continuation line 2 of the 2-line logical statement that begins at source line 157. Its exact fragment is ‘&& !query_bit && !key_bit;‘. The important operands are query_bit: the value named ’query bit’ in this block; key_bit: the value named ’key bit’ in this block. Read together, the complete operation is: This makes zero_mask_r[bit_index], the value named ’zero mask r’ in this block, equal to ‘global_bit < active_bits_r && !query_bit && !key_bit‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are global_bit: the value named ’global bit’ in this block; active_bits_r: the value named ’active bits r’ in this block; query_bit: the value named ’query bit’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase..

Line 159: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 160: `state <= ST_POPCOUNT_PARTIAL;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_POPCOUNT_PARTIAL‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_POPCOUNT_PARTIAL: the value named ’st popcount partial’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase..

Line 161: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MASK_CHUNK, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 163: `ST_POPCOUNT_PARTIAL: begin` This is the ST_POPCOUNT_PARTIAL case branch, which updates a segmented telemetry counter without a long carry chain. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_PARTIAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 164: `for (int nibble = 0; nibble < 8; nibble++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_PARTIAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 165: `spike_nibble_count_r[nibble] <=` This statement continues through source line 166; the explanation uses the complete expression rather than only the first visual fragment. This makes spike_nibble_count_r[nibble], a binary event produced when a neuron crosses its threshold, equal to ‘popcount4(spike_mask_r[nibble*4 +: 4])‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are popcount4: the value named ’popcount4’ in this block; spike_mask_r: a binary event produced when a neuron crosses its threshold; nibble: the value named ’nibble’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_PARTIAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 166: `popcount4(spike_mask_r[nibble*4 +: 4]);` This is continuation line 2 of the 2-line logical statement that begins at source line 165. Its exact fragment is ‘popcount4(spike_mask_r[nibble*4 +: 4]);‘. The important operands are popcount4: the value named ’popcount4’ in this block; spike_mask_r: a binary event produced when a neuron crosses its threshold; nibble: the value named ’nibble’ in this block. Read together, the complete operation is: This makes spike_nibble_count_r[nibble], a binary event produced when a neuron crosses its threshold, equal to ‘popcount4(spike_mask_r[nibble*4 +: 4])‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are popcount4: the value named ’popcount4’ in this block; spike_mask_r: a binary event produced when a neuron crosses its threshold; nibble: the value named ’nibble’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_PARTIAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 167: `zero_nibble_count_r[nibble] <=` This statement continues through source line 168; the explanation uses the complete expression rather than only the first visual fragment. This makes zero_nibble_count_r[nibble], an integer count retained for control or measurable telemetry, equal to ‘popcount4(zero_mask_r[nibble*4 +: 4])‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are popcount4: the value named ’popcount4’ in this block; zero_mask_r: the value named ’zero mask r’ in this block; nibble: the value named ’nibble’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_PARTIAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 168: `popcount4(zero_mask_r[nibble*4 +: 4]);` This is continuation line 2 of the 2-line logical statement that begins at source line 167. Its exact fragment is ‘popcount4(zero_mask_r[nibble*4 +: 4]);‘. The important operands are popcount4: the value named ’popcount4’ in this block; zero_mask_r: the value named ’zero mask r’ in this block; nibble: the value named ’nibble’ in this block. Read together, the complete operation is: This makes zero_nibble_count_r[nibble], an integer count retained for control or measurable telemetry, equal to ‘popcount4(zero_mask_r[nibble*4 +: 4])‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are popcount4: the value named ’popcount4’ in this block; zero_mask_r: the value named ’zero mask r’ in this block; nibble: the value named ’nibble’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_PARTIAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 169: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_PARTIAL, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 170: `state <= ST_POPCOUNT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_POPCOUNT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_POPCOUNT: the value named ’st popcount’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_PARTIAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 171: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_PARTIAL, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 173: `ST_POPCOUNT: begin` This is the ST_POPCOUNT case branch, which updates a segmented telemetry counter without a long carry chain. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT, the machine updates a segmented telemetry counter without a long carry chain..

Line 174: `for (int pair = 0; pair < 4; pair++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT, the machine updates a segmented telemetry counter without a long carry chain..

Line 175: `spike_pair_count_r[pair] <= spike_nibble_count_r[2*pair]` This statement continues through source line 176; the explanation uses the complete expression rather than only the first visual fragment. This makes spike_pair_count_r[pai a binary event produced when a neuron crosses its threshold, equal to 'spike_nibble_count_r[2*pair] + spike_nibble_count_r[2*pai It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_nibble_count_r: a binary event produced when a neuron crosses its threshold; pair: the value named 'pair' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT, the machine updates a segmented telemetry counter without a long carry chain..

Line 176: `+ spike_nibble_count_r[2*pair+1];` This is continuation line 2 of the 2-line logical statement that begins at source line 175. Its exact fragment is '+ spike_nibble_count_r[2*pair+1];'. The important operands are spike_nibble_count_r: a binary event produced when a neuron crosses its threshold; pair: the value named 'pair' in this block. Read together, the complete operation is: This makes spike_pair_count_r[pair], a binary event produced when a neuron crosses its threshold, equal to 'spike_nibble_count_r[2*pair] + spike_nibble_count_r[2*pair+1]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_nibble_count_r: a binary event produced when a neuron crosses its threshold; pair: the value named 'pair' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT, the machine updates a segmented telemetry counter without a long carry chain..

Line 177: `zero_pair_count_r[pair] <= zero_nibble_count_r[2*pair]` This statement continues through source line 178; the explanation uses the complete expression rather than only the first visual fragment. This makes zero_pair_count_r[pair an integer count retained for control or measurable telemetry, equal to 'zero_nibble_count_r[2*pair] + zero_nibble_count_r[2*pair- It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_nibble_count_r: an integer count retained for control or measurable telemetry; pair: the value named 'pair' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT, the machine updates a segmented telemetry counter without a long carry chain..

Line 178: `+ zero_nibble_count_r[2*pair+1];` This is continuation line 2 of the 2-line logical statement that begins at source line 177. Its exact fragment is '+ zero_nibble_count_r[2*pair+1];'. The important operands are zero_nibble_count_r: an integer count retained for control or measurable telemetry; pair: the value named 'pair' in this block. Read together, the complete operation is: This makes zero_pair_count_r[pair], an integer count retained for control or measurable telemetry, equal to 'zero_nibble_count_r[2*pair] + zero_nibble_count_r[2*pair+1]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_nibble_count_r: an integer count retained for control or measurable telemetry; pair: the value named 'pair' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT, the machine updates a segmented telemetry counter without a long carry chain..

Line 179: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 180: `state <= ST_POPCOUNT_HALF;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_POPCOUNT_HALF‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_POPCOUNT_HALF: the value named ’st popcount half’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT, the machine updates a segmented telemetry counter without a long carry chain..

Line 181: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 183: `ST_POPCOUNT_HALF: begin` This is the ST_POPCOUNT_HALF case branch, which updates a segmented telemetry counter without a long carry chain. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain..

Line 184: `spike_half_count_r[0] <= spike_pair_count_r[0]` This statement continues through source line 185; the explanation uses the complete expression rather than only the first visual fragment. This makes spike_half_count_r[0], a binary event produced when a neuron crosses its threshold, equal to ‘spike_pair_count_r[0] + spike_pair_count_r[1]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_pair_count_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain..

Line 185: `+ spike_pair_count_r[1];` This is continuation line 2 of the 2-line logical statement that begins at source line 184. Its exact fragment is ‘+ spike_pair_count_r[1];‘. The important operands are spike_pair_count_r: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This makes spike_half_count_r[0], a binary event produced when a neuron crosses its threshold, equal to ‘spike_pair_count_r[0] + spike_pair_count_r[1]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_pair_count_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain..

Line 186: `spike_half_count_r[1] <= spike_pair_count_r[2]` This statement continues through source line 187; the explanation uses the complete expression rather than only the first visual fragment. This makes spike_half_count_r[1], a binary event produced when a neuron crosses its threshold, equal to ‘spike_pair_count_r[2] + spike_pair_count_r[3]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_pair_count_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain..

Line 187: `+ spike_pair_count_r[3];` This is continuation line 2 of the 2-line logical statement that begins at source line 186. Its exact fragment is ‘+ spike_pair_count_r[3];‘. The important operands are spike_pair_count_r: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This makes spike_half_count_r[1], a binary event produced when a neuron crosses its threshold, equal to ‘spike_pair_count_r[2] + spike_pair_count_r[3]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_pair_count_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain..

Line 188: `zero_half_count_r[0] <= zero_pair_count_r[0]` This statement continues through source line 189; the explanation uses the complete expression rather than only the first visual fragment. This makes zero_half_count_r[0], an integer count retained for control or measurable telemetry, equal to ‘zero_pair_count_r[0] + zero_pair_count_r[1]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_pair_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain..

Line 189: `+ zero_pair_count_r[1];` This is continuation line 2 of the 2-line logical statement that begins at source line 188. Its exact fragment is '+ zero_pair_count_r[1];'. The important operands are zero_pair_count_r: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This makes zero_half_count_r[0], an integer count retained for control or measurable telemetry, equal to 'zero_pair_count_r[0] + zero_pair_count_r[1]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_pair_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain..

Line 190: `zero_half_count_r[1] <= zero_pair_count_r[2]` This statement continues through source line 191; the explanation uses the complete expression rather than only the first visual fragment. This makes zero_half_count_r[1], an integer count retained for control or measurable telemetry, equal to 'zero_pair_count_r[2] + zero_pair_count_r[3]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_pair_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain..

Line 191: `+ zero_pair_count_r[3];` This is continuation line 2 of the 2-line logical statement that begins at source line 190. Its exact fragment is '+ zero_pair_count_r[3];'. The important operands are zero_pair_count_r: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This makes zero_half_count_r[1], an integer count retained for control or measurable telemetry, equal to 'zero_pair_count_r[2] + zero_pair_count_r[3]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_pair_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain..

Line 192: `state <= ST_POPCOUNT_FINAL;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_POPCOUNT_FINAL'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_POPCOUNT_FINAL: the value named 'st popcount final' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain..

Line 193: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_HALF, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 195: `ST_POPCOUNT_FINAL: begin` This is the ST_POPCOUNT_FINAL case branch, which updates a segmented telemetry counter without a long carry chain. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_FINAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 196: `spike_chunk_count_r <= spike_half_count_r[0]` This statement continues through source line 197; the explanation uses the complete expression rather than only the first visual fragment. This makes spike_chunk_count_r, a binary event produced when a neuron crosses its threshold, equal to 'spike_half_count_r[0] + spike_half_count_r[1]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_half_count_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_FINAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 197: `+ spike_half_count_r[1];` This is continuation line 2 of the 2-line logical statement that begins at source line 196. Its exact fragment is '+ spike_half_count_r[1];'. The important operands are spike_half_count_r: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This makes spike_chunk_count_r, a binary event produced when a neuron crosses its threshold, equal to 'spike_half_count_r[0] + spike_half_count_r[1]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_half_count_r: a binary event produced when a neuron crosses its threshold. Context: the

clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_FINAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 198: `zero_chunk_count_r <= zero_half_count_r[0]` This statement continues through source line 199; the explanation uses the complete expression rather than only the first visual fragment. This makes zero_chunk_count_r, an integer count retained for control or measurable telemetry, equal to ‘zero_half_count_r[0] + zero_half_count_r[1]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_half_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_FINAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 199: `+ zero_half_count_r[1];` This is continuation line 2 of the 2-line logical statement that begins at source line 198. Its exact fragment is ‘+ zero_half_count_r[1];‘. The important operands are zero_half_count_r: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This makes zero_chunk_count_r, an integer count retained for control or measurable telemetry, equal to ‘zero_half_count_r[0] + zero_half_count_r[1]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_half_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_FINAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 200: `state <= ST_ACCUMULATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_ACCUMULATE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ACCUMULATE: the value named ’st accumulate’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_FINAL, the machine updates a segmented telemetry counter without a long carry chain..

Line 201: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_POPCOUNT_FINAL, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 203: `ST_ACCUMULATE: begin` This is the ST_ACCUMULATE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 204: `logic [8:0] spike_total;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase.. Specifically, spike_total is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 205: `logic [8:0] zero_total;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase.. Specifically, zero_total is the value named ’zero total’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 206: `spike_total = spike_count_r + {3'd0, spike_chunk_count_r};` This makes spike_total, a binary event produced when a neuron crosses its threshold, equal to ‘spike_count_r + {3’d0, spike_chunk_count_r}‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are spike_count_r: a binary event produced when a neuron crosses its threshold; d0: the value named ’d0’ in this block; spike_chunk_count_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 207: `zero_total = zero_count_r + {3'd0, zero_chunk_count_r};` This makes zero_total, the value named ’zero total’ in this block, equal to ‘zero_count_r + {3’d0, zero_chunk_count_r}‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are zero_count_r: an integer count retained for control or measurable telemetry; d0: the value named ’d0’ in this block; zero_chunk_count_r: an integer count retained

for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 208: `spike_count_r <= spike_total;` This makes spike_count_r, a binary event produced when a neuron crosses its threshold, equal to ‘spike_total‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_total: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 209: `zero_count_r <= zero_total;` This makes zero_count_r, an integer count retained for control or measurable telemetry, equal to ‘zero_total‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_total: the value named ’zero total’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 210: `if (chunk_index == $clog2(CHUNKS)'(CHUNKS - 1)) begin` This condition selects the following hardware branch only when ‘chunk_index == $clog2(CHUNKS)'(CHUNKS - 1)‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are chunk_index: an integer selecting one tensor element, lane, bank, or state entry; clog2: the value named ’clog2’ in this block; CHUNKS: the value named ’chunks’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 211: `final_spike_count_r <= spike_total;` This makes final_spike_count_r, a binary event produced when a neuron crosses its threshold, equal to ‘spike_total‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_total: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 212: `final_zero_count_r <= zero_total;` This makes final_zero_count_r, an integer count retained for control or measurable telemetry, equal to ‘zero_total‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_total: the value named ’zero total’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 213: `spike_matches <= spike_total;` This makes spike_matches, a binary event produced when a neuron crosses its threshold, equal to ‘spike_total‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are spike_total: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 214: `zero_matches <= zero_total;` This makes zero_matches, the value named ’zero matches’ in this block, equal to ‘zero_total‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are zero_total: the value named ’zero total’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 215: `state <= ST_SCORE_LATCH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_SCORE_LATCH‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SCORE_LATCH: the value named ’st score latch’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 216: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 217: `chunk_index <= chunk_index + 1'b1;` This makes chunk_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘chunk_index + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are chunk_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 218: `state <= ST_MASK_CHUNK;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_MASK_CHUNK‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MASK_CHUNK: the value named ’st mask chunk’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase..

Line 219: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 220: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ACCUMULATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 222: `ST_SCORE_LATCH: begin` This is the ST_SCORE_LATCH case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_LATCH, the machine performs the named control phase..

Line 223: `score_spike_operand_r <= final_spike_count_r;` This makes score_spike_operand_r, a binary event produced when a neuron crosses its threshold, equal to ‘final_spike_count_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are final_spike_count_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_LATCH, the machine performs the named control phase..

Line 224: `score_zero_operand_r <= final_zero_count_r;` This makes score_zero_operand_r, the value named ’score zero operand r’ in this block, equal to ‘final_zero_count_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are final_zero_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_LATCH, the machine performs the named control phase..

Line 225: `state <= ST_SCORE_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_SCORE_MULTIPLY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SCORE_MULTIPLY: the value named ’st score multiply’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_LATCH, the machine performs the named control phase..

Line 226: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_LATCH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 228: `ST_SCORE_MULTIPLY: begin` This is the ST_SCORE_MULTIPLY case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_MULTIPLY, the machine performs the named control phase..

Line 229: `alpha_product_r <= alpha_product;` This makes alpha_product_r, the programmable weight assigned to matching zero spikes in alpha-XNOR attention, equal to ‘alpha_product‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are alpha_product: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_MULTIPLY, the machine performs the named control phase..

Line 230: `state <= ST_SCORE_ADD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_SCORE_ADD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SCORE_ADD: the value named ’st score add’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_MULTIPLY, the machine performs the named control phase..

Line 231: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 233: `ST_SCORE_ADD: begin` This is the ST_SCORE_ADD case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_ADD, the machine performs the named control phase..

Line 234: `score_q8 <= {score_spike_operand_r, 8'd0} + alpha_product_r;` This makes score_q8, the value named ’score q8’ in this block, equal to ‘{score_spike_operand_r, 8’d0} + alpha_product_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are score_spike_operand_r: a binary event produced when a neuron crosses its threshold; d0: the value named ’d0’ in this block; alpha_product_r: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_ADD, the machine performs the named control phase..

Line 235: `state <= ST_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT: the value named ’st output’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_ADD, the machine performs the named control phase..

Line 236: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SCORE_ADD, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 238: `ST_OUTPUT: if (output_ready) state <= ST_IDLE;` This is the ST_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘if (output_ready) state <= ST_IDLE;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 239: `default: state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘state <= ST_IDLE;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 240: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 241: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 242: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 244: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 245: `if (VECTOR_BITS != 256) $fatal(1, "neuraedge_alpha_xnor currently requires VECTOR_BITS=256");` This condition selects the following hardware branch only when ‘VECTOR_BITS != 256) $fatal(1, "neuraedge_alpha_xnor currently requires VECTOR_BITS=256"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are VECTOR_BITS: the value named ’vector bits’ in this block; fatal: the value named ’fatal’ in this block; neuraedge_alpha_xnor: the programmable weight assigned to matching zero spikes in alpha-XNOR attention. Context: the module’s structural declarations.

Line 246: `if (VECTOR_BITS % CHUNK_BITS != 0) $fatal(1, "VECTOR_BITS must be divisible by 32");` This condition selects the following hardware branch only when ‘VECTOR_BITS % CHUNK_BITS != 0) $fatal(1, "VECTOR_BITS must be divisible by 32"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are VECTOR_BITS: the value named ’vector bits’ in this block; CHUNK_BITS: the value named ’chunk bits’ in this block; fatal: the value named ’fatal’ in this block. Context: the module’s structural declarations.

Line 247: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 248: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 250: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that computes alpha-weighted XNOR spiking similarity and streams its accumulated scores.

6 rtl/neuraedge_buffered_tensor_core.sv

Role in the complete system: loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

6.1 Beginner architecture map

Dataflow responsibility This is the tile-level controller around memories and the physical array. Commands are predecoded, validated, and then routed through activation load, weight load, sparse-index formation, issue FIFO, accumulation, and ordered result output states. A two-entry skid FIFO reserves one beat for registered READY latency, decouples the tile's 128-entry result store from parent backpressure, and delays command completion until the buffered final result is actually transferred.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_buffered_tensor_core into physical nets and primitives. The source declares 12 input-port lines, 17 output-port lines, 3 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_COMPUTE_ACCOUNT, ST_COMPUTE_CONFIG, ST_COMPUTE_DRAIN, ST_COMPUTE_OUTPUT, ST_COMPUTE_RUN, ST_COMPUTE_START, ST_COMPUTE ST_COMPUTE_VALIDATED, ST_DECODE_COMMAND, ST_IDLE, ST_LOAD_ACTIVATIONS, ST_LOAD_ACTIV ST_LOAD_CONFIG, ST_LOAD_WEIGHTS_DOT8, ST_LOAD_WEIGHTS_OUTER, ST_PREDECODE_COMMAN A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates neuraedge_active_index_buffer as u_active_index_buffer, neuraedge_activation_buffer as u_activation_buffer, neuraedge_weight_bank as u_weight_bank, neuraedge_tensor_tile as u_tensor_tile, unique as case, end as if, else as if, endcase as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

6.3 Line annotations

Line 1: `‘timescale 1ns / 1ps` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `‘default_nettype none` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_buffered_tensor_core #(` This opens neuraedge_buffered_tensor_core, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 5: `parameter int MAX_OUTER_ISSUES = 2048,` This statement continues through source line 38; the explanation uses the complete expression rather than only the first visual fragment. This fixes MAX_OUTER_ISSUES to 2048, parameter int MAX_DOT8_ISSUES = 256, parameter int COLUMN_LANES = 16) (input wire clk, input wire rst_n, input wire command_valid, output logic command_ready, input wire [41:0] command_data, output logic command_done, output logic status_error, output logic status_busy, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic [11:0] status_loaded_activations, output logic [11:0] status_loaded_weights, output logic [11:0] status_active_issues, output logic [31:0] status_input_beats, output logic [31:0] status_output_beats, output logic [31:0] status_compute_cycles, output logic [31:0] status_skipped_issues, output logic [63:0] status_dense_macs, output logic [63:0] status_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_OUTER_ISSUES denotes the value named 'max outer issues' in this block.

Line 6: `parameter int MAX_DOT8_ISSUES = 256,` This is continuation line 2 of the 34-line logical statement that begins at source line 5. Its exact fragment is ‘parameter int MAX_DOT8_ISSUES = 256,‘. The important operands are parameter: the value named 'parameter' in this block; MAX_DOT8_ISSUES: the value named 'max dot8 issues' in this block. Read together, the complete operation is: This fixes MAX_OUTER_ISSUES to 2048, parameter int MAX_DOT8_ISSUES = 256, parameter int COLUMN_LANES = 16) (input wire clk, input wire rst_n, input wire command_valid, output logic command_ready, input wire [41:0] command_data, output logic command_done, output logic status_error, output logic status_busy, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic [11:0] status_loaded_activations, output logic [11:0] status_loaded_weights, output logic [11:0] status_active_issues, output logic [31:0] status_input_beats, output logic [31:0] status_output_beats, output logic [31:0] status_compute_cycles, output logic [31:0] status_skipped_issues, output logic [63:0] status_dense_macs, output logic [63:0] status_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_OUTER_ISSUES denotes the value named 'max outer issues' in this block.

Line 38: `);` This is continuation line 34 of the 34-line logical statement that begins at source line 5. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes MAX_OUTER_ISSUES to 2048, parameter int MAX_DOT8_ISSUES = 256, parameter int COLUMN_LANES = 16) (input wire clk, input wire rst_n, input wire command_valid, output logic command_ready, input wire [41:0] command_data, output logic command_done, output logic status_error, output logic status_busy, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic [11:0] status_loaded_activations, output logic [11:0] status_loaded_weights, output logic [11:0] status_active_issues, output logic [31:0] status_input_beats, output logic [31:0] status_output_beats, output logic [31:0] status_compute_cycles, output logic [31:0] status_skipped_issues, output logic [63:0] status_dense_macs, output logic [63:0] status_spike_adds) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_OUTER_ISSUES denotes the value named 'max outer issues' in this block.

Line 39: `import neuraedge_command_pkg::*;` This imports shared package names into the current module so opcodes and mode constants have exactly one definition. The import changes compile-time name visibility; it does not create registers or consume a clock cycle.

Line 41: `localparam int WEIGHT_BANKS = 8;` This fixes WEIGHT_BANKS to 8 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; WEIGHT_BANKS denotes a learned coefficient multiplied by an activation.

Line 43: `typedef enum logic [3:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 44: `ST_IDLE = 4'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 45: `ST_LOAD_ACTIVATIONS = 4'd1,` This assigns a fixed binary encoding to state ST_LOAD_ACTIVATIONS, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 46: `ST_LOAD_WEIGHTS_OUTER = 4'd2,` This assigns a fixed binary encoding to state ST_LOAD_WEIGHTS_OUTER, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 47: `ST_LOAD_WEIGHTS_DOT8 = 4'd3,` This assigns a fixed binary encoding to state ST_LOAD_WEIGHTS_DOT8, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 48: `ST_COMPUTE_START = 4'd4,` This assigns a fixed binary encoding to state ST_COMPUTE_START, which issues arithmetic work using values already held on chip. The encoding is visible in waveforms even though the source uses the readable name.

Line 49: `ST_COMPUTE_RUN = 4'd5,` This assigns a fixed binary encoding to state ST_COMPUTE_RUN, which issues arithmetic work using values already held on chip. The encoding is visible in waveforms even though the source uses the readable name.

Line 50: `ST_COMPUTE_OUTPUT = 4'd6,` This assigns a fixed binary encoding to state ST_COMPUTE_OUTPUT, which issues arithmetic work using values already held on chip. The encoding is visible in waveforms even though the source uses the readable name.

Line 51: `ST_LOAD_ACTIVATION_DRAIN = 4'd7,` This assigns a fixed binary encoding to state ST_LOAD_ACTIVATION_DRAI which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 52: `ST_DECODE_COMMAND = 4'd8,` This assigns a fixed binary encoding to state ST_DECODE_COMMAND, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 53: `ST_COMPUTE_CONFIG = 4'd9,` This assigns a fixed binary encoding to state ST_COMPUTE_CONFIG, which issues arithmetic work using values already held on chip. The encoding is visible in waveforms even though the source uses the readable name.

Line 54: `ST_LOAD_CONFIG = 4'd10,` This assigns a fixed binary encoding to state ST_LOAD_CONFIG, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 55: `ST_COMPUTE_VALIDATE = 4'd11,` This assigns a fixed binary encoding to state ST_COMPUTE_VALIDATE, which issues arithmetic work using values already held on chip. The encoding is visible in waveforms even though the source uses the readable name.

Line 56: `ST_COMPUTE_VALIDATED = 4'd12,` This assigns a fixed binary encoding to state ST_COMPUTE_VALIDATED, which issues arithmetic work using values already held on chip. The encoding is visible in waveforms even though the source uses the readable name.

Line 57: `ST_PREDECODE_COMMAND = 4'd13,` This assigns a fixed binary encoding to state ST_PREDECODE_COMMAND, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 58: `ST_COMPUTE_ACCOUNT = 4'd14,` This assigns a fixed binary encoding to state ST_COMPUTE_ACCOUNT, which issues arithmetic work using values already held on chip. The encoding is visible in waveforms even though the source uses the readable name.

Line 59: `ST_COMPUTE_DRAIN = 4'd15` This statement continues through source line 60; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_COMPUTE_DRAIN, which issues arithmetic work using values already held on chip. The encoding is visible in waveforms even though the source uses the readable name.

Line 60: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 59. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_COMPUTE_DRAIN, which issues arithmetic work using values already held on chip. The encoding is visible in waveforms even though the source uses the readable name.

Line 62: `state_t state;` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are state_t: the finite-state-machine phase retained in flip-flops; state: the finite-state-machine phase retained in flip-flops.

Line 63: `logic [41:0] captured_command_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, captured_command_r is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 64: `logic [3:0] decoded_opcode_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, decoded_opcode_r is the value named 'decoded opcode r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 65: `logic [11:0] decoded_issue_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, decoded_issue_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 66: `logic decoded_outer_issue_error_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, decoded_outer_issue_error_r is the value named 'decoded outer issue error r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 67: `logic decoded_dot8_issue_error_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, decoded_dot8_issue_error_r is the value named 'decoded dot8 issue error r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 68: `(* dont_touch = "yes" *) logic command_done_pending_r;` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; command_done_pending_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 69: `(* dont_touch = "yes" *) logic error_event_r;` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; error_event_r: the value named 'error event r' in this block.

Line 70: `(* dont_touch = "yes" *) logic clear_error_r;` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; clear_error_r: the value named 'clear error r' in this block.

Line 71: `logic [3:0] pending_load_opcode_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pending_load_opcode_r is the value named 'pending load opcode r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 72: `logic [11:0] pending_load_issue_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pending_load_issue_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 73: `logic [7:0] pending_load_activation_zp_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pending_load_activation_zp_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 75: `// Eight 256-deep, 128-bit banks are the physical form of a 32 KiB weight` Design intent: Eight 256-deep, 128-bit banks are the physical form of a 32 KiB weight This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 76: `// tile. In` Design intent: tile. In This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 77: `// outer-product mode one bank supplies each consecutive K position. In` Design intent: outer-product mode one bank supplies each consecutive K position. In This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 78: `// Dot8 mode reads all eight banks together, exposing 8x16 weight bytes.` Design intent: Dot8 mode reads all eight banks together, exposing 8x16 weight bytes. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 79: `logic activation_write_enable;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_write_enable is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 80: `logic [10:0] activation_write_address;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_write_address is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 81: `logic [10:0] activation_read_address;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_read_address is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 82: `wire [63:0] activation_read_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_read_data is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 83: `logic [WEIGHT_BANKS-1:0] weight_write_enable;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_write_enable is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 84: `logic [7:0] weight_write_address;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_write_address is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 85: `logic [1:0] weight_write_segment;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_write_segment is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 86: `logic [WEIGHT_BANKS-1:0] weight_commit_enable_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_commit_enable_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 87: `logic [7:0] weight_commit_address_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_commit_address_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 88: `logic [1:0] weight_commit_segment_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_commit_segment_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 89: `logic [63:0] weight_commit_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_commit_data_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 90: `logic [7:0] weight_read_address;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_read_address is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 91: `wire [COLUMN_LANES*8-1:0] weight_read_data [0:WEIGHT_BANKS-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_read_data is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 93: `logic [11:0] load_requested_issues;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_requested_issues is the value named 'load requested issues' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 94: `logic [14:0] load_beats_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_beats_remaining_r is the value named 'load beats remaining r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 95: `logic load_finish_pending_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_finish_pending_r is the value named 'load finish pending r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 96: `logic [3:0] load_segment_index_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_segment_index_r is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 97: `logic [11:0] load_item_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_item_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 98: `logic [7:0] load_activation_zero_point;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_activation_zero_point is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 99: `logic weight_format_dot8;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_format_dot8 is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 100: `logic activation_classify_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_classify_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 101: `logic activation_classify_nonzero_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_classify_nonzero_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 102: `logic [10:0] activation_classify_index_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_classify_index_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 103: `logic activation_load_success_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_load_success_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 104: `wire active_index_write_enable;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_index_write_enable is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 105: `wire [10:0] active_index_read_data;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_index_read_data is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 106: `wire active_index_read_enable;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_index_read_enable is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 107: `wire [10:0] active_mapped_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, active_mapped_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 109: `(* dont_touch = "yes" *) logic [1:0] compute_mode_r;` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; compute_mode_r: the value named 'compute mode r' in this block.

Line 110: `(* dont_touch = "yes" *) logic [3:0] compute_rows_r;` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; compute_rows_r: one output-row position processed by the tensor tile.

Line 111: `(* dont_touch = "yes" *) logic [5:0] compute_columns_r;` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; compute_columns_r: one output-feature position processed in parallel.

Line 112: `logic [11:0] compute_requested_issues;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, compute_requested_issues is the value named 'compute requested issues' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 113: `logic compute_validation_error_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, compute_validation_error_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 114: `(* dont_touch = "yes" *) logic [7:0] compute_activation_zp_r;` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; compute_activation_zp_r: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 115: `(* dont_touch = "yes" *) logic [7:0] compute_weight_zp_r;` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; compute_weight_zp_r: a learned coefficient multiplied by an activation.

Line 116: `logic [11:0] schedule_pointer;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, schedule_pointer is the value named 'schedule pointer' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 117: `logic [11:0] schedule_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, schedule_remaining_r is the value named 'schedule remaining r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 118: `logic schedule_active_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, schedule_active_r is the value named 'schedule active r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 119: `logic schedule_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, schedule_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 120: `logic compute_empty_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, compute_empty_r is the value named 'compute empty r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 121: `logic compute_read_request;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, compute_read_request is the value named 'compute read request' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 122: `logic index_request_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, index_request_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 123: `logic index_request_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, index_request_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 124: `logic [10:0] index_request_address_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, index_request_address_r is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 125: `logic index_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, index_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 126: `logic index_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, index_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 127: `logic map_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, map_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 128: `logic map_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, map_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 129: `logic [10:0] mapped_index_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mapped_index_r is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 130: `logic read_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, read_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 131: `logic [2:0] read_bank_select_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, read_bank_select_r is the value named 'read bank select r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 132: `logic read_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, read_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 133: `logic memory_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, memory_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 134: `logic [2:0] memory_bank_select_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, memory_bank_select_r is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 135: `logic memory_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, memory_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 136: `logic capture_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, capture_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 137: `logic capture_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, capture_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 138: `logic [63:0] capture_activation_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, capture_activation_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 139: `logic [COLUMN_LANES*8-1:0] capture_outer_weights_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, capture_outer_weights_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 140: `logic [COLUMN_LANES*8*8-1:0] capture_dot_weights_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, capture_dot_weights_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 141: `logic [1:0] issue_fifo_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_fifo_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 142: `logic issue_fifo_write_pointer_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_fifo_write_pointer_r is the value named 'issue fifo write pointer r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 143: `logic issue_fifo_read_pointer_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_fifo_read_pointer_r is the value named 'issue fifo read pointer r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 144: `logic issue_fifo_last_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_fifo_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 145: `logic [63:0] issue_fifo_activation_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_fifo_activation_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 146: `logic [COLUMN_LANES*8-1:0] issue_fifo_outer_weights_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_fifo_outer_weights_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 147: `logic [COLUMN_LANES*8*8-1:0] issue_fifo_dot_weights_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_fifo_dot_weights_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 148: `(* dont_touch = "yes" *) logic tile_last_issue_accepted_r;` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; tile_last_issue_accepted_r: the AXI-Stream marker for the final beat of a packet or command payload.

Line 149: `logic issue_fifo_available;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_fifo_available is the value named 'issue fifo available' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 150: `logic capture_stage_available;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, capture_stage_available is the value named 'capture stage available' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 151: `logic memory_stage_available;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, memory_stage_available is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 152: `logic read_stage_available;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, read_stage_available is the value named 'read stage available' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 153: `logic map_stage_available;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, map_stage_available is the value named 'map stage available' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 154: `logic index_stage_available;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, index_stage_available is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 155: `logic index_request_stage_available;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, index_request_stage_available is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 157: `logic tile_start;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_start is the value named 'tile start' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 158: `logic tile_config_error;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_config_error is the value named 'tile config error' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 159: `logic tile_issue_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_issue_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 160: `wire tile_issue_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_issue_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 161: `logic [63:0] tile_activation_vector;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_activation_vector is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 162: `logic [COLUMN_LANES*8-1:0] tile_outer_weight_vector;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_outer_weight_vector is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 163: `logic [COLUMN_LANES*8*8-1:0] tile_dot_weight_vector;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_dot_weight_vector is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 164: `logic tile_issue_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_issue_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 165: `wire tile_result_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_result_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 166: `logic tile_result_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_result_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 167: `wire signed [47:0] tile_result_value;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_result_value is the value named 'tile result value' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 168: `wire [3:0] tile_result_row;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_result_row is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 169: `wire [5:0] tile_result_column;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_result_column is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 170: `wire tile_result_last;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_result_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 171: `// This two-entry skid FIFO breaks the external READY path before it reaches` Design intent: This two-entry skid FIFO breaks the external READY path before it reaches This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 172: `// the tile's 128-entry result store and replicated output-state controls.` Design intent: the tile's 128-entry result store and replicated output-state controls. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 173: `// A registered tile READY can remain asserted for one final transfer while` Design intent: A registered tile READY can remain asserted for one final transfer while This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 174: `// downstream backpressure arrives; the second entry is the space reserved` Design intent: downstream backpressure arrives; the second entry is the space reserved This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 175: `// for that transfer, so no result is dropped and sustained throughput stays` Design intent: for that transfer, so no result is dropped and sustained throughput stays This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 176: `// at one result per clock whenever the parent accepts one per clock.` Design intent: at one result per clock whenever the parent accepts one per clock. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 177: `logic tile_result_ready_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_result_ready_r is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 178: `logic [1:0] tensor_output_fifo_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 179: `logic tensor_output_fifo_write_pointer_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_write_pointer_r is the value named 'tensor output fifo write pointer r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 180: `logic tensor_output_fifo_read_pointer_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_read_pointer_r is the value named 'tensor output fifo read pointer r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 181: `logic [63:0] tensor_output_fifo_data_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 182: `logic tensor_output_fifo_last_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 183: `wire [63:0] tile_debug_dense_macs;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_debug_dense_macs is a count of ordinary activation-times-weight operations actually issued. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 184: `wire [63:0] tile_debug_spike_adds;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tile_debug_spike_adds is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 185: `logic [23:0] pending_dense_macs_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pending_dense_macs_low_r is a count of ordinary activation-times-weight operations actually issued. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 186: `logic pending_dense_macs_carry_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pending_dense_macs_carry_r is a count of ordinary activation-times-weight operations actually issued. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 187: `logic [23:0] pending_spike_adds_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pending_spike_adds_low_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 188: `logic pending_spike_adds_carry_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pending_spike_adds_carry_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 189: `wire issue_fifo_push = capture_valid_r && issue_fifo_available;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_fifo_push is the value named 'issue fifo push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 190: `wire issue_fifo_pop = issue_fifo_count_r != 0 && tile_issue_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, issue_fifo_pop is the value named 'issue fifo pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 191: `wire tensor_output_fifo_push = state == ST_COMPUTE_OUTPUT` This statement continues through source line 192; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_push is the value named 'tensor output fifo push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 192: `&& tile_result_valid && tile_result_ready_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 191. Its exact fragment is '&& tile_result_valid && tile_result_ready_r;'. The important operands are tile_result_valid: the producer's statement that its current payload is meaningful; tile_result_ready_r: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_push is the value named 'tensor output fifo push' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 193: `wire tensor_output_fifo_pop = tensor_output_fifo_count_r != 0` This statement continues through source line 194; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_pop is the value named 'tensor output fifo pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 194: `&& m_axis_tready;` This is continuation line 2 of the 2-line logical statement that begins at source line 193. Its exact fragment is '&& m_axis_tready;'. The important operands are m_axis_tready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_pop is the value named 'tensor output fifo pop' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 195: `wire tensor_output_fifo_head_last = tensor_output_fifo_last_r[` This statement continues through source line 196; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_head_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 196: `tensor_output_fifo_read_pointer_r];` This is continuation line 2 of the 2-line logical statement that begins at source line 195. Its exact fragment is 'tensor_output_fifo_read_pointer_r];'. The important operands are tensor_output_fifo_read_pointer_r: the value named 'tensor output fifo read pointer r' in this block. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_head_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 197: `logic [1:0] tensor_output_fifo_count_next;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, tensor_output_fifo_count_next is the value named 'tensor output fifo count next' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 199: `function automatic logic all_bytes_equal64(` Within the combinational helper all bytes equal64, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; all_bytes_equal64: the value named 'all bytes equal64' in this block.

Line 200: `input logic [63:0] values,` This declares values as a input port with width [63:0]. It carries the value named 'values' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 201: `input logic [7:0] reference` This declares reference as a input port with width [7:0]. It carries the value named 'reference' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 202: `);` Within the combinational helper all bytes equal64, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The expression is a literal or structural operator and has no hidden software state.

Line 203: `logic equal_all;` This declares hardware signal storage or wiring in the combinational helper all bytes equal64. Specifically, equal_all is the value named 'equal all' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 204: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper all bytes equal64; it has no arithmetic value of its own.

Line 205: `equal_all = 1'b1;` This makes equal_all, the value named 'equal all' in this block, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the combinational helper all bytes equal64.

Line 206: `for (int lane = 0; lane < 8; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational helper all bytes equal64.

Line 207: `equal_all = equal_all && (values[lane*8 +: 8] == reference);` This makes equal_all, the value named 'equal all' in this block, equal to 'equal_all && (values[lane*8 +: 8] == reference)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are equal_all: the value named 'equal all' in this block; values: the value named 'values' in this block; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational helper all bytes equal64.

Line 208: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper all bytes equal64; it has no arithmetic value of its own.

Line 209: `all_bytes_equal64 = equal_all;` This makes all_bytes_equal64, the value named 'all bytes equal64' in this block, equal to 'equal_all'. It is driven by combinational or procedural logic in the current evaluation. The important operands are equal_all: the value named 'equal all' in this block. Context: the combinational helper all bytes equal64.

Line 210: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper all bytes equal64; it has no arithmetic value of its own.

Line 211: `endfunction` Within the combinational helper all bytes equal64, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are endfunction: the value named 'endfunction' in this block.

Line 213: `function automatic logic [63:0] repeat_byte(input logic [7:0] value);` Within the combinational helper repeat byte, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; repeat_byte: the value named 'repeat byte' in this block.

Line 214: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper repeat byte; it has no arithmetic value of its own.

Line 215: `repeat_byte = {8{value}};` This makes repeat_byte, the value named 'repeat byte' in this block, equal to '{8{value}}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper repeat byte.

Line 216: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper repeat byte; it has no arithmetic value of its own.

Line 217: `endfunction` Within the combinational helper repeat byte, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are endfunction: the value named 'endfunction' in this block.

Line 219: `// Tile activity is at most 19 bits per command. The low 24-bit addition` Design intent: Tile activity is at most 19 bits per command. The low 24-bit addition This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 220: `// and its carry are registered on the final output beat; the following` Design intent: and its carry are registered on the final output beat; the following This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 221: `// accounting state updates the independent high 40 bits.` Design intent: accounting state updates the independent high 40 bits. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 222: `function automatic logic [24:0] add_u19_to_u24(` Within the combinational helper add u19 to u24, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; add_u19_to_u24: the value named 'add u19 to u24' in this block.

Line 223: `input logic [23:0] value,` This declares value as a input port with width [23:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 224: `input logic [18:0] increment` This declares increment as a input port with width [18:0]. It carries the value named 'increment' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 225: `);` Within the combinational helper add u19 to u24, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The expression is a literal or structural operator and has no hidden software state.

Line 226: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper add u19 to u24; it has no arithmetic value of its own.

Line 227: `add_u19_to_u24 = {1'b0, value} + {6'd0, increment};` This makes add_u19_to_u24, the value named 'add u19 to u24' in this block, equal to '{1'b0, value} + {6'd0, increment}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block; value: the value named 'value' in this block; d0: the value named 'd0' in this block. Context: the combinational helper add u19 to u24.

Line 228: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper add u19 to u24; it has no arithmetic value of its own.

Line 229: `endfunction` Within the combinational helper add u19 to u24, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are endfunction: the value named 'endfunction' in this block.

Line 231: `assign tile_start = (state == ST_COMPUTE_START);` This makes tile_start, the value named 'tile start' in this block, equal to '(state == ST_COMPUTE_START)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_START: the value named 'st compute start' in this block. Context: the module's structural declarations.

Line 232: `assign active_index_write_enable = activation_classify_valid_r` This statement continues through source line 233; the explanation uses the complete expression rather than only the first visual fragment. This makes active_index_write_enable, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘activation_classify_valid_r && activation_classify_nonzero_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are activation_classify_valid_r: the producer's statement that its current payload is meaningful; activation_classify_nonzero_r: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the module's structural declarations.

Line 233: `&& activation_classify_nonzero_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 232. Its exact fragment is ‘&& activation_classify_nonzero_r;‘. The important operands are activation_classify_nonzero_r: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This makes active_index_write_enable, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘activation_classify_valid_r && activation_classify_nonzero_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are activation_classify_valid_r: the producer's statement that its current payload is meaningful; activation_classify_nonzero_r: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the module's structural declarations.

Line 234: `// Each accepted request generates exactly one synchronous BRAM response.` Design intent: Each accepted request generates exactly one synchronous BRAM response. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 235: `// The following local register stage holds that response during downstream` Design intent: The following local register stage holds that response during downstream This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 236: `// stalls, so an unaccepted address can never overwrite accepted metadata.` Design intent: stalls, so an unaccepted address can never overwrite accepted metadata. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 237: `assign active_index_read_enable = index_request_valid_r && !compute_empty_r;` This makes active_index_read_enable, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘index_request_valid_r && !compute_empty_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are index_request_valid_r: the producer's statement that its current payload is meaningful; compute_empty_r: the value named 'compute empty r' in this block. Context: the module's structural declarations.

Line 238: `assign active_mapped_index = compute_empty_r` This statement continues through source line 239; the explanation uses the complete expression rather than only the first visual fragment. This makes active_mapped_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘compute_empty_r ? 11'd0 : active_index_read_data‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are compute_empty_r: the value named 'compute empty r' in this block; d0: the value named 'd0' in this block; active_index_read_data: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 239: `? 11'd0 : active_index_read_data;` This is continuation line 2 of the 2-line logical statement that begins at source line 238. Its exact fragment is ‘? 11'd0 : active_index_read_data;‘. The important operands are d0: the value named 'd0' in this block; active_index_read_data: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes active_mapped_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘compute_empty_r ? 11'd0 : active_index_read_data‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are compute_empty_r: the value named 'compute empty r' in this block; d0: the value named 'd0' in this block; active_index_read_data: an integer selecting one tensor element, lane, bank, or state entry. Context: the module's structural declarations.

Line 241: `neuraedge_active_index_buffer #(` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are neuraedge_active_index_buffer: local storage that decouples producer and consumer timing.

Line 242: `.DEPTH(MAX_OUTER_ISSUES),` This connects the child instance's named port 'DEPTH' to parent expression 'MAX_OUTER_ISSUES'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'max outer issues' in this block.

Line 243: `.ADDRESS_BITS(11)` This connects the child instance's named port 'ADDRESS_BITS' to parent expression '11'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named '11' in this block.

Line 244: `) u_active_index_buffer (` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are u_active_index_buffer: local storage that decouples producer and consumer timing.

Line 245: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 246: `.write_enable(active_index_write_enable),` This connects the child instance's named port 'write_enable' to parent expression 'active_index_write_enable'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an integer selecting one tensor element, lane, bank, or state entry.

Line 247: `.write_address(status_active_issues[10:0]),` This connects the child instance's named port 'write_address' to parent expression 'status_active_issues[10:0]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'status active issues' in this block.

Line 248: `.write_data(activation_classify_index_r),` This connects the child instance's named port 'write_data' to parent expression 'activation_classify_index_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 249: `.read_enable(active_index_read_enable),` This connects the child instance's named port 'read_enable' to parent expression 'active_index_read_enable'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an integer selecting one tensor element, lane, bank, or state entry.

Line 250: `.read_address(index_request_address_r),` This connects the child instance's named port 'read_address' to parent expression 'index_request_address_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an integer selecting one tensor element, lane, bank, or state entry.

Line 251: `.read_data(active_index_read_data)` This connects the child instance's named port 'read_data' to parent expression 'active_index_read_data'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an integer selecting one tensor element, lane, bank, or state entry.

Line 252: `);` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The expression is a literal or structural operator and has no hidden software state.

Line 254: `neuraedge_activation_buffer u_activation_buffer (` This instantiates module neuraedge_activation_buffer as u_activation_buffer. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 255: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 256: `.write_enable(activation_write_enable),` This connects the child instance's named port 'write_enable' to parent expression 'activation_write_enable'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 257: `.write_address(activation_write_address),` This connects the child instance's named port 'write_address' to parent expression 'activation_write_address'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 258: `.write_data(s_axis_tdata),` This connects the child instance's named port 'write_data' to parent expression 's_axis_tdata'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 's axis tdata' in this block.

Line 259: `.read_address(activation_read_address),` This connects the child instance's named port 'read_address' to parent expression 'activation_read_address'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 260: `.read_data(activation_read_data)` This connects the child instance's named port 'read_data' to parent expression 'activation_read_data'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 261: `);` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The expression is a literal or structural operator and has no hidden software state.

Line 263: `for (genvar bank = 0; bank < WEIGHT_BANKS; bank++) begin : g_weight_bank` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 264: `neuraedge_weight_bank u_weight_bank (` This instantiates module neuraedge_weight_bank as u_weight_bank. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 265: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 266: `.write_enable(weight_commit_enable_r[bank]),` This connects the child instance's named port 'write_enable' to parent expression 'weight_commit_enable_r[bank]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 267: `.write_address(weight_commit_address_r),` This connects the child instance's named port 'write_address' to parent expression 'weight_commit_address_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 268: `.write_segment(weight_commit_segment_r),` This connects the child instance's named port 'write_segment' to parent expression 'weight_commit_segment_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 269: `.write_data(weight_commit_data_r),` This connects the child instance's named port 'write_data' to parent expression 'weight_commit_data_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 270: `.read_address(weight_read_address),` This connects the child instance's named port 'read_address' to parent expression 'weight_read_address'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 271: `.read_data(weight_read_data[bank])` This connects the child instance's named port 'read_data' to parent expression 'weight_read_data[bank]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 272: `);` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The expression is a literal or structural operator and has no hidden software state.

Line 273: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 275: `neuraedge_tensor_tile #(.COLUMN_LANES(COLUMN_LANES)) u_tensor_tile (` This instantiates module neuraedge_tensor_tile as u_tensor_tile. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 276: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 277: `.rst_n(rst_n),` This connects the child instance's named port 'rst_n' to parent expression 'rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the active-low synchronous reset.

Line 278: `.start(tile_start),` This connects the child instance's named port 'start' to parent expression 'tile_start'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'tile start' in this block.

Line 279: `.compute_mode(compute_mode_r),` This connects the child instance's named port 'compute_mode' to parent expression 'compute_mode_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'compute mode r' in this block.

Line 280: `.active_rows(compute_rows_r),` This connects the child instance's named port 'active_rows' to parent expression 'compute_rows_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one output-row position processed by the tensor tile.

Line 281: `.active_columns(compute_columns_r),` This connects the child instance's named port 'active_columns' to parent expression 'compute_columns_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one output-feature position processed in parallel.

Line 282: `.activation_zero_point(compute_activation_zp_r),` This connects the child instance's named port 'activation_zero_point' to parent expression 'compute_activation_zp_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 283: `.weight_zero_point(compute_weight_zp_r),` This connects the child instance's named port 'weight_zero_point' to parent expression 'compute_weight_zp_r'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 284: `.config_error(tile_config_error),` This connects the child instance's named port 'config_error' to parent expression 'tile_config_error'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'tile config error' in this block.

Line 285: `.issue_valid(tile_issue_valid),` This connects the child instance's named port 'issue_valid' to parent expression 'tile_issue_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 286: `.issue_ready(tile_issue_ready),` This connects the child instance's named port 'issue_ready' to parent expression 'tile_issue_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 287: `.activation_vector(tile_activation_vector),` This connects the child instance's named port 'activation_vector' to parent expression 'tile_activation_vector'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and an input feature value consumed by a neuron or multiply-accumulate operation.

Line 288: `.outer_weight_vector(tile_outer_weight_vector),` This connects the child instance's named port 'outer_weight_vector' to parent expression 'tile_outer_weight_vector'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 289: `.dot_weight_vector(tile_dot_weight_vector),` This connects the child instance's named port 'dot_weight_vector to parent expression 'tile_dot_weight_vector'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a learned coefficient multiplied by an activation.

Line 290: `.issue_last(tile_issue_last),` This connects the child instance's named port 'issue_last' to parent expression 'tile_issue_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 291: `.busy(),` This connects the child instance's named port 'busy' to parent expression ''. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'busy' in this block.

Line 292: `.result_valid(tile_result_valid),` This connects the child instance's named port 'result_valid' to parent expression 'tile_result_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 293: `.result_ready(tile_result_ready),` This connects the child instance's named port 'result_ready' to parent expression 'tile_result_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 294: `.result_value(tile_result_value),` This connects the child instance's named port 'result_value' to parent expression 'tile_result_value'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'tile result value' in this block.

Line 295: `.result_row(tile_result_row),` This connects the child instance's named port 'result_row' to parent expression 'tile_result_row'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one output-row position processed by the tensor tile.

Line 296: `.result_column(tile_result_column),` This connects the child instance's named port 'result_column' to parent expression 'tile_result_column'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and one output-feature position processed in parallel.

Line 297: `.result_last(tile_result_last),` This connects the child instance's named port 'result_last' to parent expression 'tile_result_last'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the AXI-Stream marker for the final beat of a packet or command payload.

Line 298: `.debug_accepted_issues(),` This connects the child instance's named port 'debug_accepted_issues' to parent expression ''. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug accepted issues' in this block.

Line 299: `.debug_skipped_issues(),` This connects the child instance's named port 'debug_skipped_issues' to parent expression ''. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug skipped issues' in this block.

Line 300: `.debug_retired_issues(),` This connects the child instance's named port 'debug_retired_issues' to parent expression ''. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'debug retired issues' in this block.

Line 301: `.debug_dense_macs(tile_debug_dense_macs),` This connects the child instance's named port 'debug_dense_macs' to parent expression 'tile_debug_dense_macs'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a count of ordinary activation-times-weight operations actually issued.

Line 302: `.debug_spike_adds(tile_debug_spike_adds)` This connects the child instance's named port 'debug_spike_adds' to parent expression 'tile_debug_spike_adds'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a binary event produced when a neuron crosses its threshold.

Line 303: `);` Within the module's structural declarations, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The expression is a literal or structural operator and has no hidden software state.

Line 305: `` `ifndef SYNTHESIS `` This SystemVerilog preprocessor line controls compilation of the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 306: `// The tile's mathematical per-command maximum is 262,144, so its debug` Design intent: The tile's mathematical per-command maximum is 262,144, so its debug This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 307: `// counters must remain 19-bit quantities. Keep the fast accumulator's` Design intent: counters must remain 19-bit quantities. Keep the fast accumulator's This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 308: `// width assumption checked in every RTL simulation.` Design intent: width assumption checked in every RTL simulation. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 309: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 310: `if (rst_n && tile_result_valid && tile_result_ready && tile_result_last` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are rst_n: the active-low synchronous reset; tile_result_valid: the producer's statement that its current payload is meaningful; tile_result_ready: the consumer's statement that it can accept a payload this cycle.

Line 311: `&& ((|tile_debug_dense_macs[63:19])` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tile_debug_dense_macs: a count of ordinary activation-times-weight operations actually issued.

Line 312: `|| (|tile_debug_spike_adds[63:19]))) begin` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tile_debug_spike_adds: a binary event produced when a neuron crosses its threshold.

Line 313: `$fatal(1, "tile activity counter exceeded its 19-bit contract");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 314: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 315: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 316: `` `endif `` This SystemVerilog preprocessor line controls compilation of the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 318: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 319: `command_ready = (state == ST_IDLE);` This makes command_ready, the consumer's statement that it can accept a payload this cycle, equal to '(state == ST_IDLE)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 320: `status_busy = (state != ST_IDLE);` This makes status_busy, the value named 'status busy' in this block, equal to '(state != ST_IDLE)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 321: `s_axis_tready = !load_finish_pending_r` This statement continues through source line 324; the explanation uses the complete expression rather than only the first visual fragment. This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '!load_finish_pending_r && (state == ST_LOAD_ACTIVATIONS || state == ST_LOAD_WEIGHTS_OUTER || state == ST_LOAD_WEIGHTS_DOT8)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_finish_pending_r: the value named 'load finish pending r' in this block; state: the finite-state-machine phase retained in flip-flops; ST_LOAD_ACTIVATIONS:

an input feature value consumed by a neuron or multiply-accumulate operation. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 322: `&& (state == ST_LOAD_ACTIVATIONS` This is continuation line 2 of the 4-line logical statement that begins at source line 321. Its exact fragment is '&& (state == ST_LOAD_ACTIVATIONS'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '!load_finish_pending_r && (state == ST_LOAD_ACTIVATIONS || state == ST_LOAD_WEIGHTS_OUTER || state == ST_LOAD_WEIGHTS_DOT8)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_finish_pending_r: the value named 'load finish pending r' in this block; state: the finite-state-machine phase retained in flip-flops; ST_LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 323: `|| state == ST_LOAD_WEIGHTS_OUTER` This is continuation line 3 of the 4-line logical statement that begins at source line 321. Its exact fragment is '|| state == ST_LOAD_WEIGHTS_OUTER'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Read together, the complete operation is: This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '!load_finish_pending_r && (state == ST_LOAD_ACTIVATIONS || state == ST_LOAD_WEIGHTS_OUTER || state == ST_LOAD_WEIGHTS_DOT8)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_finish_pending_r: the value named 'load finish pending r' in this block; state: the finite-state-machine phase retained in flip-flops; ST_LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 324: `|| state == ST_LOAD_WEIGHTS_DOT8);` This is continuation line 4 of the 4-line logical statement that begins at source line 321. Its exact fragment is '|| state == ST_LOAD_WEIGHTS_DOT8);'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation. Read together, the complete operation is: This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '!load_finish_pending_r && (state == ST_LOAD_ACTIVATIONS || state == ST_LOAD_WEIGHTS_OUTER || state == ST_LOAD_WEIGHTS_DOT8)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_finish_pending_r: the value named 'load finish pending r' in this block; state: the finite-state-machine phase retained in flip-flops; ST_LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 326: `m_axis_tvalid = tensor_output_fifo_count_r != 0;` This makes m_axis_tvalid, the producer's statement that its current payload is meaningful, equal to 'tensor_output_fifo_count_r != 0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are tensor_output_fifo_count_r: an integer count retained for control or measurable telemetry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 327: `m_axis_tdata = tensor_output_fifo_data_r[` This statement continues through source line 328; the explanation uses the complete expression rather than only the first visual fragment. This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to 'tensor_output_fifo_data_r[tensor_output_fifo_read_pointer_r]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are tensor_output_fifo_data_r: the payload carried with the surrounding valid/ready handshake; tensor_output_fifo_read_pointer_r: the value named 'tensor output fifo read pointer r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 328: `tensor_output_fifo_read_pointer_r];` This is continuation line 2 of the 2-line logical statement that begins at source line 327. Its exact fragment is 'tensor_output_fifo_read_pointer_r];'. The important operands are tensor_output_fifo_read_pointer_r: the value named 'tensor output fifo read pointer r' in this block. Read together, the complete operation is: This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to 'tensor_output_fifo_data_r[tensor_output_fifo_read_pointer_r]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are tensor_output_fifo_data_r: the payload carried with the surrounding

valid/ready handshake; tensor_output_fifo_read_pointer_r: the value named 'tensor output fifo read pointer r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 329: `m_axis_tlast = tensor_output_fifo_head_last;` This makes m_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'tensor_output_fifo_head_last'. It is driven by combinational or procedural logic in the current evaluation. The important operands are tensor_output_fifo_head_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 330: `tile_result_ready = state == ST_COMPUTE_OUTPUT` This statement continues through source line 331; the explanation uses the complete expression rather than only the first visual fragment. This makes tile_result_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_COMPUTE_OUTPUT && tile_result_ready_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_OUTPUT: the value named 'st compute output' in this block; tile_result_ready_r: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 331: `&& tile_result_ready_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 330. Its exact fragment is '&& tile_result_ready_r;'. The important operands are tile_result_ready_r: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This makes tile_result_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_COMPUTE_OUTPUT && tile_result_ready_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_OUTPUT: the value named 'st compute output' in this block; tile_result_ready_r: the consumer's statement that it can accept a payload this cycle. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 333: `activation_write_enable = state == ST_LOAD_ACTIVATIONS` This statement continues through source line 334; the explanation uses the complete expression rather than only the first visual fragment. This makes activation_write_enable, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'state == ST_LOAD_ACTIVATIONS && s_axis_tvalid && s_axis_tready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; s_axis_tvalid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 334: `&& s_axis_tvalid && s_axis_tready;` This is continuation line 2 of the 2-line logical statement that begins at source line 333. Its exact fragment is '&& s_axis_tvalid && s_axis_tready;'. The important operands are s_axis_tvalid: the producer's statement that its current payload is meaningful; s_axis_tready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This makes activation_write_enable, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'state == ST_LOAD_ACTIVATIONS && s_axis_tvalid && s_axis_tready'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation; s_axis_tvalid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 335: `activation_write_address = load_item_index[10:0];` This makes activation_write_address, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'load_item_index[10:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_item_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 336: `weight_write_enable = '0;` This makes weight_write_enable, a learned coefficient multiplied by an activation, equal to ''0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 337: `weight_write_address = 8'd0;` This makes weight_write_address, a learned coefficient multiplied by an activation, equal to '8'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 338: `weight_write_segment = {1'b0, load_segment_index_r[0]};` This makes weight_write_segment, a learned coefficient multiplied by an activation, equal to '{1'b0, load_segment_index_r[0]}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block; load_segment_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 339: `if (state == ST_LOAD_WEIGHTS_OUTER && s_axis_tvalid && s_axis_tready) begin` This condition selects the following hardware branch only when 'state == ST_LOAD_WEIGHTS_OUTER && s_axis_tvalid && s_axis_tready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation; s_axis_tvalid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 340: `weight_write_enable[load_item_index[2:0]] = 1'b1;` This makes weight_write_enable[load_item_index[2:0]], a learned coefficient multiplied by an activation, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 341: `weight_write_address = load_item_index[10:3];` This makes weight_write_address, a learned coefficient multiplied by an activation, equal to 'load_item_index[10:3]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_item_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 342: `end else if (state == ST_LOAD_WEIGHTS_DOT8 && s_axis_tvalid && s_axis_tready) begin` This condition selects the following hardware branch only when 'state == ST_LOAD_WEIGHTS_DOT8 && s_axis_tvalid && s_axis_tready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation; s_axis_tvalid: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 343: `weight_write_enable[load_segment_index_r[3:1]] = 1'b1;` This makes weight_write_enable[load_segment_inc a learned coefficient multiplied by an activation, equal to '1'b1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b1: the value named 'b1' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 344: `weight_write_address = load_item_index[7:0];` This makes weight_write_address, a learned coefficient multiplied by an activation, equal to 'load_item_index[7:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_item_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 345: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 347: `// A registered two-entry queue terminates tile READY before it can` Design intent: A registered two-entry queue terminates tile READY before it can This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 348: `// propagate through every BRAM-response stage. Deliberately refusing` Design intent: propagate through every BRAM-response stage. Deliberately refusing This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 349: `// a same-cycle push while full costs at most one recovery cycle and` Design intent: a same-cycle push while full costs at most one recovery cycle and This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 350: `// keeps the queue credit independent of downstream combinational logic.` Design intent: keeps the queue credit independent of downstream combinational logic. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 351: `issue_fifo_available = issue_fifo_count_r != 2;` This makes issue_fifo_available, the value named 'issue fifo available' in this block, equal to 'issue_fifo_count_r != 2'. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_fifo_count_r: an integer count retained for control or measurable telemetry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 352: `capture_stage_available = !capture_valid_r || issue_fifo_available;` This makes capture_stage_available the value named 'capture stage available' in this block, equal to '!capture_valid_r || issue_fifo_available'. It is driven by combinational or procedural logic in the current evaluation. The important operands are capture_valid_r: the producer's statement that its current payload is meaningful; issue_fifo_available: the value named 'issue fifo available' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 353: `memory_stage_available = !memory_valid_r || capture_stage_available;` This makes memory_stage_availab local FPGA storage addressed by surrounding index logic, equal to '!memory_valid_r || capture_stage_available'. It is driven by combinational or procedural logic in the current evaluation. The important operands are memory_valid_r: the producer's statement that its current payload is meaningful; capture_stage_available: the value named 'capture stage available' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 354: `read_stage_available = !read_valid_r || memory_stage_available;` This makes read_stage_available, the value named 'read stage available' in this block, equal to '!read_valid_r || memory_stage_available'. It is driven by combinational or procedural logic in the current evaluation. The important operands are read_valid_r: the producer's statement that its current payload is meaningful; memory_stage_available: local FPGA storage addressed by surrounding index logic. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 355: `map_stage_available = !map_valid_r || read_stage_available;` This makes map_stage_available, the value named 'map stage available' in this block, equal to '!map_valid_r || read_stage_available'. It is driven by combinational or procedural logic in the current evaluation. The important operands are map_valid_r: the producer's statement that its current payload is meaningful; read_stage_available: the value named 'read stage available' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 356: `index_stage_available = !index_valid_r || map_stage_available;` This makes index_stage_available, an integer selecting one tensor element, lane, bank, or state entry, equal to '!index_valid_r || map_stage_available'. It is driven by combinational or procedural logic in the current evaluation. The important operands are index_valid_r: the producer's statement that its current payload is meaningful; map_stage_available: the value named 'map stage available' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 357: `index_request_stage_available = !index_request_valid_r` This statement continues through source line 358; the explanation uses the complete expression rather than only the first visual fragment. This makes index_request_stage_available, an integer selecting one tensor element, lane, bank, or state entry, equal to '!index_request_valid_r || index_stage_available'. It is driven by combinational or procedural logic in the current evaluation. The important operands are index_request_valid_r: the producer's statement that its current payload is meaningful; index_stage_available:

an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 358: `|| index_stage_available;` This is continuation line 2 of the 2-line logical statement that begins at source line 357. Its exact fragment is '|| index_stage_available;'. The important operands are index_stage_available: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes index_request_stage_available, an integer selecting one tensor element, lane, bank, or state entry, equal to '!index_request_valid_r || index_stage_available'. It is driven by combinational or procedural logic in the current evaluation. The important operands are index_request_valid_r: the producer's statement that its current payload is meaningful; index_stage_available: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 359: `compute_read_request = state == ST_COMPUTE_RUN` This statement continues through source line 361; the explanation uses the complete expression rather than only the first visual fragment. This makes compute_read_request, the value named 'compute read request' in this block, equal to 'state == ST_COMPUTE_RUN && schedule_active_r && index_request_stage_available'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_RUN: the value named 'st compute run' in this block; schedule_active_r: the value named 'schedule active r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 360: `&& schedule_active_r` This is continuation line 2 of the 3-line logical statement that begins at source line 359. Its exact fragment is '&& schedule_active_r'. The important operands are schedule_active_r: the value named 'schedule active r' in this block. Read together, the complete operation is: This makes compute_read_request, the value named 'compute read request' in this block, equal to 'state == ST_COMPUTE_RUN && schedule_active_r && index_request_stage_available'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_RUN: the value named 'st compute run' in this block; schedule_active_r: the value named 'schedule active r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 361: `&& index_request_stage_available;` This is continuation line 3 of the 3-line logical statement that begins at source line 359. Its exact fragment is '&& index_request_stage_available;'. The important operands are index_request_stage_available: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes compute_read_request, the value named 'compute read request' in this block, equal to 'state == ST_COMPUTE_RUN && schedule_active_r && index_request_stage_available'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_RUN: the value named 'st compute run' in this block; schedule_active_r: the value named 'schedule active r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 362: `activation_read_address = mapped_index_r;` This makes activation_read_address, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'mapped_index_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are mapped_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 363: `weight_read_address = compute_mode_r == MODE_DENSE_DOT8` This statement continues through source line 364; the explanation uses the complete expression rather than only the first visual fragment. This makes weight_read_address, a learned coefficient multiplied by an activation, equal to 'compute_mode_r == MODE_DENSE_DOT8 ? mapped_index_r[7:0] : mapped_index_r[10:3]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are compute_mode_r: the value named 'compute mode r' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block; mapped_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 364: `? mapped_index_r[7:0] : mapped_index_r[10:3];` This is continuation line 2 of the 2-line logical statement that begins at source line 363. Its exact fragment is '? mapped_index_r[7:0] : mapped_index_r[10:3];'. The important operands are mapped_index_r: an integer selecting one tensor element, lane, bank, or state entry. Read

together, the complete operation is: This makes weight_read_address, a learned coefficient multiplied by an activation, equal to ‘compute_mode_r == MODE_DENSE_DOT8 ? mapped_index_r[7:0] : mapped_index_r[10:3]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are compute_mode_r: the value named ’compute mode r’ in this block; MODE_DENSE_DOT8: the value named ’mode dense dot8’ in this block; mapped_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 366: `tile_issue_valid = issue_fifo_count_r != 0;` This makes tile_issue_valid, the producer’s statement that its current payload is meaningful, equal to ‘issue_fifo_count_r != 0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_fifo_count_r: an integer count retained for control or measurable telemetry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 367: `tile_issue_last = issue_fifo_last_r[issue_fifo_read_pointer_r];` This makes tile_issue_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘issue_fifo_last_r[issue_fifo_read_pointer_r]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_fifo_last_r: the AXI-Stream marker for the final beat of a packet or command payload; issue_fifo_read_pointer_r: the value named ’issue fifo read pointer r’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 368: `tile_activation_vector =` This statement continues through source line 369; the explanation uses the complete expression rather than only the first visual fragment. This makes tile_activation_vector, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘issue_fifo_activation_r[issue_fifo_read_pointer_r]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_fifo_activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; issue_fifo_read_pointer_r: the value named ’issue fifo read pointer r’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 369: `issue_fifo_activation_r[issue_fifo_read_pointer_r];` This is continuation line 2 of the 2-line logical statement that begins at source line 368. Its exact fragment is ‘issue_fifo_activation_r[issue_fifo_read_pointer_r];‘. The important operands are issue_fifo_activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; issue_fifo_read_pointer_r: the value named ’issue fifo read pointer r’ in this block. Read together, the complete operation is: This makes tile_activation_vector, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘issue_fifo_activation_r[issue_fifo_read_pointer_r]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_fifo_activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; issue_fifo_read_pointer_r: the value named ’issue fifo read pointer r’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 370: `tile_outer_weight_vector =` This statement continues through source line 371; the explanation uses the complete expression rather than only the first visual fragment. This makes tile_outer_weight_vector, a learned coefficient multiplied by an activation, equal to ‘issue_fifo_outer_weights_r[issue_fifo_read_pointer_r]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_fifo_outer_weights_r: a learned coefficient multiplied by an activation; issue_fifo_read_pointer_r: the value named ’issue fifo read pointer r’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 371: `issue_fifo_outer_weights_r[issue_fifo_read_pointer_r];` This is continuation line 2 of the 2-line logical statement that begins at source line 370. Its exact fragment is ‘issue_fifo_outer_weights_r[issue_fifo_read_pointer_r];‘. The important operands are issue_fifo_outer_weights_r: a learned coefficient multiplied by an activation; issue_fifo_read_pointer_ the value named ’issue fifo read pointer r’ in this block. Read together, the complete operation is: This makes tile_outer_weight_vector, a learned coefficient multiplied by an activation, equal to ‘issue_fifo_outer_weights_r[issue_fifo_read_p It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_fifo_outer_weights_r: a learned coefficient multiplied by an activation; issue_fifo_read_pointer_r: the value named ’issue fifo read pointer r’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 372: `tile_dot_weight_vector =` This statement continues through source line 373; the explanation uses the complete expression rather than only the first visual fragment. This makes tile_dot_weight_vector, a learned coefficient

multiplied by an activation, equal to ‘issue_fifo_dot_weights_r[issue_fifo_read_pointer_r]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_fifo_dot_weights_r: a learned coefficient multiplied by an activation; issue_fifo_read_pointer_r: the value named ’issue fifo read pointer r’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 373: `issue_fifo_dot_weights_r[issue_fifo_read_pointer_r];` This is continuation line 2 of the 2-line logical statement that begins at source line 372. Its exact fragment is ‘issue_fifo_dot_weights_r[issue_fifo_read_pointer_r];‘. The important operands are issue_fifo_dot_weights_r: a learned coefficient multiplied by an activation; issue_fifo_read_pointer_r the value named ’issue fifo read pointer r’ in this block. Read together, the complete operation is: This makes tile_dot_weight_vector, a learned coefficient multiplied by an activation, equal to ‘issue_fifo_dot_weights_r[issue_fifo_read_poin It is driven by combinational or procedural logic in the current evaluation. The important operands are issue_fifo_dot_weights_r: a learned coefficient multiplied by an activation; issue_fifo_read_pointer_r: the value named ’issue fifo read pointer r’ in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 375: `tensor_output_fifo_count_next = tensor_output_fifo_count_r;` This makes tensor_output_fifo_count_next, the value named ’tensor output fifo count next’ in this block, equal to ‘tensor_output_fifo_count_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are tensor_output_fifo_count_r: an integer count retained for control or measurable telemetry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 376: `unique case ({tensor_output_fifo_push, tensor_output_fifo_pop})` This starts a multiplexer/state decode selected by ‘{tensor_output_fifo_push, tensor_output_fifo_pop}‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 377: `2’b10: tensor_output_fifo_count_next` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are b10: the value named ’b10’ in this block; tensor_output_fifo_count_next: the value named ’tensor output fifo count next’ in this block.

Line 378: `= tensor_output_fifo_count_r + 1’b1;` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tensor_output_fifo_count_r: an integer count retained for control or measurable telemetry; b1: the value named ’b1’ in this block.

Line 379: `2’b01: tensor_output_fifo_count_next` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are b01: the value named ’b01’ in this block; tensor_output_fifo_count_next: the value named ’tensor output fifo count next’ in this block.

Line 380: `= tensor_output_fifo_count_r - 1’b1;` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tensor_output_fifo_count_r: an integer count retained for control or measurable telemetry; b1: the value named ’b1’ in this block.

Line 381: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin end‘; context is the combinational process whose outputs respond without waiting for a clock edge.

Line 382: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 383: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 385: `// The FIFO owns the timing boundary independently of the command FSM. Its` Design intent: The FIFO owns the timing boundary independently of the command FSM. Its This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 386: `// READY register is derived from post-transfer occupancy, which permits a` Design intent: READY register is derived from post-transfer occupancy, which permits a This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 387: `// simultaneous dequeue/enqueue every clock and deasserts early enough to` Design intent: simultaneous dequeue/enqueue every clock and deasserts early enough to This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 388: `// reserve the second slot when the downstream interface stops.` Design intent: reserve the second slot when the downstream interface stops. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 389: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 390: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 391: `tile_result_ready_r <= 1'b0;` This makes tile_result_ready_r, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 392: `tensor_output_fifo_count_r <= 2'd0;` This makes tensor_output_fifo_count_r, an integer count retained for control or measurable telemetry, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 393: `tensor_output_fifo_write_pointer_r <= 1'b0;` This makes tensor_output_fifo_write_pointer_r, the value named 'tensor output fifo write pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 394: `tensor_output_fifo_read_pointer_r <= 1'b0;` This makes tensor_output_fifo_read_pointer_r, the value named 'tensor output fifo read pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 395: `for (int output_entry = 0; output_entry < 2; output_entry++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 396: `tensor_output_fifo_data_r[output_entry] <= 64'd0;` This makes tensor_output_fifo_data_r[output_entry], the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 397: `tensor_output_fifo_last_r[output_entry] <= 1'b0;` This makes tensor_output_fifo_last_r[output_entry], the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 398: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 399: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 400: `if (state == ST_COMPUTE_START) begin` This condition selects the following hardware branch only when 'state == ST_COMPUTE_START' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_START: the value named 'st compute start' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 401: `tensor_output_fifo_count_r <= 2'd0;` This makes tensor_output_fifo_count_r, an integer count retained for control or measurable telemetry, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 402: `tensor_output_fifo_write_pointer_r <= 1'b0;` This makes tensor_output_fifo_write_pointer_r, the value named 'tensor output fifo write pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 403: `tensor_output_fifo_read_pointer_r <= 1'b0;` This makes tensor_output_fifo_read_pointer_r, the value named 'tensor output fifo read pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 404: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 405: `tensor_output_fifo_count_r <= tensor_output_fifo_count_next;` This makes tensor_output_fifo_count_r, an integer count retained for control or measurable telemetry, equal to 'tensor_output_fifo_count_next'. It updates after the active clock edge together with other nonblocking assignments. The important operands are tensor_output_fifo_count_next: the value named 'tensor output fifo count next' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 406: `if (tensor_output_fifo_push) begin` This condition selects the following hardware branch only when 'tensor_output_fifo_push' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are tensor_output_fifo_push: the value named 'tensor output fifo push' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 407: `tensor_output_fifo_data_r[tensor_output_fifo_write_pointer_r]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tensor_output_fifo_data_r: the payload carried with the surrounding valid/ready handshake; tensor_output_fifo_write_pointer_r: the value named 'tensor output fifo write pointer r' in this block.

Line 408: `<= {5'd0, tile_result_last, tile_result_column,` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are d0: the value named 'd0' in this block; tile_result_last: the AXI-Stream marker for the final beat of a packet or command payload; tile_result_column: one output-feature position processed in parallel.

Line 409: `tile_result_row, tile_result_value};` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tile_result_row: one output-row position processed by the tensor tile; tile_result_value: the value named 'tile result value' in this block.

Line 410: `tensor_output_fifo_last_r[tensor_output_fifo_write_pointer_r]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tensor_output_fifo_last_r: the AXI-Stream marker for the final beat of a packet or command payload; tensor_output_fifo_write_pointer_r: the value named 'tensor output fifo write pointer r' in this block.

Line 411: `<= tile_result_last;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tile_result_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 412: `tensor_output_fifo_write_pointer_r` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tensor_output_fifo_write_pointer_r: the value named 'tensor output fifo write pointer r' in this block.

Line 413: `<= !tensor_output_fifo_write_pointer_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tensor_output_fifo_write_pointer_r: the value named 'tensor output fifo write pointer r' in this block.

Line 414: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 415: `if (tensor_output_fifo_pop) begin` This condition selects the following hardware branch only when 'tensor_output_fifo_pop' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are tensor_output_fifo_pop: the value named 'tensor output fifo pop' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 416: `tensor_output_fifo_read_pointer_r` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tensor_output_fifo_read_pointer_r: the value named 'tensor output fifo read pointer r' in this block.

Line 417: `<= !tensor_output_fifo_read_pointer_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tensor_output_fifo_read_pointer_r: the value named 'tensor output fifo read pointer r' in this block.

Line 418: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 419: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 421: `tile_result_ready_r <= (state == ST_COMPUTE_OUTPUT` This statement continues through source line 423; the explanation uses the complete expression rather than only the first visual fragment. This makes tile_result_ready_r, the consumer's statement that it can accept a payload this cycle, equal to '(state == ST_COMPUTE_OUTPUT && tensor_output_fifo_count_next != 2) || (state == ST_COMPUTE_RUN && tile_last_issue_accepted_r)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_OUTPUT: the value named 'st compute output' in this block; tensor_output_fifo_count_next: the value named 'tensor output fifo count next' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 422: `&& tensor_output_fifo_count_next != 2)` This is continuation line 2 of the 3-line logical statement that begins at source line 421. Its exact fragment is '&& tensor_output_fifo_count_next != 2)'. The important operands are tensor_output_fifo_count_next: the value named 'tensor output fifo count next' in this block. Read together, the complete operation is: This makes tile_result_ready_r, the consumer's statement that it can accept a payload this cycle, equal to '(state == ST_COMPUTE_OUTPUT && tensor_output_fifo_count_next != 2) || (state == ST_COMPUTE_RUN && tile_last_issue_accepted_r)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_OUTPUT: the value named 'st compute output' in this block; tensor_output_fifo_count_next: the value named 'tensor output fifo count next' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 423: `|| (state == ST_COMPUTE_RUN && tile_last_issue_accepted_r);` This is continuation line 3 of the 3-line logical statement that begins at source line 421. Its exact fragment is '|| (state == ST_COMPUTE_RUN && tile_last_issue_accepted_r);'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_RUN: the value named 'st compute run' in this block; tile_last_issue_accepted_r: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This makes tile_result_ready_r, the consumer's statement that it can accept a payload this cycle, equal to '(state == ST_COMPUTE_OUTPUT && tensor_output_fifo_count_next != 2) || (state == ST_COMPUTE_RUN && tile_last_issue_ac
It updates after the active clock edge together with other nonblocking assignments. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_OUTPUT: the value named 'st compute output' in this block; tensor_output_fifo_count_next: the value named 'tensor output fifo count next' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 424: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 425: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 427: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 428: `if (!rst_n) begin` This is the reset branch for ‘(!rst_n‘. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 429: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 430: `captured_command_r <= 42'd0;` This makes captured_command_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘42’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 431: `decoded_opcode_r <= 4'd0;` This makes decoded_opcode_r, the value named ’decoded opcode r’ in this block, equal to ‘4’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 432: `decoded_issue_count_r <= 12'd0;` This makes decoded_issue_count_r, an integer count retained for control or measurable telemetry, equal to ‘12’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 433: `decoded_outer_issue_error_r <= 1'b0;` This makes decoded_outer_issue_error_r, the value named ’decoded outer issue error r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 434: `decoded_dot8_issue_error_r <= 1'b0;` This makes decoded_dot8_issue_error_r, the value named ’decoded dot8 issue error r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 435: `command_done_pending_r <= 1'b0;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 436: `error_event_r <= 1'b0;` This makes error_event_r, the value named ’error event r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 437: `clear_error_r <= 1'b0;` This makes clear_error_r, the value named ’clear error r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 438: `if (state == ST_COMPUTE_RUN && tile_config_error) begin` This condition selects the following hardware branch only when ‘state == ST_COMPUTE_RUN && tile_config_error‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_RUN: the value named ’st compute run’ in this block; tile_config_error: the value named ’tile config error’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 439: `error_event_r <= 1'b1;` This makes error_event_r, the value named 'error event r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 440: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 441: `pending_load_opcode_r <= 4'd0;` This makes pending_load_opcode_r, the value named 'pending load opcode r' in this block, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 442: `pending_load_issue_count_r <= 12'd0;` This makes pending_load_issue_count_r, an integer count retained for control or measurable telemetry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 443: `pending_load_activation_zp_r <= 8'd0;` This makes pending_load_activation_zp_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 444: `command_done <= 1'b0;` This makes command_done, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 445: `status_error <= 1'b0;` This makes status_error, the value named 'status error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 446: `status_loaded_activations <= 12'd0;` This makes status_loaded_activations, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 447: `status_loaded_weights <= 12'd0;` This makes status_loaded_weights, a learned coefficient multiplied by an activation, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 448: `status_active_issues <= 12'd0;` This makes status_active_issues, the value named 'status active issues' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 449: `status_input_beats <= 32'd0;` This makes status_input_beats, the value named 'status input beats' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 450: `status_output_beats <= 32'd0;` This makes status_output_beats, the value named 'status output beats' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 451: `status_compute_cycles <= 32'd0;` This makes status_compute_cycles, the value named 'status compute cycles' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 452: `status_skipped_issues <= 32'd0;` This makes status_skipped_issues, the value named 'status skipped issues' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 453: `status_dense_macs <= 64'd0;` This makes status_dense_macs, a count of ordinary activation-times-weight operations actually issued, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 454: `status_spike_adds <= 64'd0;` This makes status_spike_adds, a binary event produced when a neuron crosses its threshold, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 455: `pending_dense_macs_low_r <= 24'd0;` This makes pending_dense_macs_low_r, a count of ordinary activation-times-weight operations actually issued, equal to '24'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 456: `pending_dense_macs_carry_r <= 1'b0;` This makes pending_dense_macs_carry_r, a count of ordinary activation-times-weight operations actually issued, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 457: `pending_spike_adds_low_r <= 24'd0;` This makes pending_spike_adds_low_r, a binary event produced when a neuron crosses its threshold, equal to '24'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 458: `pending_spike_adds_carry_r <= 1'b0;` This makes pending_spike_adds_carry_r, a binary event produced when a neuron crosses its threshold, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 459: `load_requested_issues <= 12'd0;` This makes load_requested_issues, the value named 'load requested issues' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 460: `load_beats_remaining_r <= 15'd0;` This makes load_beats_remaining_r, the value named 'load beats remaining r' in this block, equal to '15'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 461: `load_finish_pending_r <= 1'b0;` This makes load_finish_pending_r, the value named 'load finish pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 462: `load_segment_index_r <= 4'd0;` This makes load_segment_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 463: `load_item_index <= 12'd0;` This makes load_item_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 464: `load_activation_zero_point <= 8'd0;` This makes load_activation_zero_point, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 465: `weight_format_dot8 <= 1'b0;` This makes weight_format_dot8, a learned coefficient multiplied by an activation, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 466: `weight_commit_enable_r <= '0;` This makes weight_commit_enable_r, a learned coefficient multiplied by an activation, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 467: `weight_commit_address_r <= 8'd0;` This makes weight_commit_address_r, a learned coefficient multiplied by an activation, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 468: `weight_commit_segment_r <= 2'd0;` This makes weight_commit_segment_r, a learned coefficient multiplied by an activation, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 469: `weight_commit_data_r <= 64'd0;` This makes weight_commit_data_r, a learned coefficient multiplied by an activation, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 470: `activation_classify_valid_r <= 1'b0;` This makes activation_classify_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 471: `activation_classify_nonzero_r <= 1'b0;` This makes activation_classify_nonzero_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 472: `activation_classify_index_r <= 11'd0;` This makes activation_classify_index_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '11'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 473: `activation_load_success_r <= 1'b0;` This makes activation_load_success_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 474: `compute_mode_r <= MODE_DENSE_OUTER;` This makes compute_mode_r, the value named 'compute mode r' in this block, equal to 'MODE_DENSE_OUTER'. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_DENSE_OUTER: the value named 'mode dense outer' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 475: `compute_rows_r <= 4'd1;` This makes compute_rows_r, one output-row position processed by the tensor tile, equal to '4'd1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 476: `compute_columns_r <= 6'd1;` This makes compute_columns_r, one output-feature position processed in parallel, equal to '6'd1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 477: `compute_requested_issues <= 12'd0;` This makes compute_requested_issues, the value named 'compute requested issues' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 478: `compute_validation_error_r <= 1'b0;` This makes compute_validation_error_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 479: `compute_activation_zp_r <= 8'd0;` This makes compute_activation_zp_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 480: `compute_weight_zp_r <= 8'd0;` This makes compute_weight_zp_r, a learned coefficient multiplied by an activation, equal to '8'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 481: `schedule_pointer <= 12'd0;` This makes schedule_pointer, the value named 'schedule pointer' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 482: `schedule_remaining_r <= 12'd0;` This makes schedule_remaining_r, the value named 'schedule remaining r' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 483: `schedule_active_r <= 1'b0;` This makes schedule_active_r, the value named 'schedule active r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 484: `schedule_last_r <= 1'b0;` This makes schedule_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 485: `compute_empty_r <= 1'b0;` This makes compute_empty_r, the value named 'compute empty r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 486: `index_request_valid_r <= 1'b0;` This makes index_request_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 487: `index_request_last_r <= 1'b0;` This makes index_request_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 488: `index_request_address_r <= 11'd0;` This makes index_request_address_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '11'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 489: `index_valid_r <= 1'b0;` This makes index_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 490: `index_last_r <= 1'b0;` This makes index_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 491: `map_valid_r <= 1'b0;` This makes map_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 492: `map_last_r <= 1'b0;` This makes map_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 493: `mapped_index_r <= 11'd0;` This makes mapped_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '11'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 494: `read_valid_r <= 1'b0;` This makes read_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 495: `read_bank_select_r <= 3'd0;` This makes read_bank_select_r, the value named 'read bank select r' in this block, equal to ‘3'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 496: `read_last_r <= 1'b0;` This makes read_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 497: `memory_valid_r <= 1'b0;` This makes memory_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 498: `memory_bank_select_r <= 3'd0;` This makes memory_bank_select_r, local FPGA storage addressed by surrounding index logic, equal to ‘3'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 499: `memory_last_r <= 1'b0;` This makes memory_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 500: `capture_valid_r <= 1'b0;` This makes capture_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 501: `capture_last_r <= 1'b0;` This makes capture_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 502: `capture_activation_r <= 64'd0;` This makes capture_activation_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘64'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 503: `capture_outer_weights_r <= '0;` This makes capture_outer_weights_r, a learned coefficient multiplied by an activation, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 504: `capture_dot_weights_r <= '0;` This makes capture_dot_weights_r, a learned coefficient multiplied by an activation, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 505: `issue_fifo_count_r <= 2'd0;` This makes issue_fifo_count_r, an integer count retained for control or measurable telemetry, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 506: `issue_fifo_write_pointer_r <= 1'b0;` This makes issue_fifo_write_pointer_r, the value named 'issue fifo write pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 507: `issue_fifo_read_pointer_r <= 1'b0;` This makes issue_fifo_read_pointer_r, the value named 'issue fifo read pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 508: `tile_last_issue_accepted_r <= 1'b0;` This makes tile_last_issue_accepted_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 509: `for (int fifo_entry = 0; fifo_entry < 2; fifo_entry++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 510: `issue_fifo_last_r[fifo_entry] <= 1'b0;` This makes issue_fifo_last_r[fifo_entry], the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 511: `issue_fifo_activation_r[fifo_entry] <= 64'd0;` This makes issue_fifo_activation_r[fifo_entry], an input feature value consumed by a neuron or multiply-accumulate operation, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 512: `issue_fifo_outer_weights_r[fifo_entry] <= '0;` This makes issue_fifo_outer_weights_r[fifo_entry], a learned coefficient multiplied by an activation, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 513: `issue_fifo_dot_weights_r[fifo_entry] <= '0;` This makes issue_fifo_dot_weights_r[fifo_entry], a learned coefficient multiplied by an activation, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 514: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 515: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 516: `// Register the accepted write request before it reaches sixteen` Design intent: Register the accepted write request before it reaches sixteen This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 517: `// BRAM enable pins. This remains a one-beat-per-cycle pipeline:` Design intent: BRAM enable pins. This remains a one-beat-per-cycle pipeline: This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 518: `// the banks commit the prior request while this stage captures` Design intent: the banks commit the prior request while this stage captures This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 519: `// the next one.` Design intent: the next one. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 520: `weight_commit_enable_r <= weight_write_enable;` This makes weight_commit_enable_r, a learned coefficient multiplied by an activation, equal to ‘weight_write_enable‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_write_enable: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 521: `if (|weight_write_enable) begin` This condition selects the following hardware branch only when ‘|weight_write_enable‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are weight_write_enable: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 522: `weight_commit_address_r <= weight_write_address;` This makes weight_commit_address_r, a learned coefficient multiplied by an activation, equal to ‘weight_write_address‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_write_address: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 523: `weight_commit_segment_r <= weight_write_segment;` This makes weight_commit_segment_r, a learned coefficient multiplied by an activation, equal to ‘weight_write_segment‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_write_segment: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge.

Line 524: `weight_commit_data_r <= s_axis_tdata;` This makes weight_commit_data_r, a learned coefficient multiplied by an activation, equal to ‘s_axis_tdata‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named ’s axis tdata’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 525: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 526: `command_done <= command_done_pending_r;` This makes command_done, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘command_done_pending_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_done_pending_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge.

Line 527: `command_done_pending_r <= 1'b0;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 528: `if (clear_error_r) status_error <= 1'b0;` This condition selects the following hardware branch only when ‘clear_error_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are clear_error_r: the value named 'clear error r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 529: `else if (error_event_r) status_error <= 1'b1;` This condition selects the following hardware branch only when ‘error_event_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are error_event_r: the value named 'error event r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 530: `error_event_r <= 1'b0;` This makes error_event_r, the value named 'error event r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 531: `clear_error_r <= 1'b0;` This makes clear_error_r, the value named 'clear error r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 532: `activation_classify_valid_r <= 1'b0;` This makes activation_classify_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 533: `tile_last_issue_accepted_r <= tile_issue_valid` This statement continues through source line 534; the explanation uses the complete expression rather than only the first visual fragment. This makes tile_last_issue_accepted_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘tile_issue_valid && tile_issue_ready && tile_issue_last‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are tile_issue_valid: the producer's statement that its current payload is meaningful; tile_issue_ready: the consumer's statement that it can accept a payload this cycle; tile_issue_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 534: `&& tile_issue_ready && tile_issue_last;` This is continuation line 2 of the 2-line logical statement that begins at source line 533. Its exact fragment is ‘&& tile_issue_ready && tile_issue_last;‘. The important operands are tile_issue_ready: the consumer's statement that it can accept a payload this cycle; tile_issue_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This makes tile_last_issue_accepted_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘tile_issue_valid && tile_issue_ready && tile_issue_last‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are tile_issue_valid: the producer's statement that its current payload is meaningful; tile_issue_ready: the consumer's statement that it can accept a payload this cycle; tile_issue_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 536: `if (issue_fifo_push) begin` This condition selects the following hardware branch only when ‘issue_fifo_push‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are issue_fifo_push: the value named 'issue fifo push' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 537: `issue_fifo_last_r[issue_fifo_write_pointer_r] <= capture_last_r;` This makes issue_fifo_last_r[issue_fifo_ the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘capture_last_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are capture_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 538: `issue_fifo_activation_r[issue_fifo_write_pointer_r]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are issue_fifo_activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; issue_fifo_write_pointer_r: the value named 'issue fifo write pointer r' in this block.

Line 539: `<= capture_activation_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are capture_activation_r: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 540: `issue_fifo_outer_weights_r[issue_fifo_write_pointer_r]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are issue_fifo_outer_weights_r: a learned coefficient multiplied by an activation; issue_fifo_write_pointer_r: the value named 'issue fifo write pointer r' in this block.

Line 541: `<= capture_outer_weights_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are capture_outer_weights_r: a learned coefficient multiplied by an activation.

Line 542: `issue_fifo_dot_weights_r[issue_fifo_write_pointer_r]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are issue_fifo_dot_weights_r: a learned coefficient multiplied by an activation; issue_fifo_write_pointer_r: the value named 'issue fifo write pointer r' in this block.

Line 543: `<= capture_dot_weights_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are capture_dot_weights_r: a learned coefficient multiplied by an activation.

Line 544: `issue_fifo_write_pointer_r <= !issue_fifo_write_pointer_r;` This makes issue_fifo_write_pointer_r, the value named 'issue fifo write pointer r' in this block, equal to '!issue_fifo_write_pointer_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_fifo_write_pointer_r: the value named 'issue fifo write pointer r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 545: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 546: `if (issue_fifo_pop) begin` This condition selects the following hardware branch only when 'issue_fifo_pop' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are issue_fifo_pop: the value named 'issue fifo pop' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 547: `issue_fifo_read_pointer_r <= !issue_fifo_read_pointer_r;` This makes issue_fifo_read_pointer_r, the value named 'issue fifo read pointer r' in this block, equal to '!issue_fifo_read_pointer_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_fifo_read_pointer_r: the value named 'issue fifo read pointer r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 548: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 549: `unique case ({issue_fifo_push, issue_fifo_pop})` This starts a multiplexer/state decode selected by ‘{issue_fifo_push, issue_fifo_pop}‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 550: `2’b10: issue_fifo_count_r <= issue_fifo_count_r + 1’b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are b10: the value named ’b10’ in this block; issue_fifo_count_r: an integer count retained for control or measurable telemetry; b1: the value named ’b1’ in this block.

Line 551: `2’b01: issue_fifo_count_r <= issue_fifo_count_r - 1’b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are b01: the value named ’b01’ in this block; issue_fifo_count_r: an integer count retained for control or measurable telemetry; b1: the value named ’b1’ in this block.

Line 552: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin end‘; context is the clocked process that updates registers only on a rising clock edge.

Line 553: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 555: `if (activation_classify_valid_r && activation_classify_nonzero_r) begin` This condition selects the following hardware branch only when ‘activation_classify_valid_r && activation_classify_nonzero_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are activation_classify_valid_r: the producer’s statement that its current payload is meaningful; activation_classify_nonzero_r: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge.

Line 556: `status_active_issues <= status_active_issues + 1’b1;` This makes status_active_issues, the value named ’status active issues’ in this block, equal to ‘status_active_issues + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_active_issues: the value named ’status active issues’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 557: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 559: `if (state == ST_COMPUTE_START || state == ST_COMPUTE_RUN` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_START: the value named ’st compute start’ in this block; ST_COMPUTE_RUN: the value named ’st compute run’ in this block.

Line 560: `|| state == ST_COMPUTE_OUTPUT` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_OUTPUT: the value named ’st compute output’ in this block.

Line 561: `|| state == ST_COMPUTE_DRAIN) begin` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMPUTE_DRAIN: the value named 'st compute drain' in this block.

Line 562: `status_compute_cycles <= status_compute_cycles + 1'b1;` This makes status_compute_cycles, the value named 'status compute cycles' in this block, equal to 'status_compute_cycles + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_compute_cycles: the value named 'status compute cycles' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 563: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 564: `if (tensor_output_fifo_pop) begin` This condition selects the following hardware branch only when 'tensor_output_fifo_pop' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are tensor_output_fifo_pop: the value named 'tensor output fifo pop' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 565: `status_output_beats <= status_output_beats + 1'b1;` This makes status_output_beats, the value named 'status output beats' in this block, equal to 'status_output_beats + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_output_beats: the value named 'status output beats' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 566: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 568: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 569: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 570: `map_valid_r <= 1'b0;` This makes map_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 571: `read_valid_r <= 1'b0;` This makes read_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 572: `memory_valid_r <= 1'b0;` This makes memory_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 573: `issue_fifo_count_r <= 2'd0;` This makes issue_fifo_count_r, an integer count retained for control or measurable telemetry, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 574: `issue_fifo_write_pointer_r <= 1'b0;` This makes issue_fifo_write_pointer_r, the value named 'issue fifo write pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 575: `issue_fifo_read_pointer_r <= 1'b0;` This makes issue_fifo_read_pointer_r, the value named 'issue fifo read pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 576: `if (command_valid) begin` This condition selects the following hardware branch only when 'command_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are command_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 577: `captured_command_r <= command_data[41:0];` This makes captured_command_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'command_data[41:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are command_data: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 578: `state <= ST_PREDECODE_COMMAND;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_PREDECODE_COMMAND'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PREDECODE_COMMAND: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 579: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 580: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 582: `ST_PREDECODE_COMMAND: begin` This is the ST_PREDECODE_COMMAND case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_PREDECODE_COMMAND, the machine performs the named control phase..

Line 583: `decoded_opcode_r <= captured_command_r[3:0];` This makes decoded_opcode_r, the value named 'decoded opcode r' in this block, equal to 'captured_command_r[3:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREDECODE_COMMAND, the machine performs the named control phase..

Line 584: `decoded_issue_count_r <= captured_command_r[25:14];` This makes decoded_issue_count_r, an integer count retained for control or measurable telemetry, equal to ‘captured_command_r[25:14]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREDECODE_COMMAND, the machine performs the named control phase..

Line 585: `decoded_outer_issue_error_r <= captured_command_r[25:14] == 0` This statement continues through source line 586; the explanation uses the complete expression rather than only the first visual fragment. This makes decoded_outer_issue_error_r, the value named ’decoded outer issue error r’ in this block, equal to ‘captured_command_r[25:14] == 0 || captured_command_r[25:14] > 12’(MAX_OUTER_ISSUES)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; MAX_OUTER_ISSUES: the value named ’max outer issues’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREDECODE_COMMAND, the machine performs the named control phase..

Line 586: `|| captured_command_r[25:14] > 12’(MAX_OUTER_ISSUES);` This is continuation line 2 of the 2-line logical statement that begins at source line 585. Its exact fragment is ‘|| captured_command_r[25:14] > 12’(MAX_OUTER_ISSUES);‘. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; MAX_OUTER_ISSUES: the value named ’max outer issues’ in this block. Read together, the complete operation is: This makes decoded_outer_issue_error_r, the value named ’decoded outer issue error r’ in this block, equal to ‘captured_command_r[25:14] == 0 || captured_command_r[25:14] > 12’(MAX_OUTER_ISSUES)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; MAX_OUTER_ISSUES: the value named ’max outer issues’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREDECODE_COMMAND, the machine performs the named control phase..

Line 587: `decoded_dot8_issue_error_r <= captured_command_r[25:14] == 0` This statement continues through source line 588; the explanation uses the complete expression rather than only the first visual fragment. This makes decoded_dot8_issue_error_r, the value named ’decoded dot8 issue error r’ in this block, equal to ‘captured_command_r[25:14] == 0 || captured_command_r[25:14] > 12’(MAX_DOT8_ISSUES)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; MAX_DOT8_ISSUES: the value named ’max dot8 issues’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREDECODE_COMMAND, the machine performs the named control phase..

Line 588: `|| captured_command_r[25:14] > 12’(MAX_DOT8_ISSUES);` This is continuation line 2 of the 2-line logical statement that begins at source line 587. Its exact fragment is ‘|| captured_command_r[25:14] > 12’(MAX_DOT8_ISSUES);‘. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; MAX_DOT8_ISSUES: the value named ’max dot8 issues’ in this block. Read together, the complete operation is: This makes decoded_dot8_issue_error_r, the value named ’decoded dot8 issue error r’ in this block, equal to ‘captured_command_r[25:14] == 0 || captured_command_r[25:14] > 12’(MAX_DOT8_ISSUES)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; MAX_DOT8_ISSUES: the value named ’max dot8 issues’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREDECODE_COMMAND, the machine performs the named control phase..

Line 589: `state <= ST_DECODE_COMMAND;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_DECODE_COMMAND‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DECODE_COMMAND: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PREDECODE_COMMAND, the machine performs the named control phase..

Line 590: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PREDECODE_COMMAND, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 592: `ST_DECODE_COMMAND: begin` This is the ST_DECODE_COMMAND case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_DECODE_COMMAND, the machine performs the named control phase..

Line 593: `// Default back to idle for immediate commands and rejected` Design intent: Default back to idle for immediate commands and rejected This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 594: `// requests. Valid streaming/compute commands override this.` Design intent: requests. Valid streaming/compute commands override this. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 595: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECODE_COMMAND, the machine performs the named control phase..

Line 596: `begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DECODE_COMMAND, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 597: `logic [3:0] opcode;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_DECODE_COMMAND, the machine performs the named control phase.. Specifically, opcode is the value named ’opcode’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 598: `logic [11:0] issue_count;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_DECODE_COMMAND, the machine performs the named control phase.. Specifically, issue_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 599: `opcode = decoded_opcode_r;` This makes opcode, the value named ’opcode’ in this block, equal to ‘decoded_opcode_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are decoded_opcode_r: the value named ’decoded opcode r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECODE_COMMAND, the machine performs the named control phase..

Line 600: `issue_count = decoded_issue_count_r;` This makes issue_count, an integer count retained for control or measurable telemetry, equal to ‘decoded_issue_count_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are decoded_issue_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_DECODE_COMMAND, the machine performs the named control phase..

Line 602: `unique case (opcode)` This starts a multiplexer/state decode selected by ‘opcode‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 603: `CMD_LOAD_ACTIVATIONS: begin` This is the CMD_LOAD_ACTIVATIONS case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 604: `if (decoded_outer_issue_error_r) begin` This condition selects the following hardware branch only when ‘decoded_outer_issue_error_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are decoded_outer_issue_error_r: the value named ’decoded outer issue error r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 605: `error_event_r <= 1'b1;` This makes error_event_r, the value named ’error event r’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 606: `status_loaded_activations <= 12'd0;` This makes status_loaded_activations, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘12’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 607: `status_active_issues <= 12'd0;` This makes status_active_issues, the value named ’status active issues’ in this block, equal to ‘12’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 608: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 609: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 610: `pending_load_opcode_r <= opcode;` This makes pending_load_opcode_r, the value named ’pending load opcode r’ in this block, equal to ‘opcode‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are opcode: the value named ’opcode’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 611: `pending_load_issue_count_r <= issue_count;` This makes pending_load_issue_count_r, an integer count retained for control or measurable telemetry, equal to ‘issue_count‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 612: `pending_load_activation_zp_r` Within the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are pending_load_activation_zp_r: an input feature value consumed by a neuron or multiply-accumulate operation.

Line 613: `<= captured_command_r[33:26];` Within the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions,

schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 614: `state <= ST_LOAD_CONFIG;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LOAD_CONFIG‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_CONFIG: the value named ’st load config’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 615: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 616: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 618: `CMD_LOAD_WEIGHTS_OUTER: begin` This is the CMD_LOAD_WEIGHTS_OUTER case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 619: `if (decoded_outer_issue_error_r) begin` This condition selects the following hardware branch only when ‘decoded_outer_issue_error_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are decoded_outer_issue_error_r: the value named ’decoded outer issue error r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 620: `error_event_r <= 1’b1;` This makes error_event_r, the value named ’error event r’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 621: `status_loaded_weights <= 12’d0;` This makes status_loaded_weights, a learned coefficient multiplied by an activation, equal to ‘12’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 622: `command_done_pending_r <= 1’b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 623: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 624: `pending_load_opcode_r <= opcode;` This makes pending_load_opcode_r, the value named ’pending load opcode r’ in this block, equal to ‘opcode‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are opcode: the value named ’opcode’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 625: `pending_load_issue_count_r <= issue_count;` This makes pending_load_issue_count_r, an integer count retained for control or measurable telemetry, equal to ‘issue_count‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 626: `state <= ST_LOAD_CONFIG;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LOAD_CONFIG‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_CONFIG: the value named ’st load config’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 627: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 628: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 630: `CMD_LOAD_WEIGHTS_DOT8: begin` This is the CMD_LOAD_WEIGHTS_DOT8 case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 631: `if (decoded_dot8_issue_error_r) begin` This condition selects the following hardware branch only when ‘decoded_dot8_issue_error_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are decoded_dot8_issue_error_r: the value named ’decoded dot8 issue error r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 632: `error_event_r <= 1’b1;` This makes error_event_r, the value named ’error event r’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 633: `status_loaded_weights <= 12’d0;` This makes status_loaded_weights, a learned coefficient multiplied by an activation, equal to ‘12’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 634: `command_done_pending_r <= 1’b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 635: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 636: `pending_load_opcode_r <= opcode;` This makes pending_load_opcode_r, the value named 'pending load opcode r' in this block, equal to 'opcode'. It updates after the active clock edge together with other nonblocking assignments. The important operands are opcode: the value named 'opcode' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 637: `pending_load_issue_count_r <= issue_count;` This makes pending_load_issue_count_r, an integer count retained for control or measurable telemetry, equal to 'issue_count'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 638: `state <= ST_LOAD_CONFIG;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LOAD_CONFIG'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_CONFIG: the value named 'st load config' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 639: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 640: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 642: `CMD_COMPUTE_DENSE_OUTER,` Within the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are CMD_COMPUTE_DENSE_OUTER: the value named 'cmd compute dense outer' in this block.

Line 643: `CMD_COMPUTE_DENSE_DOT8,` Within the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are CMD_COMPUTE_DENSE_DOT8: the value named 'cmd compute dense dot8' in this block.

Line 644: `CMD_COMPUTE_BINARY,` Within the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are CMD_COMPUTE_BINARY: the value named 'cmd compute binary' in this block.

Line 645: `CMD_COMPUTE_TERNARY: begin` This is the CMD_COMPUTE_TERNARY case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_TERNARY, the machine issues arithmetic work using values already held on chip..

Line 646: `unique case (opcode)` This starts a multiplexer/state decode selected by 'opcode'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 647: `CMD_COMPUTE_DENSE_OUTER:` This is the CMD_COMPUTE_DENSE_OUTER case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with "; context is the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_DENSE_OUTER, the machine issues arithmetic work using values already held on chip..

Line 648: `compute_mode_r <= MODE_DENSE_OUTER;` This makes compute_mode_r, the value named 'compute mode r' in this block, equal to 'MODE_DENSE_OUTER'. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_DENSE_OUTER: the value named 'mode dense outer' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_DENSE_OU the machine issues arithmetic work using values already held on chip..

Line 649: `CMD_COMPUTE_DENSE_DOT8:` This is the CMD_COMPUTE_DENSE_DOT8 case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with "; context is the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_DENSE_DOT8, the machine issues arithmetic work using values already held on chip..

Line 650: `compute_mode_r <= MODE_DENSE_DOT8;` This makes compute_mode_r, the value named 'compute mode r' in this block, equal to 'MODE_DENSE_DOT8'. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_DENSE_DOT8, the machine issues arithmetic work using values already held on chip..

Line 651: `CMD_COMPUTE_BINARY:` This is the CMD_COMPUTE_BINARY case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with "; context is the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_BINARY, the machine issues arithmetic work using values already held on chip..

Line 652: `compute_mode_r <= MODE_BINARY_WEIGHTED;` This makes compute_mode_r, the value named 'compute mode r' in this block, equal to 'MODE_BINARY_WEIGHTED'. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_BINARY_WEIGHTED: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_BINARY, the machine issues arithmetic work using values already held on chip..

Line 653: `default: compute_mode_r <= MODE_TERNARY_WEIGHTED;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'compute_mode_r <= MODE_TERNARY_WEIGHTED;'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_BINARY, the machine issues arithmetic work using values already held on chip..

Line 654: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_COMPUTE_BINARY, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 655: `compute_rows_r <= captured_command_r[7:4];` This makes compute_rows_r, one output-row position processed by the tensor tile, equal to 'captured_command_r[7:4]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge.

Line 656: `compute_columns_r <= captured_command_r[13:8];` This makes compute_columns_r, one output-feature position processed in parallel, equal to 'captured_command_r[13:8]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge.

Line 657: `compute_requested_issues <= issue_count;` This makes compute_requested_issues, the value named 'compute requested issues' in this block, equal to 'issue_count'. It updates after the active clock edge together with other nonblocking assignments. The important operands are issue_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge.

Line 658: `compute_activation_zp_r <= captured_command_r[33:26];` This makes compute_activation_zp_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'captured_command_r[33:26]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge.

Line 659: `compute_weight_zp_r <= captured_command_r[41:34];` This makes compute_weight_zp_r, a learned coefficient multiplied by an activation, equal to 'captured_command_r[41:34]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are captured_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge.

Line 660: `state <= ST_COMPUTE_VALIDATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_COMPUTE_VALIDATE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMPUTE_VALIDATE: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge.

Line 661: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 663: `CMD_CLEAR_STATUS: begin` This is the CMD_CLEAR_STATUS case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 664: `clear_error_r <= 1'b1;` This makes clear_error_r, the value named 'clear error r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 665: `status_input_beats <= 32'd0;` This makes status_input_beats, the value named 'status input beats' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 666: `status_output_beats <= 32'd0;` This makes status_output_beats, the value named 'status output beats' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 667: `status_compute_cycles <= 32'd0;` This makes status_compute_cycles, the value named 'status compute cycles' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 668: `status_skipped_issues <= 32'd0;` This makes status_skipped_issues, the value named 'status skipped issues' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 669: `status_dense_macs <= 64'd0;` This makes status_dense_macs, a count of ordinary activation-times-weight operations actually issued, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 670: `status_spike_adds <= 64'd0;` This makes status_spike_adds, a binary event produced when a neuron crosses its threshold, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 671: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 672: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 674: `default: begin` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 675: `error_event_r <= 1'b1;` This makes error_event_r, the value named 'error event r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 676: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase..

Line 677: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 678: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_CLEAR_STATUS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 679: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 680: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 682: `ST_LOAD_CONFIG: begin` This is the ST_LOAD_CONFIG case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_CONFIG, the machine stores incoming operands into local FPGA memory..

Line 683: `load_requested_issues <= pending_load_issue_count_r;` This makes load_requested_issues, the value named 'load requested issues' in this block, equal to 'pending_load_issue_count_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are pending_load_issue_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_CONFIG, the machine stores incoming operands into local FPGA memory..

Line 684: `load_segment_index_r <= 4'd0;` This makes load_segment_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_CONFIG, the machine stores incoming operands into local FPGA memory..

Line 685: `load_item_index <= 12'd0;` This makes load_item_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_CONFIG, the machine stores incoming operands into local FPGA memory..

Line 686: `load_finish_pending_r <= 1'b0;` This makes load_finish_pending_r, the value named 'load finish pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_CONFIG, the machine stores incoming operands into local FPGA memory..

Line 687: `unique case (pending_load_opcode_r)` This starts a multiplexer/state decode selected by 'pending_load_opcode_r 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 688: `CMD_LOAD_ACTIVATIONS: begin` This is the CMD_LOAD_ACTIVATIONS case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 689: `load_beats_remaining_r <=` This statement continues through source line 690; the explanation uses the complete expression rather than only the first visual fragment. This makes load_beats_remaining_r, the value named 'load beats remaining r' in this block, equal to '{3'd0, pending_load_issue_count_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; pending_load_issue_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 690: `{3'd0, pending_load_issue_count_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 689. Its exact fragment is '{3'd0, pending_load_issue_count_r};'. The important operands are d0: the value named 'd0' in this block; pending_load_issue_count_r: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This makes load_beats_remaining_r, the value named 'load beats remaining r' in this block, equal to '{3'd0, pending_load_issue_count_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; pending_load_issue_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 691: `load_activation_zero_point <= pending_load_activation_zp_r;` This makes load_activation_zero_point, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'pending_load_activation_zp_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are pending_load_activation_zp_r: an input feature value consumed by a neuron or multiply-accumulate operation. Context:

the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 692: `activation_load_success_r <= 1'b0;` This makes activation_load_success_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 693: `status_active_issues <= 12'd0;` This makes status_active_issues, the value named 'status active issues' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 694: `state <= ST_LOAD_ACTIVATIONS;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LOAD_ACTIVATIONS'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_ACTIVATIONS: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 695: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 696: `CMD_LOAD_WEIGHTS_OUTER: begin` This is the CMD_LOAD_WEIGHTS_OUTER case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 697: `load_beats_remaining_r <=` This statement continues through source line 698; the explanation uses the complete expression rather than only the first visual fragment. This makes load_beats_remaining_r, the value named 'load beats remaining r' in this block, equal to '{2'd0, pending_load_issue_count_r, 1'b0}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; pending_load_issue_count_r: an integer count retained for control or measurable telemetry; b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 698: `{2'd0, pending_load_issue_count_r, 1'b0};` This is continuation line 2 of the 2-line logical statement that begins at source line 697. Its exact fragment is '{2'd0, pending_load_issue_count_r, 1'b0};'. The important operands are d0: the value named 'd0' in this block; pending_load_issue_count_r: an integer count retained for control or measurable telemetry; b0: the value named 'b0' in this block. Read together, the complete operation is: This makes load_beats_remaining_r, the value named 'load beats remaining r' in this block, equal to '{2'd0, pending_load_issue_count_r, 1'b0}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; pending_load_issue_count_r: an integer count retained for control or measurable telemetry; b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 699: `weight_format_dot8 <= 1'b0;` This makes weight_format_dot8, a learned coefficient multiplied by an activation, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 700: `state <= ST_LOAD_WEIGHTS_OUTER;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LOAD_WEIGHTS_OUTER‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_WEIGHTS_OUTER: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 701: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 702: `default: begin` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 703: `load_beats_remaining_r <=` This statement continues through source line 704; the explanation uses the complete expression rather than only the first visual fragment. This makes load_beats_remaining_r, the value named ’load beats remaining r’ in this block, equal to ‘{2’d0, pending_load_issue_count_r[8:0], 4’d0}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block; pending_load_issue_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 704: `{2’d0, pending_load_issue_count_r[8:0], 4’d0};` This is continuation line 2 of the 2-line logical statement that begins at source line 703. Its exact fragment is ‘{2’d0, pending_load_issue_count_r[8:0], 4’d0};‘. The important operands are d0: the value named ’d0’ in this block; pending_load_issue_count_r: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This makes load_beats_remaining_r, the value named ’load beats remaining r’ in this block, equal to ‘{2’d0, pending_load_issue_count_r[8:0], 4’d0}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block; pending_load_issue_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 705: `weight_format_dot8 <= 1’b1;` This makes weight_format_dot8, a learned coefficient multiplied by an activation, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 706: `state <= ST_LOAD_WEIGHTS_DOT8;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LOAD_WEIGHTS_DOT8‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_WEIGHTS_DOT8: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 707: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 708: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state CMD_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 709: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 711: `ST_COMPUTE_CONFIG: begin` This is the ST_COMPUTE_CONFIG case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip..

Line 712: `compute_empty_r <= (status_active_issues == 0);` This makes compute_empty_r, the value named 'compute empty r' in this block, equal to ‘(status_active_issues == 0)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_active_issues: the value named 'status active issues' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip..

Line 713: `schedule_remaining_r <= status_active_issues == 0` This statement continues through source line 714; the explanation uses the complete expression rather than only the first visual fragment. This makes schedule_remaining_r, the value named 'schedule remaining r' in this block, equal to ‘status_active_issues == 0 ? 12'd1 : status_active_issues‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_active_issues: the value named 'status active issues' in this block; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip..

Line 714: `? 12'd1 : status_active_issues;` This is continuation line 2 of the 2-line logical statement that begins at source line 713. Its exact fragment is ‘? 12'd1 : status_active_issues;‘. The important operands are d1: the value named 'd1' in this block; status_active_issues: the value named 'status active issues' in this block. Read together, the complete operation is: This makes schedule_remaining_r, the value named 'schedule remaining r' in this block, equal to ‘status_active_issues == 0 ? 12'd1 : status_active_issues‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_active_issues: the value named 'status active issues' in this block; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip..

Line 715: `schedule_active_r <= 1'b1;` This makes schedule_active_r, the value named 'schedule active r' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip..

Line 716: `schedule_last_r <= status_active_issues <= 1;` This makes schedule_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘status_active_issues <= 1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_active_issues: the value named 'status active issues' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip..

Line 717: `schedule_pointer <= 12'd0;` This makes schedule_pointer, the value named 'schedule pointer' in this block, equal to ‘12'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip..

Line 718: `status_compute_cycles <= 32'd0;` This makes status_compute_cycles, the value named 'status compute cycles' in this block, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip..

Line 719: `status_output_beats <= 32'd0;` This makes status_output_beats, the value named 'status output beats' in this block, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The

important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip..

Line 720: `state <= ST_COMPUTE_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_COMPUTE_START'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMPUTE_START: the value named 'st compute start' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip..

Line 721: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_CONFIG, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 723: `ST_COMPUTE_VALIDATE: begin` This is the ST_COMPUTE_VALIDATE case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATE, the machine issues arithmetic work using values already held on chip..

Line 724: `// End the multi-field legality predicate at one local` Design intent: End the multi-field legality predicate at one local This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 725: `// register instead of placing it on every parameter mux.` Design intent: register instead of placing it on every parameter mux. This comment anchors the surrounding logic in the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

Line 726: `compute_validation_error_r <= compute_requested_issues == 0` This statement continues through source line 736; the explanation uses the complete expression rather than only the first visual fragment. This makes compute_validation_error_r, the producer's statement that its current payload is meaningful, equal to 'compute_requested_issues == 0 || compute_rows_r == 0 || compute_rows_r > 8 || compute_columns_r == 0 || compute_columns_r > 6'(COLUMN_LANES) || (compute_mode_r == MODE_DENSE_DOT8 && compute_rows_r != 1) || compute_requested_issues != status_loaded_activations || compute_requested_issues != status_loaded_weights || (compute_mode_r == MODE_DENSE_
!= weight_format_dot8'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_requested_issues: the value named 'compute requested issues' in this block; compute_rows_r: one output-row position processed by the tensor tile; compute_columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATE, the machine issues arithmetic work using values already held on chip..

Line 727: `|| compute_rows_r == 0` This is continuation line 2 of the 11-line logical statement that begins at source line 726. Its exact fragment is '|| compute_rows_r == 0'. The important operands are compute_rows_r: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes compute_validation_error_r, the producer's statement that its current payload is meaningful, equal to 'compute_requested_issues == 0 || compute_rows_r == 0 || compute_rows_r > 8 || compute_columns_r == 0 || compute_columns_r > 6'(COLUMN_LANES) || (compute_mode_r == MODE_DENSE_DOT8 && compute_rows_r != 1) || compute_requested_issues != status_loaded_activations || compute_requested_issues != status_loaded_weights || (compute_mode_r == MODE_DENSE_DOT8
!= weight_format_dot8'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_requested_issues: the value named 'compute requested issues' in this block; compute_rows_r: one output-row position processed by the tensor tile; compute_columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATE, the machine issues arithmetic work using values already held on chip..

Line 728: `|| compute_rows_r > 8` This is continuation line 3 of the 11-line logical statement that begins at source line 726. Its exact fragment is '|| compute_rows_r > 8'. The important operands are compute_rows_r: one output-row position processed by the tensor tile. Read together, the complete operation is: This makes compute_validation_error_r, the producer's statement that its current payload is meaningful, equal to 'compute_requested_issues == 0 || compute_rows_r == 0 || compute_rows_r > 8 || compute_columns_r == 0 || compute_columns_r > 6'(COLUMN_LANES) || (compute_mode_r == MODE_DENSE_DOT8 && compute_rows_r != 1) || compute_requested_issues != status_loaded_activations || compute_requested_issues != status_loaded_weights || (compute_mode_r == MODE_DENSE_DOT8 != weight_format_dot8'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_requested_issues: the value named 'compute requested issues' in this block; compute_rows_r: one output-row position processed by the tensor tile; compute_columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATE, the machine issues arithmetic work using values already held on chip..

Line 729: `|| compute_columns_r == 0` This is continuation line 4 of the 11-line logical statement that begins at source line 726. Its exact fragment is '|| compute_columns_r == 0'. The important operands are compute_columns_r: one output-feature position processed in parallel. Read together, the complete operation is: This makes compute_validation_error_r, the producer's statement that its current payload is meaningful, equal to 'compute_requested_issues == 0 || compute_rows_r == 0 || compute_rows_r > 8 || compute_columns_r == 0 || compute_columns_r > 6'(COLUMN_LANES) || (compute_mode_r == MODE_DENSE_DOT8 && compute_rows_r != 1) || compute_requested_issues != status_loaded_activations || compute_requested_issues != status_loaded_weights || (compute_mode_r == MODE_DENSE_DOT8 != weight_format_dot8'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_requested_issues: the value named 'compute requested issues' in this block; compute_rows_r: one output-row position processed by the tensor tile; compute_columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATE, the machine issues arithmetic work using values already held on chip..

Line 730: `|| compute_columns_r > 6'(COLUMN_LANES)` This is continuation line 5 of the 11-line logical statement that begins at source line 726. Its exact fragment is '|| compute_columns_r > 6'(COLUMN_LANES)'. The important operands are compute_columns_r: one output-feature position processed in parallel; COLUMN_LANES: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes compute_validation_error_r, the producer's statement that its current payload is meaningful, equal to 'compute_requested_issues == 0 || compute_rows_r == 0 || compute_rows_r > 8 || compute_columns_r == 0 || compute_columns_r > 6'(COLUMN_LANES) || (compute_mode_r == MODE_DENSE_DOT8 && compute_rows_r != 1) || compute_requested_issues != status_loaded_activations || compute_requested_issues != status_loaded_weights || (compute_mode_r == MODE_DENSE_DOT8) != weight_format_dot8'. It updates after the active clock edge together with other nonblocking assignments. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATE, the machine issues arithmetic work using values already held on chip..

Line 735: `|| (compute_mode_r == MODE_DENSE_DOT8)` This is continuation line 10 of the 11-line logical statement that begins at source line 726. Its exact fragment is '|| (compute_mode_r == MODE_DENSE_DOT8)'. The important operands are compute_mode_r: the value named 'compute mode r' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Read together, the complete operation is: This makes compute_validation_error_r, the producer's statement that its current payload is meaningful, equal to 'compute_requested_issues == 0 || compute_rows_r == 0 || compute_rows_r > 8 || compute_columns_r == 0 || compute_columns_r > 6'(COLUMN_LANES) || (compute_mode_r == MODE_DENSE_DOT8 && compute_rows_r != 1) || compute_requested_issues != status_loaded_activations || compute_requested_issues != status_loaded_weights || (compute_mode_r == MODE_DENSE_DOT8 != weight_format_dot8'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_requested_issues: the value named 'compute requested issues' in this block; compute_rows_r: one output-row position processed by the tensor tile; compute_columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATE, the machine issues arithmetic work using values already held on chip..

Line 736: `!= weight_format_dot8;` This is continuation line 11 of the 11-line logical statement that begins at source line 726. Its exact fragment is '!= weight_format_dot8;'. The important operands are weight_format_dot8: a learned co-

efficient multiplied by an activation. Read together, the complete operation is: This makes compute_validation_error_r, the producer's statement that its current payload is meaningful, equal to 'compute_requested_issues == 0 || compute_rows_r == 0 || compute_rows_r > 8 || compute_columns_r == 0 || compute_columns_r > 6'(COLUMN_LANES) || (compute_mode_r == MODE_DENSE_DOT8 && compute_rows_r != 1) || compute_requested_issues != status_loaded_activations || compute_requested_issues != status_loaded_weights || (compute_mode_r == MODE_DENSE_DOT8 != weight_format_dot8'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_requested_issues: the value named 'compute requested issues' in this block; compute_rows_r: one output-row position processed by the tensor tile; compute_columns_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATE, the machine issues arithmetic work using values already held on chip..

Line 737: `state <= ST_COMPUTE_VALIDATED;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_COMPUTE_VALIDATED'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMPUTE_VALIDATED: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATE, the machine issues arithmetic work using values already held on chip..

Line 738: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATE, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 740: `ST_COMPUTE_VALIDATED: begin` This is the ST_COMPUTE_VALIDATED case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATED, the machine issues arithmetic work using values already held on chip..

Line 741: `if (compute_validation_error_r) begin` This condition selects the following hardware branch only when 'compute_validation_error_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are compute_validation_error_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATED, the machine issues arithmetic work using values already held on chip..

Line 742: `error_event_r <= 1'b1;` This makes error_event_r, the value named 'error event r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATED, the machine issues arithmetic work using values already held on chip..

Line 743: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATED, the machine issues arithmetic work using values already held on chip..

Line 744: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATED, the machine issues arithmetic work using values already held on chip..

Line 745: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATED, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 746: `state <= ST_COMPUTE_CONFIG;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_COMPUTE_CONFIG‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMPUTE_CONFIG: the value named ’st compute config’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATED, the machine issues arithmetic work using values already held on chip..

Line 747: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATED, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 748: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_VALIDATED, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 750: `ST_LOAD_ACTIVATIONS: begin` This is the ST_LOAD_ACTIVATIONS case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 751: `if (load_finish_pending_r) begin` This condition selects the following hardware branch only when ‘load_finish_pending_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_finish_pending_r: the value named ’load finish pending r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 752: `load_finish_pending_r <= 1’b0;` This makes load_finish_pending_r, the value named ’load finish pending r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 753: `state <= ST_LOAD_ACTIVATION_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LOAD_ACTIVATION_DRAIN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_ACTIVATION_DRAIN: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 754: `end else if (s_axis_tvalid && s_axis_tready) begin` This condition selects the following hardware branch only when ‘s_axis_tvalid && s_axis_tready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tvalid: the producer’s statement that its current payload is meaningful; s_axis_tready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 755: `logic beat_is_last;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory.. Specifically, beat_is_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 756: `logic byte_vector_is_zero;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory.. Specifically, byte_vector_is_zero is the value named ’byte vector is zero’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 757: `beat_is_last = load_beats_remaining_r == 15'd1;` This makes beat_is_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘load_beats_remaining_r == 15'd1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_beats_remaining_r: the value named 'load beats remaining r' in this block; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 758: `byte_vector_is_zero = all_bytes_equal64(` This statement continues through source line 759; the explanation uses the complete expression rather than only the first visual fragment. This makes byte_vector_is_zero, the value named 'byte vector is zero' in this block, equal to ‘all_bytes_equal64(s_axis_tdata, load_activation_zero_point)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are all_bytes_equal64: the value named 'all bytes equal64' in this block; s_axis_tdata: the value named 's axis tdata' in this block; load_activation_zero_po an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 759: `s_axis_tdata, load_activation_zero_point);` This is continuation line 2 of the 2-line logical statement that begins at source line 758. Its exact fragment is ‘s_axis_tdata, load_activation_zero_point);‘. The important operands are s_axis_tdata: the value named 's axis tdata' in this block; load_activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Read together, the complete operation is: This makes byte_vector_is_zero, the value named 'byte vector is zero' in this block, equal to ‘all_bytes_equal64(s_axis_tdata, load_activation_zero_point)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are all_bytes_equal64: the value named 'all bytes equal64' in this block; s_axis_tdata: the value named 's axis tdata' in this block; load_activation_zero_point: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 760: `activation_classify_valid_r <= 1'b1;` This makes activation_classify_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 761: `activation_classify_nonzero_r <= !byte_vector_is_zero;` This makes activation_classify_nonzero_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘!byte_vector_is_zero‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are byte_vector_is_zero: the value named 'byte vector is zero' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 762: `activation_classify_index_r <= load_item_index[10:0];` This makes activation_classify_index_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘load_item_index[10:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_item_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 763: `status_input_beats <= status_input_beats + 1'b1;` This makes status_input_beats, the value named 'status input beats' in this block, equal to ‘status_input_beats + 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_input_beats: the value named 'status input beats' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 764: `load_beats_remaining_r <= load_beats_remaining_r - 1'b1;` This makes load_beats_remaining_r, the value named 'load beats remaining r' in this block, equal to ‘load_beats_remaining_r - 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_beats_remaining_r:

the value named 'load beats remaining r' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 765: `load_item_index <= load_item_index + 1'b1;` This makes load_item_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'load_item_index + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_item_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 766: `status_loaded_activations <= beat_is_last` This statement continues through source line 767; the explanation uses the complete expression rather than only the first visual fragment. This makes status_loaded_activations, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'beat_is_last ? load_requested_issues : 12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are beat_is_last: the AXI-Stream marker for the final beat of a packet or command payload; load_requested_issues: the value named 'load requested issues' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 767: `? load_requested_issues : 12'd0;` This is continuation line 2 of the 2-line logical statement that begins at source line 766. Its exact fragment is '? load_requested_issues : 12'd0;'. The important operands are load_requested_issues: the value named 'load requested issues' in this block; d0: the value named 'd0' in this block. Read together, the complete operation is: This makes status_loaded_activations, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'beat_is_last ? load_requested_issues : 12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are beat_is_last: the AXI-Stream marker for the final beat of a packet or command payload; load_requested_issues: the value named 'load requested issues' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 769: `if (s_axis_tlast != beat_is_last) error_event_r <= 1'b1;` This condition selects the following hardware branch only when 's_axis_tlast != beat_is_last' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; beat_is_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 770: `if (beat_is_last || s_axis_tlast) begin` This condition selects the following hardware branch only when 'beat_is_last || s_axis_tlast' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are beat_is_last: the AXI-Stream marker for the final beat of a packet or command payload; s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 771: `activation_load_success_r <= beat_is_last;` This makes activation_load_success_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to 'beat_is_last'. It updates after the active clock edge together with other nonblocking assignments. The important operands are beat_is_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 772: `load_finish_pending_r <= 1'b1;` This makes load_finish_pending_r, the value named 'load finish pending r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory..

Line 773: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 774: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 775: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATIONS, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 777: `ST_LOAD_ACTIVATION_DRAIN: begin` This is the ST_LOAD_ACTIVATION_DRAIN case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATION_DRAIN, the machine stores incoming operands into local FPGA memory..

Line 778: `if (!activation_classify_valid_r) begin` This condition selects the following hardware branch only when ‘!activation_classify_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are activation_classify_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATION_DRAIN, the machine stores incoming operands into local FPGA memory..

Line 779: `if (!activation_load_success_r) status_active_issues <= 12'd0;` This condition selects the following hardware branch only when ‘!activation_load_success_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are activation_load_success_r: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATION_DRAIN, the machine stores incoming operands into local FPGA memory..

Line 780: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATION_DRAIN, the machine stores incoming operands into local FPGA memory..

Line 781: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATION_DRAIN, the machine stores incoming operands into local FPGA memory..

Line 782: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATION_DRAIN, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 783: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_ACTIVATION_DRAIN, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 785: `ST_LOAD_WEIGHTS_OUTER: begin` This is the ST_LOAD_WEIGHTS_OUTER case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 786: `if (load_finish_pending_r) begin` This condition selects the following hardware branch only when ‘load_finish_pending_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_finish_pending_r: the value named ’load finish pending r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 787: `load_finish_pending_r <= 1'b0;` This makes load_finish_pending_r, the value named ’load finish pending r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 788: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 789: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 790: `end else if (s_axis_tvalid && s_axis_tready) begin` This condition selects the following hardware branch only when ‘s_axis_tvalid && s_axis_tready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tvalid: the producer’s statement that its current payload is meaningful; s_axis_tready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 791: `logic [1:0] word_segment;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory.. Specifically, word_segment is the value named ’word segment’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 792: `logic beat_is_last;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory.. Specifically, beat_is_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 793: `word_segment = {1'b0, load_segment_index_r[0]};` This makes word_segment, the value named ’word segment’ in this block, equal to ‘{1’b0, load_segment_index_r[0]}‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block; load_segment_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 794: `beat_is_last = load_beats_remaining_r == 15'd1;` This makes beat_is_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘load_beats_remaining_r == 15’d1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_beats_remaining_r: the value named ’load beats remaining r’ in this block; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 795: `status_input_beats <= status_input_beats + 1'b1;` This makes status_input_beats, the value named 'status input beats' in this block, equal to 'status_input_beats + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_input_beats: the value named 'status input beats' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 796: `load_beats_remaining_r <= load_beats_remaining_r - 1'b1;` This makes load_beats_remaining_r, the value named 'load beats remaining r' in this block, equal to 'load_beats_remaining_r - 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_beats_remaining_r: the value named 'load beats remaining r' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 797: `status_loaded_weights <= beat_is_last` This statement continues through source line 798; the explanation uses the complete expression rather than only the first visual fragment. This makes status_loaded_weights, a learned coefficient multiplied by an activation, equal to 'beat_is_last ? load_requested_issues : 12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are beat_is_last: the AXI-Stream marker for the final beat of a packet or command payload; load_requested_issues: the value named 'load requested issues' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 798: `? load_requested_issues : 12'd0;` This is continuation line 2 of the 2-line logical statement that begins at source line 797. Its exact fragment is '? load_requested_issues : 12'd0;'. The important operands are load_requested_issues: the value named 'load requested issues' in this block; d0: the value named 'd0' in this block. Read together, the complete operation is: This makes status_loaded_weights, a learned coefficient multiplied by an activation, equal to 'beat_is_last ? load_requested_issues : 12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are beat_is_last: the AXI-Stream marker for the final beat of a packet or command payload; load_requested_issues: the value named 'load requested issues' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 799: `if (word_segment == 2'd1) begin` This condition selects the following hardware branch only when 'word_segment == 2'd1' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are word_segment: the value named 'word segment' in this block; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 800: `load_item_index <= load_item_index + 1'b1;` This makes load_item_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'load_item_index + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_item_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 801: `load_segment_index_r <= 4'd0;` This makes load_segment_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory..

Line 802: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_OUTER, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 803: `load_segment_index_r <= 4'd1;` This makes load_segment_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '4'd1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d1: the value named 'd1' in this block. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tvalid: the producer's statement that its current payload is meaningful; s_axis_tready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 819: `logic beat_is_last;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory.. Specifically, beat_is_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 820: `beat_is_last = load_beats_remaining_r == 15'd1;` This makes beat_is_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'load_beats_remaining_r == 15'd1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are load_beats_remaining_r: the value named 'load beats remaining r' in this block; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 821: `status_input_beats <= status_input_beats + 1'b1;` This makes status_input_beats, the value named 'status input beats' in this block, equal to 'status_input_beats + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_input_beats: the value named 'status input beats' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 822: `load_beats_remaining_r <= load_beats_remaining_r - 1'b1;` This makes load_beats_remaining_r, the value named 'load beats remaining r' in this block, equal to 'load_beats_remaining_r - 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_beats_remaining_r: the value named 'load beats remaining r' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 823: `status_loaded_weights <= beat_is_last` This statement continues through source line 824; the explanation uses the complete expression rather than only the first visual fragment. This makes status_loaded_weights, a learned coefficient multiplied by an activation, equal to 'beat_is_last ? load_requested_issues : 12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are beat_is_last:

the AXI-Stream marker for the final beat of a packet or command payload; load_requested_issues: the value named 'load requested issues' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 824: `? load_requested_issues : 12'd0;` This is continuation line 2 of the 2-line logical statement that begins at source line 823. Its exact fragment is '? load_requested_issues : 12'd0;'. The important operands are load_requested_issues: the value named 'load requested issues' in this block; d0: the value named 'd0' in this block. Read together, the complete operation is: This makes status_loaded_weights, a learned coefficient multiplied by an activation, equal to 'beat_is_last ? load_requested_issues : 12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are beat_is_last: the AXI-Stream marker for the final beat of a packet or command payload; load_requested_issues: the value named 'load requested issues' in this block; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 825: `if (load_segment_index_r == 4'd15) begin` This condition selects the following hardware branch only when 'load_segment_index_r == 4'd15' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_segment_index_r: an integer selecting one tensor element, lane, bank, or state entry; d15: the value named 'd15' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 826: `load_item_index <= load_item_index + 1'b1;` This makes load_item_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'load_item_index + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_item_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 827: `load_segment_index_r <= 4'd0;` This makes load_segment_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 828: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 829: `load_segment_index_r <= load_segment_index_r + 1'b1;` This makes load_segment_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to 'load_segment_index_r + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_segment_index_r: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 830: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 832: `if (s_axis_tlast != beat_is_last) error_event_r <= 1'b1;` This condition selects the following hardware branch only when 's_axis_tlast != beat_is_last' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; beat_is_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 833: `if (beat_is_last || s_axis_tlast) begin` This condition selects the following hardware branch only when ‘beat_is_last || s_axis_tlast‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are beat_is_last: the AXI-Stream marker for the final beat of a packet or command payload; s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 834: `load_finish_pending_r <= 1'b1;` This makes load_finish_pending_r, the value named 'load finish pending r' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory..

Line 835: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 836: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 837: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_WEIGHTS_DOT8, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 839: `ST_COMPUTE_START: begin` This is the ST_COMPUTE_START case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 840: `schedule_pointer <= 12'd0;` This makes schedule_pointer, the value named 'schedule pointer' in this block, equal to ‘12'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 841: `index_request_valid_r <= 1'b0;` This makes index_request_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 842: `index_valid_r <= 1'b0;` This makes index_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 843: `map_valid_r <= 1'b0;` This makes map_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 844: `read_valid_r <= 1'b0;` This makes read_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 845: `memory_valid_r <= 1'b0;` This makes memory_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 846: `capture_valid_r <= 1'b0;` This makes capture_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 847: `issue_fifo_count_r <= 2'd0;` This makes issue_fifo_count_r, an integer count retained for control or measurable telemetry, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 848: `issue_fifo_write_pointer_r <= 1'b0;` This makes issue_fifo_write_pointer_r, the value named 'issue fifo write pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 849: `issue_fifo_read_pointer_r <= 1'b0;` This makes issue_fifo_read_pointer_r, the value named 'issue fifo read pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 850: `state <= ST_COMPUTE_RUN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_COMPUTE_RUN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMPUTE_RUN: the value named 'st compute run' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip..

Line 851: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_START, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 853: `ST_COMPUTE_RUN: begin` This is the ST_COMPUTE_RUN case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 854: `if (capture_stage_available) begin` This condition selects the following hardware branch only when 'capture_stage_available' is true. Both branches exist as gates; the condition controls a multiplexer rather than

making software jump. The important operands are capture_stage_available: the value named 'capture stage available' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 855: `capture_valid_r <= memory_valid_r;` This makes capture_valid_r, the producer's statement that its current payload is meaningful, equal to 'memory_valid_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are memory_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 856: `if (memory_valid_r) begin` This condition selects the following hardware branch only when 'memory_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are memory_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 857: `capture_last_r <= memory_last_r;` This makes capture_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'memory_last_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are memory_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 858: `if (compute_empty_r) begin` This condition selects the following hardware branch only when 'compute_empty_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are compute_empty_r: the value named 'compute empty r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 859: `capture_activation_r <= (compute_mode_r == MODE_DENSE_OUTER` This statement continues through source line 861; the explanation uses the complete expression rather than only the first visual fragment. This makes capture_activation_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '(compute_mode_r == MODE_DENSE_OUTER || compute_mode_r == MODE_DENSE_DOT8) ? repeat_byte(compute_activatio : 64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_mode_r: the value named 'compute mode r' in this block; MODE_DENSE_OUTER: the value named 'mode dense outer' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 860: `|| compute_mode_r == MODE_DENSE_DOT8)` This is continuation line 2 of the 3-line logical statement that begins at source line 859. Its exact fragment is '|| compute_mode_r == MODE_DENSE_DOT8)'. The important operands are compute_mode_r: the value named 'compute mode r' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Read together, the complete operation is: This makes capture_activation_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to '(compute_mode_r == MODE_DENSE_OUTER || compute_mode_r == MODE_DENSE_DOT8) ? repeat_byte(compute_activation_zp_r) : 64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_mode_r: the value named 'compute mode r' in this block; MODE_DENSE_OUTER: the value named 'mode dense outer' in this block; MODE_DENSE_DOT8: the value named 'mode dense dot8' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 861: `? repeat_byte(compute_activation_zp_r) : 64'd0;` This is continuation line 3 of the 3-line logical statement that begins at source line 859. Its exact fragment is '? repeat_byte(compute_activation_zp_r) : 64'd0;'. The important operands are repeat_byte: the value named 'repeat byte' in this block; compute_activation_zp_r: an input feature value consumed by a neuron or multiply-accumulate operation; d0: the value named 'd0' in this block. Read together, the complete operation is: This makes capture_activation_r, an input feature value consumed

by a neuron or multiply-accumulate operation, equal to ‘(compute_mode_r == MODE_DENSE_OUTER || compute_mode_r == MODE_DENSE_DOT8) ? repeat_byte(compute_activation_zp_r) : 64’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_mode_r: the value named ’compute mode r’ in this block; MODE_DENSE_OUTER: the value named ’mode dense outer’ in this block; MODE_DENSE_DOT8: the value named ’mode dense dot8’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 862: `capture_outer_weights_r <= ’0;` This makes capture_outer_weights_r, a learned coefficient multiplied by an activation, equal to ‘’0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 863: `capture_dot_weights_r <= ’0;` This makes capture_dot_weights_r, a learned coefficient multiplied by an activation, equal to ‘’0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 864: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 865: `capture_activation_r <= activation_read_data;` This makes capture_activation_r, an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘activation_read_data‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are activation_read_data: an input feature value consumed by a neuron or multiply-accumulate operation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 866: `capture_outer_weights_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are capture_outer_weights_r: a learned coefficient multiplied by an activation.

Line 867: `<= weight_read_data[memory_bank_select_r];` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are weight_read_data: a learned coefficient multiplied by an activation; memory_bank_select_r: local FPGA storage addressed by surrounding index logic.

Line 868: `capture_dot_weights_r <= {` This statement continues through source line 873; the explanation uses the complete expression rather than only the first visual fragment. This makes capture_dot_weights_r, a learned coefficient multiplied by an activation, equal to ‘{ weight_read_data[7], weight_read_data[6], weight_read_data[5], weight_read_data[4], weight_read_data[3], weight_read_data[2], weight_read_data[1], weight_read_data[0] }‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_read_data: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 869: `weight_read_data[7], weight_read_data[6],` This is continuation line 2 of the 6-line logical statement that begins at source line 868. Its exact fragment is ‘weight_read_data[7], weight_read_data[6],‘. The important operands are weight_read_data: a learned coefficient multiplied by an activation. Read together, the complete operation

is: This makes capture_dot_weights_r, a learned coefficient multiplied by an activation, equal to ‘{ weight_read_data[7], weight_read_data[6], weight_read_data[5], weight_read_data[4], weight_read_data[3], weight_read_data[2], weight_read_data weight_read_data[0] }‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_read_data: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 870: `weight_read_data[5], weight_read_data[4],` This is continuation line 3 of the 6-line logical statement that begins at source line 868. Line 874: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 875: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 876: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 878: `if (memory_stage_available) begin` This condition selects the following hardware branch only when ‘memory_stage_available‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are memory_stage_available: local FPGA storage addressed by surrounding index logic. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 879: `memory_valid_r <= read_valid_r;` This makes memory_valid_r, the producer's statement that its current payload is meaningful, equal to ‘read_valid_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are read_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 880: `if (read_valid_r) begin` This condition selects the following hardware branch only when ‘read_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 881: `memory_bank_select_r <= read_bank_select_r;` This makes memory_bank_select_r, local FPGA storage addressed by surrounding index logic, equal to ‘read_bank_select_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are read_bank_select_r: the value named 'read bank select r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 882: `memory_last_r <= read_last_r;` This makes memory_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘read_last_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are read_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 883: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 884: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 886: `if (read_stage_available) begin` This condition selects the following hardware branch only when ‘read_stage_available‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are read_stage_available: the value named 'read stage available' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 887: `read_valid_r <= map_valid_r;` This makes read_valid_r, the producer's statement that its current payload is meaningful, equal to ‘map_valid_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are map_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 888: `if (map_valid_r) begin` This condition selects the following hardware branch only when ‘map_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are map_valid_r: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 889: `read_bank_select_r <= mapped_index_r[2:0];` This makes read_bank_select_r, the value named ’read bank select r’ in this block, equal to ‘mapped_index_r[2:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are mapped_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 890: `read_last_r <= map_last_r;` This makes read_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘map_last_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are map_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 891: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 892: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 894: `if (map_stage_available) begin` This condition selects the following hardware branch only when ‘map_stage_availa is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are map_stage_available: the value named ’map stage available’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 895: `map_valid_r <= index_valid_r;` This makes map_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘index_valid_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are index_valid_r: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 896: `if (index_valid_r) begin` This condition selects the following hardware branch only when ‘index_valid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are index_valid_r: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 897: `mapped_index_r <= active_mapped_index;` This makes mapped_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘active_mapped_index‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_mapped_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 898: `map_last_r <= index_last_r;` This makes map_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘index_last_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are index_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 899: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 900: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 902: `if (index_stage_available) begin` This condition selects the following hardware branch only when 'index_stage_available' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are index_stage_available: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 903: `index_valid_r <= index_request_valid_r;` This makes index_valid_r, the producer's statement that its current payload is meaningful, equal to 'index_request_valid_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are index_request_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 904: `if (index_request_valid_r) begin` This condition selects the following hardware branch only when 'index_request_valid_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are index_request_valid_r: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 905: `index_last_r <= index_request_last_r;` This makes index_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'index_request_last_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are index_request_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 906: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 907: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 909: `if (index_request_stage_available) begin` This condition selects the following hardware branch only when 'index_request_stage_available' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are index_request_stage_available: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 910: `index_request_valid_r <= compute_read_request;` This makes index_request_valid_r, the producer's statement that its current payload is meaningful, equal to 'compute_read_request'. It updates after the active clock edge together with other nonblocking assignments. The important operands are compute_read_request: the value named 'compute read request' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 911: `if (compute_read_request) begin` This condition selects the following hardware branch only when ‘compute_read_request‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are compute_read_request: the value named ’compute read request’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 912: `index_request_address_r <= schedule_pointer[10:0];` This makes index_request_address_r, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘schedule_pointer[10:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are schedule_pointer: the value named ’schedule pointer’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 913: `index_request_last_r <= schedule_last_r;` This makes index_request_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘schedule_last_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are schedule_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 914: `schedule_last_r <= schedule_remaining_r == 12'd2;` This makes schedule_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘schedule_remaining_r == 12’d2‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are schedule_remaining_r: the value named ’schedule remaining r’ in this block; d2: the value named ’d2’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 915: `schedule_remaining_r <= schedule_remaining_r - 1'b1;` This makes schedule_remaining_r, the value named ’schedule remaining r’ in this block, equal to ‘schedule_remaining_r - 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are schedule_remaining_r: the value named ’schedule remaining r’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 916: `if (schedule_remaining_r == 12'd1) begin` This condition selects the following hardware branch only when ‘schedule_remaining_r == 12’d1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are schedule_remaining_r: the value named ’schedule remaining r’ in this block; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 917: `schedule_active_r <= 1'b0;` This makes schedule_active_r, the value named ’schedule active r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 918: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 919: `schedule_pointer <= schedule_pointer + 1'b1;` This makes schedule_pointer, the value named ’schedule pointer’ in this block, equal to ‘schedule_pointer + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are schedule_pointer: the value named ’schedule pointer’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 920: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 921: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 923: `if (tile_last_issue_accepted_r) begin` This condition selects the following hardware branch only when ‘tile_last_issue_accepted_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are tile_last_issue_accepted_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 924: `state <= ST_COMPUTE_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_COMPUTE_OUTPUT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMPUTE_OUTPUT: the value named ’st compute output’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip..

Line 925: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 926: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_RUN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 928: `ST_COMPUTE_OUTPUT: begin` This is the ST_COMPUTE_OUTPUT case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip..

Line 929: `status_skipped_issues <= {20'd0, compute_requested_issues}` This statement continues through source line 930; the explanation uses the complete expression rather than only the first visual fragment. This makes status_skipped_issues, the value named ’status skipped issues’ in this block, equal to ‘{20’d0, compute_requested_issues} - {20’d0, status_active_issues}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block; compute_requested_issues: the value named ’compute requested issues’ in this block; status_active_issues: the value named ’status active issues’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip..

Line 930: `- {20'd0, status_active_issues};` This is continuation line 2 of the 2-line logical statement that begins at source line 929. Its exact fragment is ‘- {20’d0, status_active_issues};‘. The important operands are d0: the value named ’d0’ in this block; status_active_issues: the value named ’status active issues’ in this block. Read together, the complete operation is: This makes status_skipped_issues, the value named ’status skipped issues’ in this block, equal to ‘{20’d0, compute_requested_issues} - {20’d0, status_active_issues}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block; compute_requested_issues: the value named ’compute requested issues’ in this block; status_active_issues: the value named ’status active issues’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip..

Line 931: `if (tensor_output_fifo_push) begin` This condition selects the following hardware branch only when ‘tensor_output_fifo_push‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are tensor_output_fifo_push: the value named ’tensor output fifo

push' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip..

Line 932: `if (tile_result_last) begin` This condition selects the following hardware branch only when 'tile_result_last' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are tile_result_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip..

Line 933: `{pending_dense_macs_carry_r,` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are pending_dense_macs_carry_r: a count of ordinary activation-times-weight operations actually issued.

Line 934: `pending_dense_macs_low_r}` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are pending_dense_macs_low_r: a count of ordinary activation-times-weight operations actually issued.

Line 935: `<= add_u19_to_u24(` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are add_u19_to_u24: the value named 'add u19 to u24' in this block.

Line 936: `status_dense_macs[23:0],` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are status_dense_macs: a count of ordinary activation-times-weight operations actually issued.

Line 937: `tile_debug_dense_macs[18:0]);` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tile_debug_dense_macs: a count of ordinary activation-times-weight operations actually issued.

Line 938: `{pending_spike_adds_carry_r,` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are pending_spike_adds_carry_r: a binary event produced when a neuron crosses its threshold.

Line 939: `pending_spike_adds_low_r}` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are pending_spike_adds_low_r: a binary event produced when a neuron crosses its threshold.

Line 940: `<= add_u19_to_u24(` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules

the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are add_u19_to_u24: the value named 'add u19 to u24' in this block.

Line 941: `status_spike_adds[23:0],` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are status_spike_adds: a binary event produced when a neuron crosses its threshold.

Line 942: `tile_debug_spike_adds[18:0]);` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tile_debug_spike_adds: a binary event produced when a neuron crosses its threshold.

Line 943: `state <= ST_COMPUTE_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_COMPUTE_DRAIN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMPUTE_DRAIN: the value named 'st compute drain' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip..

Line 944: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 945: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 946: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_OUTPUT, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 948: `ST_COMPUTE_DRAIN: begin` This is the ST_COMPUTE_DRAIN case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_DRAIN, the machine issues arithmetic work using values already held on chip..

Line 949: `if (tensor_output_fifo_pop` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_DRAIN, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tensor_output_fifo_pop: the value named 'tensor output fifo pop' in this block.

Line 950: `&& tensor_output_fifo_head_last) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_DRAIN, the machine issues arithmetic work using values already held on chip., this exact statement contributes to the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO. The important operands are tensor_output_fifo_head_last: the AXI-Stream marker for the final beat of a packet or command payload.

Line 951: `state <= ST_COMPUTE_ACCOUNT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_COMPUTE_ACCOUNT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMPUTE_ACCOUNT: the value named 'st compute account' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_DRAIN, the machine issues arithmetic work using values already held on chip..

Line 952: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_DRAIN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 953: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_DRAIN, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 955: `ST_COMPUTE_ACCOUNT: begin` This is the ST_COMPUTE_ACCOUNT case branch, which issues arithmetic work using values already held on chip. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 956: `status_dense_macs <= {` This statement continues through source line 960; the explanation uses the complete expression rather than only the first visual fragment. This makes status_dense_macs, a count of ordinary activation-times-weight operations actually issued, equal to ‘{ status_dense_macs[63:24] + {{39{1’b0}}, pending_dense_macs_carry_r}, pending_dense_macs_low_r }‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_dense_macs: a count of ordinary activation-times-weight operations actually issued; b0: the value named ’b0’ in this block; pending_dense_macs_carry_r: a count of ordinary activation-times-weight operations actually issued. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 957: `status_dense_macs[63:24]` This is continuation line 2 of the 5-line logical statement that begins at source line 956. Its exact fragment is ‘status_dense_macs[63:24]‘. The important operands are status_dense_macs: a count of ordinary activation-times-weight operations actually issued. Read together, the complete operation is: This makes status_dense_macs, a count of ordinary activation-times-weight operations actually issued, equal to ‘{ status_dense_macs[63:24] + {{39{1’b0}}, pending_dense_macs_carry_r}, pending_dense_macs_low_r }‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_dense_macs: a count of ordinary activation-times-weight operations actually issued; b0: the value named ’b0’ in this block; pending_dense_macs_carry_r: a count of ordinary activation-times-weight operations actually issued. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 958: `+ {{39{1’b0}}, pending_dense_macs_carry_r},` This is continuation line 3 of the 5-line logical statement that begins at source line 956. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 960: `};` This is continuation line 5 of the 5-line logical statement that begins at source line 956. Its exact fragment is '};'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This makes status_dense_macs, a count of ordinary activation-times-weight operations actually issued, equal to '{ status_dense_macs[63:24] + {{39{1'b0}}, pending_dense_macs_carry_r}, pending_dense_macs_low_r }'. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_dense_macs: a count of ordinary activation-times-weight operations actually issued; b0: the value named 'b0' in this block; pending_dense_macs_carry_r: a count of ordinary activation-times-weight operations actually issued. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 961: `status_spike_adds <= {` This statement continues through source line 965; the explanation uses the complete expression rather than only the first visual fragment. This makes status_spike_adds, a binary event produced when a neuron crosses its threshold, equal to '{ status_spike_adds[63:24] + {{39{1'b0}}, pending_spike_adds_carry_r}, pending_spike_adds_low_r }'. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_spike_adds: a binary event produced when a neuron crosses its threshold; b0: the value named 'b0' in this block; pending_spike_adds_carry_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 962: `status_spike_adds[63:24]` This is continuation line 2 of the 5-line logical statement that begins at source line 961. Its exact fragment is 'status_spike_adds[63:24]'. The important operands are status_spike_adds: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This makes status_spike_adds, a binary event produced when a neuron crosses its threshold, equal to '{ status_spike_adds[63:24] + {{39{1'b0}}, pending_spike_adds_carry_r}, pending_spike_adds_low_r }'. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_spike_adds: a binary event produced when a neuron crosses its threshold; b0: the value named 'b0' in this block; pending_spike_adds_carry_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 963: `+ {{39{1'b0}}, pending_spike_adds_carry_r},` This is continuation line 3 of the 5-line logical statement that begins at source line 961. Its exact fragment is '+ {{39{1'b0}}, pending_spike_adds_carry_r},'. The important operands are b0: the value named 'b0' in this block; pending_spike_adds_carry_r: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This makes status_spike_adds, a binary event produced when a neuron crosses its threshold, equal to '{ status_spike_adds[63:24] + {{39{1'b0}}, pending_spike_adds_carry_r}, pending_spike_adds_low_r }'. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_spike_adds: a binary event produced when a neuron crosses its threshold; b0: the value named 'b0' in this block; pending_spike_adds_carry_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 964: `pending_spike_adds_low_r` This is continuation line 4 of the 5-line logical statement that begins at source line 961. Its exact fragment is 'pending_spike_adds_low_r'. The important operands are pending_spike_adds_low_r: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This makes status_spike_adds, a binary event produced when a neuron crosses its threshold, equal to '{ status_spike_adds[63:24] + {{39{1'b0}}, pending_spike_adds_carry_r}, pending_spike_adds_low_r }'. It updates after the active clock edge together with other nonblocking assignments. The important operands are status_spike_adds: a binary event produced when a neuron crosses its threshold; b0: the value named 'b0' in this block; pending_spike_adds_carry_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 965: `};` This is continuation line 5 of the 5-line logical statement that begins at source line 961. Its exact fragment is '};'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This makes status_spike_adds, a binary event produced when a neuron crosses its threshold, equal to '{ status_spike_adds[63:24] + {{39{1'b0}}, pending_spike_adds_carry_r}, pending_spike_adds_low_r }'.

It updates after the active clock edge together with other nonblocking assignments. The important operands are status_spike_adds: a binary event produced when a neuron crosses its threshold; b0: the value named 'b0' in this block; pending_spike_adds_carry_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 966: `command_done_pending_r <= 1'b1;` This makes command_done_pending_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 967: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 968: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 970: `default: state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'state <= ST_IDLE;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip..

Line 971: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMPUTE_ACCOUNT, the machine issues arithmetic work using values already held on chip.; it has no arithmetic value of its own.

Line 972: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 973: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 975: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 976: `if (MAX_OUTER_ISSUES < 8 || MAX_OUTER_ISSUES > 2048) begin` This condition selects the following hardware branch only when 'MAX_OUTER_ISSUES < 8 || MAX_OUTER_ISSUES > 2048' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are MAX_OUTER_ISSUES: the value named 'max outer issues' in this block. Context: the module's structural declarations.

Line 977: `$fatal(1, "MAX_OUTER_ISSUES must be in [8,2048]");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 978: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 979: `if (MAX_DOT8_ISSUES != MAX_OUTER_ISSUES / 8) begin` This condition selects the following hardware branch only when ‘MAX_DOT8_ISSUES != MAX_OUTER_ISSUES / 8‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are MAX_DOT8_ISSUES: the value named ’max dot8 issues’ in this block; MAX_OUTER_ISSUES: the value named ’max outer issues’ in this block. Context: the module’s structural declarations.

Line 980: `$fatal(1, "MAX_DOT8_ISSUES must equal MAX_OUTER_ISSUES/8");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 981: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 982: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 983: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 985: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that loads activation and weight tiles, compacts sparse reduction positions, schedules the physical tensor tile, and isolates result backpressure with a registered skid FIFO.

7 rtl/neuraedge_command_pkg.sv

Role in the complete system: defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

7.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

What becomes FPGA hardware Vivado elaborates module(s) declared here into physical nets and primitives. The source declares 0 input-port lines, 0 output-port lines, 0 clocked process(es), and 0 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control This block is primarily a datapath or storage primitive rather than a large state machine. Registers still divide combinational work into cycles and hold valid/data stable during downstream stalls.

Connections to other blocks This is a leaf block: parent modules create it and connect its ports. It does not instantiate another project RTL module, so its arithmetic or storage maps directly into FPGA primitives.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

7.2 Complete source

```

7.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 3: `package neuraedge_command_pkg;` This opens neuraedge_command_pkg;, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 4: `localparam logic [3:0] CMD_TRAIN_LINEAR_BACKWARD = 4'h0;` This fixes CMD_TRAIN_LINEAR_BACKWARD to 4'h0 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_TRAIN_LINEAR_BACKW denotes the value named 'cmd train linear backward' in this block.

Line 5: `localparam logic [3:0] CMD_LOAD_ACTIVATIONS = 4'h1;` This fixes CMD_LOAD_ACTIVATIONS to 4'h1 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_LOAD_ACTIVATIONS denotes an input feature value consumed by a neuron or multiply-accumulate operation.

Line 6: `localparam logic [3:0] CMD_LOAD_WEIGHTS_OUTER = 4'h2;` This fixes CMD_LOAD_WEIGHTS_OUTER to 4'h2 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_LOAD_WEIGHTS_OUTER denotes a learned coefficient multiplied by an activation.

Line 7: `localparam logic [3:0] CMD_LOAD_WEIGHTS_DOT8 = 4'h3;` This fixes CMD_LOAD_WEIGHTS_DOT8 to 4'h3 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_LOAD_WEIGHTS_DOT8 denotes a learned coefficient multiplied by an activation.

Line 8: `localparam logic [3:0] CMD_COMPUTE_DENSE_OUTER = 4'h4;` This fixes CMD_COMPUTE_DENSE_OUTER to 4'h4 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_COMPUTE_DENSE_OUTE denotes the value named 'cmd compute dense outer' in this block.

Line 9: `localparam logic [3:0] CMD_COMPUTE_DENSE_DOT8 = 4'h5;` This fixes CMD_COMPUTE_DENSE_DOT8 to 4'h5 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_COMPUTE_DENSE_DOT8 denotes the value named 'cmd compute dense dot8' in this block.

Line 10: `localparam logic [3:0] CMD_COMPUTE_BINARY = 4'h6;` This fixes CMD_COMPUTE_BINARY to 4'h6 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_COMPUTE_BINARY denotes the value named 'cmd compute binary' in this block.

Line 11: `localparam logic [3:0] CMD_COMPUTE_TERNARY = 4'h7;` This fixes CMD_COMPUTE_TERNARY to 4'h7 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_COMPUTE_TERNARY denotes the value named 'cmd compute ternary' in this block.

Line 12: `localparam logic [3:0] CMD_ALPHA_XNOR = 4'h8;` This fixes CMD_ALPHA_XNOR to 4'h8 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_ALPHA_XNOR denotes the programmable weight assigned to matching zero spikes in alpha-XNOR attention.

Line 13: `localparam logic [3:0] CMD_VECTOR_ALU = 4'h9;` This fixes CMD_VECTOR_ALU to 4'h9 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_VECTOR_ALU denotes the value named 'cmd vector alu' in this block.

Line 14: `localparam logic [3:0] CMD_LAYERNORM = 4'ha;` This fixes CMD_LAYERNORM to 4'ha during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_LAYERNORM denotes the value named 'cmd layernorm' in this block.

Line 15: `localparam logic [3:0] CMD_LOG_SOFTMAX = 4'hb;` This fixes CMD_LOG_SOFTMAX to 4'hb during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_LOG_SOFTMAX denotes the value named 'cmd log softmax' in this block.

Line 16: `localparam logic [3:0] CMD_LIF_STEP = 4'hc;` This fixes CMD_LIF_STEP to 4'hc during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_LIF_STEP denotes the value named 'cmd lif step' in this block.

Line 17: `localparam logic [3:0] CMD_SGD_UPDATE = 4'hd;` This fixes CMD_SGD_UPDATE to 4'hd during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_SGD_UPDATE denotes the value named 'cmd sgd update' in this block.

Line 18: `localparam logic [3:0] CMD_ACTIVATION_LUT = 4'he;` This fixes CMD_ACTIVATION_LUT to 4'he during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_ACTIVATION_LUT denotes an input feature value consumed by a neuron or multiply-accumulate operation.

Line 19: `localparam logic [3:0] CMD_CLEAR_STATUS = 4'hf;` This fixes CMD_CLEAR_STATUS to 4'hf during elaboration. Vivado uses that constant to shape or simplify the generated circuit; CMD_CLEAR_STATUS denotes the value named 'cmd clear status' in this block.

Line 21: `localparam logic [1:0] MODE_DENSE_OUTER = 2'd0;` This fixes MODE_DENSE_OUTER to 2'd0 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_DENSE_OUTER denotes the value named 'mode dense outer' in this block.

Line 22: `localparam logic [1:0] MODE_DENSE_DOT8 = 2'd1;` This fixes MODE_DENSE_DOT8 to 2'd1 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_DENSE_DOT8 denotes the value named 'mode dense dot8' in this block.

Line 23: `localparam logic [1:0] MODE_BINARY_WEIGHTED = 2'd2;` This fixes MODE_BINARY_WEIGHTED to 2'd2 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_BINARY_WEIGHTED denotes a learned coefficient multiplied by an activation.

Line 24: `localparam logic [1:0] MODE_TERNARY_WEIGHTED = 2'd3;` This fixes MODE_TERNARY_WEIGHTED to 2'd3 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_TERNARY_WEIGHTED denotes a learned coefficient multiplied by an activation.

Line 26: `// The 128-bit command word is deliberately fixed-width so software can` Design intent: The 128-bit command word is deliberately fixed-width so software can This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 27: `// submit it as four ordinary 32-bit AXI-Lite register writes.` Design intent: submit it as four ordinary 32-bit AXI-Lite register writes. This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 28: `// [3:0] opcode` Design intent: [3:0] opcode This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 29: `// [7:4] active output rows` Design intent: [7:4] active output rows This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 30: `// [13:8] active output columns` Design intent: [13:8] active output columns This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 31: `// [25:14] reduction issue count` Design intent: [25:14] reduction issue count This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 32: `// [33:26] activation zero point` Design intent: [33:26] activation zero point This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 33: `// [41:34] weight zero point` Design intent: [41:34] weight zero point This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 34: `// [127:42] tensor commands: reserved and required to be zero` Design intent: [127:42] tensor commands: reserved and required to be zero This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 35: `// Other operators reinterpret the payload as documented in` Design intent: Other operators reinterpret the payload as documented in This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 36: `// docs/stream_protocol.md; opcode placement never changes.` Design intent: docs/stream_protocol.md; opcode placement never changes. This comment anchors the surrounding logic in the block that defines the shared command opcodes and tensor-mode encodings used by RTL and host software.

Line 37: `endpackage` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

8 rtl/neuraedge_descriptor_sequencer.sv

Role in the complete system: turns a multi-record DMA program into checked core commands and payload/output streams.

8.1 Beginner architecture map

Dataflow responsibility A DMA record header declares one command's payload and result lengths. The sequencer captures both halves of the 128-bit command, forwards exactly the declared payload, counts accepted results, regenerates final TLAST, and drains malformed packets so the next descriptor starts aligned.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_descriptor_sequencer into physical nets and primitives. The source declares 16 input-port lines, 14 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_COMMAND_HIGH, ST_COMMAND_LOW, ST_ERROR_DRAIN ST_HEADER, ST_PAYLOAD, ST_SUBMIT, ST_WAIT. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates unique as case, endcase as if, end as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

8.2 Complete source

```
1  `timescale 1ns / 1ps
2  `default_nettype none
3
4  // Converts one DMA stream of descriptor records into ordinary core commands.
5  // A record is header, command[63:0], command[127:64], then input_count payload
6  // beats. Header [31:0] is input_count, [62:32] is output_count, and [63] marks
7  // the final record. External TLAST appears only on the final program input beat;
8  // the sequencer regenerates the per-command TLAST required by the core.
9  module neuraedge_descriptor_sequencer (
10     input  wire clk,

```

8.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `// Converts one DMA stream of descriptor records into ordinary core commands.` Design intent: Converts one DMA stream of descriptor records into ordinary core commands. This comment anchors the surrounding logic in the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 5: `// A record is header, command[63:0], command[127:64], then input_count payload` Design intent: A record is header, command[63:0], command[127:64], then input_count payload This comment anchors the surrounding logic in the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 6: `// beats. Header [31:0] is input_count, [62:32] is output_count, and [63] marks` Design intent: beats. Header [31:0] is input_count, [62:32] is output_count, and [63] marks This comment anchors the surrounding

logic in the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 7: `// the final record. External TLAST appears only on the final program input beat;` Design intent: the final record. External TLAST appears only on the final program input beat; This comment anchors the surrounding logic in the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 8: `// the sequencer regenerates the per-command TLAST required by the core.` Design intent: the sequencer regenerates the per-command TLAST required by the core. This comment anchors the surrounding logic in the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 9: `module neuraedge_descriptor_sequencer (` This opens neuraedge_descriptor_sequencer, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 10: `input wire clk,` This declares clk as a input port with width one bit. It carries the clock that makes all registers advance together across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 11: `input wire rst_n,` This declares rst_n as a input port with width one bit. It carries the active-low synchronous reset across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 13: `input wire program_start,` This declares program_start as a input port with width one bit. It carries the value named 'program start' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 14: `input wire clear_status,` This declares clear_status as a input port with width one bit. It carries the value named 'clear status' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 15: `input wire [31:0] program_output_beats,` This declares program_output_beats as a input port with width [31:0]. It carries the value named 'program output beats' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 16: `output logic program_active,` This declares program_active as a output port with width one bit. It carries the value named 'program active' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 17: `output logic program_done,` This declares program_done as a output port with width one bit. It carries the value named 'program done' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 18: `output logic program_error,` This declares program_error as a output port with width one bit. It carries the value named 'program error' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 19: `output logic [31:0] program_records,` This declares program_records as a output port with width [31:0]. It carries the number of descriptor records accepted since program start across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 21: `input wire s_axis_tvalid,` This declares s_axis_tvalid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 22: `output logic s_axis_tready,` This declares s_axis_tready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 23: `input wire [63:0] s_axis_tdata,` This declares s_axis_tdata as a input port with width [63:0]. It carries the value named 's axis tdata' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 24: `input wire s_axis_tlast,` This declares s_axis_tlast as a input port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 26: `output logic m_axis_tvalid,` This declares m_axis_tvalid as a output port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 27: `input wire m_axis_tready,` This declares m_axis_tready as a input port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 28: `output logic [63:0] m_axis_tdata,` This declares m_axis_tdata as a output port with width [63:0]. It carries the value named 'm axis tdata' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 29: `output logic m_axis_tlast,` This declares m_axis_tlast as a output port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 31: `output logic core_command_valid,` This declares core_command_valid as a output port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 32: `input wire core_command_ready,` This declares core_command_ready as a input port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 33: `output logic [127:0] core_command_data,` This declares core_command_data as a output port with width [127:0]. It carries the 128-bit instruction selecting an engine, shape, mode, and numeric parameters across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 34: `input wire core_command_done,` This declares core_command_done as a input port with width one bit. It carries the 128-bit instruction selecting an engine, shape, mode, and numeric parameters across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 35: `input wire core_status_error,` This declares core_status_error as a input port with width one bit. It carries the value named 'core status error' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 37: `output logic core_s_valid,` This declares core_s_valid as a output port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 38: `input wire core_s_ready,` This declares core_s_ready as a input port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 39: `output logic [63:0] core_s_data,` This declares core_s_data as a output port with width [63:0]. It carries the payload carried with the surrounding valid/ready handshake across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 40: `output logic core_s_last,` This declares core_s_last as a output port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 42: `input wire core_m_valid,` This declares core_m_valid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 43: `output logic core_m_ready,` This declares core_m_ready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 44: `input wire [63:0] core_m_data,` This declares core_m_data as a input port with width [63:0]. It carries the payload carried with the surrounding valid/ready handshake across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 45: `input wire core_m_last` This declares core_m_last as a input port with width one bit. It carries the AXI-Stream marker for the final beat of a packet or command payload across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 46: `);` Within the module's structural declarations, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The expression is a literal or structural operator and has no hidden software state.

Line 47: `typedef enum logic [3:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 48: `ST_HEADER = 4'd0,` This assigns a fixed binary encoding to state ST_HEADER, which accepts and validates the descriptor record header. The encoding is visible in waveforms even though the source uses the readable name.

Line 49: `ST_COMMAND_LOW = 4'd1,` This assigns a fixed binary encoding to state ST_COMMAND_LOW, which captures command bits 63 through 0. The encoding is visible in waveforms even though the source uses the readable name.

Line 50: `ST_COMMAND_HIGH = 4'd2,` This assigns a fixed binary encoding to state ST_COMMAND_HIGH, which captures command bits 127 through 64 and checks input TLAST. The encoding is visible in waveforms even though the source uses the readable name.

Line 51: `ST_SUBMIT = 4'd3,` This assigns a fixed binary encoding to state ST_SUBMIT, which holds command-valid until the universal core accepts the instruction. The encoding is visible in waveforms even though the source uses the readable name.

Line 52: `ST_PAYLOAD = 4'd4,` This assigns a fixed binary encoding to state ST_PAYLOAD, which forwards exactly the declared number of input beats to the selected engine. The encoding is visible in waveforms even though the source uses the readable name.

Line 53: `ST_WAIT = 4'd5,` This assigns a fixed binary encoding to state ST_WAIT, which waits for both command completion and the declared output count. The encoding is visible in waveforms even though the source uses the readable name.

Line 54: `ST_ERROR_DRAIN = 4'd6` This statement continues through source line 55; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_ERROR_DRAIN, which discards remaining DMA input until TLAST so the next transfer starts aligned. The encoding is visible in waveforms even though the source uses the readable name.

Line 55: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 54. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_ERROR_DRAIN, which discards remaining DMA input until TLAST so the next transfer starts aligned. The encoding is visible in waveforms even though the source uses the readable name.

Line 57: `state_t state;` Within the module's structural declarations, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are state_t: the finite-state-machine phase retained in flip-flops; state: the finite-state-machine phase retained in flip-flops.

Line 58: `logic [127:0] descriptor_command_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, descriptor_command_r is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 59: `logic [31:0] input_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_remaining_r is the number of command payload beats still expected. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 60: `logic input_zero_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_zero_r is the value named 'input zero r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 61: `logic input_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 62: `logic [30:0] output_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_remaining_r is the number of command result beats still expected. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 63: `logic output_zero_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_zero_r is the value named 'output zero r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 64: `logic output_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 65: `logic [31:0] program_output_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_output_remaining_r is the number of result beats left in the complete descriptor program. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 66: `logic program_output_zero_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_output_zero_r is the value named 'program output zero r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 67: `logic program_output_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, program_output_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 68: `logic record_final_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, record_final_r is the value named 'record final r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 69: `logic command_done_seen_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_done_seen_r is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 70: `logic command_error_seen_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, command_error_seen_r is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 71: `logic [63:0] input_fifo_data_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 72: `logic input_fifo_last_r [0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 73: `logic input_fifo_write_pointer_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_write_pointer_r is the value named 'input fifo write pointer r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 74: `logic input_fifo_read_pointer_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_read_pointer_r is the value named 'input fifo read pointer r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 75: `logic [1:0] input_fifo_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_fifo_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 76: `logic output_buffer_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_buffer_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 77: `logic output_buffer_overrun_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_buffer_overrun_r is local storage that decouples producer and consumer timing. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 78: `logic [63:0] output_buffer_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_buffer_data_r is local storage that decouples producer and consumer timing. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 79: `logic output_buffer_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_buffer_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 80: `// Malformed descriptor detection is quarantined for one cycle. The` Design intent: Malformed descriptor detection is quarantined for one cycle. The This comment anchors the surrounding logic in the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 81: `// pending bit immediately blocks every handshake; on the following edge a` Design intent: pending bit immediately blocks every handshake; on the following edge a This comment anchors the surrounding logic in the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 82: `// local decode clears the FIFO/buffer and either stops or drains input.` Design intent: local decode clears the FIFO/buffer and either stops or drains input. This comment anchors the surrounding logic in the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 83: `// This separates error detection from a wide multi-register clear cone.` Design intent: This separates error detection from a wide multi-register clear cone. This comment anchors the surrounding logic in the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 84: `logic error_pending_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, error_pending_r is the value named 'error pending r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 85: `logic error_input_was_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, error_input_was_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 87: `wire input_accept = s_axis_tvalid && s_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_accept is the value named 'input accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 88: `wire payload_input_accept = input_accept && state == ST_PAYLOAD;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, payload_input_accept is stream data belonging to the current command. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 89: `wire core_input_accept = core_s_valid && core_s_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_input_accept is the value named 'core input accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 90: `wire output_accept = m_axis_tvalid && m_axis_tready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_accept is the value named 'output accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 91: `wire core_output_accept = core_m_valid && core_m_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_accept is the value named 'core output accept' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 92: `wire core_output_overrun = core_output_accept` This statement continues through source line 93; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_overrun is the value named 'core output overrun' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 93: `&& (output_zero_r || (output_last_r && output_buffer_valid_r));` This is continuation line 2 of the 2-line logical statement that begins at source line 92. Its exact fragment is '&& (output_zero_r || (output_last_r && output_buffer_valid_r));'. The important operands are output_zero_r: the value named 'output zero r' in this block; output_last_r: the AXI-Stream marker for the final beat of a packet or command payload; output_buffer_valid_r: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, core_output_overrun is the value named 'core output overrun' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 94: `wire record_outputs_complete = output_zero_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, record_outputs_complete is the value named 'record outputs complete' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 95: `wire record_command_complete = command_done_seen_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, record_command_complete is the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 97: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 98: `core_command_valid = program_active && !error_pending_r` This statement continues through source line 99; the explanation uses the complete expression rather than only the first visual fragment. This makes core_command_valid, the producer's statement that its current payload is meaningful, equal to 'program_active && !error_pending_r && state == ST_SUBMIT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block; state: the finite-state-machine phase retained in flip-flops. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 99: `&& state == ST_SUBMIT;` This is continuation line 2 of the 2-line logical statement that begins at source line 98. Its exact fragment is '&& state == ST_SUBMIT;'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_SUBMIT: the value named 'st submit' in this block. Read together, the complete operation is: This makes core_command_valid, the producer's statement that its current payload is meaningful, equal to 'program_active && !error_pending_r && state == ST_SUBMIT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block; state: the finite-state-machine phase retained in flip-flops. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 100: `core_command_data = descriptor_command_r;` This makes core_command_data, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 'descriptor_command_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are descriptor_command_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 102: `s_axis_tready = 1'b0;` This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to '1'b0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 103: `core_s_valid = program_active && !error_pending_r` This statement continues through source line 105; the explanation uses the complete expression rather than only the first visual fragment. This makes core_s_valid, the producer's statement that its current payload is meaningful, equal to 'program_active && !error_pending_r && (state == ST_PAYLOAD || state == ST_WAIT) && input_fifo_count_r != 0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block; state: the finite-state-machine phase retained in flip-flops. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 104: `&& (state == ST_PAYLOAD || state == ST_WAIT)` This is continuation line 2 of the 3-line logical statement that begins at source line 103. Its exact fragment is '&& (state == ST_PAYLOAD || state == ST_WAIT)'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_PAYLOAD: stream data belonging to the current command; ST_WAIT: the value named 'st wait' in this block. Read together, the complete operation is: This makes core_s_valid, the producer's statement that its current payload is meaningful, equal to 'program_active && !error_pending_r && (state == ST_PAYLOAD || state == ST_WAIT) && input_fifo_count_r != 0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block; state: the finite-state-machine phase retained in flip-flops. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 105: `&& input_fifo_count_r != 0;` This is continuation line 3 of the 3-line logical statement that begins at source line 103. Its exact fragment is '&& input_fifo_count_r != 0;'. The important operands are input_fifo_count_r: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This makes core_s_valid, the producer's statement that its current payload is meaningful, equal to 'program_active && !error_pending_r && (state == ST_PAYLOAD || state == ST_WAIT) && input_fifo_count_r != 0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block; state: the finite-state-machine phase retained in flip-flops. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 106: `core_s_data = input_fifo_data_r[input_fifo_read_pointer_r];` This makes core_s_data, the payload carried with the surrounding valid/ready handshake, equal to 'input_fifo_data_r[input_fifo_read_pointer_r]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_fifo_data_r: the payload carried with the surrounding valid/ready handshake; input_fifo_read_pointer_r: the value named 'input fifo read pointer r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 107: `core_s_last = input_fifo_last_r[input_fifo_read_pointer_r];` This makes core_s_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'input_fifo_last_r[input_fifo_read_pointer_r]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_fifo_last_r: the AXI-Stream marker for the final beat of a packet or command payload; input_fifo_read_pointer_r: the value named 'input fifo read pointer r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 108: `if (program_active && !error_pending_r) begin` This condition selects the following hardware branch only when 'program_active && !error_pending_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 109: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 110: `ST_HEADER,` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are ST_HEADER: the value named 'st header' in this block.

Line 111: `ST_COMMAND_LOW,` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are ST_COMMAND_LOW: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 112: `ST_COMMAND_HIGH: s_axis_tready = 1'b1;` This is the ST_COMMAND_HIGH case branch, which captures command bits 127 through 64 and checks input TLAST. The same-cycle action begins with 's_axis_tready =

1'b1;‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_COMMAND_HIGH, the machine captures command bits 127 through 64 and checks input TLAST..

Line 113: `ST_PAYLOAD: s_axis_tready = input_fifo_count_r != 2;` This is the ST_PAYLOAD case branch, which forwards exactly the declared number of input beats to the selected engine. The same-cycle action begins with ‘s_axis_tready = input_fifo_count_r != 2;‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine..

Line 114: `ST_ERROR_DRAIN: s_axis_tready = 1'b1;` This is the ST_ERROR_DRAIN case branch, which discards remaining DMA input until TLAST so the next transfer starts aligned. The same-cycle action begins with ‘s_axis_tready = 1'b1;‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_ERROR_DRAIN, the machine discards remaining DMA input until TLAST so the next transfer starts aligned..

Line 115: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin end‘; context is the combinational process whose outputs respond without waiting for a clock edge Within state ST_ERROR_DRAIN, the machine discards remaining DMA input until TLAST so the next transfer starts aligned..

Line 116: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge Within state ST_ERROR_DRAIN, the machine discards remaining DMA input until TLAST so the next transfer starts aligned.; it has no arithmetic value of its own.

Line 117: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 119: `m_axis_tvalid = program_active && !error_pending_r` This statement continues through source line 120; the explanation uses the complete expression rather than only the first visual fragment. This makes m_axis_tvalid, the producer's statement that its current payload is meaningful, equal to ‘program_active && !error_pending_r && output_buffer_valid_r && !output_buffer_overrun_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block; output_buffer_valid_r: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 120: `&& output_buffer_valid_r && !output_buffer_overrun_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 119. Its exact fragment is ‘&& output_buffer_valid_r && !output_buffer_overrun_r;‘. The important operands are output_buffer_valid_r: the producer's statement that its current payload is meaningful; output_buffer_overrun_r: local storage that decouples producer and consumer timing. Read together, the complete operation is: This makes m_axis_tvalid, the producer's statement that its current payload is meaningful, equal to ‘program_active && !error_pending_r && output_buffer_valid_r && !output_buffer_overrun_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block; output_buffer_valid_r: the producer's statement that its current payload is meaningful. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 121: `m_axis_tdata = output_buffer_data_r;` This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to ‘output_buffer_data_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_buffer_data_r: local storage that decouples producer and consumer timing. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 122: `m_axis_tlast = program_output_last_r;` This makes m_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘program_output_last_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_output_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 123: `core_m_ready = program_active && !error_pending_r` This statement continues through source line 125; the explanation uses the complete expression rather than only the first visual fragment. This makes core_m_ready, the consumer's statement that it can accept a payload this cycle, equal to 'program_active && !error_pending_r && (state == ST_PAYLOAD || state == ST_WAIT) && (!output_buffer_valid_r || m_axis_tready)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block; state: the finite-state-machine phase retained in flip-flops. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 124: `&& (state == ST_PAYLOAD || state == ST_WAIT)` This is continuation line 2 of the 3-line logical statement that begins at source line 123. Its exact fragment is '&& (state == ST_PAYLOAD || state == ST_WAIT)'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_PAYLOAD: stream data belonging to the current command; ST_WAIT: the value named 'st wait' in this block. Read together, the complete operation is: This makes core_m_ready, the consumer's statement that it can accept a payload this cycle, equal to 'program_active && !error_pending_r && (state == ST_PAYLOAD || state == ST_WAIT) && (!output_buffer_valid_r || m_axis_tready)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block; state: the finite-state-machine phase retained in flip-flops. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 125: `&& (!output_buffer_valid_r || m_axis_tready);` This is continuation line 3 of the 3-line logical statement that begins at source line 123. Its exact fragment is '&& (!output_buffer_valid_r || m_axis_tready);'. The important operands are output_buffer_valid_r: the producer's statement that its current payload is meaningful; m_axis_tready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This makes core_m_ready, the consumer's statement that it can accept a payload this cycle, equal to 'program_active && !error_pending_r && (state == ST_PAYLOAD || state == ST_WAIT) && (!output_buffer_valid_r || m_axis_tready)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are program_active: the value named 'program active' in this block; error_pending_r: the value named 'error pending r' in this block; state: the finite-state-machine phase retained in flip-flops. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 126: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 128: `` `define NE_ENTER_PROGRAM_ERROR(INPUT_WAS_LAST) \ `` This SystemVerilog preprocessor line controls compilation of the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 129: `begin \` Within the module's structural declarations, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The expression is a literal or structural operator and has no hidden software state.

Line 130: `program_error <= 1'b1; \` This makes program_error, the value named 'program error' in this block, equal to '1'b1; \'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 131: `error_pending_r <= 1'b1; \` This makes error_pending_r, the value named 'error pending r' in this block, equal to '1'b1; \'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the module's structural declarations.

Line 132: `error_input_was_last_r <= INPUT_WAS_LAST; \` This makes error_input_was_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'INPUT_WAS_LAST; \'. It updates after the active clock edge together with other nonblocking assignments. The important operands are INPUT_WAS_LAST: the AXI-Stream marker for the final beat of a packet or command payload. Context: the module's structural declarations.

Line 133: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 135: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 136: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 137: `state <= ST_HEADER;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_HEADER'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_HEADER: the value named 'st header' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 138: `descriptor_command_r <= 128'd0;` This makes descriptor_command_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 139: `input_remaining_r <= 32'd0;` This makes input_remaining_r, the number of command payload beats still expected, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 140: `input_zero_r <= 1'b1;` This makes input_zero_r, the value named 'input zero r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 141: `input_last_r <= 1'b0;` This makes input_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 142: `output_remaining_r <= 31'd0;` This makes output_remaining_r, the number of command result beats still expected, equal to '31'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 143: `output_zero_r <= 1'b1;` This makes output_zero_r, the value named 'output zero r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 144: `output_last_r <= 1'b0;` This makes output_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 145: `program_output_remaining_r <= 32'd0;` This makes program_output_remaining_r, the number of result beats left in the complete descriptor program, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 146: `program_output_zero_r <= 1'b1;` This makes program_output_zero_r, the value named 'program output zero r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 147: `program_output_last_r <= 1'b0;` This makes program_output_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 148: `record_final_r <= 1'b0;` This makes record_final_r, the value named 'record final r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 149: `command_done_seen_r <= 1'b0;` This makes command_done_seen_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 150: `command_error_seen_r <= 1'b0;` This makes command_error_seen_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 151: `input_fifo_data_r[0] <= 64'd0;` This makes input_fifo_data_r[0], the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 152: `input_fifo_data_r[1] <= 64'd0;` This makes input_fifo_data_r[1], the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 153: `input_fifo_last_r[0] <= 1'b0;` This makes input_fifo_last_r[0], the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 154: `input_fifo_last_r[1] <= 1'b0;` This makes input_fifo_last_r[1], the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 155: `input_fifo_write_pointer_r <= 1'b0;` This makes input_fifo_write_pointer_r, the value named 'input fifo write pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 156: `input_fifo_read_pointer_r <= 1'b0;` This makes input_fifo_read_pointer_r, the value named 'input fifo read pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 157: `input_fifo_count_r <= 2'd0;` This makes input_fifo_count_r, an integer count retained for control or measurable telemetry, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 158: `output_buffer_valid_r <= 1'b0;` This makes output_buffer_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 159: `output_buffer_overrun_r <= 1'b0;` This makes output_buffer_overrun_r, local storage that decouples producer and consumer timing, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 160: `output_buffer_data_r <= 64'd0;` This makes output_buffer_data_r, local storage that decouples producer and consumer timing, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 161: `output_buffer_last_r <= 1'b0;` This makes output_buffer_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 162: `error_pending_r <= 1'b0;` This makes error_pending_r, the value named 'error pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 163: `error_input_was_last_r <= 1'b0;` This makes error_input_was_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 164: `program_active <= 1'b0;` This makes program_active, the value named 'program active' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 165: `program_done <= 1'b0;` This makes program_done, the value named 'program done' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 166: `if (clear_status && !program_active) program_error <= 1'b0;` This condition selects the following hardware branch only when 'clear_status && !program_active' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are clear_status: the value named 'clear status' in this block; program_active: the value named 'program active' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 167: `program_error <= 1'b0;` This makes program_error, the value named 'program error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 168: `program_records <= 32'd0;` This makes program_records, the number of descriptor records accepted since program start, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 169: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 170: `program_done <= 1'b0;` This makes program_done, the value named 'program done' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 171: `unique case ({payload_input_accept, core_input_accept})` This starts a multiplexer/state decode selected by '{payload_input_accept, core_input_accept}'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 172: `2'b10: input_fifo_count_r <= input_fifo_count_r + 1'b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are b10: the value named 'b10' in this block; input_fifo_count_r: an integer count retained for control or measurable telemetry; b1: the value named 'b1' in this block.

Line 173: `2'b01: input_fifo_count_r <= input_fifo_count_r - 1'b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are b01: the value named 'b01' in this block; input_fifo_count_r: an integer count retained for control or measurable telemetry; b1: the value named 'b1' in this block.

Line 174: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the clocked process that updates registers only on a rising clock edge.

Line 175: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 176: `if (payload_input_accept) begin` This condition selects the following hardware branch only when 'payload_input_accept' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are payload_input_accept: stream data belonging to the current command. Context: the clocked process that updates registers only on a rising clock edge.

Line 177: `input_fifo_data_r[input_fifo_write_pointer_r] <= s_axis_tdata;` This makes input_fifo_data_r[input_fifo_ the payload carried with the surrounding valid/ready handshake, equal to 's_axis_tdata'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 178: `input_fifo_last_r[input_fifo_write_pointer_r]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are input_fifo_last_r: the AXI-Stream marker for the final beat of a packet or command payload; input_fifo_write_pointer_r: the value named 'input fifo write pointer r' in this block.

Line 179: `<= input_last_r;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are input_last_r: the AXI-Stream marker for the final beat of a packet or command payload.

Line 180: `input_fifo_write_pointer_r <= !input_fifo_write_pointer_r;` This makes input_fifo_write_pointer_r, the value named 'input fifo write pointer r' in this block, equal to '!input_fifo_write_pointer_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_fifo_write_pointer_r: the value named 'input fifo write pointer r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 181: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 182: `if (core_input_accept) begin` This condition selects the following hardware branch only when 'core_input_accept' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are core_input_accept: the value named 'core input accept' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 183: `input_fifo_read_pointer_r <= !input_fifo_read_pointer_r;` This makes input_fifo_read_pointer_r, the value named 'input fifo read pointer r' in this block, equal to '!input_fifo_read_pointer_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_fifo_read_pointer_r: the value named 'input fifo read pointer r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 184: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 185: `unique case ({core_output_accept, output_accept})` This starts a multiplexer/state decode selected by '{core_output_accept, output_accept}'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 186: `2'b10: output_buffer_valid_r <= 1'b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are b10: the value named 'b10' in this block; output_buffer_valid_r: the producer's statement that its current payload is meaningful; b1: the value named 'b1' in this block.

Line 187: `2'b01: output_buffer_valid_r <= 1'b0;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are b01: the value named 'b01' in this block; output_buffer_valid_r: the producer's statement that its current payload is meaningful; b0: the value named 'b0' in this block.

Line 188: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the clocked process that updates registers only on a rising clock edge.

Line 189: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 190: `if (core_output_accept) begin` This condition selects the following hardware branch only when 'core_output_accep is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are core_output_accept: the value named 'core output accept' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 191: `output_buffer_data_r <= core_m_data;` This makes output_buffer_data_r, local storage that decouples producer and consumer timing, equal to ‘core_m_data‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are core_m_data: the payload carried with the surrounding valid/ready handshake. Context: the clocked process that updates registers only on a rising clock edge.

Line 192: `output_buffer_last_r <= core_m_last;` This makes output_buffer_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘core_m_last‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are core_m_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 193: `output_buffer_overrun_r <= core_output_overrun;` This makes output_buffer_overrun_r, local storage that decouples producer and consumer timing, equal to ‘core_output_overrun‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are core_output_overrun: the value named ’core output overrun’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 194: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 195: `if (clear_status && !program_active) program_error <= 1'b0;` This condition selects the following hardware branch only when ‘clear_status && !program_active‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are clear_status: the value named ’clear status’ in this block; program_active: the value named ’program active’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 196: `if (program_start) begin` This condition selects the following hardware branch only when ‘program_start‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are program_start: the value named ’program start’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 197: `if (program_active) begin` This condition selects the following hardware branch only when ‘program_active‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are program_active: the value named ’program active’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 198: `program_error <= 1'b1;` This makes program_error, the value named ’program error’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 199: `program_done <= 1'b1;` This makes program_done, the value named ’program done’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 200: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 201: `state <= ST_HEADER;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_HEADER‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_HEADER: the value named ’st header’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 202: `descriptor_command_r <= 128'd0;` This makes descriptor_command_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '128'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 203: `input_remaining_r <= 32'd0;` This makes input_remaining_r, the number of command payload beats still expected, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 204: `input_zero_r <= 1'b1;` This makes input_zero_r, the value named 'input zero r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 205: `input_last_r <= 1'b0;` This makes input_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 206: `output_remaining_r <= 31'd0;` This makes output_remaining_r, the number of command result beats still expected, equal to '31'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 207: `output_zero_r <= 1'b1;` This makes output_zero_r, the value named 'output zero r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 208: `output_last_r <= 1'b0;` This makes output_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 209: `program_output_remaining_r <= program_output_beats;` This makes program_output_remaining_r, the number of result beats left in the complete descriptor program, equal to 'program_output_beats'. It updates after the active clock edge together with other nonblocking assignments. The important operands are program_output_beats: the value named 'program output beats' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 210: `program_output_zero_r <= program_output_beats == 0;` This makes program_output_zero_r, the value named 'program output zero r' in this block, equal to 'program_output_beats == 0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are program_output_beats: the value named 'program output beats' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 211: `program_output_last_r <= program_output_beats == 1;` This makes program_output_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'program_output_beats == 1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are program_output_beats: the value named 'program output beats' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 212: `record_final_r <= 1'b0;` This makes record_final_r, the value named 'record final r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 213: `command_done_seen_r <= 1'b0;` This makes command_done_seen_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 214: `command_error_seen_r <= 1'b0;` This makes command_error_seen_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 215: `input_fifo_write_pointer_r <= 1'b0;` This makes input_fifo_write_pointer_r, the value named 'input fifo write pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 216: `input_fifo_read_pointer_r <= 1'b0;` This makes input_fifo_read_pointer_r, the value named 'input fifo read pointer r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 217: `input_fifo_count_r <= 2'd0;` This makes input_fifo_count_r, an integer count retained for control or measurable telemetry, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 218: `output_buffer_valid_r <= 1'b0;` This makes output_buffer_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 219: `output_buffer_overrun_r <= 1'b0;` This makes output_buffer_overrun_r, local storage that decouples producer and consumer timing, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 220: `error_pending_r <= 1'b0;` This makes error_pending_r, the value named 'error pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 221: `error_input_was_last_r <= 1'b0;` This makes error_input_was_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 222: `program_active <= 1'b1;` This makes program_active, the value named 'program active' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 223: `program_error <= 1'b0;` This makes program_error, the value named 'program error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 224: `program_records <= 32'd0;` This makes program_records, the number of descriptor records accepted since program start, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 225: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 226: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 228: `if (error_pending_r) begin` This condition selects the following hardware branch only when 'error_pending_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are error_pending_r: the value named 'error pending r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 229: `error_pending_r <= 1'b0;` This makes error_pending_r, the value named 'error pending r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 230: `input_fifo_count_r <= 2'd0;` This makes input_fifo_count_r, an integer count retained for control or measurable telemetry, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 231: `output_buffer_valid_r <= 1'b0;` This makes output_buffer_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 232: `output_buffer_overrun_r <= 1'b0;` This makes output_buffer_overrun_r, local storage that decouples producer and consumer timing, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 233: `if (error_input_was_last_r) begin` This condition selects the following hardware branch only when 'error_input_was_last_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are error_input_was_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 234: `program_active <= 1'b0;` This makes program_active, the value named 'program active' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 235: `program_done <= 1'b1;` This makes program_done, the value named 'program done' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 236: `state <= ST_HEADER;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_HEADER‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_HEADER: the value named ’st header’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 237: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 238: `state <= ST_ERROR_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_ERROR_DRAIN‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ERROR_DRAIN: the value named ’st error drain’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 239: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 240: `end else if (program_active) begin` This condition selects the following hardware branch only when ‘program_active‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are program_active: the value named ’program active’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 241: `if (output_buffer_valid_r && output_buffer_overrun_r) begin` This condition selects the following hardware branch only when ‘output_buffer_valid_r && output_buffer_overrun_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_buffer_valid_r: the producer’s statement that its current payload is meaningful; output_buffer_overrun_r: local storage that decouples producer and consumer timing. Context: the clocked process that updates registers only on a rising clock edge.

Line 242: `‘NE_ENTER_PROGRAM_ERROR(record_final_r)` This SystemVerilog preprocessor line controls compilation of the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 243: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 244: `if (core_command_done) begin` This condition selects the following hardware branch only when ‘core_command_don is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are core_command_done: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge.

Line 245: `command_done_seen_r <= 1’b1;` This makes command_done_seen_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 246: `command_error_seen_r <= core_status_error;` This makes command_error_seen_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘core_status_error‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are core_status_error: the value named ’core status error’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 247: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 248: `if (output_accept) begin` This condition selects the following hardware branch only when ‘output_accept‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_accept: the value named ’output accept’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 249: `if (output_buffer_last_r != output_last_r` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are output_buffer_last_r: the AXI-Stream marker for the final beat of a packet or command payload; output_last_r: the AXI-Stream marker for the final beat of a packet or command payload.

Line 250: `|| program_output_zero_r) begin` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are program_output_zero_r: the value named ’program output zero r’ in this block.

Line 251: `‘NE_ENTER_PROGRAM_ERROR(record_final_r)` This SystemVerilog preprocessor line controls compilation of the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 252: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 253: `output_remaining_r <= output_remaining_r - 1’b1;` This makes output_remaining_r, the number of command result beats still expected, equal to ‘output_remaining_r - 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_remaining_r: the number of command result beats still expected; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 254: `program_output_remaining_r` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are program_output_remaining_r: the number of result beats left in the complete descriptor program.

Line 255: `<= program_output_remaining_r - 1’b1;` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are program_output_remaining_r: the number of result beats left in the complete descriptor program; b1: the value named ’b1’ in this block.

Line 256: `if (output_last_r) begin` This condition selects the following hardware branch only when ‘output_last_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 257: `output_zero_r <= 1’b1;` This makes output_zero_r, the value named ’output zero r’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 258: `output_last_r <= 1’b0;` This makes output_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 259: `end else if (output_remaining_r == 2) begin` This condition selects the following hardware branch only when ‘output_remaining_r == 2‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_remaining_r: the number of command result beats still expected. Context: the clocked process that updates registers only on a rising clock edge.

Line 260: `output_last_r <= 1'b1;` This makes output_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 261: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 262: `if (program_output_last_r) begin` This condition selects the following hardware branch only when ‘program_output_last_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are program_output_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 263: `program_output_zero_r <= 1'b1;` This makes program_output_zero_r, the value named ’program output zero r’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 264: `program_output_last_r <= 1'b0;` This makes program_output_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 265: `end else if (program_output_remaining_r == 2) begin` This condition selects the following hardware branch only when ‘program_output_remaining_r == 2‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are program_output_remaining_r: the number of result beats left in the complete descriptor program. Context: the clocked process that updates registers only on a rising clock edge.

Line 266: `program_output_last_r <= 1'b1;` This makes program_output_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 267: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 268: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 269: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 271: `unique case (state)` This starts a multiplexer/state decode selected by ‘state‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 272: `ST_HEADER: if (input_accept) begin` This is the ST_HEADER case branch, which accepts and validates the descriptor record header. The same-cycle action begins with ‘if (input_accept) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 273: `input_remaining_r <= s_axis_tdata[31:0];` This makes input_remaining_r, the number of command payload beats still expected, equal to ‘s_axis_tdata[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named ’s axis tdata’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 274: `input_zero_r <= s_axis_tdata[31:0] == 0;` This makes input_zero_r, the value named ’input zero r’ in this block, equal to ‘s_axis_tdata[31:0] == 0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named ’s axis tdata’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 275: `input_last_r <= s_axis_tdata[31:0] == 1;` This makes input_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘s_axis_tdata[31:0] == 1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named ’s axis tdata’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 276: `output_remaining_r <= s_axis_tdata[62:32];` This makes output_remaining_r, the number of command result beats still expected, equal to ‘s_axis_tdata[62:32]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named ’s axis tdata’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 277: `output_zero_r <= s_axis_tdata[62:32] == 0;` This makes output_zero_r, the value named ’output zero r’ in this block, equal to ‘s_axis_tdata[62:32] == 0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named ’s axis tdata’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 278: `output_last_r <= s_axis_tdata[62:32] == 1;` This makes output_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘s_axis_tdata[62:32] == 1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named ’s axis tdata’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 279: `record_final_r <= s_axis_tdata[63];` This makes record_final_r, the value named ’record final r’ in this block, equal to ‘s_axis_tdata[63]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named ’s axis tdata’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 280: `command_done_seen_r <= 1'b0;` This makes command_done_seen_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 281: `command_error_seen_r <= 1'b0;` This makes command_error_seen_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 282: `if (s_axis_tlast) 'NE_ENTER_PROGRAM_ERROR(1'b1)` This condition selects the following hardware branch only when 's_axis_tlast) 'NE_ENTER_PROGRAM_ERROR(1'b1' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; NE_ENTER_PROGRAM_ERROR: the value named 'ne enter program error' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header..

Line 283: `else state <= ST_COMMAND_LOW;` Within the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header., this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMMAND_LOW: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 284: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_HEADER, the machine accepts and validates the descriptor record header.; it has no arithmetic value of its own.

Line 286: `ST_COMMAND_LOW: if (input_accept) begin` This is the ST_COMMAND_LOW case branch, which captures command bits 63 through 0. The same-cycle action begins with 'if (input_accept) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_LOW, the machine captures command bits 63 through 0..

Line 287: `descriptor_command_r[63:0] <= s_axis_tdata;` This makes descriptor_command_r[63:0], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to 's_axis_tdata'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_LOW, the machine captures command bits 63 through 0..

Line 288: `if (s_axis_tlast) 'NE_ENTER_PROGRAM_ERROR(1'b1)` This condition selects the following hardware branch only when 's_axis_tlast) 'NE_ENTER_PROGRAM_ERROR(1'b1' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; NE_ENTER_PROGRAM_ERROR: the value named 'ne enter program error' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_LOW, the machine captures command bits 63 through 0..

Line 289: `else state <= ST_COMMAND_HIGH;` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_LOW, the machine captures command bits 63 through 0., this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_COMMAND_HIGH: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters.

Line 290: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_LOW, the machine captures command bits 63 through 0.; it has no arithmetic value of its own.

Line 292: `ST_COMMAND_HIGH: if (input_accept) begin` This is the ST_COMMAND_HIGH case branch, which captures command bits 127 through 64 and checks input TLAST. The same-cycle action begins with ‘if (input_accept) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_HIGH, the machine captures command bits 127 through 64 and checks input TLAST..

Line 293: `descriptor_command_r[127:64] <= s_axis_tdata;` This makes descriptor_command_r[127:64], the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘s_axis_tdata‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named ’s axis tdata’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_HIGH, the machine captures command bits 127 through 64 and checks input TLAST..

Line 294: `if (s_axis_tlast != (record_final_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_HIGH, the machine captures command bits 127 through 64 and checks input TLAST., this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; record_final_r: the value named ’record final r’ in this block.

Line 295: `&& input_zero_r)) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_HIGH, the machine captures command bits 127 through 64 and checks input TLAST., this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are input_zero_r: the value named ’input zero r’ in this block.

Line 296: `‘NE_ENTER_PROGRAM_ERROR(s_axis_tlast)` This SystemVerilog preprocessor line controls compilation of the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 297: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_HIGH, the machine captures command bits 127 through 64 and checks input TLAST.; it has no arithmetic value of its own.

Line 298: `state <= ST_SUBMIT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_SUBMIT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SUBMIT: the value named ’st submit’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_HIGH, the machine captures command bits 127 through 64 and checks input TLAST..

Line 299: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_HIGH, the machine captures command bits 127 through 64 and checks input TLAST.; it has no arithmetic value of its own.

Line 300: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMAND_HIGH, the machine captures command bits 127 through 64 and checks input TLAST.; it has no arithmetic value of its own.

Line 302: `ST_SUBMIT: if (core_command_ready) begin` This is the ST_SUBMIT case branch, which holds command-valid until the universal core accepts the instruction. The same-cycle action begins with ‘if (core_command_ready) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_SUBMIT, the machine holds command-valid until the universal core accepts the instruction..

Line 303: `program_records <= program_records + 1’b1;` This makes program_records, the number of descriptor records accepted since program start, equal to ‘program_records + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are program_records: the number of descriptor records accepted since program start; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBMIT, the machine holds command-valid until the universal core accepts the instruction..

Line 304: `if (input_zero_r) state <= ST_WAIT;` This condition selects the following hardware branch only when ‘input_zero_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_zero_r: the value named ’input zero r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SUBMIT, the machine holds command-valid until the universal core accepts the instruction..

Line 305: `else state <= ST_PAYLOAD;` Within the clocked process that updates registers only on a rising clock edge Within state ST_SUBMIT, the machine holds command-valid until the universal core accepts the instruction., this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_PAYLOAD: stream data belonging to the current command.

Line 306: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SUBMIT, the machine holds command-valid until the universal core accepts the instruction.; it has no arithmetic value of its own.

Line 308: `ST_PAYLOAD: if (input_accept) begin` This is the ST_PAYLOAD case branch, which forwards exactly the declared number of input beats to the selected engine. The same-cycle action begins with ‘if (input_accept) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine..

Line 309: `if (s_axis_tlast != (record_final_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine., this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload; record_final_r: the value named ’record final r’ in this block.

Line 310: `&& input_last_r)) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine., this exact statement contributes to the block that turns a multi-record DMA program into checked core commands and payload/output streams. The important operands are input_last_r: the AXI-Stream marker for the final beat of a packet or command payload.

Line 311: `‘NE_ENTER_PROGRAM_ERROR(s_axis_tlast)` This SystemVerilog preprocessor line controls compilation of the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 312: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine.; it has no arithmetic value of its own.

Line 313: `input_remaining_r <= input_remaining_r - 1’b1;` This makes input_remaining_r, the number of command payload beats still expected, equal to ‘input_remaining_r - 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_remaining_r: the number of command payload beats still expected; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine..

Line 314: `if (input_last_r) begin` This condition selects the following hardware branch only when ‘input_last_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine..

Line 315: `input_zero_r <= 1'b1;` This makes input_zero_r, the value named 'input zero r' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine..

Line 316: `input_last_r <= 1'b0;` This makes input_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine..

Line 317: `state <= ST_WAIT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_WAIT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_WAIT: the value named 'st wait' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine..

Line 318: `end else if (input_remaining_r == 2) begin` This condition selects the following hardware branch only when 'input_remaining_r == 2' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_remaining_r: the number of command payload beats still expected. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine..

Line 319: `input_last_r <= 1'b1;` This makes input_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine..

Line 320: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine.; it has no arithmetic value of its own.

Line 321: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine.; it has no arithmetic value of its own.

Line 322: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PAYLOAD, the machine forwards exactly the declared number of input beats to the selected engine.; it has no arithmetic value of its own.

Line 324: `ST_WAIT: begin` This is the ST_WAIT case branch, which waits for both command completion and the declared output count. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 325: `if (record_command_complete && record_outputs_complete) begin` This condition selects the following hardware branch only when 'record_command_complete && record_outputs_complete' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are record_command_complete: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters; record_outputs_complete: the value named 'record outputs complete' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 326: `command_done_seen_r <= 1'b0;` This makes command_done_seen_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 327: `command_error_seen_r <= 1'b0;` This makes command_error_seen_r, the 128-bit instruction selecting an engine, shape, mode, and numeric parameters, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 328: `if (command_error_seen_r) begin` This condition selects the following hardware branch only when ‘command_error_seen_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are command_error_seen_r: the 128-bit instruction selecting an engine, shape, mode, and numeric parameters. Context: the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 329: `‘NE_ENTER_PROGRAM_ERROR(record_final_r)` This SystemVerilog preprocessor line controls compilation of the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 330: `end else if (record_final_r) begin` This condition selects the following hardware branch only when ‘record_final_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are record_final_r: the value named ’record final r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 331: `if (!program_output_zero_r) begin` This condition selects the following hardware branch only when ‘!program_output_zero_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are program_output_zero_r: the value named ’program output zero r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 332: `‘NE_ENTER_PROGRAM_ERROR(1'b1)` This SystemVerilog preprocessor line controls compilation of the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 333: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 334: `program_active <= 1'b0;` This makes program_active, the value named ’program active’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 335: `program_done <= 1'b1;` This makes program_done, the value named ’program done’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 336: `state <= ST_HEADER;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_HEADER‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_HEADER: the value named ’st header’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 337: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 338: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 339: `state <= ST_HEADER;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_HEADER‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_HEADER: the value named ’st header’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count..

Line 340: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 341: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 342: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 344: `ST_ERROR_DRAIN: if (input_accept && s_axis_tlast) begin` This is the ST_ERROR_DRAIN case branch, which discards remaining DMA input until TLAST so the next transfer starts aligned. The same-cycle action begins with ‘if (input_accept && s_axis_tlast) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_ERROR_DRAIN, the machine discards remaining DMA input until TLAST so the next transfer starts aligned..

Line 345: `program_active <= 1’b0;` This makes program_active, the value named ’program active’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ERROR_DRAIN, the machine discards remaining DMA input until TLAST so the next transfer starts aligned..

Line 346: `program_done <= 1’b1;` This makes program_done, the value named ’program done’ in this block, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ERROR_DRAIN, the machine discards remaining DMA input until TLAST so the next transfer starts aligned..

Line 347: `state <= ST_HEADER;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_HEADER‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_HEADER: the value named ’st header’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ERROR_DRAIN, the machine discards remaining DMA input until TLAST so the next transfer starts aligned..

Line 348: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ERROR_DRAIN, the machine discards remaining DMA input until TLAST so the next transfer starts aligned.; it has no arithmetic value of its own.

Line 350: `default: `NE_ENTER_PROGRAM_ERROR(1'b0)` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with "NE_ENTER_PROGRAM_ERROR(1'b0)‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_ERROR_DRAIN, the machine discards remaining DMA input until TLAST so the next transfer starts aligned..

Line 351: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ERROR_DRAIN, the machine discards remaining DMA input until TLAST so the next transfer starts aligned.; it has no arithmetic value of its own.

Line 352: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 353: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 354: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 355: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 356: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 358: `‘undef NE_ENTER_PROGRAM_ERROR` This SystemVerilog preprocessor line controls compilation of the block that turns a multi-record DMA program into checked core commands and payload/output streams.

Line 360: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that turns a multi-record DMA program into checked core commands and payload/output streams.

9 rtl/neuraedge_gradient_accumulator_bank.sv

Role in the complete system: stores one lane of exact cross-command backward gradients in inferred distributed memory.

9.1 Beginner architecture map

Dataflow responsibility This file's end-to-end responsibility is to stores one lane of exact cross-command backward gradients in inferred distributed memory.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_gradient_accumulator_bank into physical nets and primitives. The source declares 5 input-port lines, 1 output-port lines, 1 clocked process(es), and 0 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control This block is primarily a datapath or storage primitive rather than a large state machine. Registers still divide combinational work into cycles and hold valid/data stable during downstream stalls.

Connections to other blocks This is a leaf block: parent modules create it and connect its ports. It does not instantiate another project RTL module, so its arithmetic or storage maps directly into FPGA primitives.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

9.2 Complete source

```
1  `timescale 1ns / 1ps
2  `default_nettype none
3
4  // Stores one lane of exact 47-bit backward-gradient partial sums.
5  module neuraedge_gradient_accumulator_bank (
6      input  wire clk,
7      input  wire write_enable,
8      input  wire [3:0] write_address,
9      input  wire signed [46:0] write_data,
10     input  wire [3:0] read_address,
11     output wire signed [46:0] read_data
12 );
13     // One asynchronous read and one synchronous write match a 7-series
14     // distributed-RAM inference template. There is intentionally no reset:
15     // the parent selects zero until a complete non-accumulating command has
16     // established valid contents for every active address.
17     (* ram_style = "distributed" *)
18     logic signed [46:0] memory [0:15];
19
20     assign read_data = memory[read_address];
21
22     always_ff @(posedge clk) begin
23         if (write_enable) memory[write_address] <= write_data;
24     end
25 endmodule
26
27 `default_nettype wire
```

9.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `// Stores one lane of exact 47-bit backward-gradient partial sums.` Design intent: Stores one lane of exact 47-bit backward-gradient partial sums. This comment anchors the surrounding logic in the block that stores one lane of exact cross-command backward gradients in inferred distributed memory.

Line 5: `module neuraedge_gradient_accumulator_bank (` This opens neuraedge_gradient_accumulator_bank, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that stores one lane of exact cross-command backward gradients in inferred distributed memory.

Line 6: `input wire clk,` This declares clk as a input port with width one bit. It carries the clock that makes all registers advance together across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 7: `input wire write_enable,` This declares write_enable as a input port with width one bit. It carries a control bit that permits the associated state or storage update across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 8: `input wire [3:0] write_address,` This declares write_address as a input port with width [3:0]. It carries the value named 'write address' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 9: `input wire signed [46:0] write_data,` This declares write_data as a input port with width [46:0]. It carries the payload carried with the surrounding valid/ready handshake across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 10: `input wire [3:0] read_address,` This declares read_address as a input port with width [3:0]. It carries the value named 'read address' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 11: `output wire signed [46:0] read_data` This declares read_data as a output port with width [46:0]. It carries the payload carried with the surrounding valid/ready handshake across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 12: `);` Within the module's structural declarations, this exact statement contributes to the block that stores one lane of exact cross-command backward gradients in inferred distributed memory. The expression is a literal or structural operator and has no hidden software state.

Line 13: `// One asynchronous read and one synchronous write match a 7-series` Design intent: One asynchronous read and one synchronous write match a 7-series This comment anchors the surrounding logic in the block that stores one lane of exact cross-command backward gradients in inferred distributed memory.

Line 14: `// distributed-RAM inference template. There is intentionally no reset:` Design intent: distributed-RAM inference template. There is intentionally no reset: This comment anchors the surrounding logic in the block that stores one lane of exact cross-command backward gradients in inferred distributed memory.

Line 15: `// the parent selects zero until a complete non-accumulating command has` Design intent: the parent selects zero until a complete non-accumulating command has This comment anchors the surrounding logic in the block that stores one lane of exact cross-command backward gradients in inferred distributed memory.

Line 16: `// established valid contents for every active address.` Design intent: established valid contents for every active address. This comment anchors the surrounding logic in the block that stores one lane of exact cross-command backward gradients in inferred distributed memory.

Line 17: `(* ram_style = "distributed" *)` Within the module's structural declarations, this exact statement contributes to the block that stores one lane of exact cross-command backward gradients in inferred distributed memory. The important operands are ram_style: the value named 'ram style' in this block; distributed: the value named 'distributed' in this block.

Line 18: `logic signed [46:0] memory [0:15];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, memory is local FPGA storage addressed by surrounding index logic. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 20: `assign read_data = memory[read_address];` This makes read_data, the payload carried with the surrounding valid/ready handshake, equal to 'memory[read_address]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are memory: local FPGA storage addressed by surrounding index logic; read_address: the value named 'read address' in this block. Context: the module's structural declarations.

Line 22: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 23: `if (write_enable) memory[write_address] <= write_data;` This condition selects the following hardware branch only when 'write_enable' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are write_enable: a control bit that permits the associated state or storage update. Context: the clocked process that updates registers only on a rising clock edge.

Line 24: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 25: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 27: `` `default_nettype wire `` This SystemVerilog preprocessor line controls compilation of the block that stores one lane of exact cross-command backward gradients in inferred distributed memory.

10 rtl/neuraedge_integer_layernorm.sv

Role in the complete system: evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

10.1 Beginner architecture map

Dataflow responsibility The block first stores a vector while accumulating its sum and squared sum. It derives integer mean and variance, invokes the iterative square-root and divider, applies per-element gamma and beta, saturates the result, and preserves output data whenever downstream ready is low.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_integer_layernorm into physical nets and primitives. The source declares 12 input-port lines, 12 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_IDLE, ST_LOAD, ST_MEAN_ABSOLUTE_HIGH, ST_MEAN_A ST_MEAN_COMMIT, ST_MEAN_PREPARE, ST_MEAN_START, ST_MEAN_WAIT, ST_OUTPUT_BETA, ST_OUTPUT_CENTER, ST_OUTPUT_GAMMA_CROSS, ST_OUTPUT_GAMMA_LATCH, ST_OUTPUT_GAMM ST_OUTPUT_GAMMA_MULTIPLY, ST_OUTPUT_GAMMA_OPERANDS, ST_OUTPUT_HOLD, ST_OUTPUT_L ST_OUTPUT_NORMALIZE_ABSOLUTE and additional states. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates neuraedge_udivider as u_divider, neuraedge_isqrt64 as u_sqrt, begin as if, else as if, unique as case, end as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

10.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_integer_layernorm #(` This opens neuraedge_integer_layernorm, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 5: `parameter int MAX_FEATURES = 2048,` This statement continues through source line 31; the explanation uses the complete expression rather than only the first visual fragment. This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 6: `parameter int VALUE_BITS = 24` This is continuation line 2 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'parameter int VALUE_BITS = 24'. The important operands are parameter: the value named 'parameter' in this block; VALUE_BITS: the value named 'value bits' in this block. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 7: `) (` This is continuation line 3 of the 27-line logical statement that begins at source line 5. Its exact fragment is ') ('. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 8: `input wire clk,` This is continuation line 4 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire clk,'. The important operands are input: the value named 'input' in this block; clk: the clock that makes all registers advance together. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic

start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 9: `input wire rst_n,` This is continuation line 5 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire rst_n,'. The important operands are input: the value named 'input' in this block; rst_n: the active-low synchronous reset. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 10: `input wire start_valid,` This is continuation line 6 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire start_valid,'. The important operands are input: the value named 'input' in this block; start_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 11: `output logic start_ready,` This is continuation line 7 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic start_ready,'. The important operands are output: the value named 'output' in this block; start_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 12: `input wire [11:0] feature_count,` This is continuation line 8 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire [11:0] feature_count,'. The important operands are input: the value named 'input' in this block; feature_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic

[31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 13: `input wire [31:0] epsilon,` This is continuation line 9 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire [31:0] epsilon,'. The important operands are input: the value named 'input' in this block; epsilon: the value named 'epsilon' in this block. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 14: `input wire sample_valid,` This is continuation line 10 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire sample_valid,'. The important operands are input: the value named 'input' in this block; sample_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 15: `output logic sample_ready,` This is continuation line 11 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic sample_ready,'. The important operands are output: the value named 'output' in this block; sample_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 16: `input wire signed [VALUE_BITS-1:0] sample_value,` This is continuation line 12 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [VALUE_BITS-1:0] sample_value,'. The important operands are input: the value named 'input' in this block; VALUE_BITS: the value named 'value bits' in this block; sample_value: the value named 'sample value' in this block. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 17: `input wire signed [VALUE_BITS-1:0] sample_gamma_q15,` This is continuation line 13 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [VALUE_BITS-1:0] sample_gamma_q15,'. The important operands are input: the value named 'input' in this block; VALUE_BITS: the value named 'value bits' in this block; sample_gamma_q15: the learned multiplicative LayerNorm parameter. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 18: `input wire signed [VALUE_BITS-1:0] sample_beta,` This is continuation line 14 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [VALUE_BITS-1:0] sample_beta,'. The important operands are input: the value named 'input' in this block; VALUE_BITS: the value named 'value bits' in this block; sample_beta: the learned additive LayerNorm parameter. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 19: `input wire sample_last,` This is continuation line 15 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire sample_last,'. The important operands are input: the value named 'input' in this block; sample_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 20: `output logic result_valid,` This is continuation line 16 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic result_valid,'. The important operands are output: the value named 'output' in this block; result_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 21: `input wire result_ready,` This is continuation line 17 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'input wire result_ready,'. The important operands are input: the value named 'input' in this block; result_ready: the consumer's statement that it can accept a payload this cycle. Read together,

the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 22: `output logic signed [31:0] result_value,` This is continuation line 18 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic signed [31:0] result_value,'. The important operands are output: the value named 'output' in this block; result_value: the value named 'result value' in this block. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 23: `output logic [11:0] result_index,` This is continuation line 19 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic [11:0] result_index,'. The important operands are output: the value named 'output' in this block; result_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 24: `output logic result_last,` This is continuation line 20 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic result_last,'. The important operands are output: the value named 'output' in this block; result_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 25: `output logic config_error,` This is continuation line 21 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic config_error,'. The important operands are output: the value named 'output' in this block; config_error: the value named 'config error' in this block. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output

logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 26: `output logic [31:0] cycle_count,` This is continuation line 22 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] cycle_count,'. The important operands are output: the value named 'output' in this block; cycle_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 27: `output logic signed [31:0] debug_mean,` This is continuation line 23 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic signed [31:0] debug_mean,'. The important operands are output: the value named 'output' in this block; debug_mean: the arithmetic average used by normalization. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 28: `output logic [31:0] debug_variance,` This is continuation line 24 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] debug_variance,'. The important operands are output: the value named 'output' in this block; debug_variance: the average squared distance from the mean. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 29: `output logic [31:0] debug_sigma,` This is continuation line 25 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] debug_sigma,'. The important operands are output: the value named 'output' in this block; debug_sigma: the value named 'debug sigma' in this block. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 30: `output logic [31:0] debug_reciprocal_q31` This is continuation line 26 of the 27-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] debug_reciprocal_q31'. The important operands are output: the value named 'output' in this block; debug_reciprocal_q31: the value named 'debug reciprocal q31' in this block. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 31: `);` This is continuation line 27 of the 27-line logical statement that begins at source line 5. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes MAX_FEATURES to 2048, parameter int VALUE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [11:0] feature_count, input wire [31:0] epsilon, input wire sample_valid, output logic sample_ready, input wire signed [VALUE_BITS-1:0] sample_value, input wire signed [VALUE_BITS-1:0] sample_gamma_q15, input wire signed [VALUE_BITS-1:0] sample_beta, input wire sample_last, output logic result_valid, input wire result_ready, output logic signed [31:0] result_value, output logic [11:0] result_index, output logic result_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [31:0] debug_mean, output logic [31:0] debug_variance, output logic [31:0] debug_sigma, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_FEATURES denotes the value named 'max features' in this block.

Line 32: `// The normalization datapath is deliberately deeply registered. Each state` Design intent: The normalization datapath is deliberately deeply registered. Each state This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 33: `// performs one memory access, multiply, carry-chain operation, or comparison;` Design intent: performs one memory access, multiply, carry-chain operation, or comparison; This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 34: `// no state hides a multi-operation arithmetic expression from timing analysis.` Design intent: no state hides a multi-operation arithmetic expression from timing analysis. This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 35: `typedef enum logic [5:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 36: `ST_IDLE = 6'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 37: `ST_LOAD = 6'd1,` This assigns a fixed binary encoding to state ST_LOAD, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 38: `ST_MEAN_START = 6'd2,` This assigns a fixed binary encoding to state ST_MEAN_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 39: `ST_MEAN_WAIT = 6'd3,` This assigns a fixed binary encoding to state ST_MEAN_WAIT, which waits for both command completion and the declared output count. The encoding is visible in waveforms even though the source uses the readable name.

Line 40: `ST_VARIANCE_READ = 6'd4,` This assigns a fixed binary encoding to state ST_VARIANCE_READ, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 41: `ST_VARIANCE_CENTER = 6'd5,` This assigns a fixed binary encoding to state ST_VARIANCE_CENTER, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 42: `ST_VARIANCE_SQUARE = 6'd6,` This assigns a fixed binary encoding to state ST_VARIANCE_SQUARE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 43: `ST_VARIANCE_ACCUMULATE = 6'd7,` This assigns a fixed binary encoding to state ST_VARIANCE_ACCUMULATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 44: `ST_VARIANCE_START = 6'd8,` This assigns a fixed binary encoding to state ST_VARIANCE_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 45: `ST_VARIANCE_WAIT = 6'd9,` This assigns a fixed binary encoding to state ST_VARIANCE_WAIT, which waits for both command completion and the declared output count. The encoding is visible in waveforms even though the source uses the readable name.

Line 46: `ST_SQRT_START = 6'd10,` This assigns a fixed binary encoding to state ST_SQRT_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 47: `ST_SQRT_WAIT = 6'd11,` This assigns a fixed binary encoding to state ST_SQRT_WAIT, which waits for both command completion and the declared output count. The encoding is visible in waveforms even though the source uses the readable name.

Line 48: `ST_RECIPROCAL_START = 6'd12,` This assigns a fixed binary encoding to state ST_RECIPROCAL_START, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 49: `ST_RECIPROCAL_WAIT = 6'd13,` This assigns a fixed binary encoding to state ST_RECIPROCAL_WAIT, which waits for both command completion and the declared output count. The encoding is visible in waveforms even though the source uses the readable name.

Line 50: `ST_OUTPUT_READ = 6'd14,` This assigns a fixed binary encoding to state ST_OUTPUT_READ, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 51: `ST_OUTPUT_CENTER = 6'd15,` This assigns a fixed binary encoding to state ST_OUTPUT_CENTER, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 52: `ST_OUTPUT_NORMALIZE_MULTIPLY = 6'd16,` This assigns a fixed binary encoding to state ST_OUTPUT_NORMALIZE which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 53: `ST_OUTPUT_NORMALIZE_ABSOLUTE = 6'd17,` This assigns a fixed binary encoding to state ST_OUTPUT_NORMALIZE which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 54: `ST_OUTPUT_NORMALIZE_ROUND = 6'd18,` This assigns a fixed binary encoding to state ST_OUTPUT_NORMALIZE_R which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 55: `ST_OUTPUT_NORMALIZE_SIGN = 6'd19,` This assigns a fixed binary encoding to state ST_OUTPUT_NORMALIZE_SI which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 56: `ST_OUTPUT_GAMMA_MULTIPLY = 6'd20,` This assigns a fixed binary encoding to state ST_OUTPUT_GAMMA_MULTI which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 57: `ST_OUTPUT_SCALE_ABSOLUTE = 6'd21,` This assigns a fixed binary encoding to state ST_OUTPUT_SCALE_ABSOLU which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 58: `ST_OUTPUT_SCALE_ROUND = 6'd22,` This assigns a fixed binary encoding to state ST_OUTPUT_SCALE_ROUND, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 59: `ST_OUTPUT_SCALE_SIGN = 6'd23,` This assigns a fixed binary encoding to state ST_OUTPUT_SCALE_SIGN, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 60: `ST_OUTPUT_BETA = 6'd24,` This assigns a fixed binary encoding to state ST_OUTPUT_BETA, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 61: `ST_OUTPUT_SATURATE = 6'd25,` This assigns a fixed binary encoding to state ST_OUTPUT_SATURATE, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 62: `ST_OUTPUT_HOLD = 6'd26,` This assigns a fixed binary encoding to state ST_OUTPUT_HOLD, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 63: `ST_VARIANCE_LATCH = 6'd27,` This assigns a fixed binary encoding to state ST_VARIANCE_LATCH, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 64: `ST_OUTPUT_LATCH = 6'd28,` This assigns a fixed binary encoding to state ST_OUTPUT_LATCH, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 65: `ST_OUTPUT_NORMALIZE_LATCH = 6'd29,` This assigns a fixed binary encoding to state ST_OUTPUT_NORMALIZE_L which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 66: `ST_OUTPUT_GAMMA_LATCH = 6'd30,` This assigns a fixed binary encoding to state ST_OUTPUT_GAMMA_LATCH, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 67: `ST_VARIANCE_SQUARE_LATCH = 6'd31,` This assigns a fixed binary encoding to state ST_VARIANCE_SQUARE_LAT which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 68: `ST_OUTPUT_NORMALIZE_OPERANDS = 6'd32,` This assigns a fixed binary encoding to state ST_OUTPUT_NORMALIZE which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 69: `ST_OUTPUT_NORMALIZE_CLAMP = 6'd33,` This assigns a fixed binary encoding to state ST_OUTPUT_NORMALIZE_C which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 70: `ST_OUTPUT_GAMMA_OPERANDS = 6'd34,` This assigns a fixed binary encoding to state ST_OUTPUT_GAMMA_OPERA which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 71: `ST_OUTPUT_GAMMA_CROSS = 6'd35,` This assigns a fixed binary encoding to state ST_OUTPUT_GAMMA_CROSS, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 72: `ST_OUTPUT_GAMMA_LOW = 6'd36,` This assigns a fixed binary encoding to state ST_OUTPUT_GAMMA_LOW, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 73: `ST_MEAN_ADJUST = 6'd37,` This assigns a fixed binary encoding to state ST_MEAN_ADJUST, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 74: `ST_MEAN_COMMIT = 6'd38,` This assigns a fixed binary encoding to state ST_MEAN_COMMIT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 75: `ST_VARIANCE_SQUARE_PARTIAL = 6'd39,` This assigns a fixed binary encoding to state ST_VARIANCE_SQUARE_PA which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 76: `ST_VARIANCE_SQUARE_ADD = 6'd40,` This assigns a fixed binary encoding to state ST_VARIANCE_SQUARE_ADD, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 77: `ST_MEAN_PREPARE = 6'd41,` This assigns a fixed binary encoding to state ST_MEAN_PREPARE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 78: `ST_VARIANCE_ACCUMULATE_HIGH = 6'd42,` This assigns a fixed binary encoding to state ST_VARIANCE_ACCUMULA which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 79: `ST_OUTPUT_NORMALIZE_ABSOLUTE_HIGH = 6'd43,` This assigns a fixed binary encoding to state ST_OUTPUT_NORMA which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 80: `ST_MEAN_ABSOLUTE_HIGH = 6'd44` This statement continues through source line 81; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_MEAN_ABSOLUTE_HIGH, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 81: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 80. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_MEAN_ABSOLUTE_HIGH, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 83: `state_t state;` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are state_t: the finite-state-machine phase retained in flip-flops; state: the finite-state-machine phase retained in flip-flops.

Line 84: `(* ram_style = "block" *) logic signed [VALUE_BITS-1:0] value_mem [0:MAX_FEATURES-1];` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are ram_style: the value named 'ram style' in this block; block: the value named 'block' in this block; VALUE_BITS: the value named 'value bits' in this block.

Line 85: `(* ram_style = "block" *) logic signed [VALUE_BITS-1:0] gamma_mem [0:MAX_FEATURES-1];` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are ram_style: the value named 'ram style' in this block; block: the value named 'block' in this block; VALUE_BITS: the value named 'value bits' in this block.

Line 86: `(* ram_style = "block" *) logic signed [VALUE_BITS-1:0] beta_mem [0:MAX_FEATURES-1];` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are ram_style: the value named 'ram style' in this block; block: the value named 'block' in this block; VALUE_BITS: the value named 'value bits' in this block.

Line 88: `logic [11:0] feature_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, feature_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 89: `logic [31:0] epsilon_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, epsilon_r is the value named 'epsilon r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 90: `logic [11:0] load_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 91: `logic [11:0] samples_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, samples_remaining_r is the value named 'samples remaining r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 92: `logic [11:0] variance_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_index is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 93: `logic [11:0] variance_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_remaining_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 94: `logic [11:0] output_index_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_index_r is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 95: `logic [11:0] output_remaining_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_remaining_r is the number of command result beats still expected. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 96: `logic signed [47:0] sum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sum_r is the value named 'sum r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 97: `logic [63:0] mean_numerator_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mean_numerator_r is the arithmetic average used by normalization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 98: `logic [31:0] mean_absolute_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mean_absolute_low_r is the arithmetic average used by normalization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 99: `logic mean_absolute_carry_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mean_absolute_carry_r is the arithmetic average used by normalization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 100: `logic [63:0] variance_sum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_sum_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 101: `logic [31:0] variance_sum_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_sum_low_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 102: `logic variance_sum_carry_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_sum_carry_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 103: `logic signed [31:0] mean_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mean_r is the arithmetic average used by normalization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 104: `logic mean_negative_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mean_negative_r is the arithmetic average used by normalization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 105: `logic mean_has_remainder_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mean_has_remainder_r is the arithmetic average used by normalization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 106: `logic [31:0] mean_quotient_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mean_quotient_r is the arithmetic average used by normalization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 107: `logic [31:0] mean_magnitude_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mean_magnitude_r is the arithmetic average used by normalization. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 108: `logic [31:0] variance_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 109: `logic [31:0] sigma_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sigma_r is the value named 'sigma r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 110: `logic [31:0] reciprocal_q31_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, reciprocal_q31_r is the value named 'reciprocal q31 r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 112: `logic signed [VALUE_BITS-1:0] output_value_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_value_r is the value named 'output value r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 113: `logic signed [VALUE_BITS-1:0] output_gamma_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_gamma_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 114: `logic signed [VALUE_BITS-1:0] output_beta_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_beta_r is the learned additive LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 115: `logic signed [VALUE_BITS-1:0] output_value_ram_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_value_ram_r is the value named 'output value ram r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 116: `logic signed [VALUE_BITS-1:0] output_gamma_ram_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_gamma_ram_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 117: `logic signed [VALUE_BITS-1:0] output_beta_ram_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_beta_ram_r is the learned additive LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 118: `logic signed [VALUE_BITS-1:0] variance_value_ram_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_value_ram_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 119: `logic signed [VALUE_BITS-1:0] variance_value_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_value_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 120: `logic signed [24:0] variance_centered_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_centered_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 121: `logic [23:0] variance_magnitude_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_magnitude_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 122: `logic [35:0] variance_square_low_product_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_square_low_product_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 123: `logic [35:0] variance_square_high_product_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_square_high_product_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 124: `logic [49:0] variance_square_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_square_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 125: `logic [49:0] variance_square_latched_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, variance_square_latched_r is the average squared distance from the mean. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 126: `(* dont_touch = "yes" *) logic signed [24:0] output_centered_r;` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; output_centered_r: the value named 'output centered r' in this block.

Line 127: `logic signed [24:0] normalized_centered_operand_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_centered_operand_r is the value named 'normalized centered operand r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 128: `logic [31:0] normalized_reciprocal_operand_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_reciprocal_operand_r is the value named 'normalized reciprocal operand r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 129: `logic signed [41:0] normalized_low_product_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_low_product_r is the value named 'normalized low product r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 130: `logic signed [41:0] normalized_high_product_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_high_product_r is the value named 'normalized high product r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 131: `logic signed [57:0] normalized_product_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_product_r is the value named 'normalized product r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 132: `logic normalized_negative_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_negative_r is the value named 'normalized negative r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 133: `logic [31:0] normalized_magnitude_low_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_magnitude_low_r is the value named 'normalized magnitude low r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 134: `logic normalized_magnitude_carry_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_magnitude_carry_r is the value named 'normalized magnitude carry r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 135: `logic [63:0] normalized_magnitude_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_magnitude_r is the value named 'normalized magnitude r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 136: `logic [63:0] normalized_rounded_magnitude_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_rounded_magnitude_r is the value named 'normalized rounded magnitude r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 137: `logic [31:0] normalized_clamped_magnitude_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, normalized_clamped_magnitude_r is the value named 'normalized clamped magnitude r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 138: `(* dont_touch = "yes" *) logic signed [31:0] normalized_r;` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are dont_touch: the value named 'dont touch' in this block; yes: the value named 'yes' in this block; normalized_r: the value named 'normalized r' in this block.

Line 139: `logic signed [31:0] gamma_normalized_operand_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_normalized_operand_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 140: `logic signed [VALUE_BITS-1:0] gamma_scale_operand_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_scale_operand_r is the real-value spacing represented by one quantized integer step. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 141: `logic signed [33:0] gamma_partial_ll_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_partial_ll_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 142: `logic signed [24:0] gamma_partial_lh_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_partial_lh_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 143: `logic signed [32:0] gamma_partial_hl_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_partial_hl_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 144: `logic signed [23:0] gamma_partial_hh_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_partial_hh_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 145: `logic signed [33:0] gamma_cross_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_cross_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 146: `logic signed [49:0] gamma_low_cross_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_low_cross_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 147: `logic signed [55:0] gamma_product_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_product_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 148: `logic scale_negative_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, scale_negative_r is the real-value spacing represented by one quantized integer step. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 149: `logic [55:0] scale_magnitude_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, scale_magnitude_r is the real-value spacing represented by one quantized integer step. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 150: `logic [55:0] scale_rounded_magnitude_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, scale_rounded_magnitude_r is the real-value spacing represented by one quantized integer step. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 151: `logic signed [55:0] scaled_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, scaled_r is the real-value spacing represented by one quantized integer step. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 152: `logic signed [63:0] scaled_beta_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, scaled_beta_r is the real-value spacing represented by one quantized integer step. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 153: `logic result_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 155: `// A difference between two signed 24-bit values fits in 25 bits and its` Design intent: A difference between two signed 24-bit values fits in 25 bits and its This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 156: `// magnitude fits in 24 unsigned bits. Two 24 x 12 DSP products therefore` Design intent: magnitude fits in 24 unsigned bits. Two 24 x 12 DSP products therefore This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 157: `// form the exact square without a multi-DSP combinational cascade.` Design intent: form the exact square without a multi-DSP combinational cascade. This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 158: `(* use_dsp = "yes" *) wire [35:0] variance_square_low_product =` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; variance_square_low_product: the average squared distance from the mean.

Line 159: `variance_magnitude_r[23:0] * variance_magnitude_r[11:0];` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are variance_magnitude_r: the average squared distance from the mean.

Line 160: `(* use_dsp = "yes" *) wire [35:0] variance_square_high_product =` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; variance_square_high_product: the average squared distance from the mean.

Line 161: `variance_magnitude_r[23:0] * variance_magnitude_r[23:12];` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are variance_magnitude_r: the average squared distance from the mean.

Line 163: `// A 24-bit sample minus its mean needs only 25 signed bits. Splitting the` Design intent: A 24-bit sample minus its mean needs only 25 signed bits. Splitting the This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 164: `// unsigned Q31 reciprocal into two 16-bit limbs lets each exact partial` Design intent: unsigned Q31 reciprocal into two 16-bit limbs lets each exact partial This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 165: `// product fit one DSP48E1 without an unregistered PCIN cascade.` Design intent: product fit one DSP48E1 without an unregistered PCIN cascade. This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 166: `(* use_dsp = "yes" *) wire signed [41:0] normalized_low_product =` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; normalized_low_product: the value named 'normalized low product' in this block.

Line 167: `normalized_centered_operand_r` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are normalized_centered_operand_r: the value named 'normalized centered operand r' in this block.

Line 168: `* $signed({1'b0, normalized_reciprocal_operand_r[15:0]});` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are b0: the value named 'b0' in this block; normalized_reciprocal_operand_r: the value named 'normalized reciprocal operand r' in this block.

Line 169: `(* use_dsp = "yes" *) wire signed [41:0] normalized_high_product =` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; normalized_high_product: the value named 'normalized high product' in this block.

Line 170: `normalized_centered_operand_r` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are normalized_centered_operand_r: the value named 'normalized centered operand r' in this block.

Line 171: `* $signed({1'b0, normalized_reciprocal_operand_r[31:16]});` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are b0: the value named 'b0' in this block; normalized_reciprocal_operand_r: the value named 'normalized reciprocal operand r' in this block.

Line 173: `// The signed 32 x 24 gamma multiply is four exact base-2^16 limb` Design intent: The signed 32 x 24 gamma multiply is four exact base-2^16 limb This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 174: `// products. Low limbs are made explicitly positive by a leading zero;` Design intent: products. Low limbs are made explicitly positive by a leading zero; This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 175: `// high limbs retain the sign of the original two's-complement operand.` Design intent: high limbs retain the sign of the original two's-complement operand. This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 176: `wire signed [16:0] gamma_normalized_low =` This statement continues through source line 177; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_normalized_low is the learned multiplicative LayerNorm parameter; gamma_normalized_operand_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 177: `$signed({1'b0, gamma_normalized_operand_r[15:0]});` This is continuation line 2 of the 2-line logical statement that begins at source line 176. Its exact fragment is '$signed({1'b0, gamma_normalized_operand_r[15:0]});'. The important operands are b0: the value named 'b0' in this block; gamma_normalized_operand_r: the learned multiplicative LayerNorm parameter. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_normalized_low is the learned multiplicative LayerNorm parameter; gamma_normalized_operand_r is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 178: `wire signed [15:0] gamma_normalized_high =` This statement continues through source line 179; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_normalized_high is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 179: `$signed(gamma_normalized_operand_r[31:16]);` This is continuation line 2 of the 2-line logical statement that begins at source line 178. Its exact fragment is '$signed(gamma_normalized_operand_r[31:16]);'. The important operands are gamma_normalized_operand_r: the learned multiplicative LayerNorm parameter. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically,

gamma_normalized_high is the learned multiplicative LayerNorm parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 180: `wire signed [16:0] gamma_scale_low =` This statement continues through source line 181; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_scale_low is the real-value spacing represented by one quantized integer step; gamma_scale_operand_r is the real-value spacing represented by one quantized integer step. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 181: `$signed({1'b0, gamma_scale_operand_r[15:0]});` This is continuation line 2 of the 2-line logical statement that begins at source line 180. Its exact fragment is '$signed({1'b0, gamma_scale_operand_r[15:0]});'. The important operands are b0: the value named 'b0' in this block; gamma_scale_operand_r: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_scale_low is the real-value spacing represented by one quantized integer step; gamma_scale_operand_r is the real-value spacing represented by one quantized integer step. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 182: `wire signed [7:0] gamma_scale_high =` This statement continues through source line 183; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_scale_high is the real-value spacing represented by one quantized integer step. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 183: `$signed(gamma_scale_operand_r[23:16]);` This is continuation line 2 of the 2-line logical statement that begins at source line 182. Its exact fragment is '$signed(gamma_scale_operand_r[23:16]);'. The important operands are gamma_scale_operand_r: the real-value spacing represented by one quantized integer step. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, gamma_scale_high is the real-value spacing represented by one quantized integer step. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 184: `(* use_dsp = "yes" *) wire signed [33:0] gamma_partial_ll =` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; gamma_partial_ll: the learned multiplicative LayerNorm parameter.

Line 185: `gamma_normalized_low * gamma_scale_low;` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are gamma_normalized_low: the learned multiplicative LayerNorm parameter; gamma_scale_low: the real-value spacing represented by one quantized integer step.

Line 186: `(* use_dsp = "yes" *) wire signed [24:0] gamma_partial_lh =` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; gamma_partial_lh: the learned multiplicative LayerNorm parameter.

Line 187: `gamma_normalized_low * gamma_scale_high;` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are gamma_normalized_low: the learned multiplicative LayerNorm parameter; gamma_scale_high: the real-value spacing represented by one quantized integer step.

Line 188: `(* use_dsp = "yes" *) wire signed [32:0] gamma_partial_hl =` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are use_dsp: the value named

'use dsp' in this block; yes: the value named 'yes' in this block; gamma_partial_hl: the learned multiplicative LayerNorm parameter.

Line 189: `gamma_normalized_high * gamma_scale_low;` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are gamma_normalized_high: the learned multiplicative LayerNorm parameter; gamma_scale_low: the real-value spacing represented by one quantized integer step.

Line 190: `(* use_dsp = "yes" *) wire signed [23:0] gamma_partial_hh =` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block; gamma_partial_hh: the learned multiplicative LayerNorm parameter.

Line 191: `gamma_normalized_high * gamma_scale_high;` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are gamma_normalized_high: the learned multiplicative LayerNorm parameter; gamma_scale_high: the real-value spacing represented by one quantized integer step.

Line 193: `logic divider_input_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 194: `wire divider_input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 195: `logic [63:0] divider_numerator;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_numerator is the value named 'divider numerator' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 196: `logic [31:0] divider_denominator;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_denominator is the value named 'divider denominator' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 197: `wire divider_output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 198: `logic divider_output_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 199: `wire [63:0] divider_quotient;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_quotient is the value named 'divider quotient' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 200: `wire [31:0] divider_remainder;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_remainder is the value named 'divider remainder' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 201: `wire divider_zero;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, divider_zero is the value named 'divider zero' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 203: `logic sqrt_input_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_input_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 204: `wire sqrt_input_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_input_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 205: `logic [63:0] sqrt_radicand;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_radicand is the value named 'sqrt radicand' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 206: `wire sqrt_output_valid;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_output_valid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 207: `logic sqrt_output_ready;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_output_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 208: `wire [31:0] sqrt_root;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, sqrt_root is the value named 'sqrt root' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 210: `neuraedge_udivider u_divider (` This instantiates module neuraedge_udivider as u_divider. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 211: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 212: `.input_valid(divider_input_valid), .input_ready(divider_input_ready),` This connects the child instance's named port 'input_valid' to parent expression 'divider_input_valid), .input_ready(divider_input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 213: `.numerator(divider_numerator), .denominator(divider_denominator),` This connects the child instance's named port 'numerator' to parent expression 'divider_numerator), .denominator(divider_denominator'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'divider numerator), .denominator(divider denominator' in this block.

Line 214: `.output_valid(divider_output_valid), .output_ready(divider_output_ready),` This connects the child instance's named port 'output_valid' to parent expression 'divider_output_valid), .output_ready(divider_output_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 215: `.quotient(divider_quotient), .remainder(divider_remainder),` This connects the child instance's named port 'quotient' to parent expression 'divider_quotient), .remainder(divider_remainder'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'divider quotient), .remainder(divider remainder' in this block.

Line 216: `.divide_by_zero(divider_zero)` This connects the child instance's named port 'divide_by_zero' to parent expression 'divider_zero'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'divider zero' in this block.

Line 217: `);` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The expression is a literal or structural operator and has no hidden software state.

Line 219: `neuraedge_isqrt64 u_sqrt (` This instantiates module neuraedge_isqrt64 as u_sqrt. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 220: `.clk(clk), .rst_n(rst_n),` This connects the child instance's named port 'clk' to parent expression 'clk), .rst_n(rst_n'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 221: `.input_valid(sqrt_input_valid), .input_ready(sqrt_input_ready),` This connects the child instance's named port 'input_valid' to parent expression 'sqrt_input_valid), .input_ready(sqrt_input_ready'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 222: `.radicand(sqrt_radicand), .output_valid(sqrt_output_valid),` This connects the child instance's named port 'radicand' to parent expression 'sqrt_radicand), .output_valid(sqrt_output_valid'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the producer's statement that its current payload is meaningful.

Line 223: `.output_ready(sqrt_output_ready), .root(sqrt_root),` This connects the child instance's named port 'output_ready' to parent expression 'sqrt_output_ready), .root(sqrt_root'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the consumer's statement that it can accept a payload this cycle.

Line 224: `.remainder()` This connects the child instance's named port 'remainder' to parent expression ''. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the value named 'remainder' in this block.

Line 225: `);` Within the module's structural declarations, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The expression is a literal or structural operator and has no hidden software state.

Line 227: `function automatic logic signed [31:0] saturate_s32(` Within the combinational helper saturate s32, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; saturate_s32: the value named 'saturate s32' in this block.

Line 228: `input logic signed [63:0] value` This declares value as a input port with width [63:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 229: `);` Within the combinational helper saturate s32, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The expression is a literal or structural operator and has no hidden software state.

Line 230: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s32; it has no arithmetic value of its own.

Line 231: `if (value[63:32] == {32{value[31]}}) saturate_s32 = value[31:0];` This condition selects the following hardware branch only when 'value[63:32] == {32{value[31]}}' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the combinational helper saturate s32.

Line 232: `else if (value[63]) saturate_s32 = 32'sh80000000;` This condition selects the following hardware branch only when ‘value[63]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the combinational helper saturate s32.

Line 233: `else saturate_s32 = 32'sh7fffffff;` Within the combinational helper saturate s32, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are saturate_s32: the value named 'saturate s32' in this block; sh7fffffff: the value named 'sh7fffffff' in this block.

Line 234: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s32; it has no arithmetic value of its own.

Line 235: `endfunction` Within the combinational helper saturate s32, this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are endfunction: the value named 'endfunction' in this block.

Line 237: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 238: `start_ready = state == ST_IDLE;` This makes start_ready, the consumer's statement that it can accept a payload this cycle, equal to ‘state == ST_IDLE‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 239: `sample_ready = state == ST_LOAD;` This makes sample_ready, the consumer's statement that it can accept a payload this cycle, equal to ‘state == ST_LOAD‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LOAD: the value named 'st load' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 240: `result_valid = state == ST_OUTPUT_HOLD;` This makes result_valid, the producer's statement that its current payload is meaningful, equal to ‘state == ST_OUTPUT_HOLD‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_OUTPUT_HOLD: the value named 'st output hold' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 241: `result_index = output_index_r;` This makes result_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 242: `result_last = result_last_r;` This makes result_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘result_last_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 244: `divider_input_valid = state == ST_MEAN_START` This statement continues through source line 245; the explanation uses the complete expression rather than only the first visual fragment. This makes divider_input_valid, the producer's statement that its current payload is meaningful, equal to ‘state == ST_MEAN_START || state == ST_VARIANCE_START || state == ST_RECIPROCAL_START‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_MEAN_START: the arithmetic average used by normalization; ST_VARIANCE_START: the average squared distance from the mean. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 245: `|| state == ST_VARIANCE_START || state == ST_RECIPROCAL_START;` This is continuation line 2 of the 2-line logical statement that begins at source line 244. Its exact fragment is '|| state == ST_VARIANCE_START || state == ST_RECIPROCAL_START;'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_VARIANCE_START: the average squared distance from the mean; ST_RECIPROCAL_START: the value named 'st reciprocal start' in this block. Read together, the complete operation is: This makes divider_input_valid, the producer's statement that its current payload is meaningful, equal to 'state == ST_MEAN_START || state == ST_VARIANCE_START || state == ST_RECIPROCAL_START'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_MEAN_START: the arithmetic average used by normalization; ST_VARIANCE_START: the average squared distance from the mean. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 246: `divider_output_ready = state == ST_MEAN_WAIT` This statement continues through source line 247; the explanation uses the complete expression rather than only the first visual fragment. This makes divider_output_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_MEAN_WAIT || state == ST_VARIANCE_WAIT || state == ST_RECIPROCAL_WAIT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_MEAN_WAIT: the arithmetic average used by normalization; ST_VARIANCE_WAIT: the average squared distance from the mean. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 247: `|| state == ST_VARIANCE_WAIT || state == ST_RECIPROCAL_WAIT;` This is continuation line 2 of the 2-line logical statement that begins at source line 246. Its exact fragment is '|| state == ST_VARIANCE_WAIT || state == ST_RECIPROCAL_WAIT;'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_VARIANCE_WAIT: the average squared distance from the mean; ST_RECIPROCAL_WAIT: the value named 'st reciprocal wait' in this block. Read together, the complete operation is: This makes divider_output_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_MEAN_WAIT || state == ST_VARIANCE_WAIT || state == ST_RECIPROCAL_WAIT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_MEAN_WAIT: the arithmetic average used by normalization; ST_VARIANCE_WAIT: the average squared distance from the mean. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 248: `divider_numerator = 64'd0;` This makes divider_numerator, the value named 'divider numerator' in this block, equal to '64'd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 249: `divider_denominator = {20'd0, feature_count_r};` This makes divider_denominator, the value named 'divider denominator' in this block, equal to '{20'd0, feature_count_r}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block; feature_count_r: an integer count retained for control or measurable telemetry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 250: `if (state == ST_MEAN_START) begin` This condition selects the following hardware branch only when 'state == ST_MEAN_START' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_MEAN_START: the arithmetic average used by normalization. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 251: `divider_numerator = mean_numerator_r;` This makes divider_numerator, the value named 'divider numerator' in this block, equal to 'mean_numerator_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are mean_numerator_r: the arithmetic average used by normalization. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 252: `end else if (state == ST_VARIANCE_START) begin` This condition selects the following hardware branch only when 'state == ST_VARIANCE_START' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are state: the finite-state-machine phase retained in

flip-flops; ST_VARIANCE_START: the average squared distance from the mean. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 253: `divider_numerator = variance_sum_r;` This makes divider_numerator, the value named 'divider numerator' in this block, equal to 'variance_sum_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are variance_sum_r: the average squared distance from the mean. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 254: `end else if (state == ST_RECIPROCAL_START) begin` This condition selects the following hardware branch only when 'state == ST_RECIPROCAL_START' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_RECIPROCAL_START: the value named 'st reciprocal start' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 255: `divider_numerator = 64'd2147483647;` This makes divider_numerator, the value named 'divider numerator' in this block, equal to '64'd2147483647'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d2147483647: the value named 'd2147483647' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 256: `divider_denominator = sigma_r;` This makes divider_denominator, the value named 'divider denominator' in this block, equal to 'sigma_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sigma_r: the value named 'sigma r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 257: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 259: `sqrt_input_valid = state == ST_SQRT_START;` This makes sqrt_input_valid, the producer's statement that its current payload is meaningful, equal to 'state == ST_SQRT_START'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_SQRT_START: the value named 'st sqrt start' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 260: `sqrt_output_ready = state == ST_SQRT_WAIT;` This makes sqrt_output_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_SQRT_WAIT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_SQRT_WAIT: the value named 'st sqrt wait' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 261: `sqrt_radicand = {32'd0, variance_r} + {32'd0, epsilon_r};` This makes sqrt_radicand, the value named 'sqrt radicand' in this block, equal to '{32'd0, variance_r} + {32'd0, epsilon_r}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block; variance_r: the average squared distance from the mean; epsilon_r: the value named 'epsilon r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 263: `debug_mean = mean_r;` This makes debug_mean, the arithmetic average used by normalization, equal to 'mean_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are mean_r: the arithmetic average used by normalization. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 264: `debug_variance = variance_r;` This makes debug_variance, the average squared distance from the mean, equal to 'variance_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are variance_r: the average squared distance from the mean. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 265: `debug_sigma = sigma_r;` This makes debug_sigma, the value named 'debug sigma' in this block, equal to 'sigma_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sigma_r: the value named 'sigma r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 266: `debug_reciprocal_q31 = reciprocal_q31_r;` This makes debug_reciprocal_q31, the value named 'debug reciprocal q31' in this block, equal to 'reciprocal_q31_r'. It is driven by combinational or procedural logic in the current evaluation. The important operands are reciprocal_q31_r: the value named 'reciprocal q31 r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 267: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 269: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 270: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 271: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 272: `feature_count_r <= 12'd0;` This makes feature_count_r, an integer count retained for control or measurable telemetry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 273: `epsilon_r <= 32'd0;` This makes epsilon_r, the value named 'epsilon r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 274: `load_index <= 12'd0;` This makes load_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 275: `samples_remaining_r <= 12'd0;` This makes samples_remaining_r, the value named 'samples remaining r' in this block, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 276: `variance_index <= 12'd0;` This makes variance_index, the average squared distance from the mean, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 277: `variance_remaining_r <= 12'd0;` This makes variance_remaining_r, the average squared distance from the mean, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 278: `output_index_r <= 12'd0;` This makes output_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 279: `output_remaining_r <= 12'd0;` This makes output_remaining_r, the number of command result beats still expected, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 280: `sum_r <= 48'sd0;` This makes sum_r, the value named 'sum r' in this block, equal to '48'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 281: `mean_numerator_r <= 64'd0;` This makes mean_numerator_r, the arithmetic average used by normalization, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 282: `mean_absolute_low_r <= 32'd0;` This makes mean_absolute_low_r, the arithmetic average used by normalization, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 283: `mean_absolute_carry_r <= 1'b0;` This makes mean_absolute_carry_r, the arithmetic average used by normalization, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 284: `variance_sum_r <= 64'd0;` This makes variance_sum_r, the average squared distance from the mean, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 285: `variance_sum_low_r <= 32'd0;` This makes variance_sum_low_r, the average squared distance from the mean, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 286: `variance_sum_carry_r <= 1'b0;` This makes variance_sum_carry_r, the average squared distance from the mean, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 287: `mean_r <= 32'sd0;` This makes mean_r, the arithmetic average used by normalization, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 288: `mean_negative_r <= 1'b0;` This makes mean_negative_r, the arithmetic average used by normalization, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 289: `mean_has_remainder_r <= 1'b0;` This makes mean_has_remainder_r, the arithmetic average used by normalization, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 290: `mean_quotient_r <= 32'd0;` This makes mean_quotient_r, the arithmetic average used by normalization, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 291: `mean_magnitude_r <= 32'd0;` This makes mean_magnitude_r, the arithmetic average used by normalization, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 292: `variance_r <= 32'd0;` This makes variance_r, the average squared distance from the mean, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 293: `sigma_r <= 32'd1;` This makes sigma_r, the value named 'sigma r' in this block, equal to ‘32'd1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 294: `reciprocal_q31_r <= 32'd0;` This makes reciprocal_q31_r, the value named 'reciprocal q31 r' in this block, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 295: `output_value_r <= '0;` This makes output_value_r, the value named 'output value r' in this block, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 296: `output_gamma_r <= '0;` This makes output_gamma_r, the learned multiplicative LayerNorm parameter, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 297: `output_beta_r <= '0;` This makes output_beta_r, the learned additive LayerNorm parameter, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 298: `output_value_ram_r <= '0;` This makes output_value_ram_r, the value named 'output value ram r' in this block, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 299: `output_gamma_ram_r <= '0;` This makes output_gamma_ram_r, the learned multiplicative LayerNorm parameter, equal to ‘'0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 300: `output_beta_ram_r <= '0;` This makes output_beta_ram_r, the learned additive LayerNorm parameter, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 301: `variance_value_ram_r <= '0;` This makes variance_value_ram_r, the average squared distance from the mean, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 302: `variance_value_r <= '0;` This makes variance_value_r, the average squared distance from the mean, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 303: `variance_centered_r <= 25'sd0;` This makes variance_centered_r, the average squared distance from the mean, equal to ‘25'sd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 304: `variance_magnitude_r <= 24'd0;` This makes variance_magnitude_r, the average squared distance from the mean, equal to ‘24'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 305: `variance_square_low_product_r <= 36'd0;` This makes variance_square_low_product_r, the average squared distance from the mean, equal to ‘36'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 306: `variance_square_high_product_r <= 36'd0;` This makes variance_square_high_product_r, the average squared distance from the mean, equal to ‘36'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 307: `variance_square_r <= 50'd0;` This makes variance_square_r, the average squared distance from the mean, equal to ‘50'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 308: `variance_square_latched_r <= 50'd0;` This makes variance_square_latched_r, the average squared distance from the mean, equal to ‘50'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 309: `output_centered_r <= 25'sd0;` This makes output_centered_r, the value named 'output centered r' in this block, equal to ‘25'sd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 310: `normalized_centered_operand_r <= 25'sd0;` This makes normalized_centered_operand_r, the value named 'normalized centered operand r' in this block, equal to ‘25'sd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 311: `normalized_reciprocal_operand_r <= 32'd0;` This makes normalized_reciprocal_operand_r, the value named 'normalized reciprocal operand r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 312: `normalized_low_product_r <= 42'sd0;` This makes normalized_low_product_r, the value named 'normalized low product r' in this block, equal to '42'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 313: `normalized_high_product_r <= 42'sd0;` This makes normalized_high_product_r, the value named 'normalized high product r' in this block, equal to '42'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 314: `normalized_product_r <= 58'sd0;` This makes normalized_product_r, the value named 'normalized product r' in this block, equal to '58'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 315: `normalized_negative_r <= 1'b0;` This makes normalized_negative_r, the value named 'normalized negative r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 316: `normalized_magnitude_low_r <= 32'd0;` This makes normalized_magnitude_low_r, the value named 'normalized magnitude low r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 317: `normalized_magnitude_carry_r <= 1'b0;` This makes normalized_magnitude_carry_r, the value named 'normalized magnitude carry r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 318: `normalized_magnitude_r <= 64'd0;` This makes normalized_magnitude_r, the value named 'normalized magnitude r' in this block, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 319: `normalized_rounded_magnitude_r <= 64'd0;` This makes normalized_rounded_magnitude_r, the value named 'normalized rounded magnitude r' in this block, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 320: `normalized_clamped_magnitude_r <= 32'd0;` This makes normalized_clamped_magnitude_r, the value named 'normalized clamped magnitude r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 321: `normalized_r <= 32'sd0;` This makes normalized_r, the value named 'normalized r' in this block, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 322: `gamma_normalized_operand_r <= 32'sd0;` This makes gamma_normalized_operand_r, the learned multiplicative LayerNorm parameter, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 323: `gamma_scale_operand_r <= '0;` This makes gamma_scale_operand_r, the real-value spacing represented by one quantized integer step, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 324: `gamma_partial_ll_r <= 34'sd0;` This makes gamma_partial_ll_r, the learned multiplicative LayerNorm parameter, equal to '34'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 325: `gamma_partial_lh_r <= 25'sd0;` This makes gamma_partial_lh_r, the learned multiplicative LayerNorm parameter, equal to '25'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 326: `gamma_partial_hl_r <= 33'sd0;` This makes gamma_partial_hl_r, the learned multiplicative LayerNorm parameter, equal to '33'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 327: `gamma_partial_hh_r <= 24'sd0;` This makes gamma_partial_hh_r, the learned multiplicative LayerNorm parameter, equal to '24'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 328: `gamma_cross_r <= 34'sd0;` This makes gamma_cross_r, the learned multiplicative LayerNorm parameter, equal to '34'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 329: `gamma_low_cross_r <= 50'sd0;` This makes gamma_low_cross_r, the learned multiplicative LayerNorm parameter, equal to '50'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 330: `gamma_product_r <= 56'sd0;` This makes gamma_product_r, the learned multiplicative LayerNorm parameter, equal to '56'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 331: `scale_negative_r <= 1'b0;` This makes scale_negative_r, the real-value spacing represented by one quantized integer step, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 332: `scale_magnitude_r <= 56'd0;` This makes scale_magnitude_r, the real-value spacing represented by one quantized integer step, equal to '56'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 333: `scale_rounded_magnitude_r <= 56'd0;` This makes scale_rounded_magnitude_r, the real-value spacing represented by one quantized integer step, equal to '56'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 334: `scaled_r <= 56'sd0;` This makes scaled_r, the real-value spacing represented by one quantized integer step, equal to '56'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 335: `scaled_beta_r <= 64'sd0;` This makes scaled_beta_r, the real-value spacing represented by one quantized integer step, equal to '64'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 336: `result_last_r <= 1'b0;` This makes result_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 337: `result_value <= 32'sd0;` This makes result_value, the value named 'result value' in this block, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 338: `config_error <= 1'b0;` This makes config_error, the value named 'config error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 339: `cycle_count <= 32'd0;` This makes cycle_count, an integer count retained for control or measurable telemetry, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 340: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 341: `if (state != ST_IDLE) cycle_count <= cycle_count + 1'b1;` This condition selects the following hardware branch only when 'state != ST_IDLE' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 342: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 343: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 344: `if (start_valid) begin` This condition selects the following hardware branch only when 'start_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are start_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 345: `cycle_count <= 32'd0;` This makes cycle_count, an integer count retained for control or measurable telemetry, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 346: `config_error <= feature_count == 0` This statement continues through source line 347; the explanation uses the complete expression rather than only the first visual fragment. This makes config_error, the value named 'config error' in this block, equal to 'feature_count == 0 || feature_count > 12'(MAX_FEATURES)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are feature_count: an integer count retained for control or measurable telemetry; MAX_FEATURES: the value named 'max features' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 347: `|| feature_count > 12'(MAX_FEATURES);` This is continuation line 2 of the 2-line logical statement that begins at source line 346. Its exact fragment is '|| feature_count > 12'(MAX_FEATURES);'. The important operands are feature_count: an integer count retained for control or measurable telemetry; MAX_FEATURES: the value named 'max features' in this block. Read together, the complete operation is: This makes config_error, the value named 'config error' in this block, equal to 'feature_count == 0 || feature_count > 12'(MAX_FEATURES)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are feature_count: an integer count retained for control or measurable telemetry; MAX_FEATURES: the value named 'max features' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 348: `feature_count_r <= feature_count;` This makes feature_count_r, an integer count retained for control or measurable telemetry, equal to 'feature_count'. It updates after the active clock edge together with other nonblocking assignments. The important operands are feature_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 349: `epsilon_r <= epsilon;` This makes epsilon_r, the value named 'epsilon r' in this block, equal to 'epsilon'. It updates after the active clock edge together with other nonblocking assignments. The important operands are epsilon: the value named 'epsilon' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 350: `// Clearing on every accepted start keeps feature-count` Design intent: Clearing on every accepted start keeps feature-count This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 351: `// validation out of the 48-bit sum register enable.` Design intent: validation out of the 48-bit sum register enable. This comment anchors the surrounding logic in the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

Line 352: `sum_r <= 48'sd0;` This makes sum_r, the value named 'sum r' in this block, equal to '48'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 353: `if (feature_count == 0` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are feature_count: an integer count retained for control or measurable telemetry.

Line 354: `|| feature_count > 12'(MAX_FEATURES)) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are feature_count: an integer count retained for control or measurable telemetry; MAX_FEATURES: the value named 'max features' in this block.

Line 355: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 356: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 357: `load_index <= 12'd0;` This makes load_index, an integer selecting one tensor element, lane, bank, or state entry, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 358: `samples_remaining_r <= feature_count;` This makes samples_remaining_r, the value named 'samples remaining r' in this block, equal to 'feature_count'. It updates after the active clock edge together with other nonblocking assignments. The important operands are feature_count: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 359: `state <= ST_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LOAD'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD: the value named 'st load' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 360: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 361: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 362: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 364: `ST_LOAD: begin` This is the ST_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 365: `if (sample_valid) begin` This condition selects the following hardware branch only when 'sample_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sample_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 366: `logic signed [47:0] sample_extended;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.. Specifically, sample_extended is the value named 'sample extended' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 367: `logic expected_last;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.. Specifically, expected_last is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 368: `sample_extended = {{(48-VALUE_BITS){sample_value[VALUE_BITS-1]}}, sample_value};` This makes sample_extended, the value named 'sample extended' in this block, equal to '{{(48-VALUE_BITS){sample_value[VALUE_BITS-1]}}, sample_value}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are VALUE_BITS: the value named 'value bits' in this block; sample_value: the value named 'sample value' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 369: `expected_last = samples_remaining_r == 12'd1;` This makes expected_last, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'samples_remaining_r == 12'd1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are samples_remaining_r: the value named 'samples remaining r' in this block; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 370: `value_mem[load_index[10:0]] <= sample_value;` This makes value_mem[load_index[10:0]], local FPGA storage addressed by surrounding index logic, equal to 'sample_value'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sample_value: the value named 'sample value' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 371: `gamma_mem[load_index[10:0]] <= sample_gamma_q15;` This makes gamma_mem[load_index[10:0]], the learned multiplicative LayerNorm parameter, equal to 'sample_gamma_q15'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sample_gamma_q15: the learned multiplicative LayerNorm parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 372: `beta_mem[load_index[10:0]] <= sample_beta;` This makes beta_mem[load_index[10:0]], the learned additive LayerNorm parameter, equal to 'sample_beta'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sample_beta: the learned additive LayerNorm parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 373: `sum_r <= sum_r + sample_extended;` This makes sum_r, the value named 'sum r' in this block, equal to 'sum_r + sample_extended'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sum_r: the value named 'sum r' in this block; sample_extended: the value named 'sample extended' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 374: `if (sample_last != expected_last) begin` This condition selects the following hardware branch only when 'sample_last != expected_last' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sample_last: the AXI-Stream marker for the final beat of a packet or command payload; expected_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 375: `config_error <= 1'b1;` This makes config_error, the value named 'config error' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 376: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 377: `if (expected_last) begin` This condition selects the following hardware branch only when 'expected_last' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are expected_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 378: `state <= ST_MEAN_PREPARE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MEAN_PREPARE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MEAN_PREPARE: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 379: `end else if (sample_last) begin` This condition selects the following hardware branch only when 'sample_last' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sample_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 380: `config_error <= 1'b1;` This makes config_error, the value named 'config error' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 381: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 382: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 383: `load_index <= load_index + 1'b1;` This makes load_index, an integer selecting one tensor element, lane, bank, or state entry, equal to 'load_index + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 384: `samples_remaining_r <= samples_remaining_r - 1'b1;` This makes samples_remaining_r, the value named 'samples remaining r' in this block, equal to 'samples_remaining_r - 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are samples_remaining_r: the value named 'samples remaining r' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory..

Line 385: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 386: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 387: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 389: `ST_MEAN_PREPARE: begin` This is the ST_MEAN_PREPARE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase..

Line 390: `logic [32:0] absolute_low;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase.. Specifically, absolute_low is the value named ’absolute low’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 391: `if (sum_r < 0) begin` This condition selects the following hardware branch only when ‘sum_r $<$ 0‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sum_r: the value named ’sum r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase..

Line 392: `absolute_low = {1'b0, ~sum_r[31:0]} + 1'b1;` This makes absolute_low, the value named ’absolute low’ in this block, equal to ‘{1’b0, ~sum_r[31:0]} + 1’b1‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block; sum_r: the value named ’sum r’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase..

Line 393: `mean_absolute_low_r <= absolute_low[31:0];` This makes mean_absolute_low_r, the arithmetic average used by normalization, equal to ‘absolute_low[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are absolute_low: the value named ’absolute low’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase..

Line 394: `mean_absolute_carry_r <= absolute_low[32];` This makes mean_absolute_carry_r, the arithmetic average used by normalization, equal to ‘absolute_low[32]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are absolute_low: the value named ’absolute low’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase..

Line 395: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 396: `mean_absolute_low_r <= sum_r[31:0];` This makes mean_absolute_low_r, the arithmetic average used by normalization, equal to ‘sum_r[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are sum_r: the value named ’sum r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase..

Line 397: `mean_absolute_carry_r <= 1'b0;` This makes mean_absolute_carry_r, the arithmetic average used by normalization, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase..

Line 398: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 399: `state <= ST_MEAN_ABSOLUTE_HIGH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_MEAN_ABSOLUTE_HIGH‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MEAN_ABSOLUTE_HIGH: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase..

Line 400: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_PREPARE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 402: `ST_MEAN_ABSOLUTE_HIGH: begin` This is the ST_MEAN_ABSOLUTE_HIGH case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase..

Line 403: `logic [15:0] absolute_high;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase.. Specifically, absolute_high is the value named 'absolute high' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 404: `if (sum_r < 0) begin` This condition selects the following hardware branch only when ‘sum_r < 0‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sum_r: the value named 'sum r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase..

Line 405: `absolute_high = ~sum_r[47:32]` This statement continues through source line 406; the explanation uses the complete expression rather than only the first visual fragment. This makes absolute_high, the value named 'absolute high' in this block, equal to ‘~sum_r[47:32] + 16'(mean_absolute_carry_r)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are sum_r: the value named 'sum r' in this block; mean_absolute_carry_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase..

Line 406: `+ 16'(mean_absolute_carry_r);` This is continuation line 2 of the 2-line logical statement that begins at source line 405. Its exact fragment is ‘+ 16'(mean_absolute_carry_r);‘. The important operands are mean_absolute_carry_r: the arithmetic average used by normalization. Read together, the complete operation is: This makes absolute_high, the value named 'absolute high' in this block, equal to ‘~sum_r[47:32] + 16'(mean_absolute_carry_r)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are sum_r: the value named 'sum r' in this block; mean_absolute_carry_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase..

Line 407: `mean_numerator_r <= {` This statement continues through source line 408; the explanation uses the complete expression rather than only the first visual fragment. This makes mean_numerator_r, the arithmetic average used by normalization, equal to ‘{ 16'd0, absolute_high, mean_absolute_low_r}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this

block; absolute_high: the value named 'absolute high' in this block; mean_absolute_low_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase..

Line 408: `16'd0, absolute_high, mean_absolute_low_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 407. Its exact fragment is '16'd0, absolute_high, mean_absolute_low_r};'. The important operands are d0: the value named 'd0' in this block; absolute_high: the value named 'absolute high' in this block; mean_absolute_low_r: the arithmetic average used by normalization. Read together, the complete operation is: This makes mean_numerator_r, the arithmetic average used by normalization, equal to '{ 16'd0, absolute_high, mean_absolute_low_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; absolute_high: the value named 'absolute high' in this block; mean_absolute_low_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase..

Line 409: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 410: `mean_numerator_r <= {` This statement continues through source line 411; the explanation uses the complete expression rather than only the first visual fragment. This makes mean_numerator_r, the arithmetic average used by normalization, equal to '{ 16'd0, sum_r[47:32], mean_absolute_low_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; sum_r: the value named 'sum r' in this block; mean_absolute_low_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase..

Line 411: `16'd0, sum_r[47:32], mean_absolute_low_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 410. Its exact fragment is '16'd0, sum_r[47:32], mean_absolute_low_r};'. The important operands are d0: the value named 'd0' in this block; sum_r: the value named 'sum r' in this block; mean_absolute_low_r: the arithmetic average used by normalization. Read together, the complete operation is: This makes mean_numerator_r, the arithmetic average used by normalization, equal to '{ 16'd0, sum_r[47:32], mean_absolute_low_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block; sum_r: the value named 'sum r' in this block; mean_absolute_low_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase..

Line 412: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 413: `state <= ST_MEAN_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MEAN_START'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MEAN_START: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase..

Line 414: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ABSOLUTE_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 416: `ST_MEAN_START: begin` This is the ST_MEAN_START case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_START, the machine performs the named control phase..

Line 417: `if (divider_input_ready) state <= ST_MEAN_WAIT;` This condition selects the following hardware branch only when ‘divider_input_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are divider_input_ready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_START, the machine performs the named control phase..

Line 418: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_START, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 420: `ST_MEAN_WAIT: begin` This is the ST_MEAN_WAIT case branch, which waits for both command completion and the declared output count. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_WAIT, the machine waits for both command completion and the declared output count..

Line 421: `if (divider_output_valid) begin` This condition selects the following hardware branch only when ‘divider_output_valid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are divider_output_valid: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_WAIT, the machine waits for both command completion and the declared output count..

Line 422: `mean_negative_r <= sum_r < 0;` This makes mean_negative_r, the arithmetic average used by normalization, equal to ‘sum_r $<$ 0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are sum_r: the value named ’sum r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_WAIT, the machine waits for both command completion and the declared output count..

Line 423: `mean_has_remainder_r <= divider_remainder != 0;` This makes mean_has_remainder_r, the arithmetic average used by normalization, equal to ‘divider_remainder != 0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are divider_remainder: the value named ’divider remainder’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_WAIT, the machine waits for both command completion and the declared output count..

Line 424: `mean_quotient_r <= divider_quotient[31:0];` This makes mean_quotient_r, the arithmetic average used by normalization, equal to ‘divider_quotient[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are divider_quotient: the value named ’divider quotient’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_WAIT, the machine waits for both command completion and the declared output count..

Line 425: `config_error <= config_error || divider_zero;` This makes config_error, the value named ’config error’ in this block, equal to ‘config_error || divider_zero‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are config_error: the value named ’config error’ in this block; divider_zero: the value named ’divider zero’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_WAIT, the machine waits for both command completion and the declared output count..

Line 426: `state <= ST_MEAN_ADJUST;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_MEAN_ADJUST‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MEAN_ADJUST: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_WAIT, the machine waits for both command completion and the declared output count..

Line 427: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 428: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 430: `ST_MEAN_ADJUST: begin` This is the ST_MEAN_ADJUST case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ADJUST, the machine performs the named control phase..

Line 431: `mean_magnitude_r <= mean_quotient_r` This statement continues through source line 432; the explanation uses the complete expression rather than only the first visual fragment. This makes mean_magnitude_r, the arithmetic average used by normalization, equal to ‘mean_quotient_r + (mean_negative_r && mean_has_remainder_r)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are mean_quotient_r: the arithmetic average used by normalization; mean_negative_r: the arithmetic average used by normalization; mean_has_remainder_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ADJUST, the machine performs the named control phase..

Line 432: `+ (mean_negative_r && mean_has_remainder_r);` This is continuation line 2 of the 2-line logical statement that begins at source line 431. Its exact fragment is ‘+ (mean_negative_r && mean_has_remainder_r);‘. The important operands are mean_negative_r: the arithmetic average used by normalization; mean_has_remainder_r: the arithmetic average used by normalization. Read together, the complete operation is: This makes mean_magnitude_r, the arithmetic average used by normalization, equal to ‘mean_quotient_r + (mean_negative_r && mean_has_remainder_r)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are mean_quotient_r: the arithmetic average used by normalization; mean_negative_r: the arithmetic average used by normalization; mean_has_remainder_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ADJUST, the machine performs the named control phase..

Line 433: `state <= ST_MEAN_COMMIT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_MEAN_COMMIT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MEAN_COMMIT: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ADJUST, the machine performs the named control phase..

Line 434: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_ADJUST, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 436: `ST_MEAN_COMMIT: begin` This is the ST_MEAN_COMMIT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_COMMIT, the machine performs the named control phase..

Line 437: `mean_r <= mean_negative_r` This statement continues through source line 439; the explanation uses the complete expression rather than only the first visual fragment. This makes mean_r, the arithmetic average used by normalization, equal to ‘mean_negative_r ? -$signed(mean_magnitude_r) : $signed(mean_magnitude_r)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are mean_negative_r: the arithmetic average used by normalization; mean_magnitude_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_COMMIT, the machine performs the named control phase..

Line 438: `? -$signed(mean_magnitude_r)` This is continuation line 2 of the 3-line logical statement that begins at source line 437. Its exact fragment is ‘? -$signed(mean_magnitude_r)‘. The important operands are mean_magnitude_r: the arithmetic average used by normalization. Read together, the complete operation is: This makes mean_r, the arithmetic average used by normalization, equal to ‘mean_negative_r ? -$signed(mean_magnitude_r) : $signed(mean_magnitude_r)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are

mean_negative_r: the arithmetic average used by normalization; mean_magnitude_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_COMMIT, the machine performs the named control phase..

Line 439: `: $signed(mean_magnitude_r);` This is continuation line 3 of the 3-line logical statement that begins at source line 437. Its exact fragment is ': $signed(mean_magnitude_r);'. The important operands are mean_magnitude_r: the arithmetic average used by normalization. Read together, the complete operation is: This makes mean_r, the arithmetic average used by normalization, equal to 'mean_negative_r ? -$signed(mean_magnitude_r) : $signed(mean_magnitude_r)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are mean_negative_r: the arithmetic average used by normalization; mean_magnitude_r: the arithmetic average used by normalization. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_COMMIT, the machine performs the named control phase..

Line 440: `variance_index <= 12'd0;` This makes variance_index, the average squared distance from the mean, equal to '12'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_COMMIT, the machine performs the named control phase..

Line 441: `variance_remaining_r <= feature_count_r;` This makes variance_remaining_r, the average squared distance from the mean, equal to 'feature_count_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are feature_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_COMMIT, the machine performs the named control phase..

Line 442: `variance_sum_r <= 64'd0;` This makes variance_sum_r, the average squared distance from the mean, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_COMMIT, the machine performs the named control phase..

Line 443: `state <= ST_VARIANCE_READ;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_VARIANCE_READ'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_READ: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_COMMIT, the machine performs the named control phase..

Line 444: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MEAN_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 446: `ST_VARIANCE_READ: begin` This is the ST_VARIANCE_READ case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_READ, the machine performs the named control phase..

Line 447: `variance_value_ram_r <= value_mem[variance_index[10:0]];` This makes variance_value_ram_r, the average squared distance from the mean, equal to 'value_mem[variance_index[10:0]]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are value_mem: local FPGA storage addressed by surrounding index logic; variance_index: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_READ, the machine performs the named control phase..

Line 448: `state <= ST_VARIANCE_LATCH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_VARIANCE_LATCH'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_LATCH: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_READ, the machine performs the named control phase..

Line 449: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_READ, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 451: `ST_VARIANCE_LATCH: begin` This is the ST_VARIANCE_LATCH case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_LATCH, the machine performs the named control phase..

Line 452: `variance_value_r <= variance_value_ram_r;` This makes variance_value_r, the average squared distance from the mean, equal to 'variance_value_ram_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are variance_value_ram_r: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_LATCH, the machine performs the named control phase..

Line 453: `state <= ST_VARIANCE_CENTER;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_VARIANCE_CENTER'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_CENTER: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_LATCH, the machine performs the named control phase..

Line 454: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_LATCH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 456: `ST_VARIANCE_CENTER: begin` This is the ST_VARIANCE_CENTER case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_CENTER, the machine performs the named control phase..

Line 457: `variance_centered_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_CENTER, the machine performs the named control phase., this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are variance_centered_r: the average squared distance from the mean.

Line 458: `<= $signed({variance_value_r[23], variance_value_r})` Within the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_CENTER, the machine performs the named control phase., this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are variance_value_r: the average squared distance from the mean.

Line 459: `- $signed({mean_r[31], mean_r[23:0]});` Within the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_CENTER, the machine performs the named control phase., this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are mean_r: the arithmetic average used by normalization.

Line 460: `state <= ST_VARIANCE_SQUARE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_VARIANCE_SQUARE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_SQUARE: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_CENTER, the machine performs the named control phase..

Line 461: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_CENTER, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 463: `ST_VARIANCE_SQUARE: begin` This is the ST_VARIANCE_SQUARE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE, the machine performs the named control phase..

Line 464: `variance_magnitude_r <= variance_centered_r[24]` This statement continues through source line 466; the explanation uses the complete expression rather than only the first visual fragment. This makes variance_magnitude_r, the average squared distance from the mean, equal to ‘variance_centered_r[24] ? (~variance_centered_r[23:0] + 1’b1) : variance_centered_r[23:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are variance_centered_r: the average squared distance from the mean; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE, the machine performs the named control phase..

Line 465: `? (~variance_centered_r[23:0] + 1'b1)` This is continuation line 2 of the 3-line logical statement that begins at source line 464. Its exact fragment is ‘? (~variance_centered_r[23:0] + 1’b1)‘. The important operands are variance_centered_r: the average squared distance from the mean; b1: the value named ’b1’ in this block. Read together, the complete operation is: This makes variance_magnitude_r, the average squared distance from the mean, equal to ‘variance_centered_r[24] ? (~variance_centered_r[23:0] + 1’b1) : variance_centered_r[23:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are variance_centered_r: the average squared distance from the mean; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE, the machine performs the named control phase..

Line 466: `: variance_centered_r[23:0];` This is continuation line 3 of the 3-line logical statement that begins at source line 464. Its exact fragment is ‘: variance_centered_r[23:0];‘. The important operands are variance_centered_r: the average squared distance from the mean. Read together, the complete operation is: This makes variance_magnitude_r, the average squared distance from the mean, equal to ‘variance_centered_r[24] ? (~variance_centered_r[23:0] + 1’b1) : variance_centered_r[23:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are variance_centered_r: the average squared distance from the mean; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE, the machine performs the named control phase..

Line 467: `state <= ST_VARIANCE_SQUARE_PARTIAL;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_VARIANCE_SQUARE_PARTIAL‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_SQUARE_PARTIAL: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE, the machine performs the named control phase..

Line 468: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 470: `ST_VARIANCE_SQUARE_PARTIAL: begin` This is the ST_VARIANCE_SQUARE_PARTIAL case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_PARTIAL, the machine performs the named control phase..

Line 471: `variance_square_low_product_r <= variance_square_low_product;` This makes variance_square_low_product_
the average squared distance from the mean, equal to ‘variance_square_low_product‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are variance_square_low_product: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_PARTIAL, the machine performs the named control phase..

Line 472: `variance_square_high_product_r <= variance_square_high_product;` This makes variance_square_high_produ
the average squared distance from the mean, equal to ‘variance_square_high_product‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are variance_square_high_product: the

average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_PARTIAL, the machine performs the named control phase..

Line 473: `state <= ST_VARIANCE_SQUARE_ADD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_VARIANCE_SQUARE_ADD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_SQUARE_ADD: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_PARTIAL, the machine performs the named control phase..

Line 474: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_PARTIAL, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 476: `ST_VARIANCE_SQUARE_ADD: begin` This is the ST_VARIANCE_SQUARE_ADD case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_ADD, the machine performs the named control phase..

Line 477: `variance_square_r <= {14'd0, variance_square_low_product_r}` This statement continues through source line 478; the explanation uses the complete expression rather than only the first visual fragment. This makes variance_square_r, the average squared distance from the mean, equal to ‘{14’d0, variance_square_low_product_r} + {2’d0, variance_square_high_product_r, 12’d0}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block; variance_square_low_product_r: the average squared distance from the mean; variance_square_high_product_r: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_ADD, the machine performs the named control phase..

Line 478: `+ {2'd0, variance_square_high_product_r, 12'd0};` This is continuation line 2 of the 2-line logical statement that begins at source line 477. Its exact fragment is ‘+ {2’d0, variance_square_high_product_r, 12’d0};‘. The important operands are d0: the value named ’d0’ in this block; variance_square_high_product_r: the average squared distance from the mean. Read together, the complete operation is: This makes variance_square_r, the average squared distance from the mean, equal to ‘{14’d0, variance_square_low_product_r} + {2’d0, variance_square_high_product_r, 12’d0}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block; variance_square_low_product_r: the average squared distance from the mean; variance_square_high_product_r: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_ADD, the machine performs the named control phase..

Line 479: `state <= ST_VARIANCE_SQUARE_LATCH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_VARIANCE_SQUARE_LATCH‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_SQUARE_LATCH: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_ADD, the machine performs the named control phase..

Line 480: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_ADD, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 482: `ST_VARIANCE_SQUARE_LATCH: begin` This is the ST_VARIANCE_SQUARE_LATCH case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_LATCH, the machine performs the named control phase..

Line 483: `variance_square_latched_r <= variance_square_r;` This makes variance_square_latched_r, the average squared distance from the mean, equal to ‘variance_square_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are variance_square_r: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_LAT the machine performs the named control phase..

Line 484: `state <= ST_VARIANCE_ACCUMULATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_VARIANCE_ACCUMULATE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_ACCUMULATE: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_LATCH, the machine performs the named control phase..

Line 485: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_SQUARE_LATCH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 487: `ST_VARIANCE_ACCUMULATE: begin` This is the ST_VARIANCE_ACCUMULATE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE, the machine performs the named control phase..

Line 488: `logic [32:0] low_sum;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE, the machine performs the named control phase.. Specifically, low_sum is the value named ’low sum’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 489: `low_sum = {1'b0, variance_sum_r[31:0]}` This statement continues through source line 490; the explanation uses the complete expression rather than only the first visual fragment. This makes low_sum, the value named ’low sum’ in this block, equal to ‘{1’b0, variance_sum_r[31:0]} + {1’b0, variance_square_latched_r[31:0]}‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block; variance_sum_r: the average squared distance from the mean; variance_square_latched_r: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE, the machine performs the named control phase..

Line 490: `+ {1'b0, variance_square_latched_r[31:0]};` This is continuation line 2 of the 2-line logical statement that begins at source line 489. Its exact fragment is ‘+ {1’b0, variance_square_latched_r[31:0]};‘. The important operands are b0: the value named ’b0’ in this block; variance_square_latched_r: the average squared distance from the mean. Read together, the complete operation is: This makes low_sum, the value named ’low sum’ in this block, equal to ‘{1’b0, variance_sum_r[31:0]} + {1’b0, variance_square_latched_r[31:0]}‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block; variance_sum_r: the average squared distance from the mean; variance_square_latched_r: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE, the machine performs the named control phase..

Line 491: `variance_sum_low_r <= low_sum[31:0];` This makes variance_sum_low_r, the average squared distance from the mean, equal to ‘low_sum[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are low_sum: the value named ’low sum’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE, the machine performs the named control phase..

Line 492: `variance_sum_carry_r <= low_sum[32];` This makes variance_sum_carry_r, the average squared distance from the mean, equal to ‘low_sum[32]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are low_sum: the value named ’low sum’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE, the machine performs the named control phase..

Line 493: `state <= ST_VARIANCE_ACCUMULATE_HIGH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_VARIANCE_ACCUMULATE_HIGH‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_ACCUMULATE_HIGH: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE, the machine performs the named control phase..

Line 494: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 496: `ST_VARIANCE_ACCUMULATE_HIGH: begin` This is the ST_VARIANCE_ACCUMULATE_HIGH case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 497: `logic [32:0] high_sum;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase.. Specifically, high_sum is the value named ’high sum’ in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 498: `high_sum = {1'b0, variance_sum_r[63:32]}` This statement continues through source line 500; the explanation uses the complete expression rather than only the first visual fragment. This makes high_sum, the value named ’high sum’ in this block, equal to ‘{1’b0, variance_sum_r[63:32]} + {1’b0, 14’d0, variance_square_latched_r[49:32]} + variance_sum_carry_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block; variance_sum_r: the average squared distance from the mean; d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 499: `+ {1'b0, 14'd0, variance_square_latched_r[49:32]}` This is continuation line 2 of the 3-line logical statement that begins at source line 498. Its exact fragment is ‘+ {1’b0, 14’d0, variance_square_latched_r[49:32]}‘. The important operands are b0: the value named ’b0’ in this block; d0: the value named ’d0’ in this block; variance_square_latched_r: the average squared distance from the mean. Read together, the complete operation is: This makes high_sum, the value named ’high sum’ in this block, equal to ‘{1’b0, variance_sum_r[63:32]} + {1’b0, 14’d0, variance_square_latched_r[49:32]} + variance_sum_carry_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block; variance_sum_r: the average squared distance from the mean; d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 500: `+ variance_sum_carry_r;` This is continuation line 3 of the 3-line logical statement that begins at source line 498. Its exact fragment is ‘+ variance_sum_carry_r;‘. The important operands are variance_sum_carry_r: the average squared distance from the mean. Read together, the complete operation is: This makes high_sum, the value named ’high sum’ in this block, equal to ‘{1’b0, variance_sum_r[63:32]} + {1’b0, 14’d0, variance_square_latched_r[49:32]} + variance_sum_carry_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named ’b0’ in this block; variance_sum_r: the average squared distance from the mean; d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 501: `variance_sum_r <= {high_sum[31:0], variance_sum_low_r};` This makes variance_sum_r, the average squared distance from the mean, equal to ‘{high_sum[31:0], variance_sum_low_r}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are high_sum: the value named ’high sum’ in this block; variance_sum_low_r: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 502: `if (high_sum[32]) config_error <= 1'b1;` This condition selects the following hardware branch only when ‘high_sum[32]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are high_sum: the value named 'high sum' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 503: `if (variance_remaining_r == 12'd1) begin` This condition selects the following hardware branch only when ‘variance_remaining_r == 12'd1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are variance_remaining_r: the average squared distance from the mean; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 504: `state <= ST_VARIANCE_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_VARIANCE_START‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_START: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 505: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 506: `variance_index <= variance_index + 1'b1;` This makes variance_index, the average squared distance from the mean, equal to ‘variance_index + 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are variance_index: the average squared distance from the mean; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 507: `variance_remaining_r <= variance_remaining_r - 1'b1;` This makes variance_remaining_r, the average squared distance from the mean, equal to ‘variance_remaining_r - 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are variance_remaining_r: the average squared distance from the mean; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 508: `state <= ST_VARIANCE_READ;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_VARIANCE_READ‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_VARIANCE_READ: the average squared distance from the mean. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase..

Line 509: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 510: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_ACCUMULATE_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 512: `ST_VARIANCE_START: begin` This is the ST_VARIANCE_START case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_START, the machine performs the named control phase..

Line 513: `if (divider_input_ready) state <= ST_VARIANCE_WAIT;` This condition selects the following hardware branch only when ‘divider_input_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are divider_input_ready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_START, the machine performs the named control phase..

Line 514: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_START, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 516: `ST_VARIANCE_WAIT: begin` This is the ST_VARIANCE_WAIT case branch, which waits for both command completion and the declared output count. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_WAIT, the machine waits for both command completion and the declared output count..

Line 517: `if (divider_output_valid) begin` This condition selects the following hardware branch only when ‘divider_output_valid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are divider_output_valid: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_WAIT, the machine waits for both command completion and the declared output count..

Line 518: `variance_r <= divider_quotient[31:0];` This makes variance_r, the average squared distance from the mean, equal to ‘divider_quotient[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are divider_quotient: the value named ’divider quotient’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_WAIT, the machine waits for both command completion and the declared output count..

Line 519: `config_error <= config_error || divider_zero;` This makes config_error, the value named ’config error’ in this block, equal to ‘config_error || divider_zero‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are config_error: the value named ’config error’ in this block; divider_zero: the value named ’divider zero’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_WAIT, the machine waits for both command completion and the declared output count..

Line 520: `state <= ST_SQRT_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_SQRT_START‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SQRT_START: the value named ’st sqrt start’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_WAIT, the machine waits for both command completion and the declared output count..

Line 521: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 522: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_VARIANCE_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 524: `ST_SQRT_START: begin` This is the ST_SQRT_START case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_SQRT_START, the machine performs the named control phase..

Line 525: `if (sqrt_input_ready) state <= ST_SQRT_WAIT;` This condition selects the following hardware branch only when ‘sqrt_input_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sqrt_input_ready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SQRT_START, the machine performs the named control phase..

Line 526: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SQRT_START, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 528: `ST_SQRT_WAIT: begin` This is the ST_SQRT_WAIT case branch, which waits for both command completion and the declared output count. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_SQRT_WAIT, the machine waits for both command completion and the declared output count..

Line 529: `if (sqrt_output_valid) begin` This condition selects the following hardware branch only when ‘sqrt_output_valid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are sqrt_output_valid: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SQRT_WAIT, the machine waits for both command completion and the declared output count..

Line 530: `sigma_r <= sqrt_root == 0 ? 32'd1 : sqrt_root;` This makes sigma_r, the value named ’sigma r’ in this block, equal to ‘sqrt_root == 0 ? 32’d1 : sqrt_root‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are sqrt_root: the value named ’sqrt root’ in this block; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SQRT_WAIT, the machine waits for both command completion and the declared output count..

Line 531: `state <= ST_RECIPROCAL_START;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_RECIPROCAL_START‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_RECIPROCAL_START: the value named ’st reciprocal start’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SQRT_WAIT, the machine waits for both command completion and the declared output count..

Line 532: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SQRT_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 533: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SQRT_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 535: `ST_RECIPROCAL_START: begin` This is the ST_RECIPROCAL_START case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_START, the machine performs the named control phase..

Line 536: `if (divider_input_ready) state <= ST_RECIPROCAL_WAIT;` This condition selects the following hardware branch only when ‘divider_input_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are divider_input_ready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_START, the machine performs the named control phase..

Line 537: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_START, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 539: `ST_RECIPROCAL_WAIT: begin` This is the ST_RECIPROCAL_WAIT case branch, which waits for both command completion and the declared output count. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 540: `if (divider_output_valid) begin` This condition selects the following hardware branch only when ‘divider_output_valid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are divider_output_valid: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 541: `reciprocal_q31_r <= divider_quotient[31:0];` This makes reciprocal_q31_r, the value named ’reciprocal q31 r’ in this block, equal to ‘divider_quotient[31:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are divider_quotient: the value named ’divider quotient’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 542: `output_index_r <= 12'd0;` This makes output_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘12’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 543: `output_remaining_r <= feature_count_r;` This makes output_remaining_r, the number of command result beats still expected, equal to ‘feature_count_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are feature_count_r: an integer count retained for control or measurable telemetry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 544: `config_error <= config_error || divider_zero;` This makes config_error, the value named ’config error’ in this block, equal to ‘config_error || divider_zero‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are config_error: the value named ’config error’ in this block; divider_zero: the value named ’divider zero’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 545: `state <= ST_OUTPUT_READ;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_READ‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_READ: the value named ’st output read’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count..

Line 546: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 547: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_RECIPROCAL_WAIT, the machine waits for both command completion and the declared output count.; it has no arithmetic value of its own.

Line 549: `ST_OUTPUT_READ: begin` This is the ST_OUTPUT_READ case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_READ, the machine presents computed results under valid/ready backpressure..

Line 550: `output_value_ram_r <= value_mem[output_index_r[10:0]];` This makes output_value_ram_r, the value named 'output value ram r' in this block, equal to 'value_mem[output_index_r[10:0]]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are value_mem: local FPGA storage addressed by surrounding index logic; output_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_READ, the machine presents computed results under valid/ready backpressure..

Line 551: `output_gamma_ram_r <= gamma_mem[output_index_r[10:0]];` This makes output_gamma_ram_r, the learned multiplicative LayerNorm parameter, equal to 'gamma_mem[output_index_r[10:0]]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are gamma_mem: the learned multiplicative LayerNorm parameter; output_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_READ, the machine presents computed results under valid/ready backpressure..

Line 552: `output_beta_ram_r <= beta_mem[output_index_r[10:0]];` This makes output_beta_ram_r, the learned additive LayerNorm parameter, equal to 'beta_mem[output_index_r[10:0]]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are beta_mem: the learned additive LayerNorm parameter; output_index_r: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_READ, the machine presents computed results under valid/ready backpressure..

Line 553: `state <= ST_OUTPUT_LATCH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_LATCH'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_LATCH: the value named 'st output latch' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_READ, the machine presents computed results under valid/ready backpressure..

Line 554: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_READ, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 556: `ST_OUTPUT_LATCH: begin` This is the ST_OUTPUT_LATCH case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_LATCH, the machine presents computed results under valid/ready backpressure..

Line 557: `output_value_r <= output_value_ram_r;` This makes output_value_r, the value named 'output value r' in this block, equal to 'output_value_ram_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_value_ram_r: the value named 'output value ram r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_LATCH, the machine presents computed results under valid/ready backpressure..

Line 558: `output_gamma_r <= output_gamma_ram_r;` This makes output_gamma_r, the learned multiplicative LayerNorm parameter, equal to 'output_gamma_ram_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_gamma_ram_r: the learned multiplicative LayerNorm parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_LATCH, the machine presents computed results under valid/ready backpressure..

Line 559: `output_beta_r <= output_beta_ram_r;` This makes output_beta_r, the learned additive LayerNorm parameter, equal to 'output_beta_ram_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_beta_ram_r: the learned additive LayerNorm parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_LATCH, the machine presents computed results under valid/ready backpressure..

Line 560: `state <= ST_OUTPUT_CENTER;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_CENTER‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_CENTER: the value named ’st output center’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_LATCH, the machine presents computed results under valid/ready backpressure..

Line 561: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_LATCH, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 563: `ST_OUTPUT_CENTER: begin` This is the ST_OUTPUT_CENTER case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_CENTER, the machine presents computed results under valid/ready backpressure..

Line 564: `output_centered_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_CENTER, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are output_centered_r: the value named ’output centered r’ in this block.

Line 565: `<= $signed({output_value_r[23], output_value_r})` Within the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_CENTER, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are output_value_r: the value named ’output value r’ in this block.

Line 566: `- $signed({mean_r[31], mean_r[23:0]});` Within the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_CENTER, the machine presents computed results under valid/ready backpressure., this exact statement contributes to the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating. The important operands are mean_r: the arithmetic average used by normalization.

Line 567: `state <= ST_OUTPUT_NORMALIZE_OPERANDS;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_NORMALIZE_OPERANDS‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_NORMALIZE_OPERANDS: the value named ’st output normalize operands’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_CENTER, the machine presents computed results under valid/ready backpressure..

Line 568: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_CENTER, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 570: `ST_OUTPUT_NORMALIZE_OPERANDS: begin` This is the ST_OUTPUT_NORMALIZE_OPERANDS case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_OPERAND the machine presents computed results under valid/ready backpressure..

Line 571: `normalized_centered_operand_r <= output_centered_r;` This makes normalized_centered_operand_r, the value named ’normalized centered operand r’ in this block, equal to ‘output_centered_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_centered_r: the value named ’output centered r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_OPERANDS, the machine presents computed results under valid/ready backpressure..

Line 572: `normalized_reciprocal_operand_r <= reciprocal_q31_r;` This makes normalized_reciprocal_operand_r, the value named 'normalized reciprocal operand r' in this block, equal to 'reciprocal_q31_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are reciprocal_q31_r: the value named 'reciprocal q31 r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_OPERANDS, the machine presents computed results under valid/ready backpressure..

Line 573: `state <= ST_OUTPUT_NORMALIZE_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_NORMALIZE_MULTIPLY'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_NORMALIZE_MULTIPLY: the value named 'st output normalize multiply' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_OPERANDS, the machine presents computed results under valid/ready backpressure..

Line 574: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_OPERANDS, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 576: `ST_OUTPUT_NORMALIZE_MULTIPLY: begin` This is the ST_OUTPUT_NORMALIZE_MULTIPLY case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_MULTIPLY the machine presents computed results under valid/ready backpressure..

Line 577: `normalized_low_product_r <= normalized_low_product;` This makes normalized_low_product_r, the value named 'normalized low product r' in this block, equal to 'normalized_low_product'. It updates after the active clock edge together with other nonblocking assignments. The important operands are normalized_low_product: the value named 'normalized low product' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_MULTIPLY, the machine presents computed results under valid/ready backpressure..

Line 578: `normalized_high_product_r <= normalized_high_product;` This makes normalized_high_product_r, the value named 'normalized high product r' in this block, equal to 'normalized_high_product'. It updates after the active clock edge together with other nonblocking assignments. The important operands are normalized_high_product: the value named 'normalized high product' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_MULTIPLY, the machine presents computed results under valid/ready backpressure..

Line 579: `state <= ST_OUTPUT_NORMALIZE_LATCH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_NORMALIZE_LATCH'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_NORMALIZE_LATCH: the value named 'st output normalize latch' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_MULTIPLY, the machine presents computed results under valid/ready backpressure..

Line 580: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_MULTIPLY, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 582: `ST_OUTPUT_NORMALIZE_LATCH: begin` This is the ST_OUTPUT_NORMALIZE_LATCH case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_LATCH, the machine presents computed results under valid/ready backpressure..

Line 583: `normalized_product_r <=` This statement continues through source line 586; the explanation uses the complete expression rather than only the first visual fragment. This makes normalized_product_r, the value named 'normalized product r' in this block, equal to '{{16{normalized_low_product_r[41]}}, normalized_low_product_r} + ($signed({{16{normalized_high_product_r[41]}}, normalized_high_product_r}) <<< 16)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are normalized_low_product_r: the value named 'normalized low product r' in this block; normalized_high_product_r: the value named 'normalized high product r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_LATCH, the machine presents computed results under valid/ready backpressure..

Line 584: `{{16{normalized_low_product_r[41]}}, normalized_low_product_r}` This is continuation line 2 of the 4-line logical statement that begins at source line 583. Its exact fragment is '{{16{normalized_low_product_r[41]}}, normalized_low_product_r}'. The important operands are normalized_low_product_r: the value named 'normalized low product r' in this block. Read together, the complete operation is: This makes normalized_product_r, the value named 'normalized product r' in this block, equal to '{{16{normalized_low_product_r[41]}}, normalized_low_product_r} + ($signed({{16{normalized_high_product_r[41]}}, normalized_high_product_r}) <<< 16)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are normalized_low_product_r: the value named 'normalized low product r' in this block; normalized_high_product_r: the value named 'normalized high product r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_LATCH, the machine presents computed results under valid/ready backpressure..

Line 585: `+ ($signed({{16{normalized_high_product_r[41]}},` This is continuation line 3 of the 4-line logical statement that begins at source line 583. Its exact fragment is '+ ($signed({{16{normalized_high_product_r[41]}},'. The important operands are normalized_high_product_r: the value named 'normalized high product r' in this block. Read together, the complete operation is: This makes normalized_product_r, the value named 'normalized product r' in this block, equal to '{{16{normalized_low_product_r[41]}}, normalized_low_product_r} + ($signed({{16{normalized_high_product_r}) <<< 16)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are normalized_low_product_r: the value named 'normalized low product r' in this block; normalized_high_product_r: the value named 'normalized high product r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_LATCH, the machine presents computed results under valid/ready backpressure..

Line 586: `normalized_high_product_r}) <<< 16);` This is continuation line 4 of the 4-line logical statement that begins at source line 583. Its exact fragment is 'normalized_high_product_r}) <<< 16);'. The important operands are normalized_high_product_r: the value named 'normalized high product r' in this block. Read together, the complete operation is: This makes normalized_product_r, the value named 'normalized product r' in this block, equal to '{{16{normalized_low_product_r[41]}}, normalized_low_product_r} + ($signed({{16{normalized_high_product_r[41]}}, normalized_high_product_r}) <<< 16)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are normalized_low_product_r: the value named 'normalized low product r' in this block; normalized_high_product_r: the value named 'normalized high product r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_LATCH, the machine presents computed results under valid/ready backpressure..

Line 587: `state <= ST_OUTPUT_NORMALIZE_ABSOLUTE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_NORMALIZE_ABSOLUTE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_NORMALIZE_ABSOLUTE: the value named 'st output normalize absolute' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_LATCH, the machine presents computed results under valid/ready backpressure..

Line 588: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_LATCH, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 590: `ST_OUTPUT_NORMALIZE_ABSOLUTE: begin` This is the ST_OUTPUT_NORMALIZE_ABSOLUTE case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; con-

text is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_ABSOLUTE, the machine presents computed results under valid/ready backpressure..

Line 591: `logic [32:0] magnitude_low;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_ABSOLUTE, the machine presents computed results under valid/ready backpressure.. Specifically, magnitude_low is the value named 'magnitude low' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 592: `normalized_negative_r <= normalized_product_r[57];` This makes normalized_negative_r, the value named 'normalized negative r' in this block, equal to 'normalized_product_r[57]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are normalized_product_r: the value named 'normalized product r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_ABSOLUTE, the machine presents computed results under valid/ready backpressure..

Line 593: `magnitude_low = normalized_product_r[57]` This statement continues through source line 595; the explanation uses the complete expression rather than only the first visual fragment. This makes magnitude_low, the value named 'magnitude low' in this block, equal to 'normalized_product_r[57] ? {1'b0, ~normalized_product_r[31:0]} + 1'b1 : {1'b0, normalized_product_r[31:0]}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are normalized_product_r: the value named 'normalized product r' in this block; b0: the value named 'b0' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_NORMALIZE_ABSOLUTE, the machine presents computed results under valid/ready backpressure..

Line 594: `? {1'b0, ~normalized_product_r[31:0]} + 1'b1` This is continuation line 2 of the 3-line logical statement that begins at source line 593. Its exact fragment is '? {1'b0, ~normalized_product_r[31:0]} + 1'b1'. The important operands are b0: the value named 'b0' in this block; normalized_product_r: the value named 'normalized product r' in this block; b1: the value named 'b1' in this block. Read together, the complete operation is: This makes magnitude_low, the value named 'magnitude low' in this block, equal to 'normalized_product_r[57] ? {1'b0, ~normalized_product_r[31:0]} + 1'b1 : {1'b0, normalized_product_r[31:0]}'. Read together, the complete operation is: This makes scaled_r, the real-value spacing represented by one quantized integer step, equal to 'scale_negative_r ? -$signed(scale_rounded_magnitude_r) : $signed(scale_rounded_magnitude_r)'. It updates after the active clock edge together with other nonblocking assignments. The important operands are scale_negative_r: the real-value spacing represented by one quantized integer step; scale_rounded_magnitude_r: the real-value spacing represented by one quantized integer step. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_SCALE_SIGN, the machine presents computed results under valid/ready backpressure..

Line 697: `state <= ST_OUTPUT_BETA;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT_BETA'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_BETA: the learned additive LayerNorm parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_SCALE_SIGN, the machine presents computed results under valid/ready backpressure..

Line 698: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_SCALE_SIGN, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 700: `ST_OUTPUT_BETA: begin` This is the ST_OUTPUT_BETA case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_BETA, the machine presents computed results under valid/ready backpressure..

Line 701: `scaled_beta_r <= {{8{scaled_r[55]}}, scaled_r}` This statement continues through source line 702; the explanation uses the complete expression rather than only the first visual fragment. This makes scaled_beta_r, the real-value spacing represented by one quantized integer step, equal to '{{8{scaled_r[55]}}, scaled_r} + {{(64-VALUE_BITS){output_beta_r[VALUE_BITS-1]}}, output_beta_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are scaled_r: the real-value spacing represented by one quantized integer step; VALUE_BITS: the value named 'value bits' in this block; output_beta_r: the learned additive LayerNorm parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_BETA, the machine presents computed results under valid/ready backpressure..

Line 702: `+ {{(64-VALUE_BITS){output_beta_r[VALUE_BITS-1]}}, output_beta_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 701. Its exact fragment is '+ {{(64-VALUE_BITS){output_beta_r[VALUE_1]}}, output_beta_r};'. The important operands are VALUE_BITS: the value named 'value bits' in this block; output_beta_r: the learned additive LayerNorm parameter. Read together, the complete operation is: This makes scaled_beta_r, the real-value spacing represented by one quantized integer step, equal to '{{8{scaled_r[55]}}, scaled_r} + {{(64-VALUE_BITS){output_beta_r[VALUE_BITS-1]}}, output_beta_r}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are scaled_r: the real-value spacing represented by one quantized integer step; VALUE_BITS: the value named 'value bits' in this block; output_beta_r: the learned additive LayerNorm parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_BETA, the machine presents computed results under valid/ready backpressure..

Line 703: `state <= ST_OUTPUT_SATURATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_SATURATE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_SATURATE: the value named ’st output saturate’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_BETA, the machine presents computed results under valid/ready backpressure..

Line 704: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_BETA, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 706: `ST_OUTPUT_SATURATE: begin` This is the ST_OUTPUT_SATURATE case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_SATURATE, the machine presents computed results under valid/ready backpressure..

Line 707: `result_value <= saturate_s32(scaled_beta_r);` This makes result_value, the value named ’result value’ in this block, equal to ‘saturate_s32(scaled_beta_r)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturate_s32: the value named ’saturate s32’ in this block; scaled_beta_r: the real-value spacing represented by one quantized integer step. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_SATURATE, the machine presents computed results under valid/ready backpressure..

Line 708: `result_last_r <= output_remaining_r == 12'd1;` This makes result_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘output_remaining_r == 12’d1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_remaining_r: the number of command result beats still expected; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_SATURATE, the machine presents computed results under valid/ready backpressure..

Line 709: `state <= ST_OUTPUT_HOLD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_HOLD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_HOLD: the value named ’st output hold’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_SATURATE, the machine presents computed results under valid/ready backpressure..

Line 710: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_SATURATE, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 712: `ST_OUTPUT_HOLD: begin` This is the ST_OUTPUT_HOLD case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 713: `if (result_ready) begin` This condition selects the following hardware branch only when ‘result_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_ready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 714: `if (result_last) begin` This condition selects the following hardware branch only when ‘result_last‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_last: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 715: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 716: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 717: `output_index_r <= output_index_r + 1'b1;` This makes output_index_r, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘output_index_r + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_index_r: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 718: `output_remaining_r <= output_remaining_r - 1'b1;` This makes output_remaining_r, the number of command result beats still expected, equal to ‘output_remaining_r - 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are output_remaining_r: the number of command result beats still expected; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 719: `state <= ST_OUTPUT_READ;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_READ‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_READ: the value named ’st output read’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 720: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 721: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 722: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 724: `default: state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘state <= ST_IDLE;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure..

Line 725: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_HOLD, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 726: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 727: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 729: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 730: `if (MAX_FEATURES < 1 || MAX_FEATURES > 2048) $fatal(1, "MAX_FEATURES must be in [1,2048]");` This condition selects the following hardware branch only when ‘MAX_FEATURES $<$ 1 || MAX_FEATURES $>$ 2048) $fatal(1, "MAX_FEATURES must be in [1,2048]"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are MAX_FEATURES: the value named ’max features’ in this block; fatal: the value named ’fatal’ in this block; must: the value named ’must’ in this block. Context: the module’s structural declarations.

Line 731: `if (VALUE_BITS != 24) $fatal(1, "neuraedge_integer_layernorm currently requires VALUE_BITS=24");` This condition selects the following hardware branch only when ‘VALUE_BITS != 24) $fatal(1, "neuraedge_integer_layernorm currently requires VALUE_BITS=24"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are VALUE_BITS: the value named ’value bits’ in this block; fatal: the value named ’fatal’ in this block; neuraedge_integer_layernorm: the value named ’neuraedge integer layernorm’ in this block. Context: the module’s structural declarations.

Line 732: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 733: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 735: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that evaluates integer LayerNorm by accumulating moments, taking an integer square root, dividing, scaling, and saturating.

11 rtl/neuraedge_isqrt64.sv

Role in the complete system: computes an exact floor square root of an unsigned 64-bit radicand with an iterative restoring algorithm.

11.1 Beginner architecture map

Dataflow responsibility One iteration examines the next two radicand bits, shifts the partial remainder, conditionally subtracts the trial divisor, and appends one root bit. After 32 iterations the 32-bit result is exactly floor(sqrt(radicand)); a widened subtraction bit makes borrow detection explicit.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_isqrt64 into physical nets and primitives. The source declares 5 input-port lines, 4 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_IDLE, ST_OUTPUT, ST_ROOT. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates unique as case. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

`default_nettype wire
```

11.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_isqrt64 (` This opens neuraedge_isqrt64, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that computes an exact floor square root of an unsigned 64-bit radicand with an iterative restoring algorithm.

Line 5: `input wire clk,` This declares clk as a input port with width one bit. It carries the clock that makes all registers advance together across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 6: `input wire rst_n,` This declares rst_n as a input port with width one bit. It carries the active-low synchronous reset across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 7: `input wire input_valid,` This declares input_valid as a input port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 8: `output logic input_ready,` This declares input_ready as a output port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 9: `input wire [63:0] radicand,` This declares radicand as a input port with width [63:0]. It carries the value named 'radicand' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 10: `output logic output_valid,` This declares output_valid as a output port with width one bit. It carries the producer's statement that its current payload is meaningful across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 11: `input wire output_ready,` This declares output_ready as a input port with width one bit. It carries the consumer's statement that it can accept a payload this cycle across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 12: `output logic [31:0] root,` This declares root as a output port with width [31:0]. It carries the value named 'root' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 13: `output logic [32:0] remainder` This declares remainder as a output port with width [32:0]. It carries the value named 'remainder' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 14: `);` Within the module's structural declarations, this exact statement contributes to the block that computes an exact floor square root of an unsigned 64-bit radicand with an iterative restoring algorithm. The expression is a literal or structural operator and has no hidden software state.

Line 15: `typedef enum logic [1:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 16: `ST_IDLE = 2'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 17: `ST_ROOT = 2'd1,` This assigns a fixed binary encoding to state ST_ROOT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 18: `ST_OUTPUT = 2'd2` This statement continues through source line 19; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 19: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 18. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 21: `state_t state;` Within the module's structural declarations, this exact statement contributes to the block that computes an exact floor square root of an unsigned 64-bit radicand with an iterative restoring algorithm. The important operands are state_t: the finite-state-machine phase retained in flip-flops; state: the finite-state-machine phase retained in flip-flops.

Line 22: `logic [63:0] radicand_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, radicand_r is the value named 'radicand r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 23: `logic [31:0] root_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, root_r is the value named 'root r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 24: `// Before the final digit, remainder < 2*partial_root+1 < 2^32. The final` Design intent: Before the final digit, remainder < 2*partial_root+1 < 2^32. The final This comment anchors the surrounding logic in the block that computes an exact floor square root of an unsigned 64-bit radicand with an iterative restoring algorithm.

Line 25: `// remainder may need bit 32 and is written directly to the output port.` Design intent: remainder may need bit 32 and is written directly to the output port. This comment anchors the surrounding logic in the block that computes an exact floor square root of an unsigned 64-bit radicand with an iterative restoring algorithm.

Line 26: `logic [31:0] remainder_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, remainder_r is the value named 'remainder r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 27: `logic [5:0] pair_count;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pair_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 29: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 30: `input_ready = state == ST_IDLE;` This makes input_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_IDLE'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 31: `output_valid = state == ST_OUTPUT;` This makes output_valid, the producer's statement that its current payload is meaningful, equal to 'state == ST_OUTPUT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_OUTPUT: the value named 'st output' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 32: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 34: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 35: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 36: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_IDLE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named ’st idle’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 37: `radicand_r <= 64'd0;` This makes radicand_r, the value named ’radicand r’ in this block, equal to ‘64’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 38: `root_r <= 32'd0;` This makes root_r, the value named ’root r’ in this block, equal to ‘32’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 39: `remainder_r <= 32'd0;` This makes remainder_r, the value named ’remainder r’ in this block, equal to ‘32’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 40: `pair_count <= 6'd0;` This makes pair_count, an integer count retained for control or measurable telemetry, equal to ‘6’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 41: `root <= 32'd0;` This makes root, the value named ’root’ in this block, equal to ‘32’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 42: `remainder <= 33'd0;` This makes remainder, the value named ’remainder’ in this block, equal to ‘33’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 43: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 44: `unique case (state)` This starts a multiplexer/state decode selected by ‘state‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 45: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 46: `if (input_valid) begin` This condition selects the following hardware branch only when ‘input_valid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_valid: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 47: `radicand_r <= radicand;` This makes radicand_r, the value named ’radicand r’ in this block, equal to ‘radicand‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are radicand: the value named ’radicand’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 48: `root_r <= 32'd0;` This makes root_r, the value named 'root r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 49: `remainder_r <= 32'd0;` This makes remainder_r, the value named 'remainder r' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 50: `pair_count <= 6'd0;` This makes pair_count, an integer count retained for control or measurable telemetry, equal to '6'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 51: `state <= ST_ROOT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_ROOT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ROOT: the value named 'st root' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 52: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 53: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 55: `ST_ROOT: begin` This is the ST_ROOT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 56: `logic [33:0] shifted_remainder;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase.. Specifically, shifted_remainder is the value named 'shifted remainder' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 57: `logic [33:0] trial_divisor;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase.. Specifically, trial_divisor is the value named 'trial divisor' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 58: `logic [33:0] trial_difference;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase.. Specifically, trial_difference is the value named 'trial difference' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 59: `logic [32:0] next_remainder;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase.. Specifically, next_remainder is the value named 'next remainder' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 60: `logic [31:0] next_root;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase.. Specifically, next_root is the value named 'next root' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 61: `shifted_remainder = {remainder_r, radicand_r[63:62]};` This makes shifted_remainder, the value named 'shifted remainder' in this block, equal to '{remainder_r, radicand_r[63:62]}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are remainder_r: the value named 'remainder r' in this block; radicand_r: the value named 'radicand r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 62: `trial_divisor = {root_r, 2'b01};` This makes trial_divisor, the value named 'trial divisor' in this block, equal to '{root_r, 2'b01}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are root_r: the value named 'root r' in this block; b01: the value named 'b01' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 63: `// One widened subtraction produces both the candidate` Design intent: One widened subtraction produces both the candidate This comment anchors the surrounding logic in the block that computes an exact floor square root of an unsigned 64-bit radicand with an iterative restoring algorithm.

Line 64: `// remainder and its unsigned borrow. This removes the` Design intent: remainder and its unsigned borrow. This removes the This comment anchors the surrounding logic in the block that computes an exact floor square root of an unsigned 64-bit radicand with an iterative restoring algorithm.

Line 65: `// serial compare-then-subtract carry chains.` Design intent: serial compare-then-subtract carry chains. This comment anchors the surrounding logic in the block that computes an exact floor square root of an unsigned 64-bit radicand with an iterative restoring algorithm.

Line 66: `trial_difference = shifted_remainder - trial_divisor;` This makes trial_difference, the value named 'trial difference' in this block, equal to 'shifted_remainder - trial_divisor'. It is driven by combinational or procedural logic in the current evaluation. The important operands are shifted_remainder: the value named 'shifted remainder' in this block; trial_divisor: the value named 'trial divisor' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 67: `if (!trial_difference[33]) begin` This condition selects the following hardware branch only when '!trial_difference[33]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are trial_difference: the value named 'trial difference' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 68: `next_remainder = trial_difference[32:0];` This makes next_remainder, the value named 'next remainder' in this block, equal to 'trial_difference[32:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are trial_difference: the value named 'trial difference' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 69: `next_root = {root_r[30:0], 1'b1};` This makes next_root, the value named 'next root' in this block, equal to '{root_r[30:0], 1'b1}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are root_r: the value named 'root r' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 70: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 71: `next_remainder = shifted_remainder[32:0];` This makes next_remainder, the value named 'next remainder' in this block, equal to 'shifted_remainder[32:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are shifted_remainder: the value named 'shifted remainder' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 72: `next_root = {root_r[30:0], 1'b0};` This makes next_root, the value named 'next root' in this block, equal to '{root_r[30:0], 1'b0}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are root_r: the value named 'root r' in this block; b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 73: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 74: `radicand_r <= {radicand_r[61:0], 2'b00};` This makes radicand_r, the value named 'radicand r' in this block, equal to '{radicand_r[61:0], 2'b00}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are radicand_r: the value named 'radicand r' in this block; b00: the value named 'b00' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 75: `remainder_r <= next_remainder[31:0];` This makes remainder_r, the value named 'remainder r' in this block, equal to 'next_remainder[31:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_remainder: the value named 'next remainder' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 76: `root_r <= next_root;` This makes root_r, the value named 'root r' in this block, equal to 'next_root'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_root: the value named 'next root' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 78: `if (pair_count == 6'd31) begin` This condition selects the following hardware branch only when 'pair_count == 6'd31' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pair_count: an integer count retained for control or measurable telemetry; d31: the value named 'd31' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 79: `root <= next_root;` This makes root, the value named 'root' in this block, equal to 'next_root'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_root: the value named 'next root' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 80: `remainder <= next_remainder;` This makes remainder, the value named 'remainder' in this block, equal to 'next_remainder'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_remainder: the value named 'next remainder' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 81: `state <= ST_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT: the value named ’st output’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 82: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 83: `pair_count <= pair_count + 1'b1;` This makes pair_count, an integer count retained for control or measurable telemetry, equal to ‘pair_count + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are pair_count: an integer count retained for control or measurable telemetry; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase..

Line 84: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 85: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROOT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 87: `ST_OUTPUT: begin` This is the ST_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 88: `if (output_ready) state <= ST_IDLE;` This condition selects the following hardware branch only when ‘output_ready‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_ready: the consumer’s statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 89: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 91: `default: state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘state <= ST_IDLE;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 92: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 93: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 94: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 95: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 97: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that computes an exact floor square root of an unsigned 64-bit radicand with an iterative restoring algorithm.

12 rtl/neuraedge_lif_bank.sv

Role in the complete system: stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting.

12.1 Beginner architecture map

Dataflow responsibility Each of 32 lanes reads persistent membrane state, applies the leak shift, adds signed input current, compares against threshold, emits a spike, and writes either reset or integrated membrane back. Segmented counters avoid a long telemetry carry chain on the 200 MHz datapath.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_lif_bank into physical nets and primitives. The source declares 11 input-port lines, 7 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_COMMIT, ST_COUNT_DONE, ST_COUNT_LOW, ST_COUNT_WORD1, ST_COUNT_WORD2, ST_COUNT_WORD3, ST_GROUP_LOAD, ST_IDLE, ST_INTEGRAT ST_LEAK, ST_LEAK_SUBTRACT, ST_OUTPUT, ST_SATURATE, ST_THRESHOLD_COMPARE. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates unique as case, end as for, endcase as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

305 `default_nettype wire
```

12.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `module neuraedge_lif_bank #(` This opens neuraedge_lif_bank, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting.

Line 5: `parameter int LANES = 32,` This statement continues through source line 27; the explanation uses the complete expression rather than only the first visual fragment. This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 6: `parameter int LANES_PER_CYCLE = 8,` This is continuation line 2 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'parameter int LANES_PER_CYCLE = 8,'. The important operands are parameter: the value named 'parameter' in this block; LANES_PER_CYCLE: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 7: `parameter int MEMBRANE_BITS = 24,` This is continuation line 3 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'parameter int MEMBRANE_BITS = 24,'. The important operands are parameter: the value named 'parameter' in this block; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 8: `parameter int CURRENT_BITS = 16` This is continuation line 4 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'parameter int CURRENT_BITS = 16'. The important operands are parameter: the value named 'parameter' in this block; CURRENT_BITS: the value named 'current bits' in this block. Read together,

the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 9: `) (` This is continuation line 5 of the 23-line logical statement that begins at source line 5. Its exact fragment is ‘) (‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 10: `input wire clk,` This is continuation line 6 of the 23-line logical statement that begins at source line 5. Its exact fragment is ‘input wire clk,‘. The important operands are input: the value named ’input’ in this block; clk: the clock that makes all registers advance together. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 11: `input wire rst_n,` This is continuation line 7 of the 23-line logical statement that begins at source line 5. Its exact fragment is ‘input wire rst_n,‘. The important operands are input: the value named ’input’ in this block; rst_n: the active-low synchronous reset. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 12: `input wire clear_state,` This is continuation line 8 of the 23-line logical statement that begins at source line 5. Its exact fragment is ‘input wire clear_state,‘. The important operands are input: the value named ’input’ in this block; clear_state: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during

elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 13: `input wire clear_counters,` This is continuation line 9 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'input wire clear_counters,'. The important operands are input: the value named 'input' in this block; clear_counters: a hardware telemetry register that accumulates measured events. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 14: `input wire input_valid,` This is continuation line 10 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'input wire input_valid,'. The important operands are input: the value named 'input' in this block; input_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 15: `output logic input_ready,` This is continuation line 11 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'output logic input_ready,'. The important operands are output: the value named 'output' in this block; input_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 16: `input wire [LANES*CURRENT_BITS-1:0] current_vector,` This is continuation line 12 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'input wire [LANES*CURRENT_BITS-1:0] current_vector,'. The important operands are input: the value named 'input' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; CURRENT_BITS: the value named 'current bits' in this block. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 17: `input wire [4:0] leak_shift,` This is continuation line 13 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'input wire [4:0] leak_shift,'. The important operands are input: the value named 'input' in this block; leak_shift: the retained fraction of prior membrane state. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 18: `input wire signed [MEMBRANE_BITS-1:0] threshold,` This is continuation line 14 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [MEMBRANE_BITS-1:0] threshold,'. The important operands are input: the value named 'input' in this block; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps; threshold: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 19: `input wire signed [MEMBRANE_BITS-1:0] reset_value,` This is continuation line 15 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [MEMBRANE_BITS-1:0] reset_value,'. The important operands are input: the value named 'input' in this block; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps; reset_value: the value named 'reset value' in this block. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 20: `output logic output_valid,` This is continuation line 16 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'output logic output_valid,'. The important operands are output: the value named 'output' in this block; output_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 21: `input wire output_ready,` This is continuation line 17 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'input wire output_ready,'. The important operands are input: the value named 'input' in this block; output_ready: the consumer's statement that it can accept a payload this cycle. Read together,

the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 22: `output logic [LANES-1:0] spikes,` This is continuation line 18 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'output logic [LANES-1:0] spikes,'. The important operands are output: the value named 'output' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; spikes: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 23: `output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector,` This is continuation line 19 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector,'. The important operands are output: the value named 'output' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 24: `output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector,` This is continuation line 20 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector,'. The important operands are output: the value named 'output' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 25: `output logic [31:0] timestep_count,` This is continuation line 21 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] timestep_count,'. The important operands are output: the value named 'output' in this block; timestep_count: one discrete SNN update instant. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state,

input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 26: `output logic [63:0] total_spike_count` This is continuation line 22 of the 23-line logical statement that begins at source line 5. Its exact fragment is 'output logic [63:0] total_spike_count'. The important operands are output: the value named 'output' in this block; total_spike_count: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 27: `);` This is continuation line 23 of the 23-line logical statement that begins at source line 5. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes LANES to 32, parameter int LANES_PER_CYCLE = 8, parameter int MEMBRANE_BITS = 24, parameter int CURRENT_BITS = 16) (input wire clk, input wire rst_n, input wire clear_state, input wire clear_counters, input wire input_valid, output logic input_ready, input wire [LANES*CURRENT_BITS-1:0] current_vector, input wire [4:0] leak_shift, input wire signed [MEMBRANE_BITS-1:0] threshold, input wire signed [MEMBRANE_BITS-1:0] reset_value, output logic output_valid, input wire output_ready, output logic [LANES-1:0] spikes, output logic [LANES*MEMBRANE_BITS-1:0] membrane_vector, output logic [LANES*MEMBRANE_BITS-1:0] pre_reset_membrane_vector, output logic [31:0] timestep_count, output logic [63:0] total_spike_count) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 28: `localparam int GROUPS = LANES / LANES_PER_CYCLE;` This fixes GROUPS to LANES / LANES_PER_CYCLE during elaboration. Vivado uses that constant to shape or simplify the generated circuit; GROUPS denotes the value named 'groups' in this block.

Line 30: `typedef enum logic [3:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 31: `ST_IDLE = 4'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 32: `ST_GROUP_LOAD = 4'd1,` This assigns a fixed binary encoding to state ST_GROUP_LOAD, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 33: `ST_LEAK = 4'd2,` This assigns a fixed binary encoding to state ST_LEAK, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 34: `ST_INTEGRATE = 4'd3,` This assigns a fixed binary encoding to state ST_INTEGRATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 35: `ST_SATURATE = 4'd4,` This assigns a fixed binary encoding to state ST_SATURATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 36: `ST_COMMIT = 4'd5,` This assigns a fixed binary encoding to state ST_COMMIT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 37: `ST_OUTPUT = 4'd6,` This assigns a fixed binary encoding to state ST_OUTPUT, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 38: `ST_LEAK_SUBTRACT = 4'd7,` This assigns a fixed binary encoding to state ST_LEAK_SUBTRACT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 39: `ST_THRESHOLD_COMPARE = 4'd8,` This assigns a fixed binary encoding to state ST_THRESHOLD_COMPARE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 40: `ST_COUNT_LOW = 4'd9,` This assigns a fixed binary encoding to state ST_COUNT_LOW, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 41: `ST_COUNT_WORD1 = 4'd10,` This assigns a fixed binary encoding to state ST_COUNT_WORD1, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 42: `ST_COUNT_WORD2 = 4'd11,` This assigns a fixed binary encoding to state ST_COUNT_WORD2, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 43: `ST_COUNT_WORD3 = 4'd12,` This assigns a fixed binary encoding to state ST_COUNT_WORD3, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 44: `ST_COUNT_DONE = 4'd13` This statement continues through source line 45; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_COUNT_DONE, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 45: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 44. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_COUNT_DONE, which updates a segmented telemetry counter without a long carry chain. The encoding is visible in waveforms even though the source uses the readable name.

Line 47: `state_t state;` Within the module's structural declarations, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are state_t: the finite-state-machine phase retained in flip-flops; state: the finite-state-machine phase retained in flip-flops.

Line 48: `logic signed [MEMBRANE_BITS-1:0] membrane [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, membrane is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 49: `logic signed [MEMBRANE_BITS-1:0] pre_reset_membrane [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pre_reset_membrane is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 50: `logic [LANES*CURRENT_BITS-1:0] current_vector_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, current_vector_r is the value named 'current vector r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 51: `logic [4:0] leak_shift_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, leak_shift_r is the retained fraction of prior membrane state. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 52: `logic signed [MEMBRANE_BITS-1:0] threshold_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, threshold_r is the membrane level at which a neuron emits a spike. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 53: `logic signed [MEMBRANE_BITS-1:0] reset_value_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, reset_value_r is the value named 'reset value r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 54: `logic [$clog2(GROUPS)-1:0] group_index;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, group_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 55: `logic [LANES-1:0] spike_work_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, spike_work_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 56: `logic [6:0] step_spike_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, step_spike_count_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 57: `logic [6:0] completed_step_spike_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, completed_step_spike_count_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 58: `logic [16:0] counter_sum_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, counter_sum_r is a hardware telemetry register that accumulates measured events. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 59: `logic signed [MEMBRANE_BITS-1:0] group_membrane_r [0:LANES_PER_CYCLE-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, group_membrane_r is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 60: `logic signed [CURRENT_BITS-1:0] group_current_r [0:LANES_PER_CYCLE-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, group_current_r is the value named 'group current r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 61: `logic signed [MEMBRANE_BITS:0] leak_shifted_r [0:LANES_PER_CYCLE-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, leak_shifted_r is the retained fraction of prior membrane state. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 62: `logic signed [MEMBRANE_BITS:0] leaked_r [0:LANES_PER_CYCLE-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, leaked_r is the retained fraction of prior membrane state. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 63: `logic signed [MEMBRANE_BITS:0] integrated_r [0:LANES_PER_CYCLE-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, integrated_r is the value named 'integrated r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 64: `logic signed [MEMBRANE_BITS-1:0] saturated_r [0:LANES_PER_CYCLE-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, saturated_r is the value named 'saturated r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 65: `logic [LANES_PER_CYCLE-1:0] group_spikes_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, group_spikes_r is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 67: `function automatic logic signed [MEMBRANE_BITS-1:0] saturate_membrane(` Within the combinational helper saturate membrane, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps.

Line 68: `input logic signed [MEMBRANE_BITS:0] value` This declares value as a input port with width [MEMBRANE_BITS:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 69: `);` Within the combinational helper saturate membrane, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The expression is a literal or structural operator and has no hidden software state.

Line 70: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate membrane; it has no arithmetic value of its own.

Line 71: `unique case (value[MEMBRANE_BITS:MEMBRANE_BITS-1])` This starts a multiplexer/state decode selected by ‘value[MEMBRANE_BITS:MEMBRANE_BITS-1]‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 72: `2'b01: saturate_membrane = {1'b0, {(MEMBRANE_BITS-1){1'b1}}};` Within the combinational helper saturate membrane, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are b01: the value named 'b01' in this block; saturate_membrane: the persistent LIF neuron state carrying charge between timesteps; b0: the value named 'b0' in this block.

Line 73: `2'b10: saturate_membrane = {1'b1, {(MEMBRANE_BITS-1){1'b0}}};` Within the combinational helper saturate membrane, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are b10: the value named 'b10' in this block; saturate_membrane: the persistent LIF neuron state carrying charge between timesteps; b1: the value named 'b1' in this block.

Line 74: `default:  saturate_membrane = value[MEMBRANE_BITS-1:0];` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'saturate_membrane = value[MEMBRANE_BITS-1:0];'; context is the combinational helper saturate membrane.

Line 75: `endcase` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate membrane; it has no arithmetic value of its own.

Line 76: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate membrane; it has no arithmetic value of its own.

Line 77: `endfunction` Within the combinational helper saturate membrane, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are endfunction: the value named 'endfunction' in this block.

Line 79: `function automatic logic [3:0] popcount8(input logic [7:0] value);` Within the combinational helper popcount8, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; popcount8: the value named 'popcount8' in this block.

Line 80: `logic [1:0] pair0;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, pair0 is the value named 'pair0' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 81: `logic [1:0] pair1;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, pair1 is the value named 'pair1' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 82: `logic [1:0] pair2;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, pair2 is the value named 'pair2' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 83: `logic [1:0] pair3;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, pair3 is the value named 'pair3' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 84: `logic [2:0] half0;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, half0 is the value named 'half0' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 85: `logic [2:0] half1;` This declares hardware signal storage or wiring in the combinational helper popcount8. Specifically, half1 is the value named 'half1' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 86: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper popcount8; it has no arithmetic value of its own.

Line 87: `pair0 = value[0] + value[1];` This makes pair0, the value named 'pair0' in this block, equal to 'value[0] + value[1]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper popcount8.

Line 88: `pair1 = value[2] + value[3];` This makes pair1, the value named 'pair1' in this block, equal to 'value[2] + value[3]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper popcount8.

Line 89: `pair2 = value[4] + value[5];` This makes pair2, the value named 'pair2' in this block, equal to 'value[4] + value[5]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper popcount8.

Line 90: `pair3 = value[6] + value[7];` This makes pair3, the value named 'pair3' in this block, equal to 'value[6] + value[7]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper popcount8.

Line 91: `half0 = pair0 + pair1;` This makes half0, the value named 'half0' in this block, equal to 'pair0 + pair1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are pair0: the value named 'pair0' in this block; pair1: the value named 'pair1' in this block. Context: the combinational helper popcount8.

Line 92: `half1 = pair2 + pair3;` This makes half1, the value named 'half1' in this block, equal to 'pair2 + pair3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are pair2: the value named 'pair2' in this block; pair3: the value named 'pair3' in this block. Context: the combinational helper popcount8.

Line 93: `popcount8 = half0 + half1;` This makes popcount8, the value named 'popcount8' in this block, equal to 'half0 + half1'. It is driven by combinational or procedural logic in the current evaluation. The important operands are half0: the value named 'half0' in this block; half1: the value named 'half1' in this block. Context: the combinational helper popcount8.

Line 94: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper popcount8; it has no arithmetic value of its own.

Line 95: `endfunction` Within the combinational helper popcount8, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are endfunction: the value named 'endfunction' in this block.

Line 97: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 98: `input_ready = state == ST_IDLE;` This makes input_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_IDLE'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 99: `output_valid = state == ST_OUTPUT;` This makes output_valid, the producer's statement that its current payload is meaningful, equal to 'state == ST_OUTPUT'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_OUTPUT: the value named 'st output' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 100: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 101: `membrane_vector[lane*MEMBRANE_BITS +: MEMBRANE_BITS] = membrane[lane];` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are membrane_vector: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps.

Line 102: `pre_reset_membrane_vector[lane*MEMBRANE_BITS +: MEMBRANE_BITS]` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are pre_reset_membrane_vector: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps.

Line 103: `= pre_reset_membrane[lane];` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are pre_reset_membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 104: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 105: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 107: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 108: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 109: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 110: `current_vector_r <= '0;` This makes current_vector_r, the value named 'current vector r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 111: `leak_shift_r <= 5'd0;` This makes leak_shift_r, the retained fraction of prior membrane state, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 112: `threshold_r <= '0;` This makes threshold_r, the membrane level at which a neuron emits a spike, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 113: `reset_value_r <= '0;` This makes reset_value_r, the value named 'reset value r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 114: `group_index <= '0;` This makes group_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 115: `spike_work_r <= '0;` This makes spike_work_r, a binary event produced when a neuron crosses its threshold, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 116: `step_spike_count_r <= 7'd0;` This makes step_spike_count_r, a binary event produced when a neuron crosses its threshold, equal to ‘7'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 117: `completed_step_spike_count_r <= 7'd0;` This makes completed_step_spike_count_r, a binary event produced when a neuron crosses its threshold, equal to ‘7'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 118: `counter_sum_r <= 17'd0;` This makes counter_sum_r, a hardware telemetry register that accumulates measured events, equal to ‘17'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 119: `group_spikes_r <= '0;` This makes group_spikes_r, a binary event produced when a neuron crosses its threshold, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 120: `spikes <= '0;` This makes spikes, a binary event produced when a neuron crosses its threshold, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 121: `timestep_count <= 32'd0;` This makes timestep_count, one discrete SNN update instant, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 122: `total_spike_count <= 64'd0;` This makes total_spike_count, a binary event produced when a neuron crosses its threshold, equal to ‘64'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 123: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 124: `membrane[lane] <= '0;` This makes membrane[lane], the persistent LIF neuron state carrying charge between timesteps, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 125: `pre_reset_membrane[lane] <= '0;` This makes pre_reset_membrane[lane], the persistent LIF neuron state carrying charge between timesteps, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 126: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 127: `for (int lane = 0; lane < LANES_PER_CYCLE; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 128: `group_membrane_r[lane] <= '0;` This makes group_membrane_r[lane], the persistent LIF neuron state carrying charge between timesteps, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 129: `group_current_r[lane] <= '0;` This makes group_current_r[lane], the value named 'group current r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 130: `leak_shifted_r[lane] <= '0;` This makes leak_shifted_r[lane], the retained fraction of prior membrane state, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 131: `leaked_r[lane] <= '0;` This makes leaked_r[lane], the retained fraction of prior membrane state, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 132: `integrated_r[lane] <= '0;` This makes integrated_r[lane], the value named 'integrated r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 133: `saturated_r[lane] <= '0;` This makes saturated_r[lane], the value named 'saturated r' in this block, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 134: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 135: `end else if (clear_state) begin` This condition selects the following hardware branch only when 'clear_state' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are clear_state: the finite-state-machine phase retained in flip-flops. Context: the clocked process that updates registers only on a rising clock edge.

Line 136: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 137: `spike_work_r <= '0;` This makes spike_work_r, a binary event produced when a neuron crosses its threshold, equal to ''0'. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 138: `spikes <= '0;` This makes spikes, a binary event produced when a neuron crosses its threshold, equal to ''0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge.

Line 139: `timestep_count <= 32'd0;` This makes timestep_count, one discrete SNN update instant, equal to ‘32'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 140: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 141: `membrane[lane] <= reset_value;` This makes membrane[lane], the persistent LIF neuron state carrying charge between timesteps, equal to ‘reset_value‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are reset_value: the value named 'reset value' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 142: `pre_reset_membrane[lane] <= reset_value;` This makes pre_reset_membrane[lane], the persistent LIF neuron state carrying charge between timesteps, equal to ‘reset_value‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are reset_value: the value named 'reset value' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 143: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 144: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 145: `unique case (state)` This starts a multiplexer/state decode selected by ‘state‘. ‘unique‘ allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 146: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 147: `if (input_valid) begin` This condition selects the following hardware branch only when ‘input_valid‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 148: `current_vector_r <= current_vector;` This makes current_vector_r, the value named 'current vector r' in this block, equal to ‘current_vector‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are current_vector: the value named 'current vector' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 149: `leak_shift_r <= leak_shift;` This makes leak_shift_r, the retained fraction of prior membrane state, equal to ‘leak_shift‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are leak_shift: the retained fraction of prior membrane state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 150: `threshold_r <= threshold;` This makes threshold_r, the membrane level at which a neuron emits a spike, equal to ‘threshold‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are threshold: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 151: `reset_value_r <= reset_value;` This makes reset_value_r, the value named ’reset value r’ in this block, equal to ‘reset_value‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are reset_value: the value named ’reset value’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 152: `group_index <= '0;` This makes group_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘’0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 153: `spike_work_r <= '0;` This makes spike_work_r, a binary event produced when a neuron crosses its threshold, equal to ‘’0‘. It updates after the active clock edge together with other nonblocking assignments. The expression is a literal or structural operator and has no hidden software state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 154: `step_spike_count_r <= 7'd0;` This makes step_spike_count_r, a binary event produced when a neuron crosses its threshold, equal to ‘7’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 155: `state <= ST_GROUP_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_GROUP_LOAD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_GROUP_LOAD: the value named ’st group load’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 156: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 157: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 159: `ST_GROUP_LOAD: begin` This is the ST_GROUP_LOAD case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands into local FPGA memory..

Line 160: `for (int local_lane = 0; local_lane < LANES_PER_CYCLE; local_lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands into local FPGA memory..

Line 161: `logic [$clog2(LANES)-1:0] lane;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands into local FPGA memory.. Specifically, lane is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 162: `lane = $clog2(LANES)'(` This statement continues through source line 163; the explanation uses the complete expression rather than only the first visual fragment. This makes lane, one parallel arithmetic element within a vector or tensor datapath, equal to '$clog2(LANES)'(group_index * LANES_PER_CYCLE + local_lane)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are clog2: the value named 'clog2' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; group_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands into local FPGA memory..

Line 163: `group_index * LANES_PER_CYCLE + local_lane);` This is continuation line 2 of the 2-line logical statement that begins at source line 162. Its exact fragment is 'group_index * LANES_PER_CYCLE + local_lane);'. The important operands are group_index: an integer selecting one tensor element, lane, bank, or state entry; LANES_PER_CYCLE: one parallel arithmetic element within a vector or tensor datapath; local_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes lane, one parallel arithmetic element within a vector or tensor datapath, equal to '$clog2(LANES)'(group_index * LANES_PER_CYCLE + local_lane)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are clog2: the value named 'clog2' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; group_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands into local FPGA memory..

Line 164: `group_membrane_r[local_lane] <= membrane[lane];` This makes group_membrane_r[local_lane], the persistent LIF neuron state carrying charge between timesteps, equal to 'membrane[lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are membrane: the persistent LIF neuron state carrying charge between timesteps; lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands into local FPGA memory..

Line 165: `group_current_r[local_lane] <= $signed(` This statement continues through source line 166; the explanation uses the complete expression rather than only the first visual fragment. This makes group_current_r[local_lane], the value named 'group current r' in this block, equal to '$signed(current_vector_r[lane*CURRENT_BITS +: CURRENT_BITS])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are current_vector_r: the value named 'current vector r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; CURRENT_BITS: the value named 'current bits' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands into local FPGA memory..

Line 166: `current_vector_r[lane*CURRENT_BITS +: CURRENT_BITS]);` This is continuation line 2 of the 2-line logical statement that begins at source line 165. Its exact fragment is 'current_vector_r[lane*CURRENT_BITS +: CURRENT_BITS]);'. The important operands are current_vector_r: the value named 'current vector r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; CURRENT_BITS: the value named 'current bits' in this block. Read together, the complete operation is: This makes group_current_r[local_lane], the value named 'group current r' in this block, equal to '$signed(current_vector_r[lane*CURRENT_BITS +: CURRENT_BITS])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are current_vector_r: the value named 'current vector r' in this block; lane: one parallel arithmetic element within a vector or tensor datapath; CURRENT_BITS: the value named 'current bits' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands into local FPGA memory..

Line 167: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands

into local FPGA memory.; it has no arithmetic value of its own.

Line 168: `state <= ST_LEAK;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LEAK‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LEAK: the retained fraction of prior membrane state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands into local FPGA memory..

Line 169: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_GROUP_LOAD, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 171: `ST_LEAK: begin` This is the ST_LEAK case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase..

Line 172: `for (int local_lane = 0; local_lane < LANES_PER_CYCLE; local_lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase..

Line 173: `logic signed [MEMBRANE_BITS:0] membrane_extended;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase.. Specifically, membrane_extended is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 174: `membrane_extended = {` This statement continues through source line 176; the explanation uses the complete expression rather than only the first visual fragment. This makes membrane_extended, the persistent LIF neuron state carrying charge between timesteps, equal to ‘{ group_membrane_r[local_lane][MEMBRANE_BITS-1], group_membrane_r[local_lane]}‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are group_membrane_r: the persistent LIF neuron state carrying charge between timesteps; local_lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase..

Line 175: `group_membrane_r[local_lane][MEMBRANE_BITS-1],` This is continuation line 2 of the 3-line logical statement that begins at source line 174. Its exact fragment is ‘group_membrane_r[local_lane][MEMBRANE_BITS-1],‘. The important operands are group_membrane_r: the persistent LIF neuron state carrying charge between timesteps; local_lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This makes membrane_extended, the persistent LIF neuron state carrying charge between timesteps, equal to ‘{ group_membrane_r[local_lane][ME
1], group_membrane_r[local_lane]}‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are group_membrane_r: the persistent LIF neuron state carrying charge between timesteps; local_lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase..

Line 176: `group_membrane_r[local_lane]};` This is continuation line 3 of the 3-line logical statement that begins at source line 174. Its exact fragment is ‘group_membrane_r[local_lane]};‘. The important operands are group_membrane_r: the persistent LIF neuron state carrying charge between timesteps; local_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes membrane_extended, the persistent LIF neuron state carrying charge between timesteps, equal to ‘{ group_membrane_r[local_lane][MEMBRANE_BITS-1], group_membrane_r[local_lane]}‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are group_membrane_r: the persistent LIF neuron state carrying charge between timesteps; local_lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF

neuron state carrying charge between timesteps. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase..

Line 177: `leak_shifted_r[local_lane] <=` This statement continues through source line 178; the explanation uses the complete expression rather than only the first visual fragment. This makes leak_shifted_r[local_lane], the retained fraction of prior membrane state, equal to 'membrane_extended >>> leak_shift_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are membrane_extended: the persistent LIF neuron state carrying charge between timesteps; leak_shift_r: the retained fraction of prior membrane state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase..

Line 178: `membrane_extended >>> leak_shift_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 177. Its exact fragment is 'membrane_extended >>> leak_shift_r;'. The important operands are membrane_extended: the persistent LIF neuron state carrying charge between timesteps; leak_shift_r: the retained fraction of prior membrane state. Read together, the complete operation is: This makes leak_shifted_r[local_lane], the retained fraction of prior membrane state, equal to 'membrane_extended >>> leak_shift_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are membrane_extended: the persistent LIF neuron state carrying charge between timesteps; leak_shift_r: the retained fraction of prior membrane state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase..

Line 179: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 180: `state <= ST_LEAK_SUBTRACT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LEAK_SUBTRACT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LEAK_SUBTRACT: the retained fraction of prior membrane state. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase..

Line 181: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LEAK, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 183: `ST_LEAK_SUBTRACT: begin` This is the ST_LEAK_SUBTRACT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LEAK_SUBTRACT, the machine performs the named control phase..

Line 184: `for (int local_lane = 0; local_lane < LANES_PER_CYCLE; local_lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LEAK_SUBTRACT, the machine performs the named control phase..

Line 185: `logic signed [MEMBRANE_BITS:0] membrane_extended;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_LEAK_SUBTRACT, the machine performs the named control phase.. Specifically, membrane_extended is the persistent LIF neuron state carrying charge between timesteps. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 186: `membrane_extended = {` This statement continues through source line 188; the explanation uses the complete expression rather than only the first visual fragment. This makes membrane_extended, the persistent LIF neuron state carrying charge between timesteps, equal to '{ group_membrane_r[local_lane][MEMBRANE_BITS-1], group_membrane_r[local_lane]}'. It is driven by combinational or procedural logic in the current evaluation. The

important operands are group_membrane_r: the persistent LIF neuron state carrying charge between timesteps; local_lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LEAK_SUBTRACT, the machine performs the named control phase..

Line 187: `group_membrane_r[local_lane][MEMBRANE_BITS-1],` This is continuation line 2 of the 3-line logical statement that begins at source line 186. Its exact fragment is 'group_membrane_r[local_lane][MEMBRANE_BITS-1],'. The important operands are group_membrane_r: the persistent LIF neuron state carrying charge between timesteps; local_lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Read together, the complete operation is: This makes membrane_extended, the persistent LIF neuron state carrying charge between timesteps, equal to '{ group_membrane_r[local_lane][ME 1], group_membrane_r[local_lane]}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are group_membrane_r: the persistent LIF neuron state carrying charge between timesteps; local_lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LEAK_SUBTRACT, the machine performs the named control phase..

Line 188: `group_membrane_r[local_lane]};` This is continuation line 3 of the 3-line logical statement that begins at source line 186. Its exact fragment is 'group_membrane_r[local_lane]};'. The important operands are group_membrane_r: the persistent LIF neuron state carrying charge between timesteps; local_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes membrane_extended, the persistent LIF neuron state carrying charge between timesteps, equal to '{ group_membrane_r[local_lane][MEMBRANE_BITS-1], group_membrane_r[local_lane]}'. Context: the clocked process that updates registers only on a rising clock edge Within state ST_INTEGRATE, the machine performs the named control phase..

Line 200: `group_current_r[local_lane]});` This is continuation line 4 of the 4-line logical statement that begins at source line 197. Its exact fragment is 'group_current_r[local_lane]});'. The important operands are group_current_r: the value named 'group current r' in this block; local_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes integrated_r[local_lane], the value named 'integrated r' in this block, equal to 'leaked_r[local_lane] + $signed({{(MEMBRANE_BITS+1-CURRENT_BITS){ group_current_r[local_lane][CUR
1]}}, group_current_r[local_lane]})'. It updates after the active clock edge together with other nonblocking assignments. The important operands are leaked_r: the retained fraction of prior membrane state; local_lane: one parallel arithmetic element within a vector or tensor datapath; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between

timesteps. Context: the clocked process that updates registers only on a rising clock edge Within state ST_INTEGRATE, the machine performs the named control phase..

Line 201: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_INTEGRATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 202: `state <= ST_SATURATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_SATURATE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SATURATE: the value named 'st saturate' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_INTEGRATE, the machine performs the named control phase..

Line 203: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_INTEGRATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 205: `ST_SATURATE: begin` This is the ST_SATURATE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase..

Line 206: `for (int local_lane = 0; local_lane < LANES_PER_CYCLE; local_lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase..

Line 207: `saturated_r[local_lane] <=` This statement continues through source line 208; the explanation uses the complete expression rather than only the first visual fragment. This makes saturated_r[local_lane], the value named 'saturated r' in this block, equal to 'saturate_membrane(integrated_r[local_lane])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturate_membrane: the persistent LIF neuron state carrying charge between timesteps; integrated_r: the value named 'integrated r' in this block; local_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase..

Line 208: `saturate_membrane(integrated_r[local_lane]);` This is continuation line 2 of the 2-line logical statement that begins at source line 207. Its exact fragment is 'saturate_membrane(integrated_r[local_lane]);'. The important operands are saturate_membrane: the persistent LIF neuron state carrying charge between timesteps; integrated_r: the value named 'integrated r' in this block; local_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes saturated_r[local_lane], the value named 'saturated r' in this block, equal to 'saturate_membrane(integrated_r[local_lane])'. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturate_membrane: the persistent LIF neuron state carrying charge between timesteps; integrated_r: the value named 'integrated r' in this block; local_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase..

Line 209: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 210: `state <= ST_THRESHOLD_COMPARE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_THRESHOLD_COMPARE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_THRESHOLD_COMPARE: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase..

Line 211: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 213: `ST_THRESHOLD_COMPARE: begin` This is the ST_THRESHOLD_COMPARE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_THRESHOLD_COMPARE, the machine performs the named control phase..

Line 214: `for (int local_lane = 0; local_lane < LANES_PER_CYCLE; local_lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_THRESHOLD_COMPARE, the machine performs the named control phase..

Line 215: `group_spikes_r[local_lane] <=` This statement continues through source line 216; the explanation uses the complete expression rather than only the first visual fragment. This makes group_spikes_r[local_lane], a binary event produced when a neuron crosses its threshold, equal to ‘saturated_r[local_lane] >= threshold_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturated_r: the value named ’saturated r’ in this block; local_lane: one parallel arithmetic element within a vector or tensor datapath; threshold_r: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state ST_THRESHOLD_COMPARE, the machine performs the named control phase..

Line 216: `saturated_r[local_lane] >= threshold_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 215. Its exact fragment is ‘saturated_r[local_lane] >= threshold_r;‘. The important operands are saturated_r: the value named ’saturated r’ in this block; local_lane: one parallel arithmetic element within a vector or tensor datapath; threshold_r: the membrane level at which a neuron emits a spike. Read together, the complete operation is: This makes group_spikes_r[local_lane], a binary event produced when a neuron crosses its threshold, equal to ‘saturated_r[local_lane] >= threshold_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturated_r: the value named ’saturated r’ in this block; local_lane: one parallel arithmetic element within a vector or tensor datapath; threshold_r: the membrane level at which a neuron emits a spike. Context: the clocked process that updates registers only on a rising clock edge Within state ST_THRESHOLD_COMPARE, the machine performs the named control phase..

Line 217: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_THRESHOLD_COMPARE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 218: `state <= ST_COMMIT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_COMMIT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMMIT: the value named ’st commit’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_THRESHOLD_COMPARE, the machine performs the named control phase..

Line 219: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_THRESHOLD_COMPARE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 221: `ST_COMMIT: begin` This is the ST_COMMIT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 222: `logic [LANES-1:0] next_spikes;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control

phase.. Specifically, next_spikes is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 223: `logic [3:0] group_spike_count;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.. Specifically, group_spike_count is a binary event produced when a neuron crosses its threshold. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 224: `next_spikes = spike_work_r;` This makes next_spikes, a binary event produced when a neuron crosses its threshold, equal to ‘spike_work_r‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are spike_work_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 225: `for (int local_lane = 0; local_lane < LANES_PER_CYCLE; local_lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 226: `logic [$clog2(LANES)-1:0] lane;` This declares hardware signal storage or wiring in the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.. Specifically, lane is one parallel arithmetic element within a vector or tensor datapath. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 227: `lane = $clog2(LANES)'(` This statement continues through source line 228; the explanation uses the complete expression rather than only the first visual fragment. This makes lane, one parallel arithmetic element within a vector or tensor datapath, equal to ‘$clog2(LANES)'(group_index * LANES_PER_CYCLE + local_lane)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are clog2: the value named 'clog2' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; group_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 228: `group_index * LANES_PER_CYCLE + local_lane);` This is continuation line 2 of the 2-line logical statement that begins at source line 227. Its exact fragment is ‘group_index * LANES_PER_CYCLE + local_lane);‘. The important operands are group_index: an integer selecting one tensor element, lane, bank, or state entry; LANES_PER_CYCLE: one parallel arithmetic element within a vector or tensor datapath; local_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes lane, one parallel arithmetic element within a vector or tensor datapath, equal to ‘$clog2(LANES)'(group_index * LANES_PER_CYCLE + local_lane)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are clog2: the value named 'clog2' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath; group_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 229: `pre_reset_membrane[lane] <= saturated_r[local_lane];` This makes pre_reset_membrane[lane], the persistent LIF neuron state carrying charge between timesteps, equal to ‘saturated_r[local_lane]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturated_r: the value named 'saturated r' in this block; local_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 230: `if (group_spikes_r[local_lane]) begin` This condition selects the following hardware branch only when ‘group_spikes_r[local_lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are group_spikes_r: a binary event produced when a neuron crosses its threshold; local_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 231: `membrane[lane] <= reset_value_r;` This makes membrane[lane], the persistent LIF neuron state carrying charge between timesteps, equal to ‘reset_value_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are reset_value_r: the value named ’reset value r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 232: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 233: `membrane[lane] <= saturated_r[local_lane];` This makes membrane[lane], the persistent LIF neuron state carrying charge between timesteps, equal to ‘saturated_r[local_lane]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are saturated_r: the value named ’saturated r’ in this block; local_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 234: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 235: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 236: `next_spikes[group_index*LANES_PER_CYCLE +: LANES_PER_CYCLE]` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase., this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are next_spikes: a binary event produced when a neuron crosses its threshold; group_index: an integer selecting one tensor element, lane, bank, or state entry; LANES_PER_CYCLE: one parallel arithmetic element within a vector or tensor datapath.

Line 237: `= group_spikes_r;` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase., this exact statement contributes to the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting. The important operands are group_spikes_r: a binary event produced when a neuron crosses its threshold.

Line 238: `group_spike_count = popcount8(group_spikes_r);` This makes group_spike_count, a binary event produced when a neuron crosses its threshold, equal to ‘popcount8(group_spikes_r)‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are popcount8: the value named ’popcount8’ in this block; group_spikes_r: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 239: `spike_work_r <= next_spikes;` This makes spike_work_r, a binary event produced when a neuron crosses its threshold, equal to ‘next_spikes‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_spikes: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 240: `step_spike_count_r <= step_spike_count_r` This statement continues through source line 241; the explanation uses the complete expression rather than only the first visual fragment. This makes step_spike_count_r, a binary event produced when a neuron crosses its threshold, equal to ‘step_spike_count_r + {3’d0, group_spike_count}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are step_spike_count_r: a binary event produced when a neuron crosses its threshold; d0: the value named ’d0’ in this

block; group_spike_count: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 241: `+ {3'd0, group_spike_count};` This is continuation line 2 of the 2-line logical statement that begins at source line 240. Its exact fragment is '+ {3'd0, group_spike_count};'. The important operands are d0: the value named 'd0' in this block; group_spike_count: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This makes step_spike_count_r, a binary event produced when a neuron crosses its threshold, equal to 'step_spike_count_r + {3'd0, group_spike_count}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are step_spike_count_r: a binary event produced when a neuron crosses its threshold; d0: the value named 'd0' in this block; group_spike_count: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 243: `if (group_index == $clog2(GROUPS)'(GROUPS - 1)) begin` This condition selects the following hardware branch only when 'group_index == $clog2(GROUPS)'(GROUPS - 1)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are group_index: an integer selecting one tensor element, lane, bank, or state entry; clog2: the value named 'clog2' in this block; GROUPS: the value named 'groups' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 244: `spikes <= next_spikes;` This makes spikes, a binary event produced when a neuron crosses its threshold, equal to 'next_spikes'. It updates after the active clock edge together with other nonblocking assignments. The important operands are next_spikes: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 245: `timestep_count <= timestep_count + 1'b1;` This makes timestep_count, one discrete SNN update instant, equal to 'timestep_count + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are timestep_count: one discrete SNN update instant; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 246: `completed_step_spike_count_r <= step_spike_count_r` This statement continues through source line 247; the explanation uses the complete expression rather than only the first visual fragment. This makes completed_step_spike_cour a binary event produced when a neuron crosses its threshold, equal to 'step_spike_count_r + {3'd0, group_spike_count}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are step_spike_count_r: a binary event produced when a neuron crosses its threshold; d0: the value named 'd0' in this block; group_spike_count: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 247: `+ {3'd0, group_spike_count};` This is continuation line 2 of the 2-line logical statement that begins at source line 246. Its exact fragment is '+ {3'd0, group_spike_count};'. The important operands are d0: the value named 'd0' in this block; group_spike_count: a binary event produced when a neuron crosses its threshold. Read together, the complete operation is: This makes completed_step_spike_count_r, a binary event produced when a neuron crosses its threshold, equal to 'step_spike_count_r + {3'd0, group_spike_count}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are step_spike_count_r: a binary event produced when a neuron crosses its threshold; d0: the value named 'd0' in this block; group_spike_count: a binary event produced when a neuron crosses its threshold. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 248: `state <= ST_COUNT_LOW;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_COUNT_LOW'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COUNT_LOW: the value named 'st count low' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 249: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 250: `group_index <= group_index + 1'b1;` This makes group_index, an integer selecting one tensor element, lane, bank, or state entry, equal to ‘group_index + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are group_index: an integer selecting one tensor element, lane, bank, or state entry; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 251: `state <= ST_GROUP_LOAD;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_GROUP_LOAD‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_GROUP_LOAD: the value named ’st group load’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 252: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 253: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 255: `// The cumulative diagnostic counter is deliberately updated` Design intent: The cumulative diagnostic counter is deliberately updated This comment anchors the surrounding logic in the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting.

Line 256: `// as four 16-bit words. A monolithic 64-bit addition placed a` Design intent: as four 16-bit words. A monolithic 64-bit addition placed a This comment anchors the surrounding logic in the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting.

Line 257: `// popcount and long carry chain on the 200 MHz neuron path.` Design intent: popcount and long carry chain on the 200 MHz neuron path. This comment anchors the surrounding logic in the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting.

Line 258: `ST_COUNT_LOW: begin` This is the ST_COUNT_LOW case branch, which updates a segmented telemetry counter without a long carry chain. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_LOW, the machine updates a segmented telemetry counter without a long carry chain..

Line 259: `counter_sum_r <= {1'b0, total_spike_count[15:0]}` This statement continues through source line 260; the explanation uses the complete expression rather than only the first visual fragment. This makes counter_sum_r, a hardware telemetry register that accumulates measured events, equal to ‘{1’b0, total_spike_count[15:0]} + {10’d0, completed_step_spike_count_r}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block; total_spike_count: a binary event produced when a neuron crosses its threshold; d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_LOW, the machine updates a segmented telemetry counter without a long carry chain..

Line 260: `+ {10'd0, completed_step_spike_count_r};` This is continuation line 2 of the 2-line logical statement that begins at source line 259. Its exact fragment is ‘+ {10’d0, completed_step_spike_count_r};‘. The important operands are d0: the value named ’d0’ in this block; completed_step_spike_count_r: a binary event produced

when a neuron crosses its threshold. Read together, the complete operation is: This makes counter_sum_r, a hardware telemetry register that accumulates measured events, equal to ‘{1’b0, total_spike_count[15:0]} + {10’d0, completed_step_spike_count_r}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block; total_spike_count: a binary event produced when a neuron crosses its threshold; d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_LOW, the machine updates a segmented telemetry counter without a long carry chain..

Line 261: `state <= ST_COUNT_WORD1;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_COUNT_WORD1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COUNT_WORD1: the value named ’st count word1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_LOW, the machine updates a segmented telemetry counter without a long carry chain..

Line 262: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_LOW, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 264: `ST_COUNT_WORD1: begin` This is the ST_COUNT_WORD1 case branch, which updates a segmented telemetry counter without a long carry chain. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD1, the machine updates a segmented telemetry counter without a long carry chain..

Line 265: `total_spike_count[15:0] <= counter_sum_r[15:0];` This makes total_spike_count[15:0], a binary event produced when a neuron crosses its threshold, equal to ‘counter_sum_r[15:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are counter_sum_r: a hardware telemetry register that accumulates measured events. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD1, the machine updates a segmented telemetry counter without a long carry chain..

Line 266: `counter_sum_r <= {1’b0, total_spike_count[31:16]}` This statement continues through source line 267; the explanation uses the complete expression rather than only the first visual fragment. This makes counter_sum_r, a hardware telemetry register that accumulates measured events, equal to ‘{1’b0, total_spike_count[31:16]} + {16’d0, counter_sum_r[16]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block; total_spike_count: a binary event produced when a neuron crosses its threshold; d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD1, the machine updates a segmented telemetry counter without a long carry chain..

Line 267: `+ {16’d0, counter_sum_r[16]};` This is continuation line 2 of the 2-line logical statement that begins at source line 266. Its exact fragment is ‘+ {16’d0, counter_sum_r[16]};‘. The important operands are d0: the value named ’d0’ in this block; counter_sum_r: a hardware telemetry register that accumulates measured events. Read together, the complete operation is: This makes counter_sum_r, a hardware telemetry register that accumulates measured events, equal to ‘{1’b0, total_spike_count[31:16]} + {16’d0, counter_sum_r[16]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block; total_spike_count: a binary event produced when a neuron crosses its threshold; d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD1, the machine updates a segmented telemetry counter without a long carry chain..

Line 268: `state <= ST_COUNT_WORD2;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_COUNT_WORD2‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COUNT_WORD2: the value named ’st count word2’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD1, the machine updates a segmented telemetry counter without a long carry chain..

Line 269: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD1, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 271: `ST_COUNT_WORD2: begin` This is the ST_COUNT_WORD2 case branch, which updates a segmented telemetry counter without a long carry chain. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD2, the machine updates a segmented telemetry counter without a long carry chain..

Line 272: `total_spike_count[31:16] <= counter_sum_r[15:0];` This makes total_spike_count[31:16], a binary event produced when a neuron crosses its threshold, equal to ‘counter_sum_r[15:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are counter_sum_r: a hardware telemetry register that accumulates measured events. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD2, the machine updates a segmented telemetry counter without a long carry chain..

Line 273: `counter_sum_r <= {1'b0, total_spike_count[47:32]}` This statement continues through source line 274; the explanation uses the complete expression rather than only the first visual fragment. This makes counter_sum_r, a hardware telemetry register that accumulates measured events, equal to ‘{1’b0, total_spike_count[47:32]} + {16’d0, counter_sum_r[16]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block; total_spike_count: a binary event produced when a neuron crosses its threshold; d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD2, the machine updates a segmented telemetry counter without a long carry chain..

Line 274: `+ {16'd0, counter_sum_r[16]};` This is continuation line 2 of the 2-line logical statement that begins at source line 273. Its exact fragment is ‘+ {16’d0, counter_sum_r[16]};‘. The important operands are d0: the value named ’d0’ in this block; counter_sum_r: a hardware telemetry register that accumulates measured events. Read together, the complete operation is: This makes counter_sum_r, a hardware telemetry register that accumulates measured events, equal to ‘{1’b0, total_spike_count[47:32]} + {16’d0, counter_sum_r[16]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block; total_spike_count: a binary event produced when a neuron crosses its threshold; d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD2, the machine updates a segmented telemetry counter without a long carry chain..

Line 275: `state <= ST_COUNT_WORD3;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_COUNT_WORD3‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COUNT_WORD3: the value named ’st count word3’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD2, the machine updates a segmented telemetry counter without a long carry chain..

Line 276: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD2, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 278: `ST_COUNT_WORD3: begin` This is the ST_COUNT_WORD3 case branch, which updates a segmented telemetry counter without a long carry chain. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD3, the machine updates a segmented telemetry counter without a long carry chain..

Line 279: `total_spike_count[47:32] <= counter_sum_r[15:0];` This makes total_spike_count[47:32], a binary event produced when a neuron crosses its threshold, equal to ‘counter_sum_r[15:0]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are counter_sum_r: a hardware telemetry register that accumulates measured events. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD3, the machine updates a segmented telemetry counter without a long carry chain..

Line 280: `counter_sum_r <= {1'b0, total_spike_count[63:48]}` This statement continues through source line 281; the explanation uses the complete expression rather than only the first visual fragment. This makes counter_sum_r, a hardware telemetry register that accumulates measured events, equal to '{1'b0, total_spike_count[63:48]} + {16'd0, counter_sum_r[16]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block; total_spike_count: a binary event produced when a neuron crosses its threshold; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD3, the machine updates a segmented telemetry counter without a long carry chain..

Line 281: `+ {16'd0, counter_sum_r[16]};` This is continuation line 2 of the 2-line logical statement that begins at source line 280. Its exact fragment is '+ {16'd0, counter_sum_r[16]};'. The important operands are d0: the value named 'd0' in this block; counter_sum_r: a hardware telemetry register that accumulates measured events. Read together, the complete operation is: This makes counter_sum_r, a hardware telemetry register that accumulates measured events, equal to '{1'b0, total_spike_count[63:48]} + {16'd0, counter_sum_r[16]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block; total_spike_count: a binary event produced when a neuron crosses its threshold; d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD3, the machine updates a segmented telemetry counter without a long carry chain..

Line 282: `state <= ST_COUNT_DONE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_COUNT_DONE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COUNT_DONE: the value named 'st count done' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD3, the machine updates a segmented telemetry counter without a long carry chain..

Line 283: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_WORD3, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 285: `ST_COUNT_DONE: begin` This is the ST_COUNT_DONE case branch, which updates a segmented telemetry counter without a long carry chain. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_DONE, the machine updates a segmented telemetry counter without a long carry chain..

Line 286: `total_spike_count[63:48] <= counter_sum_r[15:0];` This makes total_spike_count[63:48], a binary event produced when a neuron crosses its threshold, equal to 'counter_sum_r[15:0]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are counter_sum_r: a hardware telemetry register that accumulates measured events. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_DONE, the machine updates a segmented telemetry counter without a long carry chain..

Line 287: `state <= ST_OUTPUT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_OUTPUT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT: the value named 'st output' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_DONE, the machine updates a segmented telemetry counter without a long carry chain..

Line 288: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COUNT_DONE, the machine updates a segmented telemetry counter without a long carry chain.; it has no arithmetic value of its own.

Line 290: `ST_OUTPUT: if (output_ready) state <= ST_IDLE;` This is the ST_OUTPUT case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with 'if (output_ready) state <= ST_IDLE;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 291: `default:  state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘state <= ST_IDLE;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure..

Line 292: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 293: `if (clear_counters) total_spike_count <= 64'd0;` This condition selects the following hardware branch only when ‘clear_counters‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are clear_counters: a hardware telemetry register that accumulates measured events. Context: the clocked process that updates registers only on a rising clock edge.

Line 294: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 295: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 297: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 298: `if (LANES != 32) $fatal(1, "neuraedge_lif_bank currently requires LANES=32");` This condition selects the following hardware branch only when ‘LANES != 32) $fatal(1, "neuraedge_lif_bank currently requires LANES=32"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are LANES: one parallel arithmetic element within a vector or tensor datapath; fatal: the value named 'fatal' in this block; neuraedge_lif_bank: the value named 'neuraedge lif bank' in this block. Context: the module's structural declarations.

Line 299: `if (LANES_PER_CYCLE != 8) $fatal(1, "neuraedge_lif_bank currently requires LANES_PER_CYCLE=8");` This condition selects the following hardware branch only when ‘LANES_PER_CYCLE != 8) $fatal(1, "neuraedge_lif_bank currently requires LANES_PER_CYCLE=8"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are LANES_PER_CYCLE: one parallel arithmetic element within a vector or tensor datapath; fatal: the value named 'fatal' in this block; neuraedge_lif_bank: the value named 'neuraedge lif bank' in this block. Context: the module's structural declarations.

Line 300: `if (LANES % LANES_PER_CYCLE != 0) $fatal(1, "LANES_PER_CYCLE must divide LANES");` This condition selects the following hardware branch only when ‘LANES % LANES_PER_CYCLE != 0) $fatal(1, "LANES_PER_CYCLE must divide LANES"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are LANES: one parallel arithmetic element within a vector or tensor datapath; LANES_PER_CYCLE: one parallel arithmetic element within a vector or tensor datapath; fatal: the value named 'fatal' in this block. Context: the module's structural declarations.

Line 301: `if (CURRENT_BITS >= MEMBRANE_BITS) $fatal(1, "CURRENT_BITS must be smaller than MEMBRANE_BITS");` This condition selects the following hardware branch only when ‘CURRENT_BITS >= MEMBRANE_BITS) $fatal(1, "CURRENT_BITS must be smaller than MEMBRANE_BITS"‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are CURRENT_BITS: the value named 'current bits' in this block; MEMBRANE_BITS: the persistent LIF neuron state carrying charge between timesteps; fatal: the value named 'fatal' in this block. Context: the module's structural declarations.

Line 302: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 303: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 305: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that stores 32 persistent membrane values and applies leak, integration, threshold, reset, and spike counting.

13 rtl/neuraedge_linear_backward8.sv

Role in the complete system: computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

13.1 Beginner architecture map

Dataflow responsibility A command declares up to eight rows, input features, and output features. Streamed activations, signed weights, and output gradients are buffered in four-lane halves; sixteen signed DSP products are accumulated per cycle. The controller first reduces dY times transposed W into dX, then transposed X times dY into dW, retaining 47-bit partial sums across tiled commands when requested. Separate magnitude, rounding-bias, shift, sign, and saturation states preserve the reference round-once result while breaking the long FPGA timing path.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_linear_backward8 into physical nets and primitives. The source declares 22 input-port lines, 10 output-port lines, 1 clocked process(es), and 2 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_ADD_ACCUMULATOR, ST_COMMIT, ST_CONFIGURE, ST_DONE, ST_IDLE, ST_LOAD_COMMIT_DRAIN, ST_LOAD_DY, ST_LOAD_W, ST_LOAD_X, ST_MULTIPLY, ST_OUTPUT_DW, ST_OUTPUT_DX, ST_PAIR, ST_PRODUCT, ST_REDUCE, ST_REDUCTION_SUM, ST_REGISTER_OPERANDS, ST_ROUND_BIAS and additional states. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates begin as if, else as if, endfunction as for, neuraedge_gradient_accumulator_ as u_bank, end as for, end as if, unique as case, endcase as if. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

13.3 Line annotations

Line 1: `` `timescale 1ns / 1ps `` This simulation directive selects nanoseconds as the time unit and picoseconds as the timestamp precision; it does not create FPGA logic.

Line 2: `` `default_nettype none `` This compiler directive forbids accidental implicit one-bit wires, turning misspelled signal names into errors instead of unintended hardware.

Line 4: `// Exact tiled reverse-mode engine for Y = XW:` Design intent: Exact tiled reverse-mode engine for Y = XW: This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 5: `// dX = dY * transpose(W), dW = transpose(X) * dY.` Design intent: dX = dY * transpose(W), dW = transpose(X) * dY. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 6: `// The external tile remains 8x8x8, while a 4x4 DSP array traverses two` Design intent: The external tile remains 8x8x8, while a 4x4 DSP array traverses two This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 7: `// result-column groups and up to two reduction groups. One shared 47-bit` Design intent: result-column groups and up to two reduction groups. One shared 47-bit This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 8: `// accumulator bank preserves cross-command partial sums until the compiler` Design intent: accumulator bank preserves cross-command partial sums until the compiler This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 9: `// requests the final rounded output.` Design intent: requests the final rounded output. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 10: `module neuraedge_linear_backward8 #(` This opens neuraedge_linear_backward8, an independently compiled hardware definition. Its ports and statements collectively describe circuitry that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 11: `parameter int LANES = 8` This statement continues through source line 45; the explanation uses the complete expression rather than only the first visual fragment. This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output

Line 23: `input wire [4:0] weight_gradient_shift,` This is continuation line 13 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'input wire [4:0] weight_gradient_shift,'. The important operands are input: the value named 'input' in this block; weight_gradient_shift: a learned coefficient multiplied by an activation. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 24: `input wire [1:0] gradient_mode,` This is continuation line 14 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'input wire [1:0] gradient_mode,'. The important operands are input: the value named 'input' in this block; gradient_mode: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 25: `input wire accumulate_result,` This is continuation line 15 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'input wire accumulate_result,'. The important operands are input: the value named 'input' in this block; accumulate_result: the value named 'accumulate result' in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 26: `input wire suppress_output,` This is continuation line 16 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'input wire suppress_output,'. The important operands are input: the value named 'input' in this block; suppress_output: the value named 'suppress output' in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 27: `input wire reserved_nonzero,` This is continuation line 17 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'input wire reserved_nonzero,'. The important operands are input: the value named 'input' in this block; reserved_nonzero: the value named 'reserved nonzero' in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 29: `input wire s_axis_tvalid,` This is continuation line 19 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'input wire s_axis_tvalid,'. The important operands are input: the value named 'input' in this block; s_axis_tvalid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 30: `output logic s_axis_tready,` This is continuation line 20 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'output logic s_axis_tready,'. The important operands are output: the value named 'output' in this block; s_axis_tready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 31: `input wire [63:0] s_axis_tdata,` This is continuation line 21 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'input wire [63:0] s_axis_tdata,'. The important operands are input: the value named 'input' in this block; s_axis_tdata: the value named 's axis tdata' in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs,

input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 32: `input wire s_axis_tlast,` This is continuation line 22 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'input wire s_axis_tlast,'. The important operands are input: the value named 'input' in this block; s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 34: `output logic m_axis_tvalid,` This is continuation line 24 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'output logic m_axis_tvalid,'. The important operands are output: the value named 'output' in this block; m_axis_tvalid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 35: `input wire m_axis_tready,` This is continuation line 25 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'input wire m_axis_tready,'. The important operands are input: the value named 'input' in this block; m_axis_tready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 36: `output logic [63:0] m_axis_tdata,` This is continuation line 26 of the 35-line logical statement that begins at source line 11. Its exact fragment is 'output logic [63:0] m_axis_tdata,'. The important operands are output: the value named 'output' in this block; m_axis_tdata: the value named 'm axis tdata' in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles,

output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 37: `output logic m_axis_tlast,` This is continuation line 27 of the 35-line logical statement that begins at source line 11. Its exact fragment is ‘output logic m_axis_tlast,‘. The important operands are output: the value named ’output’ in this block; m_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 39: `output logic busy,` This is continuation line 29 of the 35-line logical statement that begins at source line 11. Its exact fragment is ‘output logic busy,‘. The important operands are output: the value named ’output’ in this block; busy: the value named ’busy’ in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 40: `output logic done,` This is continuation line 30 of the 35-line logical statement that begins at source line 11. Its exact fragment is ‘output logic done,‘. The important operands are output: the value named ’output’ in this block; done: the value named ’done’ in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 41: `output logic config_error,` This is continuation line 31 of the 35-line logical statement that begins at source line 11. Its exact fragment is ‘output logic config_error,‘. The important operands are output: the value named ’output’ in this block; config_error: the value named ’config error’ in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 42: `(* extract_enable = "no" *)` This is continuation line 32 of the 35-line logical statement that begins at source line 11. Its exact fragment is ‘(* extract_enable = "no" *)‘. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named ’no’ in this block. Read together,

the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 43: `output logic [31:0] completed_tiles,` This is continuation line 33 of the 35-line logical statement that begins at source line 11. Its exact fragment is ‘output logic [31:0] completed_tiles,‘. The important operands are output: the value named ’output’ in this block; completed_tiles: the value named ’completed tiles’ in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 44: `output logic [31:0] active_cycles` This is continuation line 34 of the 35-line logical statement that begins at source line 11. Its exact fragment is ‘output logic [31:0] active_cycles‘. The important operands are output: the value named ’output’ in this block; active_cycles: the value named ’active cycles’ in this block. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 45: `);` This is continuation line 35 of the 35-line logical statement that begins at source line 11. Its exact fragment is ‘);‘. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes LANES to 8) (input wire clk, input wire rst_n, input wire clear_counters, input wire start_valid, output logic start_ready, input wire [3:0] active_rows, input wire [3:0] active_inputs, input wire [3:0] active_outputs, input wire [4:0] input_gradient_shift, input wire [4:0] weight_gradient_shift, input wire [1:0] gradient_mode, input wire accumulate_result, input wire suppress_output, input wire reserved_nonzero, input wire s_axis_tvalid, output logic s_axis_tready, input wire [63:0] s_axis_tdata, input wire s_axis_tlast, output logic m_axis_tvalid, input wire m_axis_tready, output logic [63:0] m_axis_tdata, output logic m_axis_tlast, output logic busy, output logic done, output logic config_error, (* extract_enable = "no" *) output logic [31:0] completed_tiles, output logic [31:0] active_cycles) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 46: `localparam int RESULT_LANES = 4;` This fixes RESULT_LANES to 4 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; RESULT_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 47: `localparam int REDUCTION_LANES = 4;` This fixes REDUCTION_LANES to 4 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; REDUCTION_LANES denotes one parallel arithmetic element within a vector or tensor datapath.

Line 49: `localparam logic [1:0] MODE_BOTH = 2'd0;` This fixes MODE_BOTH to 2'd0 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_BOTH denotes the value named 'mode both' in this block.

Line 50: `localparam logic [1:0] MODE_INPUT_GRADIENT = 2'd1;` This fixes MODE_INPUT_GRADIENT to 2'd1 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_INPUT_GRADIENT denotes the signed loss derivative used to update a learned parameter.

Line 51: `localparam logic [1:0] MODE_WEIGHT_GRADIENT = 2'd2;` This fixes MODE_WEIGHT_GRADIENT to 2'd2 during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MODE_WEIGHT_GRADIENT denotes a learned coefficient multiplied by an activation.

Line 53: `typedef enum logic [4:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 54: `ST_IDLE = 5'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 55: `ST_LOAD_X = 5'd1,` This assigns a fixed binary encoding to state ST_LOAD_X, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 56: `ST_LOAD_W = 5'd2,` This assigns a fixed binary encoding to state ST_LOAD_W, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 57: `ST_LOAD_DY = 5'd3,` This assigns a fixed binary encoding to state ST_LOAD_DY, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 58: `ST_MULTIPLY = 5'd4,` This assigns a fixed binary encoding to state ST_MULTIPLY, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 59: `ST_PRODUCT = 5'd5,` This assigns a fixed binary encoding to state ST_PRODUCT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 60: `ST_PAIR = 5'd6,` This assigns a fixed binary encoding to state ST_PAIR, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 61: `ST_REDUCE = 5'd7,` This assigns a fixed binary encoding to state ST_REDUCE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 62: `ST_COMMIT = 5'd8,` This assigns a fixed binary encoding to state ST_COMMIT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 63: `ST_OUTPUT_DX = 5'd9,` This assigns a fixed binary encoding to state ST_OUTPUT_DX, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 64: `ST_OUTPUT_DW = 5'd10,` This assigns a fixed binary encoding to state ST_OUTPUT_DW, which presents computed results under valid/ready backpressure. The encoding is visible in waveforms even though the source uses the readable name.

Line 65: `ST_SWITCH_DW = 5'd11,` This assigns a fixed binary encoding to state ST_SWITCH_DW, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 66: `ST_DONE = 5'd12,` This assigns a fixed binary encoding to state ST_DONE, which raises completion for one cycle and returns control to idle. The encoding is visible in waveforms even though the source uses the readable name.

Line 67: `ST_ROUND_MAGNITUDE = 5'd13,` This assigns a fixed binary encoding to state ST_ROUND_MAGNITUDE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 68: `ST_ROUND_BIAS = 5'd14,` This assigns a fixed binary encoding to state ST_ROUND_BIAS, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 69: `ST_ROUND_SHIFT = 5'd15,` This assigns a fixed binary encoding to state ST_ROUND_SHIFT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 70: `ST_ROUND_SIGN = 5'd16,` This assigns a fixed binary encoding to state ST_ROUND_SIGN, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 71: `ST_SATURATE = 5'd17,` This assigns a fixed binary encoding to state ST_SATURATE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 72: `ST_ADD_ACCUMULATOR = 5'd18,` This assigns a fixed binary encoding to state ST_ADD_ACCUMULATOR, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 73: `ST_STORE_ACCUMULATOR = 5'd19,` This assigns a fixed binary encoding to state ST_STORE_ACCUMULATOR, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 74: `ST_REDUCTION_SUM = 5'd20,` This assigns a fixed binary encoding to state ST_REDUCTION_SUM, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 75: `ST_STORE_RESULT = 5'd21,` This assigns a fixed binary encoding to state ST_STORE_RESULT, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 76: `ST_REGISTER_OPERANDS = 5'd22,` This assigns a fixed binary encoding to state ST_REGISTER_OPERANDS, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 77: `ST_CONFIGURE = 5'd23,` This assigns a fixed binary encoding to state ST_CONFIGURE, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 78: `ST_ROUND_MAGNITUDE_HIGH = 5'd24,` This assigns a fixed binary encoding to state ST_ROUND_MAGNITUDE_HIGH which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 79: `ST_ROUND_BIAS_HIGH = 5'd25,` This assigns a fixed binary encoding to state ST_ROUND_BIAS_HIGH, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 80: `ST_ROUND_SIGN_HIGH = 5'd26,` This assigns a fixed binary encoding to state ST_ROUND_SIGN_HIGH, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.

Line 81: `ST_LOAD_COMMIT_DRAIN = 5'd27` This statement continues through source line 82; the explanation uses the complete expression rather than only the first visual fragment. This assigns a fixed binary encoding to state ST_LOAD_COMMIT_DRAIN, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 82: `} state_t;` This is continuation line 2 of the 2-line logical statement that begins at source line 81. Its exact fragment is '} state_t;'. The important operands are state_t: the finite-state-machine phase retained in flip-flops. Read together, the complete operation is: This assigns a fixed binary encoding to state ST_LOAD_COMMIT_DRAIN, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 84: `// Keep the compact encoding, but route next-state decisions to D rather` Design intent: Keep the compact encoding, but route next-state decisions to D rather This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 85: `// than the tighter-setup CE pin used by automatic enable extraction.` Design intent: than the tighter-setup CE pin used by automatic enable extraction. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 86: `(* fsm_encoding = "sequential", extract_enable = "no" *) state_t state;` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are fsm_encoding: the value named 'fsm encoding' in this block; sequential: the value named 'sequential' in this block; extract_enable: a control bit that permits the associated state or storage update.

Line 87: `logic [3:0] rows_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rows_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 88: `logic [3:0] inputs_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, inputs_r is the value named 'inputs r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 89: `logic [3:0] outputs_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, outputs_r is the value named 'outputs r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 90: `logic [4:0] dw_shift_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dw_shift_r is the value named 'dw shift r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 91: `logic [4:0] result_shift_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_shift_r is the value named 'result shift r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 92: `logic [46:0] rounding_bias_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rounding_bias_r is an additive learned offset applied after accumulation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 93: `logic [1:0] mode_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, mode_r is the value named 'mode r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 94: `logic [1:0] compute_mode_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, compute_mode_r is the value named 'compute mode r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 95: `logic suppress_output_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, suppress_output_r is the value named 'suppress output r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 96: `logic accumulate_result_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulate_result_r is the value named 'accumulate result r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 97: `logic start_configuration_invalid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, start_configuration_invalid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 98: `logic [1:0] requested_accumulator_mode_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, requested_accumulator_mode_r is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 99: `logic [3:0] requested_accumulator_rows_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, requested_accumulator_rows_r is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 100: `logic [3:0] requested_accumulator_columns_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, requested_accumulator_columns_r is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 101: `logic [3:0] compute_result_row_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, compute_result_row_count_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 102: `logic [3:0] compute_result_column_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, compute_result_column_count_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 103: `logic [3:0] compute_reduction_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, compute_reduction_count_r is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 105: `// Each lane owns a preserved copy of the mode-select bit. This limits the` Design intent: Each lane owns a preserved copy of the mode-select bit. This limits the This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 106: `// physical fanout into the four DSP lanes while retaining one logical mode.` Design intent: physical fanout into the four DSP lanes while retaining one logical mode. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 107: `(* keep = "true", dont_touch = "true" *)` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are keep: the value named 'keep' in this block; dont_touch: the value named 'dont touch' in this block.

Line 108: `logic [RESULT_LANES-1:0] input_gradient_lane_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_gradient_lane_r is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 110: `// These banks are loaded under several FSM states. Implementing the hold` Design intent: These banks are loaded under several FSM states. Implementing the hold This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 111: `// condition on D keeps a distant state decode off thousands of FDRE CE` Design intent: condition on D keeps a distant state decode off thousands of FDRE CE This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 112: `// pins and lets Vivado place each small input mux beside its register.` Design intent: pins and lets Vivado place each small input mux beside its register. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 113: `(* extract_enable = "no" *)` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block.

Line 114: `logic signed [15:0] activation_r [0:LANES-1][0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 115: `(* extract_enable = "no" *)` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block.

Line 116: `logic signed [15:0] weight_r [0:LANES-1][0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 117: `(* extract_enable = "no" *)` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block.

Line 118: `logic signed [15:0] output_gradient_r [0:LANES-1][0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_gradient_r is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 120: `// Four banks provide the four independent reads and writes needed by the` Design intent: Four banks provide the four independent reads and writes needed by the This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 121: `// result lanes. Each bank stores one column from both four-column groups` Design intent: result lanes. Each bank stores one column from both four-column groups This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 122: `// for every row: address = {row, column_group}. Commands that do not` Design intent: for every row: address = {row, column_group}. Commands that do not This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 123: `// accumulate select mathematical zero instead of clearing the RAM. This` Design intent: accumulate select mathematical zero instead of clearing the RAM. This This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 124: `// preserves exact accumulation while removing a clear/hold/store mux and` Design intent: preserves exact accumulation while removing a clear/hold/store mux and This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 125: `// its FSM control route from 3,008 individual flip-flops.` Design intent: its FSM control route from 3,008 individual flip-flops. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 126: `wire signed [46:0] accumulator_bank_read_data` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are accumulator_bank_read_data: a widened running sum that prevents intermediate overflow.

Line 127: `[0:RESULT_LANES-1];` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are RESULT_LANES: one parallel arithmetic element within a vector or tensor datapath.

Line 128: `wire signed [46:0] accumulator_bank_write_data` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are accumulator_bank_write_data: a widened running sum that prevents intermediate overflow.

Line 129: `[0:RESULT_LANES-1];` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are RESULT_LANES: one parallel arithmetic element within a vector or tensor datapath.

Line 130: `wire [RESULT_LANES-1:0] accumulator_bank_write_enable;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulator_bank_write_enable is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 131: `logic accumulator_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulator_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 132: `logic [1:0] accumulator_mode_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulator_mode_r is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 133: `logic [3:0] accumulator_rows_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulator_rows_r is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 134: `logic [3:0] accumulator_columns_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulator_columns_r is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 136: `logic signed [31:0] result_row_buffer_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_row_buffer_r is local storage that decouples producer and consumer timing. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 137: `// Eight signed 16x16 products fit exactly in 35 bits. Keeping this` Design intent: Eight signed 16x16 products fit exactly in 35 bits. Keeping this This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 138: `// command-local sum at its mathematical width shortens the carry chain;` Design intent: command-local sum at its mathematical width shortens the carry chain; This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 139: `// it is sign-extended only when added to the retained 47-bit accumulator.` Design intent: it is sign-extended only when added to the retained 47-bit accumulator. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 140: `logic signed [34:0] row_partial_r [0:RESULT_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, row_partial_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 141: `logic signed [33:0] reduction_sum_r [0:RESULT_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, reduction_sum_r is the value named 'reduction sum r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 142: `logic signed [46:0] selected_accumulator_r [0:RESULT_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, selected_accumulator_r is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 143: `logic signed [47:0] accumulated_wide_r [0:RESULT_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulated_wide_r is the value named 'accumulated wide r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 144: `logic commit_lane_valid_r [0:RESULT_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, commit_lane_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 145: `logic [46:0] rounding_value_r [0:RESULT_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rounding_value_r is the value named 'rounding value r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 146: `logic rounding_negative_r [0:RESULT_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rounding_negative_r is the value named 'rounding negative r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 147: `logic rounding_carry_r [0:RESULT_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, rounding_carry_r is the value named 'rounding carry r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 148: `logic signed [31:0] saturated_result_r [0:RESULT_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, saturated_result_r is the value named 'saturated result r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 150: `logic [3:0] load_row_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_row_r is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 151: `logic load_half_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_half_r is the value named 'load half r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 152: `logic load_final_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_final_r is the value named 'load final r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 153: `// Stream VALID previously participated directly in the D-input mux for` Design intent: Stream VALID previously participated directly in the D-input mux for This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 154: `// all 3,072 operand-bank bits. This elastic stage accepts one beat every` Design intent: all 3,072 operand-bank bits. This elastic stage accepts one beat every This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 155: `// clock, while the row-local commit enables below terminate control near` Design intent: clock, while the row-local commit enables below terminate control near This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 156: `// the destination registers. The payload stage can consume its old beat` Design intent: the destination registers. The payload stage can consume its old beat This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 157: `// and capture the next operand class on the same edge.` Design intent: and capture the next operand class on the same edge. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 158: `logic input_stage_valid_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_stage_valid_r is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 159: `logic [63:0] input_stage_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_stage_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 160: `logic input_stage_last_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_stage_last_r is the AXI-Stream marker for the final beat of a packet or command payload. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 161: `logic [63:0] load_commit_data_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_commit_data_r is the payload carried with the surrounding valid/ready handshake. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 162: `logic [1:0] activation_write_enable_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, activation_write_enable_r is an input feature value consumed by a neuron or multiply-accumulate operation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 163: `logic [1:0] weight_write_enable_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, weight_write_enable_r is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 164: `logic [1:0] output_gradient_write_enable_r [0:LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_gradient_write_enable_r is the signed loss derivative used to update a learned parameter. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 165: `// Keep the row hold as a D-input mux. A dedicated CE would put the` Design intent: Keep the row hold as a D-input mux. A dedicated CE would put the This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 166: `// multi-state row-update decode on the FDRE CE pin, whose setup time is` Design intent: multi-state row-update decode on the FDRE CE pin, whose setup time is This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 167: `// tighter than the data input on 7-series devices.` Design intent: tighter than the data input on 7-series devices. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 168: `(* extract_enable = "no" *) logic [3:0] result_row_r;` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are extract_enable: a control bit that permits the associated state or storage update; no: the value named 'no' in this block; result_row_r: one output-row position processed by the tensor tile.

Line 169: `logic column_group_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, column_group_r is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 170: `logic reduction_group_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, reduction_group_r is the value named 'reduction group r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 171: `logic [1:0] output_word_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, output_word_r is the value named 'output word r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 173: `wire [2:0] load_row_index = load_row_r[2:0];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, load_row_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 174: `wire [2:0] result_row_index = result_row_r[2:0];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_row_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 175: `wire [3:0] accumulator_address = {result_row_index, column_group_r};` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulator_address is a widened running sum that prevents intermediate overflow; column_group_r} is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 176: `wire [3:0] result_row_count = compute_result_row_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_row_count is one output-row position processed by the tensor tile. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 177: `wire [3:0] result_column_count = compute_result_column_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_column_count is one output-feature position processed in parallel. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 178: `wire [3:0] reduction_count = compute_reduction_count_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, reduction_count is an integer count retained for control or measurable telemetry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 179: `wire input_load_state = state == ST_LOAD_X || state == ST_LOAD_W` This statement continues through source line 180; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_load_state is the finite-state-machine phase retained in flip-flops. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 180: `|| state == ST_LOAD_DY;` This is continuation line 2 of the 2-line logical statement that begins at source line 179. Its exact fragment is '|| state == ST_LOAD_DY;'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_LOAD_DY: the value named 'st load dy' in this block. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_load_state is the finite-state-machine phase retained in flip-flops. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 181: `wire input_stage_consume = input_stage_valid_r && input_load_state;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_stage_consume is the value named 'input stage consume' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 182: `wire input_stage_ready = !input_stage_valid_r || input_stage_consume;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_stage_ready is the consumer's statement that it can accept a payload this cycle. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 183: `wire input_final_buffered = state == ST_LOAD_DY && input_stage_valid_r` This statement continues through source line 184; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_final_buffered is

local storage that decouples producer and consumer timing. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 184: `&& load_half_r && load_final_r;` This is continuation line 2 of the 2-line logical statement that begins at source line 183. Its exact fragment is '&& load_half_r && load_final_r;'. The important operands are load_half_r: the value named 'load half r' in this block; load_final_r: the value named 'load final r' in this block. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, input_final_buffered is local storage that decouples producer and consumer timing. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 185: `wire [1:0] requested_accumulator_mode = gradient_mode == MODE_WEIGHT_GRADIENT` This statement continues through source line 186; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, requested_accumulator_mode is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 186: `? MODE_WEIGHT_GRADIENT : MODE_INPUT_GRADIENT;` This is continuation line 2 of the 2-line logical statement that begins at source line 185. Its exact fragment is '? MODE_WEIGHT_GRADIENT : MODE_INPUT_GRADIENT;'. The important operands are MODE_WEIGHT_GRADIENT: a learned coefficient multiplied by an activation; MODE_INPUT_GI the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, requested_accumulator_mode is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 187: `wire [3:0] requested_accumulator_rows = gradient_mode == MODE_WEIGHT_GRADIENT` This statement continues through source line 188; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, requested_accumulator_rows is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 188: `? active_inputs : active_rows;` This is continuation line 2 of the 2-line logical statement that begins at source line 187. Its exact fragment is '? active_inputs : active_rows;'. The important operands are active_inputs: the value named 'active inputs' in this block; active_rows: one output-row position processed by the tensor tile. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, requested_accumulator_rows is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 189: `wire [3:0] requested_accumulator_columns = gradient_mode == MODE_WEIGHT_GRADIENT` This statement continues through source line 190; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, requested_accumulator_columns is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 190: `? active_outputs : active_inputs;` This is continuation line 2 of the 2-line logical statement that begins at source line 189. Its exact fragment is '? active_outputs : active_inputs;'. The important operands are active_outputs: the value named 'active outputs' in this block; active_inputs: the value named 'active inputs' in this block. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, requested_accumulator_columns is a widened running sum that prevents intermediate overflow. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 191: `wire dimensions_invalid = active_rows == 0 || active_rows > 4'(LANES)` This statement continues through source line 193; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dimensions_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 192: `|| active_inputs == 0 || active_inputs > 4'(LANES)` This is continuation line 2 of the 3-line logical statement that begins at source line 191. Its exact fragment is '|| active_inputs == 0 || active_inputs > 4'(LANES)'. The important operands are active_inputs: the value named 'active inputs' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dimensions_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 193: `|| active_outputs == 0 || active_outputs > 4'(LANES);` This is continuation line 3 of the 3-line logical statement that begins at source line 191. Its exact fragment is '|| active_outputs == 0 || active_outputs > 4'(LANES);'. The important operands are active_outputs: the value named 'active outputs' in this block; LANES: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, dimensions_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 194: `wire accumulation_shape_invalid = accumulate_result && (` This statement continues through source line 199; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulation_shape_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 195: `gradient_mode == MODE_BOTH` This is continuation line 2 of the 6-line logical statement that begins at source line 194. Its exact fragment is 'gradient_mode == MODE_BOTH'. The important operands are gradient_mode: the signed loss derivative used to update a learned parameter; MODE_BOTH: the value named 'mode both' in this block. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulation_shape_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 196: `|| !accumulator_valid_r` This is continuation line 3 of the 6-line logical statement that begins at source line 194. Its exact fragment is '|| !accumulator_valid_r'. The important operands are accumulator_valid_r: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulation_shape_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 197: `|| accumulator_mode_r != requested_accumulator_mode` This is continuation line 4 of the 6-line logical statement that begins at source line 194. Its exact fragment is '|| accumulator_mode_r != requested_accumulator_mode'. The important operands are accumulator_mode_r: a widened running sum that prevents intermediate overflow; requested_accumulator_mode: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulation_shape_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 198: `|| accumulator_rows_r != requested_accumulator_rows` This is continuation line 5 of the 6-line logical statement that begins at source line 194. Its exact fragment is '|| accumulator_rows_r != requested_accumulator_rows'. The important operands are accumulator_rows_r: a widened running sum that prevents intermediate overflow; requested_accumulator_rows: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulation_shape_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 199: `|| accumulator_columns_r != requested_accumulator_columns);` This is continuation line 6 of the 6-line logical statement that begins at source line 194. Its exact fragment is '|| accumulator_columns_r != requested_accumulator_col

The important operands are accumulator_columns_r: a widened running sum that prevents intermediate overflow; requested_accumulator_columns: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, accumulation_shape_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 200: `wire start_configuration_invalid = reserved_nonzero || dimensions_invalid` This statement continues through source line 201; the explanation uses the complete expression rather than only the first visual fragment. This declares hardware signal storage or wiring in the module's structural declarations. Specifically, start_configuration_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 201: `|| gradient_mode == 2'd3 || accumulation_shape_invalid;` This is continuation line 2 of the 2-line logical statement that begins at source line 200. Its exact fragment is '|| gradient_mode == 2'd3 || accumulation_shape_invalid;'. The important operands are gradient_mode: the signed loss derivative used to update a learned parameter; d3: the value named 'd3' in this block; accumulation_shape_invalid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This declares hardware signal storage or wiring in the module's structural declarations. Specifically, start_configuration_invalid is the producer's statement that its current payload is meaningful. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 203: `logic signed [15:0] multiplier_left [0:RESULT_LANES-1][0:REDUCTION_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_left is the value named 'multiplier left' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 204: `logic signed [15:0] multiplier_right [0:RESULT_LANES-1][0:REDUCTION_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_right is the value named 'multiplier right' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 205: `(* keep = "true", dont_touch = "true" *)` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are keep: the value named 'keep' in this block; dont_touch: the value named 'dont touch' in this block.

Line 206: `logic signed [15:0] multiplier_left_r [0:RESULT_LANES-1][0:REDUCTION_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_left_r is the value named 'multiplier left r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 207: `(* keep = "true", dont_touch = "true" *)` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are keep: the value named 'keep' in this block; dont_touch: the value named 'dont touch' in this block.

Line 208: `logic signed [15:0] multiplier_right_r [0:RESULT_LANES-1][0:REDUCTION_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_right_r is the value named 'multiplier right r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 209: `logic signed [15:0] multiplier_left_dsp_r [0:RESULT_LANES-1][0:REDUCTION_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_left_dsp_r is the value named 'multiplier left dsp r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 210: `logic signed [15:0] multiplier_right_dsp_r [0:RESULT_LANES-1][0:REDUCTION_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, multiplier_right_dsp_r is the value named 'multiplier right dsp r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 211: `(* use_dsp = "yes" *) wire signed [31:0]` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are use_dsp: the value named 'use dsp' in this block; yes: the value named 'yes' in this block.

Line 212: `multiplier_product [0:RESULT_LANES-1][0:REDUCTION_LANES-1];` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are multiplier_product: the value named 'multiplier product' in this block; RESULT_LANES: one parallel arithmetic element within a vector or tensor datapath; REDUCTION_LANES: one parallel arithmetic element within a vector or tensor datapath.

Line 213: `logic signed [31:0] product_r [0:RESULT_LANES-1][0:REDUCTION_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, product_r is the value named 'product r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 214: `logic signed [32:0] pair_sum_r [0:RESULT_LANES-1][0:1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pair_sum_r is the value named 'pair sum r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 215: `// This local pulse drives only the eight pair-reduction DSP registers.` Design intent: This local pulse drives only the eight pair-reduction DSP registers. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 216: `// Registering it near the array avoids routing the shared FSM decode to` Design intent: Registering it near the array avoids routing the shared FSM decode to This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 217: `// DSP clock-enable pins, whose setup requirement is especially tight.` Design intent: DSP clock-enable pins, whose setup requirement is especially tight. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 218: `logic pair_update_r;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, pair_update_r is the value named 'pair update r' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 220: `wire [3:0] result_column_index [0:RESULT_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, result_column_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 221: `wire [3:0] reduction_index [0:REDUCTION_LANES-1];` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, reduction_index is an integer selecting one tensor element, lane, bank, or state entry. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 222: `logic [191:0] packed_weight_gradient;` This declares hardware signal storage or wiring in the module's structural declarations. Specifically, packed_weight_gradient is a learned coefficient multiplied by an activation. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 224: `function automatic logic signed [46:0] saturate_s47(` Within the combinational helper saturate s47, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; saturate_s47: the value named 'saturate s47' in this block.

Line 225: `input logic signed [47:0] value` This declares value as a input port with width [47:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 226: `);` Within the combinational helper saturate s47, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The expression is a literal or structural operator and has no hidden software state.

Line 227: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s47; it has no arithmetic value of its own.

Line 228: `if (value[47] == value[46]) saturate_s47 = value[46:0];` This condition selects the following hardware branch only when 'value[47] == value[46]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the combinational helper saturate s47.

Line 229: `else if (value[47]) saturate_s47 = {1'b1, {46{1'b0}}};` This condition selects the following hardware branch only when 'value[47]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the combinational helper saturate s47.

Line 230: `else saturate_s47 = {1'b0, {46{1'b1}}};` Within the combinational helper saturate s47, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are saturate_s47: the value named 'saturate s47' in this block; b0: the value named 'b0' in this block; b1: the value named 'b1' in this block.

Line 231: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s47; it has no arithmetic value of its own.

Line 232: `endfunction` Within the combinational helper saturate s47, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are endfunction: the value named 'endfunction' in this block.

Line 234: `function automatic logic [46:0] round_bias(` Within the combinational helper round bias, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; round_bias: an additive learned offset applied after accumulation.

Line 235: `input logic [4:0] shift` This declares shift as a input port with width [4:0]. It carries the value named 'shift' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 236: `);` Within the combinational helper round bias, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The expression is a literal or structural operator and has no hidden software state.

Line 237: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper round bias; it has no arithmetic value of its own.

Line 238: `if (shift == 0) round_bias = 47'd0;` This condition selects the following hardware branch only when 'shift == 0' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are shift: the value named 'shift' in this block. Context: the combinational helper round bias.

Line 239: `else round_bias = 47'd1 << (shift - 1'b1);` Within the combinational helper round bias, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are round_bias: an additive learned offset applied after accumulation; d1: the value named 'd1' in this block; shift: the value named 'shift' in this block.

Line 240: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper round bias; it has no arithmetic value of its own.

Line 241: `endfunction` Within the combinational helper round bias, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are endfunction: the value named 'endfunction' in this block.

Line 243: `function automatic logic signed [31:0] saturate_s32(` Within the combinational helper saturate s32, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; saturate_s32: the value named 'saturate s32' in this block.

Line 244: `input logic signed [46:0] value` This declares value as a input port with width [46:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 245: `);` Within the combinational helper saturate s32, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The expression is a literal or structural operator and has no hidden software state.

Line 246: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s32; it has no arithmetic value of its own.

Line 247: `// A signed value fits in 32 bits exactly when every discarded bit` Design intent: A signed value fits in 32 bits exactly when every discarded bit This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 248: `// is a copy of bit 31. This is equivalent to range comparisons,` Design intent: is a copy of bit 31. This is equivalent to range comparisons, This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 249: `// but uses equality/reduction logic instead of two carry chains.` Design intent: but uses equality/reduction logic instead of two carry chains. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 250: `if (value[46:31] == {16{value[31]}}) begin` This condition selects the following hardware branch only when 'value[46:31] == {16{value[31]}}' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named 'value' in this block. Context: the combinational helper saturate s32.

Line 251: `saturate_s32 = value[31:0];` This makes saturate_s32, the value named 'saturate s32' in this block, equal to 'value[31:0]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named 'value' in this block. Context: the combinational helper saturate s32.

Line 252: `end else if (value[46]) begin` This condition selects the following hardware branch only when ‘value[46]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named ’value’ in this block. Context: the combinational helper saturate s32.

Line 253: `saturate_s32 = 32'sh80000000;` This makes saturate_s32, the value named ’saturate s32’ in this block, equal to ‘32’sh80000000‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are sh80000000: the value named ’sh80000000’ in this block. Context: the combinational helper saturate s32.

Line 254: `end else begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s32; it has no arithmetic value of its own.

Line 255: `saturate_s32 = 32'sh7fffffff;` This makes saturate_s32, the value named ’saturate s32’ in this block, equal to ‘32’sh7fffffff‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are sh7fffffff: the value named ’sh7fffffff’ in this block. Context: the combinational helper saturate s32.

Line 256: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s32; it has no arithmetic value of its own.

Line 257: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s32; it has no arithmetic value of its own.

Line 258: `endfunction` Within the combinational helper saturate s32, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are endfunction: the value named ’endfunction’ in this block.

Line 260: `function automatic logic signed [23:0] saturate_s24(` Within the combinational helper saturate s24, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are function: the value named ’function’ in this block; automatic: the value named ’automatic’ in this block; saturate_s24: the value named ’saturate s24’ in this block.

Line 261: `input logic signed [46:0] value` This declares value as a input port with width [46:0]. It carries the value named ’value’ in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 262: `);` Within the combinational helper saturate s24, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The expression is a literal or structural operator and has no hidden software state.

Line 263: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s24; it has no arithmetic value of its own.

Line 264: `if (value[46:23] == {24{value[23]}}) begin` This condition selects the following hardware branch only when ‘value[46:23] == {24{value[23]}}‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named ’value’ in this block. Context: the combinational helper saturate s24.

Line 265: `saturate_s24 = value[23:0];` This makes saturate_s24, the value named ’saturate s24’ in this block, equal to ‘value[23:0]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are value: the value named ’value’ in this block. Context: the combinational helper saturate s24.

Line 266: `end else if (value[46]) begin` This condition selects the following hardware branch only when ‘value[46]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are value: the value named ’value’ in this block. Context: the combinational helper saturate s24.

Line 267: `saturate_s24 = 24'sh800000;` This makes saturate_s24, the value named 'saturate s24' in this block, equal to '24'sh800000'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sh800000: the value named 'sh800000' in this block. Context: the combinational helper saturate s24.

Line 268: `end else begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s24; it has no arithmetic value of its own.

Line 269: `saturate_s24 = 24'sh7fffff;` This makes saturate_s24, the value named 'saturate s24' in this block, equal to '24'sh7fffff'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sh7fffff: the value named 'sh7fffff' in this block. Context: the combinational helper saturate s24.

Line 270: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s24; it has no arithmetic value of its own.

Line 271: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s24; it has no arithmetic value of its own.

Line 272: `endfunction` Within the combinational helper saturate s24, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are endfunction: the value named 'endfunction' in this block.

Line 274: `function automatic logic signed [31:0] saturate_s24_extended(` Within the combinational helper saturate s24 extended, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are function: the value named 'function' in this block; automatic: the value named 'automatic' in this block; saturate_s24_extended: the value named 'saturate s24 extended' in this block.

Line 275: `input logic signed [46:0] value` This declares value as a input port with width [46:0]. It carries the value named 'value' in this block across the module boundary; a port is a bundle of physical FPGA nets, not a software argument.

Line 276: `);` Within the combinational helper saturate s24 extended, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The expression is a literal or structural operator and has no hidden software state.

Line 277: `logic signed [23:0] saturated;` This declares hardware signal storage or wiring in the combinational helper saturate s24 extended. Specifically, saturated is the value named 'saturated' in this block. Widths in square brackets count from the stated most-significant bit down to the least-significant bit.

Line 278: `begin` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s24 extended; it has no arithmetic value of its own.

Line 279: `saturated = saturate_s24(value);` This makes saturated, the value named 'saturated' in this block, equal to 'saturate_s24(value)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturate_s24: the value named 'saturate s24' in this block; value: the value named 'value' in this block. Context: the combinational helper saturate s24 extended.

Line 280: `saturate_s24_extended = {{8{saturated[23]}}, saturated};` This makes saturate_s24_extended, the value named 'saturate s24 extended' in this block, equal to '{{8{saturated[23]}}, saturated}'. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturated: the value named 'saturated' in this block. Context: the combinational helper saturate s24 extended.

Line 281: `end` This structural keyword opens or closes the branch/process scope described as the combinational helper saturate s24 extended; it has no arithmetic value of its own.

Line 282: `endfunction` Within the combinational helper saturate s24 extended, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are endfunction: the value named 'endfunction' in this block.

Line 284: `for (genvar bank = 0; bank < RESULT_LANES; bank++) begin : g_accumulator_bank` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 285: `assign accumulator_bank_write_enable[bank] =` This statement continues through source line 286; the explanation uses the complete expression rather than only the first visual fragment. This makes accumulator_bank_write_enable[ba a widened running sum that prevents intermediate overflow, equal to 'state == ST_STORE_ACCUMULATOR && commit_lane_valid_r[bank]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_STORE_ACCUMULATOR: a widened running sum that prevents intermediate overflow; commit_lane_valid_r: the producer's statement that its current payload is meaningful. Context: the module's structural declarations.

Line 286: `state == ST_STORE_ACCUMULATOR && commit_lane_valid_r[bank];` This is continuation line 2 of the 2-line logical statement that begins at source line 285. Its exact fragment is 'state == ST_STORE_ACCUMULATOR && commit_lane_valid_r[bank];'. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_STORE_ACCUMULATOR: a widened running sum that prevents intermediate overflow; commit_lane_valid_r: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This makes accumulator_bank_write_enable[bank], a widened running sum that prevents intermediate overflow, equal to 'state == ST_STORE_ACCUMULATOR && commit_lane_valid_r[bank]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_STORE_ACCUMULATOR: a widened running sum that prevents intermediate overflow; commit_lane_valid_r: the producer's statement that its current payload is meaningful. Context: the module's structural declarations.

Line 287: `assign accumulator_bank_write_data[bank] =` This statement continues through source line 288; the explanation uses the complete expression rather than only the first visual fragment. This makes accumulator_bank_write_data[bank], a widened running sum that prevents intermediate overflow, equal to 'saturate_s47(accumulated_wide_r[bank])'. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturate_s47: the value named 'saturate s47' in this block; accumulated_wide_r: the value named 'accumulated wide r' in this block; bank: the value named 'bank' in this block. Context: the module's structural declarations.

Line 288: `saturate_s47(accumulated_wide_r[bank]);` This is continuation line 2 of the 2-line logical statement that begins at source line 287. Its exact fragment is 'saturate_s47(accumulated_wide_r[bank]);'. The important operands are saturate_s47: the value named 'saturate s47' in this block; accumulated_wide_r: the value named 'accumulated wide r' in this block; bank: the value named 'bank' in this block. Read together, the complete operation is: This makes accumulator_bank_write_data[bank], a widened running sum that prevents intermediate overflow, equal to 'saturate_s47(accumulated_wide_r[bank])'. It is driven by combinational or procedural logic in the current evaluation. The important operands are saturate_s47: the value named 'saturate s47' in this block; accumulated_wide_r: the value named 'accumulated wide r' in this block; bank: the value named 'bank' in this block. Context: the module's structural declarations.

Line 290: `neuraedge_gradient_accumulator_bank u_bank (` This instantiates module neuraedge_gradient_accumulator_ban as u_bank. Synthesis creates that subordinate circuit and connects its ports in the lines that follow.

Line 291: `.clk(clk),` This connects the child instance's named port 'clk' to parent expression 'clk'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and the clock that makes all registers advance together.

Line 292: `.write_enable(accumulator_bank_write_enable[bank]),` This connects the child instance's named port 'write_enable' to parent expression 'accumulator_bank_write_enable[bank]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a widened running sum that prevents intermediate overflow.

Line 293: `.write_address(accumulator_address),` This connects the child instance's named port 'write_address' to parent expression 'accumulator_address'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a widened running sum that prevents intermediate overflow.

Line 294: `.write_data(accumulator_bank_write_data[bank]),` This connects the child instance's named port 'write_data' to parent expression 'accumulator_bank_write_data[bank]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a widened running sum that prevents intermediate overflow.

Line 295: `.read_address(accumulator_address),` This connects the child instance's named port 'read_address' to parent expression 'accumulator_address'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a widened running sum that prevents intermediate overflow.

Line 296: `.read_data(accumulator_bank_read_data[bank])` This connects the child instance's named port 'read_data' to parent expression 'accumulator_bank_read_data[bank]'. The connection is a physical net bundle after synthesis; direction is declared in the child module, and a widened running sum that prevents intermediate overflow.

Line 297: `);` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The expression is a literal or structural operator and has no hidden software state.

Line 298: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 300: `for (genvar result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 301: `result_lane++) begin : g_result_lane` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath; g_result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 302: `assign result_column_index[result_lane] =` This statement continues through source line 303; the explanation uses the complete expression rather than only the first visual fragment. This makes result_column_index[result_lane], an integer selecting one tensor element, lane, bank, or state entry, equal to '(column_group_r ? 4'd4 : 4'd0) + 4'(result_lane)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are column_group_r: one output-feature position processed in parallel; d4: the value named 'd4' in this block; d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 303: `(column_group_r ? 4'd4 : 4'd0) + 4'(result_lane);` This is continuation line 2 of the 2-line logical statement that begins at source line 302. Its exact fragment is '(column_group_r ? 4'd4 : 4'd0) + 4'(result_lane);'. The important operands are column_group_r: one output-feature position processed in parallel; d4: the value named 'd4' in this block; d0: the value named 'd0' in this block. Read together, the complete operation is: This makes result_column_index[result_lane], an integer selecting one tensor element, lane, bank, or state entry, equal to '(column_group_r ? 4'd4 : 4'd0) + 4'(result_lane)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are column_group_r: one output-feature position processed in parallel; d4: the value named 'd4' in this block; d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 304: `for (genvar reduction_lane = 0;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 305: `reduction_lane < REDUCTION_LANES; reduction_lane++) begin : g_multiplier` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are reduction_lane: one parallel arithmetic element within a vector or tensor datapath; REDUCTION_LANES: one parallel arithmetic element within a vector or tensor datapath; g_multiplier: the value named 'g multiplier' in this block.

Line 306: `assign multiplier_product[result_lane][reduction_lane] =` This statement continues through source line 308; the explanation uses the complete expression rather than only the first visual fragment. This makes multiplier_product[result_lane][reduction_lane], the value named 'multiplier product' in this block, equal to 'multiplier_left_dsp_r[resul * multiplier_right_dsp_r[result_lane][reduction_lane]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are multiplier_left_dsp_r: the value named 'multiplier left dsp r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the module's structural declarations.

Line 307: `multiplier_left_dsp_r[result_lane][reduction_lane]` This is continuation line 2 of the 3-line logical statement that begins at source line 306. Its exact fragment is 'multiplier_left_dsp_r[result_lane][reduction_lane]'. The important operands are multiplier_left_dsp_r: the value named 'multiplier left dsp r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes multiplier_product[result_lane][reduction_lane], the value named 'multiplier product' in this block, equal to 'multiplier_left_dsp_r[result_lane][reduction_lane] * multiplier_right_dsp_r[result_lane][reduction_lane]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are multiplier_left_dsp_r: the value named 'multiplier left dsp r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the module's structural declarations.

Line 308: `* multiplier_right_dsp_r[result_lane][reduction_lane];` This is continuation line 3 of the 3-line logical statement that begins at source line 306. Its exact fragment is '* multiplier_right_dsp_r[result_lane][reduction_lane];'. The important operands are multiplier_right_dsp_r: the value named 'multiplier right dsp r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes multiplier_product[result_lane][reduction_lane], the value named 'multiplier product' in this block, equal to 'multiplier_left_dsp_r[result_lane][reduction_lane] * multiplier_right_dsp_r[result_lane][reduction_lane]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are multiplier_left_dsp_r: the value named 'multiplier left dsp r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the module's structural declarations.

Line 309: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 310: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 312: `for (genvar reduction_lane = 0; reduction_lane < REDUCTION_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the module's structural declarations.

Line 313: `reduction_lane++) begin : g_reduction_index` Within the module's structural declarations, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are reduction_lane: one parallel arithmetic element within a vector or tensor datapath; g_reduction_index: an integer selecting one tensor element, lane, bank, or state entry.

Line 314: `assign reduction_index[reduction_lane] =` This statement continues through source line 315; the explanation uses the complete expression rather than only the first visual fragment. This makes reduction_index[reduction_lane], an integer selecting one tensor element, lane, bank, or state entry, equal to '(reduction_group_r ? 4'd4 : 4'd0) + 4'(reduction_lane)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are

reduction_group_r: the value named 'reduction group r' in this block; d4: the value named 'd4' in this block; d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 315: `(reduction_group_r ? 4'd4 : 4'd0) + 4'(reduction_lane);` This is continuation line 2 of the 2-line logical statement that begins at source line 314. Its exact fragment is '(reduction_group_r ? 4'd4 : 4'd0) + 4'(reduction_lane);'. The important operands are reduction_group_r: the value named 'reduction group r' in this block; d4: the value named 'd4' in this block; d0: the value named 'd0' in this block. Read together, the complete operation is: This makes reduction_index[reduction_lane], an integer selecting one tensor element, lane, bank, or state entry, equal to '(reduction_group_r ? 4'd4 : 4'd0) + 4'(reduction_lane)'. It is driven by combinational or procedural logic in the current evaluation. The important operands are reduction_group_r: the value named 'reduction group r' in this block; d4: the value named 'd4' in this block; d0: the value named 'd0' in this block. Context: the module's structural declarations.

Line 316: `end` This structural keyword opens or closes the branch/process scope described as the module's structural declarations; it has no arithmetic value of its own.

Line 318: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 319: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 320: `result_lane++) begin` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 321: `for (int reduction_lane = 0; reduction_lane < REDUCTION_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 322: `reduction_lane++) begin` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are reduction_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 323: `multiplier_left[result_lane][reduction_lane] = 16'sd0;` This makes multiplier_left[result_lane][reduction_la the value named 'multiplier left' in this block, equal to '16'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 324: `multiplier_right[result_lane][reduction_lane] = 16'sd0;` This makes multiplier_right[result_lane][reduction the value named 'multiplier right' in this block, equal to '16'sd0'. It is driven by combinational or procedural logic in the current evaluation. The important operands are sd0: the value named 'sd0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 325: `if (result_row_r < result_row_count` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_row_r: one output-row position processed by the tensor tile; result_row_count: one output-row position processed by the tensor tile.

Line 326: `&& result_column_index[result_lane] < result_column_count` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_column_index: an integer selecting one tensor element, lane, bank, or state entry; result_lane: one parallel arithmetic element within a vector or tensor datapath; result_column_count: one output-feature position processed in parallel.

Line 327: `&& reduction_index[reduction_lane] < reduction_count) begin` Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_count: an integer count retained for control or measurable telemetry.

Line 328: `if (input_gradient_lane_r[result_lane]) begin` This condition selects the following hardware branch only when ‘input_gradient_lane_r[result_lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_gradient_lane_r: the signed loss derivative used to update a learned parameter; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 329: `multiplier_left[result_lane][reduction_lane] =` This statement continues through source line 331; the explanation uses the complete expression rather than only the first visual fragment. This makes multiplier_left[result_lane][reduc the value named ’multiplier left’ in this block, equal to ‘output_gradient_r[result_row_index] [reduction_index[reduction_lane][2:0] It is driven by combinational or procedural logic in the current evaluation. The important operands are output_gradient_r: the signed loss derivative used to update a learned parameter; result_row_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 330: `output_gradient_r[result_row_index]` This is continuation line 2 of the 3-line logical statement that begins at source line 329. Its exact fragment is ‘output_gradient_r[result_row_index]‘. The important operands are output_gradient_r: the signed loss derivative used to update a learned parameter; result_row_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes multiplier_left[result_lane][reduction_lane], the value named ’multiplier left’ in this block, equal to ‘output_gradient_r[result_row_inde [reduction_index[reduction_lane][2:0]]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_gradient_r: the signed loss derivative used to update a learned parameter; result_row_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 331: `[reduction_index[reduction_lane][2:0]];` This is continuation line 3 of the 3-line logical statement that begins at source line 329. Its exact fragment is ‘[reduction_index[reduction_lane][2:0]];‘. The important operands are reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes multiplier_left[result_lane][reduction_lane], the value named ’multiplier left’ in this block, equal to ‘output_gradient_r[result_row_inde [reduction_index[reduction_lane][2:0]]‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_gradient_r: the signed loss derivative used to update a learned parameter; result_row_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_index: an integer selecting one tensor element, lane, bank, or state entry. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 332: `multiplier_right[result_lane][reduction_lane] =` This statement continues through source line 334; the explanation uses the complete expression rather than only the first visual fragment. This makes multiplier_right[result_lane][redu the value named ’multiplier right’ in this block, equal to ‘weight_r[result_column_index[result_lane][2:0]] [reduction_index[reductio It is driven by combinational or procedural logic in the current evaluation. The important operands are weight_r: a learned coefficient multiplied by an activation; result_column_index: an integer selecting one tensor element, lane,

bank, or state entry; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 333: `weight_r[result_column_index[result_lane][2:0]]` This is continuation line 2 of the 3-line logical statement that begins at source line 332. Its exact fragment is 'weight_r[result_column_index[result_lane][2:0]]'. The important operands are weight_r: a learned coefficient multiplied by an activation; result_column_index: an integer selecting one tensor element, lane, bank, or state entry; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes multiplier_right[result_lane][reduction_lane], the value named 'multiplier right' in this block, equal to 'weight_r[result_column_index[result_lane][2:0]] [reduction_index[reduction_lane][2
It is driven by combinational or procedural logic in the current evaluation. The important operands are weight_r: a learned coefficient multiplied by an activation; result_column_index: an integer selecting one tensor element, lane, bank, or state entry; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 334: `[reduction_index[reduction_lane][2:0]];` This is continuation line 3 of the 3-line logical statement that begins at source line 332. Its exact fragment is '[reduction_index[reduction_lane][2:0]];'. The important operands are reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes multiplier_right[result_lane][reduction_lane], the value named 'multiplier right' in this block, equal to 'weight_r[result_column_index[re
[reduction_index[reduction_lane][2:0]]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are weight_r: a learned coefficient multiplied by an activation; result_column_index: an integer selecting one tensor element, lane, bank, or state entry; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 335: `end else begin` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 336: `multiplier_left[result_lane][reduction_lane] =` This statement continues through source line 338; the explanation uses the complete expression rather than only the first visual fragment. This makes multiplier_left[result_lane][reduc
the value named 'multiplier left' in this block, equal to 'activation_r[reduction_index[reduction_lane][2:0]] [result_row_index]'.
It is driven by combinational or procedural logic in the current evaluation. The important operands are activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 337: `activation_r[reduction_index[reduction_lane][2:0]]` This is continuation line 2 of the 3-line logical statement that begins at source line 336. Its exact fragment is 'activation_r[reduction_index[reduction_lane][2:0]]'. The important operands are activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes multiplier_left[result_lane][reduction_lane], the value named 'multiplier left' in this block, equal to 'activation_r[reduction_index[reducti
[result_row_index]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 338: `[result_row_index];` This is continuation line 3 of the 3-line logical statement that begins at source line 336. Its exact fragment is '[result_row_index];'. The important operands are result_row_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This makes multiplier_left[result_lane][reduction_lane], the value named 'multiplier left' in this block, equal to 'activation_r[reduction_index[reducti
[result_row_index]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 339: `multiplier_right[result_lane][reduction_lane] =` This statement continues through source line 341; the explanation uses the complete expression rather than only the first visual fragment. This makes multiplier_right[result_lane][redu the value named 'multiplier right' in this block, equal to 'output_gradient_r[reduction_index[reduction_lane][2:0]] [result_column_index[result_lane][2:0]]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_gradient_r: the signed loss derivative used to update a learned parameter; reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 340: `output_gradient_r[reduction_index[reduction_lane][2:0]]` This is continuation line 2 of the 3-line logical statement that begins at source line 339. Its exact fragment is 'output_gradient_r[reduction_index[reduction_lane][2:0]]'. The important operands are output_gradient_r: the signed loss derivative used to update a learned parameter; reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes multiplier_right[result_lane][reduction_lane], the value named 'multiplier right' in this block, equal to 'output_gradient_r[reduction_ind [result_column_index[result_lane][2:0]]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_gradient_r: the signed loss derivative used to update a learned parameter; reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 341: `[result_column_index[result_lane][2:0]];` This is continuation line 3 of the 3-line logical statement that begins at source line 339. Its exact fragment is '[result_column_index[result_lane][2:0]];'. The important operands are result_column_index: an integer selecting one tensor element, lane, bank, or state entry; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes multiplier_right[result_lane][reduction_lane], the value named 'multiplier right' in this block, equal to 'output_gradient_r[reduction_index[reduction_lane][2:0]] [result_column_index[result_lane][2:0]]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are output_gradient_r: the signed loss derivative used to update a learned parameter; reduction_index: an integer selecting one tensor element, lane, bank, or state entry; reduction_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 342: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 343: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 344: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 345: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 347: `packed_weight_gradient = '0;` This makes packed_weight_gradient, a learned coefficient multiplied by an activation, equal to ''0'. It is driven by combinational or procedural logic in the current evaluation. The expression is a literal or structural operator and has no hidden software state. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 348: `for (int lane = 0; lane < LANES; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 349: `packed_weight_gradient[lane*24 +: 24] =` This statement continues through source line 350; the explanation uses the complete expression rather than only the first visual fragment. Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are packed_weight_gradient: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath; result_row_buffer_r: local storage that decouples producer and consumer timing.

Line 350: `result_row_buffer_r[lane][23:0];` This is continuation line 2 of the 2-line logical statement that begins at source line 349. Its exact fragment is 'result_row_buffer_r[lane][23:0];'. The important operands are result_row_buffer_r: local storage that decouples producer and consumer timing; lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: Within the combinational process whose outputs respond without waiting for a clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are packed_weight_gradient: a learned coefficient multiplied by an activation; lane: one parallel arithmetic element within a vector or tensor datapath; result_row_buffer_r: local storage that decouples producer and consumer timing.

Line 351: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 352: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 354: `always_comb begin` This opens combinational logic. Vivado builds gates and multiplexers whose outputs continuously follow the inputs, and the language requires every assigned output to receive a value on every path.

Line 355: `start_ready = state == ST_IDLE;` This makes start_ready, the consumer's statement that it can accept a payload this cycle, equal to 'state == ST_IDLE'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 356: `busy = state != ST_IDLE;` This makes busy, the value named 'busy' in this block, equal to 'state != ST_IDLE'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 357: `done = state == ST_DONE;` This makes done, the value named 'done' in this block, equal to 'state == ST_DONE'. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_DONE: the value named 'st done' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 358: `s_axis_tready = input_load_state && input_stage_ready` This statement continues through source line 359; the explanation uses the complete expression rather than only the first visual fragment. This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to 'input_load_state && input_stage_ready && !input_final_buffered'. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_load_state: the finite-state-machine phase retained in flip-flops; input_stage_ready: the consumer's statement that it can accept a payload this cycle; input_final_buffered: local storage that decouples producer and consumer timing. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 359: `&& !input_final_buffered;` This is continuation line 2 of the 2-line logical statement that begins at source line 358. Its exact fragment is '&& !input_final_buffered;'. The important operands are input_final_buffered: local storage that decouples producer and consumer timing. Read together, the complete operation is: This makes s_axis_tready, the consumer's statement that it can accept a payload this cycle, equal to 'input_load_state && input_stage_ready && !input_final_buffered'. It is driven by combinational or procedural logic in the current evaluation. The important operands are input_load_state: the finite-state-machine phase retained in flip-flops; input_stage_ready:

the consumer's statement that it can accept a payload this cycle; input_final_buffered: local storage that decouples producer and consumer timing. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 360: `m_axis_tvalid = state == ST_OUTPUT_DX || state == ST_OUTPUT_DW;` This makes m_axis_tvalid, the producer's statement that its current payload is meaningful, equal to ‘state == ST_OUTPUT_DX || state == ST_OUTPUT_DW‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_OUTPUT_DX: the value named 'st output dx' in this block; ST_OUTPUT_DW: the value named 'st output dw' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 361: `m_axis_tdata = 64'd0;` This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to ‘64'd0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are d0: the value named 'd0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 362: `m_axis_tlast = 1'b0;` This makes m_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to ‘1'b0‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are b0: the value named 'b0' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 363: `// compute_mode_r is fixed before an output row starts. Selecting data` Design intent: compute_mode_r is fixed before an output row starts. Selecting data This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 364: `// with it avoids putting the large FSM state decode in the stream-data` Design intent: with it avoids putting the large FSM state decode in the stream-data This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 365: `// path while preserving the same value whenever tvalid is asserted.` Design intent: path while preserving the same value whenever tvalid is asserted. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 366: `if (compute_mode_r == MODE_INPUT_GRADIENT) begin` This condition selects the following hardware branch only when ‘compute_mode_r == MODE_INPUT_GRADIENT‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are compute_mode_r: the value named 'compute mode r' in this block; MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 367: `m_axis_tdata = {` This statement continues through source line 370; the explanation uses the complete expression rather than only the first visual fragment. This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to ‘{ result_row_buffer_r[output_word_r*2 + 1], result_row_buffer_r[output_word_r*2] }‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_row_buffer_r: local storage that decouples producer and consumer timing; output_word_r: the value named 'output word r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 368: `result_row_buffer_r[output_word_r*2 + 1],` This is continuation line 2 of the 4-line logical statement that begins at source line 367. Its exact fragment is ‘result_row_buffer_r[output_word_r*2 + 1],‘. The important operands are result_row_buffer_r: local storage that decouples producer and consumer timing; output_word_r: the value named 'output word r' in this block. Read together, the complete operation is: This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to ‘{ result_row_buffer_r[output_word_r*2 + 1], result_row_buffer_r[output_word_r*2 }‘. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_row_buffer_r: local storage that decouples producer and consumer timing; output_word_r: the value named 'output word r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 369: `result_row_buffer_r[output_word_r*2]` This is continuation line 3 of the 4-line logical statement that begins at source line 367. Its exact fragment is 'result_row_buffer_r[output_word_r*2]'. The important operands are result_row_buffer_r: local storage that decouples producer and consumer timing; output_word_r: the value named 'output word r' in this block. Read together, the complete operation is: This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to '{ result_row_buffer_r[output_word_r*2 + 1], result_row_buffer_r[output_word_r*2] }'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_row_buffer_r: local storage that decouples producer and consumer timing; output_word_r: the value named 'output word r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 370: `};` This is continuation line 4 of the 4-line logical statement that begins at source line 367. Its exact fragment is '};'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to '{ result_row_buffer_r[output_word_r*2 + 1], result_row_buffer_r[output_word_r*2] }'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_row_buffer_r: local storage that decouples producer and consumer timing; output_word_r: the value named 'output word r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 371: `m_axis_tlast = mode_r == MODE_INPUT_GRADIENT` This statement continues through source line 372; the explanation uses the complete expression rather than only the first visual fragment. This makes m_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'mode_r == MODE_INPUT_GRADIENT && result_row_r == rows_r - 1'b1 && output_word_r == 3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are mode_r: the value named 'mode r' in this block; MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter; result_row_r: one output-row position processed by the tensor tile. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 372: `&& result_row_r == rows_r - 1'b1 && output_word_r == 3;` This is continuation line 2 of the 2-line logical statement that begins at source line 371. Its exact fragment is '&& result_row_r == rows_r - 1'b1 && output_word_r == 3;'. The important operands are result_row_r: one output-row position processed by the tensor tile; rows_r: one output-row position processed by the tensor tile; b1: the value named 'b1' in this block. Read together, the complete operation is: This makes m_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'mode_r == MODE_INPUT_GRADIENT && result_row_r == rows_r - 1'b1 && output_word_r == 3'. It is driven by combinational or procedural logic in the current evaluation. The important operands are mode_r: the value named 'mode r' in this block; MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter; result_row_r: one output-row position processed by the tensor tile. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 373: `end else begin` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 374: `m_axis_tdata = packed_weight_gradient[output_word_r*64 +: 64];` This makes m_axis_tdata, the value named 'm axis tdata' in this block, equal to 'packed_weight_gradient[output_word_r*64 +: 64]'. It is driven by combinational or procedural logic in the current evaluation. The important operands are packed_weight_gradient: a learned coefficient multiplied by an activation; output_word_r: the value named 'output word r' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 375: `m_axis_tlast = result_row_r == inputs_r - 1'b1` This statement continues through source line 376; the explanation uses the complete expression rather than only the first visual fragment. This makes m_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'result_row_r == inputs_r - 1'b1 && output_word_r == 2'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_row_r: one output-row position processed by the tensor tile; inputs_r: the value named 'inputs r' in this block; b1: the value named 'b1' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 376: `&& output_word_r == 2;` This is continuation line 2 of the 2-line logical statement that begins at source line 375. Its exact fragment is '&& output_word_r == 2;'. The important operands are output_word_r: the value

named 'output word r' in this block. Read together, the complete operation is: This makes m_axis_tlast, the AXI-Stream marker for the final beat of a packet or command payload, equal to 'result_row_r == inputs_r - 1'b1 && output_word_r == 2'. It is driven by combinational or procedural logic in the current evaluation. The important operands are result_row_r: one output-row position processed by the tensor tile; inputs_r: the value named 'inputs r' in this block; b1: the value named 'b1' in this block. Context: the combinational process whose outputs respond without waiting for a clock edge.

Line 377: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 378: `end` This structural keyword opens or closes the branch/process scope described as the combinational process whose outputs respond without waiting for a clock edge; it has no arithmetic value of its own.

Line 380: `always_ff @(posedge clk) begin` This opens clocked sequential logic. Everything assigned with '<=' inside becomes a flip-flop or memory write and changes at a clock edge, which creates the accelerator's notion of cycles and persistent state.

Line 381: `if (!rst_n) begin` This is the reset branch for '(!rst_n'. While reset is asserted, the following assignments force control state, handshakes, counters, and error flags to known values so no stale pre-reset transaction can be mistaken for valid work. Context: the clocked process that updates registers only on a rising clock edge.

Line 382: `state <= ST_IDLE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_IDLE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 383: `rows_r <= 4'd0;` This makes rows_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 384: `inputs_r <= 4'd0;` This makes inputs_r, the value named 'inputs r' in this block, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 385: `outputs_r <= 4'd0;` This makes outputs_r, the value named 'outputs r' in this block, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 386: `dw_shift_r <= 5'd0;` This makes dw_shift_r, the value named 'dw shift r' in this block, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 387: `result_shift_r <= 5'd0;` This makes result_shift_r, the value named 'result shift r' in this block, equal to '5'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 388: `rounding_bias_r <= 47'd0;` This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to '47'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 389: `mode_r <= MODE_BOTH;` This makes mode_r, the value named 'mode r' in this block, equal to 'MODE_BOTH'. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_BOTH: the value named 'mode both' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 390: `compute_mode_r <= MODE_INPUT_GRADIENT;` This makes compute_mode_r, the value named 'compute mode r' in this block, equal to 'MODE_INPUT_GRADIENT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge.

Line 391: `suppress_output_r <= 1'b0;` This makes suppress_output_r, the value named 'suppress output r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 392: `accumulate_result_r <= 1'b0;` This makes accumulate_result_r, the value named 'accumulate result r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 393: `start_configuration_invalid_r <= 1'b0;` This makes start_configuration_invalid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 394: `requested_accumulator_mode_r <= MODE_INPUT_GRADIENT;` This makes requested_accumulator_mode_r, a widened running sum that prevents intermediate overflow, equal to 'MODE_INPUT_GRADIENT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge.

Line 395: `requested_accumulator_rows_r <= 4'd0;` This makes requested_accumulator_rows_r, a widened running sum that prevents intermediate overflow, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 396: `requested_accumulator_columns_r <= 4'd0;` This makes requested_accumulator_columns_r, a widened running sum that prevents intermediate overflow, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 397: `compute_result_row_count_r <= 4'd0;` This makes compute_result_row_count_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 398: `compute_result_column_count_r <= 4'd0;` This makes compute_result_column_count_r, one output-feature position processed in parallel, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 399: `compute_reduction_count_r <= 4'd0;` This makes compute_reduction_count_r, an integer count retained for control or measurable telemetry, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 400: `input_gradient_lane_r <= {RESULT_LANES{1'b1}};` This makes input_gradient_lane_r, the signed loss derivative used to update a learned parameter, equal to '{RESULT_LANES{1'b1}}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are RESULT_LANES: one parallel arithmetic element within a vector or tensor datapath; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 401: `load_row_r <= 4'd0;` This makes load_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 402: `load_half_r <= 1'b0;` This makes load_half_r, the value named 'load half r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 403: `load_final_r <= 1'b0;` This makes load_final_r, the value named 'load final r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 404: `input_stage_valid_r <= 1'b0;` This makes input_stage_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 405: `input_stage_data_r <= 64'd0;` This makes input_stage_data_r, the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 406: `input_stage_last_r <= 1'b0;` This makes input_stage_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 407: `load_commit_data_r <= 64'd0;` This makes load_commit_data_r, the payload carried with the surrounding valid/ready handshake, equal to '64'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 408: `result_row_r <= 4'd0;` This makes result_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 409: `column_group_r <= 1'b0;` This makes column_group_r, one output-feature position processed in parallel, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 410: `reduction_group_r <= 1'b0;` This makes reduction_group_r, the value named 'reduction group r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 411: `output_word_r <= 2'd0;` This makes output_word_r, the value named 'output word r' in this block, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 412: `accumulator_valid_r <= 1'b0;` This makes accumulator_valid_r, the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 413: `accumulator_mode_r <= MODE_INPUT_GRADIENT;` This makes accumulator_mode_r, a widened running sum that prevents intermediate overflow, equal to 'MODE_INPUT_GRADIENT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge.

Line 414: `accumulator_rows_r <= 4'd0;` This makes accumulator_rows_r, a widened running sum that prevents intermediate overflow, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 415: `accumulator_columns_r <= 4'd0;` This makes accumulator_columns_r, a widened running sum that prevents intermediate overflow, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 416: `pair_update_r <= 1'b0;` This makes pair_update_r, the value named 'pair update r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 417: `config_error <= 1'b0;` This makes config_error, the value named 'config error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 418: `completed_tiles <= 32'd0;` This makes completed_tiles, the value named 'completed tiles' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 419: `active_cycles <= 32'd0;` This makes active_cycles, the value named 'active cycles' in this block, equal to '32'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 420: `for (int row = 0; row < LANES; row++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 421: `result_row_buffer_r[row] <= 32'sd0;` This makes result_row_buffer_r[row], local storage that decouples producer and consumer timing, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 422: `activation_write_enable_r[row] <= 2'b00;` This makes activation_write_enable_r[row], an input feature value consumed by a neuron or multiply-accumulate operation, equal to '2'b00'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b00: the value named 'b00' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 423: `weight_write_enable_r[row] <= 2'b00;` This makes weight_write_enable_r[row], a learned coefficient multiplied by an activation, equal to '2'b00'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b00: the value named 'b00' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 424: `output_gradient_write_enable_r[row] <= 2'b00;` This makes output_gradient_write_enable_r[row], the signed loss derivative used to update a learned parameter, equal to '2'b00'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b00: the value named 'b00' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 425: `for (int column = 0; column < LANES; column++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 426: `activation_r[row][column] <= 16'sd0;` This makes activation_r[row][column], an input feature value consumed by a neuron or multiply-accumulate operation, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 427: `weight_r[row][column] <= 16'sd0;` This makes weight_r[row][column], a learned coefficient multiplied by an activation, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 428: `output_gradient_r[row][column] <= 16'sd0;` This makes output_gradient_r[row][column], the signed loss derivative used to update a learned parameter, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 429: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 430: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 431: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 432: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 433: `row_partial_r[result_lane] <= 35'sd0;` This makes row_partial_r[result_lane], one output-row position processed by the tensor tile, equal to '35'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 434: `reduction_sum_r[result_lane] <= 34'sd0;` This makes reduction_sum_r[result_lane], the value named 'reduction sum r' in this block, equal to '34'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 435: `selected_accumulator_r[result_lane] <= 47'sd0;` This makes selected_accumulator_r[result_lane], a widened running sum that prevents intermediate overflow, equal to '47'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 436: `accumulated_wide_r[result_lane] <= 48'sd0;` This makes accumulated_wide_r[result_lane], the value named 'accumulated wide r' in this block, equal to '48'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 437: `commit_lane_valid_r[result_lane] <= 1'b0;` This makes commit_lane_valid_r[result_lane], the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 438: `rounding_value_r[result_lane] <= 47'd0;` This makes rounding_value_r[result_lane], the value named 'rounding value r' in this block, equal to '47'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 439: `rounding_negative_r[result_lane] <= 1'b0;` This makes rounding_negative_r[result_lane], the value named 'rounding negative r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 440: `rounding_carry_r[result_lane] <= 1'b0;` This makes rounding_carry_r[result_lane], the value named 'rounding carry r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 441: `saturated_result_r[result_lane] <= 32'sd0;` This makes saturated_result_r[result_lane], the value named 'saturated result r' in this block, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 442: `for (int reduction_lane = 0;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 443: `reduction_lane < REDUCTION_LANES; reduction_lane++) begin` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are reduction_lane: one parallel arithmetic element within a vector or tensor datapath; REDUCTION_LANES: one parallel arithmetic element within a vector or tensor datapath.

Line 444: `multiplier_left_r[result_lane][reduction_lane] <= 16'sd0;` This makes multiplier_left_r[result_lane][reduct the value named 'multiplier left r' in this block, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 445: `multiplier_right_r[result_lane][reduction_lane] <= 16'sd0;` This makes multiplier_right_r[result_lane][red the value named 'multiplier right r' in this block, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 446: `multiplier_left_dsp_r[result_lane][reduction_lane] <= 16'sd0;` This makes multiplier_left_dsp_r[result_la the value named 'multiplier left dsp r' in this block, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 447: `multiplier_right_dsp_r[result_lane][reduction_lane] <= 16'sd0;` This makes multiplier_right_dsp_r[result the value named 'multiplier right dsp r' in this block, equal to '16'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 448: `product_r[result_lane][reduction_lane] <= 32'sd0;` This makes product_r[result_lane][reduction_lane], the value named 'product r' in this block, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 449: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 450: `pair_sum_r[result_lane][0] <= 33'sd0;` This makes pair_sum_r[result_lane][0], the value named 'pair sum r' in this block, equal to '33'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 451: `pair_sum_r[result_lane][1] <= 33'sd0;` This makes pair_sum_r[result_lane][1], the value named 'pair sum r' in this block, equal to '33'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 452: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 453: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 454: `if (state != ST_IDLE) active_cycles <= active_cycles + 1'b1;` This condition selects the following hardware branch only when 'state != ST_IDLE' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_IDLE: the value named 'st idle' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 455: `pair_update_r <= state == ST_PRODUCT;` This makes pair_update_r, the value named 'pair update r' in this block, equal to 'state == ST_PRODUCT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are state: the finite-state-machine phase retained in flip-flops; ST_PRODUCT: the value named 'st product' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 457: `// The single elastic slot is fall-through only at clock edges: an` Design intent: The single elastic slot is fall-through only at clock edges: an This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 458: `// old buffered beat can be consumed while the next stream beat is` Design intent: old buffered beat can be consumed while the next stream beat is This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 459: `// captured. On the final dY beat READY is withheld because there is` Design intent: captured. On the final dY beat READY is withheld because there is This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 460: `// no following operand class to prefetch.` Design intent: no following operand class to prefetch. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 461: `if (input_stage_ready) begin` This condition selects the following hardware branch only when 'input_stage_ready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_stage_ready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 462: `input_stage_valid_r <= s_axis_tvalid && s_axis_tready;` This makes input_stage_valid_r, the producer's statement that its current payload is meaningful, equal to 's_axis_tvalid && s_axis_tready'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tvalid: the producer's statement that its current payload is meaningful; s_axis_tready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 463: `if (s_axis_tvalid && s_axis_tready) begin` This condition selects the following hardware branch only when 's_axis_tvalid && s_axis_tready' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are s_axis_tvalid: the producer's statement that its current payload is meaningful; s_axis_tready: the consumer's statement that it can accept a payload this cycle. Context: the clocked process that updates registers only on a rising clock edge.

Line 464: `input_stage_data_r <= s_axis_tdata;` This makes input_stage_data_r, the payload carried with the surrounding valid/ready handshake, equal to 's_axis_tdata'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tdata: the value named 's axis tdata' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 465: `input_stage_last_r <= s_axis_tlast;` This makes input_stage_last_r, the AXI-Stream marker for the final beat of a packet or command payload, equal to 's_axis_tlast'. It updates after the active clock edge together with other nonblocking assignments. The important operands are s_axis_tlast: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge.

Line 466: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 467: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 469: `// Apply the previous beat's row-local commit and prepare one-hot` Design intent: Apply the previous beat's row-local commit and prepare one-hot This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 470: `// enables for the beat consumed this cycle. Each enable drives` Design intent: enables for the beat consumed this cycle. Each enable drives This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 471: `// only four 16-bit destinations, replacing the former chip-wide` Design intent: only four 16-bit destinations, replacing the former chip-wide This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 472: `// stream-VALID/state route into all three operand banks.` Design intent: stream-VALID/state route into all three operand banks. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 473: `for (int row = 0; row < LANES; row++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 474: `for (int half = 0; half < 2; half++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 475: `if (activation_write_enable_r[row][half]) begin` This condition selects the following hardware branch only when ‘activation_write_enable_r[row][half]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are activation_write_enable_r: an input feature value consumed by a neuron or multiply-accumulate operation; row: one output-row position processed by the tensor tile; half: the value named ’half’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 476: `for (int lane = 0; lane < 4; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 477: `activation_r[row][half*4 + lane]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are activation_r: an input feature value consumed by a neuron or multiply-accumulate operation; row: one output-row position processed by the tensor tile; half: the value named ’half’ in this block.

Line 478: `<= load_commit_data_r[lane*16 +: 16];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are load_commit_data_r: the payload carried with the surrounding valid/ready handshake; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 479: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 480: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 481: `if (weight_write_enable_r[row][half]) begin` This condition selects the following hardware branch only when ‘weight_write_enable_r[row][half]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are weight_write_enable_r: a learned coefficient multiplied by an activation; row: one output-row position processed by the tensor tile; half: the value named ’half’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 482: `for (int lane = 0; lane < 4; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 483: `weight_r[row][half*4 + lane]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are weight_r: a learned coefficient multiplied by an activation; row: one output-row position processed by the tensor tile; half: the value named 'half' in this block.

Line 484: `<= load_commit_data_r[lane*16 +: 16];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are load_commit_data_r: the payload carried with the surrounding valid/ready handshake; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 485: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 486: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 487: `if (output_gradient_write_enable_r[row][half]) begin` This condition selects the following hardware branch only when ‘output_gradient_write_enable_r[row][half]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_gradient_write_enable_r: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile; half: the value named 'half' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 488: `for (int lane = 0; lane < 4; lane++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 489: `output_gradient_r[row][half*4 + lane]` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are output_gradient_r: the signed loss derivative used to update a learned parameter; row: one output-row position processed by the tensor tile; half: the value named 'half' in this block.

Line 490: `<= load_commit_data_r[lane*16 +: 16];` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are load_commit_data_r: the payload carried with the surrounding valid/ready handshake; lane: one parallel arithmetic element within a vector or tensor datapath.

Line 491: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 492: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 493: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 494: `activation_write_enable_r[row] <= 2'b00;` This makes activation_write_enable_r[row], an input feature value consumed by a neuron or multiply-accumulate operation, equal to ‘2'b00‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b00: the value named 'b00' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 495: `weight_write_enable_r[row] <= 2'b00;` This makes weight_write_enable_r[row], a learned coefficient multiplied by an activation, equal to '2'b00'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b00: the value named 'b00' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 496: `output_gradient_write_enable_r[row] <= 2'b00;` This makes output_gradient_write_enable_r[row], the signed loss derivative used to update a learned parameter, equal to '2'b00'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b00: the value named 'b00' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 497: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 498: `if (input_stage_valid_r && input_load_state) begin` This condition selects the following hardware branch only when 'input_stage_valid_r && input_load_state' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_stage_valid_r: the producer's statement that its current payload is meaningful; input_load_state: the finite-state-machine phase retained in flip-flops. Context: the clocked process that updates registers only on a rising clock edge.

Line 499: `load_commit_data_r <= input_stage_data_r;` This makes load_commit_data_r, the payload carried with the surrounding valid/ready handshake, equal to 'input_stage_data_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_stage_data_r: the payload carried with the surrounding valid/ready handshake. Context: the clocked process that updates registers only on a rising clock edge.

Line 500: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 501: `ST_LOAD_X: activation_write_enable_r[load_row_index]` This is the ST_LOAD_X case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'activation_write_enable_r[load_row_index context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 502: `[load_half_r] <= 1'b1;` Within the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are load_half_r: the value named 'load half r' in this block; b1: the value named 'b1' in this block.

Line 503: `ST_LOAD_W: weight_write_enable_r[load_row_index]` This is the ST_LOAD_W case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'weight_write_enable_r[load_row_index]'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 504: `[load_half_r] <= 1'b1;` Within the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are load_half_r: the value named 'load half r' in this block; b1: the value named 'b1' in this block.

Line 505: `ST_LOAD_DY: output_gradient_write_enable_r[load_row_index]` This is the ST_LOAD_DY case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'output_gradient_write_enable_r[loac context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 506: `[load_half_r] <= 1'b1;` Within the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are load_half_r: the value named 'load half r' in this block; b1: the value named 'b1' in this block.

Line 507: `default: begin end` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin end'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 508: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 509: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 511: `if (pair_update_r) begin` This condition selects the following hardware branch only when 'pair_update_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are pair_update_r: the value named 'pair update r' in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 512: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge.

Line 513: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge, this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 514: `pair_sum_r[result_lane][0] <=` This statement continues through source line 516; the explanation uses the complete expression rather than only the first visual fragment. This makes pair_sum_r[result_lane][0], the value named 'pair sum r' in this block, equal to '{product_r[result_lane][0][31], product_r[result_lane][0]} + {product_r[result_lane][1][31], product_r[result_lane][1]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge.

Line 515: `{product_r[result_lane][0][31], product_r[result_lane][0]}` This is continuation line 2 of the 3-line logical statement that begins at source line 514. Its exact fragment is '{product_r[result_lane][0][31], product_r[result_lane][0]}'. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes pair_sum_r[result_lane][0], the value named 'pair sum r' in this block, equal to '{product_r[result_lane][0][31], product_r[result_lane][0]} + {product_r[result_lane][1][31], product_r[result_lane][1]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge.

Line 516: `+ {product_r[result_lane][1][31], product_r[result_lane][1]};` This is continuation line 3 of the 3-line logical statement that begins at source line 514. Its exact fragment is '+ {product_r[result_lane][1][31], product_r[result_lane][1]};'. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes

pair_sum_r[result_lane][0], the value named 'pair sum r' in this block, equal to '{product_r[result_lane][0][31], product_r[result_lane][0]} + {product_r[result_lane][1][31], product_r[result_lane][1]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge.

Line 517: `pair_sum_r[result_lane][1] <=` This statement continues through source line 519; the explanation uses the complete expression rather than only the first visual fragment. This makes pair_sum_r[result_lane][1], the value named 'pair sum r' in this block, equal to '{product_r[result_lane][2][31], product_r[result_lane][2]} + {product_r[result_lane][3][31], product_r[result_lane][3]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge.

Line 518: `{product_r[result_lane][2][31], product_r[result_lane][2]}` This is continuation line 2 of the 3-line logical statement that begins at source line 517. Its exact fragment is '{product_r[result_lane][2][31], product_r[result_lane][2]}'. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes pair_sum_r[result_lane][1], the value named 'pair sum r' in this block, equal to '{product_r[result_lane][2][31], product_r[result_lane][2]} + {product_r[result_lane][3][31], product_r[result_lane][3]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge.

Line 519: `+ {product_r[result_lane][3][31], product_r[result_lane][3]};` This is continuation line 3 of the 3-line logical statement that begins at source line 517. Its exact fragment is '+ {product_r[result_lane][3][31], product_r[result_lane][3]};'. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes pair_sum_r[result_lane][1], the value named 'pair sum r' in this block, equal to '{product_r[result_lane][2][31], product_r[result_lane][2]} + {product_r[result_lane][3][31], product_r[result_lane][3]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge.

Line 520: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 521: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 522: `unique case (state)` This starts a multiplexer/state decode selected by 'state'. 'unique' allows tools to diagnose overlapping or missing legal choices and optimize on the expectation that one branch matches.

Line 523: `ST_IDLE: begin` This is the ST_IDLE case branch, which waits for a new operation and does not consume payload data. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 524: `if (start_valid) begin` This condition selects the following hardware branch only when 'start_valid' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are start_valid: the producer's statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 525: `rows_r <= active_rows;` This makes rows_r, one output-row position processed by the tensor tile, equal to ‘active_rows‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_rows: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 526: `inputs_r <= active_inputs;` This makes inputs_r, the value named ’inputs r’ in this block, equal to ‘active_inputs‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_inputs: the value named ’active inputs’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 527: `outputs_r <= active_outputs;` This makes outputs_r, the value named ’outputs r’ in this block, equal to ‘active_outputs‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_outputs: the value named ’active outputs’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 528: `dw_shift_r <= weight_gradient_shift;` This makes dw_shift_r, the value named ’dw shift r’ in this block, equal to ‘weight_gradient_shift‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 529: `if (gradient_mode == MODE_WEIGHT_GRADIENT) begin` This condition selects the following hardware branch only when ‘gradient_mode == MODE_WEIGHT_GRADIENT‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are gradient_mode: the signed loss derivative used to update a learned parameter; MODE_WEIGHT_GRADIENT: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 530: `result_shift_r <= weight_gradient_shift;` This makes result_shift_r, the value named ’result shift r’ in this block, equal to ‘weight_gradient_shift‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 531: `rounding_bias_r <= round_bias(weight_gradient_shift);` This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to ‘round_bias(weight_gradient_shift)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are round_bias: an additive learned offset applied after accumulation; weight_gradient_shift: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 532: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 533: `result_shift_r <= input_gradient_shift;` This makes result_shift_r, the value named ’result shift r’ in this block, equal to ‘input_gradient_shift‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are input_gradient_shift: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 534: `rounding_bias_r <= round_bias(input_gradient_shift);` This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to ‘round_bias(input_gradient_shift)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are round_bias: an additive learned offset applied after accumulation; input_gradient_shift: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 535: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 536: `mode_r <= gradient_mode;` This makes mode_r, the value named ’mode r’ in this block, equal to ‘gradient_mode‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are gradient_mode: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 537: `compute_mode_r <= requested_accumulator_mode;` This makes compute_mode_r, the value named ’compute mode r’ in this block, equal to ‘requested_accumulator_mode‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are requested_accumulator_mode: a widened running sum that prevents intermediate overflow. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 538: `suppress_output_r <= suppress_output;` This makes suppress_output_r, the value named ’suppress output r’ in this block, equal to ‘suppress_output‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are suppress_output: the value named ’suppress output’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 539: `accumulate_result_r <= accumulate_result;` This makes accumulate_result_r, the value named ’accumulate result r’ in this block, equal to ‘accumulate_result‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are accumulate_result: the value named ’accumulate result’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 540: `start_configuration_invalid_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are start_configuration_invalid_r: the producer’s statement that its current payload is meaningful.

Line 541: `<= start_configuration_invalid;` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are start_configuration_invalid: the producer’s statement that its current payload is meaningful.

Line 542: `requested_accumulator_mode_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are requested_accumulator_mode_r: a widened running sum that prevents intermediate overflow.

Line 543: `<= requested_accumulator_mode;` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are requested_accumulator_mode: a widened running sum that prevents intermediate overflow.

Line 544: `requested_accumulator_rows_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are requested_accumulator_rows_r: a widened running sum that prevents intermediate overflow.

Line 545: `<= requested_accumulator_rows;` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are requested_accumulator_rows: a widened running sum that prevents intermediate overflow.

Line 546: `requested_accumulator_columns_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are requested_accumulator_columns_r: a widened running sum that prevents intermediate overflow.

Line 547: `<= requested_accumulator_columns;` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are requested_accumulator_columns: a widened running sum that prevents intermediate overflow.

Line 548: `input_gradient_lane_r <= {RESULT_LANES{` This statement continues through source line 550; the explanation uses the complete expression rather than only the first visual fragment. This makes input_gradient_lane_r, the signed loss derivative used to update a learned parameter, equal to ‘{RESULT_LANES{ requested_accumulator_mode == MODE_INPUT_GRADIENT}}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are RESULT_LANES: one parallel arithmetic element within a vector or tensor datapath; requested_accumulator_mode: a widened running sum that prevents intermediate overflow; MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 549: `requested_accumulator_mode` This is continuation line 2 of the 3-line logical statement that begins at source line 548. Its exact fragment is ‘requested_accumulator_mode‘. The important operands are requested_accumulator_mode: a widened running sum that prevents intermediate overflow. Read together, the complete operation is: This makes input_gradient_lane_r, the signed loss derivative used to update a learned parameter, equal to ‘{RESULT_LANES{ requested_accumulator_mode == MODE_INPUT_GRADIENT}}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are RESULT_LANES: one parallel arithmetic element within a vector or tensor datapath; requested_accumulator_mode: a widened running sum that prevents intermediate overflow; MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 550: `== MODE_INPUT_GRADIENT}};` This is continuation line 3 of the 3-line logical statement that begins at source line 548. Its exact fragment is ‘== MODE_INPUT_GRADIENT}};‘. The important operands are MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter. Read together, the complete operation is: This makes input_gradient_lane_r, the signed loss derivative used to update a learned parameter, equal to ‘{RESULT_LANES{ requested_accumulator_mode == MODE_INPUT_GRADIENT}}‘. It updates after the active clock edge together

with other nonblocking assignments. The important operands are RESULT_LANES: one parallel arithmetic element within a vector or tensor datapath; requested_accumulator_mode: a widened running sum that prevents intermediate overflow; MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 551: `if (requested_accumulator_mode` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are requested_accumulator_mode: a widened running sum that prevents intermediate overflow.

Line 552: `== MODE_INPUT_GRADIENT) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter.

Line 553: `compute_result_row_count_r <= active_rows;` This makes compute_result_row_count_r, one output-row position processed by the tensor tile, equal to 'active_rows'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_rows: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 554: `compute_result_column_count_r <= active_inputs;` This makes compute_result_column_count_r, one output-feature position processed in parallel, equal to 'active_inputs'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_inputs: the value named 'active inputs' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 555: `compute_reduction_count_r <= active_outputs;` This makes compute_reduction_count_r, an integer count retained for control or measurable telemetry, equal to 'active_outputs'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_outputs: the value named 'active outputs' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 556: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 557: `compute_result_row_count_r <= active_inputs;` This makes compute_result_row_count_r, one output-row position processed by the tensor tile, equal to 'active_inputs'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_inputs: the value named 'active inputs' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 558: `compute_result_column_count_r <= active_outputs;` This makes compute_result_column_count_r, one output-feature position processed in parallel, equal to 'active_outputs'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_outputs: the value named 'active outputs' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 559: `compute_reduction_count_r <= active_rows;` This makes compute_reduction_count_r, an integer count retained for control or measurable telemetry, equal to 'active_rows'. It updates after the active clock edge together with other nonblocking assignments. The important operands are active_rows: one output-row position processed by the

tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 560: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 561: `load_row_r <= 4'd0;` This makes load_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 562: `load_half_r <= 1'b0;` This makes load_half_r, the value named 'load half r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 563: `result_row_r <= 4'd0;` This makes result_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 564: `column_group_r <= 1'b0;` This makes column_group_r, one output-feature position processed in parallel, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 565: `reduction_group_r <= 1'b0;` This makes reduction_group_r, the value named 'reduction group r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 566: `output_word_r <= 2'd0;` This makes output_word_r, the value named 'output word r' in this block, equal to '2'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 567: `config_error <= 1'b0;` This makes config_error, the value named 'config error' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 568: `for (int row = 0; row < LANES; row++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 569: `result_row_buffer_r[row] <= 32'sd0;` This makes result_row_buffer_r[row], local storage that decouples producer and consumer timing, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 570: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 571: `state <= ST_CONFIGURE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_CONFIGURE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_CONFIGURE: the value named ’st configure’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data..

Line 572: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 573: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_IDLE, the machine waits for a new operation and does not consume payload data.; it has no arithmetic value of its own.

Line 575: `ST_CONFIGURE: begin` This is the ST_CONFIGURE case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 576: `config_error <= start_configuration_invalid_r;` This makes config_error, the value named ’config error’ in this block, equal to ‘start_configuration_invalid_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are start_configuration_invalid_r: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 577: `if (start_configuration_invalid_r) begin` This condition selects the following hardware branch only when ‘start_configuration_invalid_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are start_configuration_invalid_r: the producer’s statement that its current payload is meaningful. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 578: `state <= ST_DONE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_DONE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DONE: the value named ’st done’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 579: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 580: `accumulator_valid_r <= 1’b1;` This makes accumulator_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 581: `accumulator_mode_r <= requested_accumulator_mode_r;` This makes accumulator_mode_r, a widened running sum that prevents intermediate overflow, equal to ‘requested_accumulator_mode_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are requested_accumulator_mode_r: a widened running sum that prevents intermediate overflow. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 582: `accumulator_rows_r <= requested_accumulator_rows_r;` This makes accumulator_rows_r, a widened running sum that prevents intermediate overflow, equal to ‘requested_accumulator_rows_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are requested_accumulator_rows_r: a widened running sum that prevents intermediate overflow. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 583: `accumulator_columns_r` Within the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are accumulator_columns_r: a widened running sum that prevents intermediate overflow.

Line 584: `<= requested_accumulator_columns_r;` Within the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are requested_accumulator_columns_r: a widened running sum that prevents intermediate overflow.

Line 585: `if (mode_r == MODE_INPUT_GRADIENT) begin` This condition selects the following hardware branch only when ‘mode_r == MODE_INPUT_GRADIENT‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are mode_r: the value named ’mode r’ in this block; MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 586: `load_final_r <= inputs_r == 4'd1;` This makes load_final_r, the value named ’load final r’ in this block, equal to ‘inputs_r == 4’d1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are inputs_r: the value named ’inputs r’ in this block; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 587: `state <= ST_LOAD_W;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LOAD_W‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_W: the value named ’st load w’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 588: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 589: `load_final_r <= rows_r == 4'd1;` This makes load_final_r, the value named ’load final r’ in this block, equal to ‘rows_r == 4’d1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are rows_r: one output-row position processed by the tensor tile; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 590: `state <= ST_LOAD_X;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LOAD_X‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_X: the value named ’st load x’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase..

Line 591: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 592: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 593: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_CONFIGURE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 595: `ST_LOAD_X: if (input_stage_valid_r) begin` This is the ST_LOAD_X case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘if (input_stage_valid_r) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 596: `if (input_stage_last_r) config_error <= 1'b1;` This condition selects the following hardware branch only when ‘input_stage_last_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_stage_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 597: `if (!load_half_r) load_half_r <= 1'b1;` This condition selects the following hardware branch only when ‘!load_half_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_half_r: the value named 'load half r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 598: `else if (load_final_r) begin` This condition selects the following hardware branch only when ‘load_final_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_final_r: the value named 'load final r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 599: `load_row_r <= 4'd0;` This makes load_row_r, one output-row position processed by the tensor tile, equal to ‘4'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 600: `load_half_r <= 1'b0;` This makes load_half_r, the value named 'load half r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 601: `if (mode_r == MODE_WEIGHT_GRADIENT) begin` This condition selects the following hardware branch only when ‘mode_r == MODE_WEIGHT_GRADIENT‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are mode_r: the value named 'mode r' in this block; MODE_WEIGHT_GRADIENT: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 602: `load_final_r <= rows_r == 4'd1;` This makes load_final_r, the value named 'load final r' in this block, equal to ‘rows_r == 4'd1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are rows_r: one output-row position processed by the tensor tile; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 603: `state <= ST_LOAD_DY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LOAD_DY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_DY: the value named ’st load dy’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 604: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 605: `load_final_r <= inputs_r == 4'd1;` This makes load_final_r, the value named ’load final r’ in this block, equal to ‘inputs_r == 4’d1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are inputs_r: the value named ’inputs r’ in this block; d1: the value named ’d1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 606: `state <= ST_LOAD_W;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LOAD_W‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_W: the value named ’st load w’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 607: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 608: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 609: `load_row_r <= load_row_r + 1'b1;` This makes load_row_r, one output-row position processed by the tensor tile, equal to ‘load_row_r + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_row_r: one output-row position processed by the tensor tile; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 610: `load_half_r <= 1'b0;` This makes load_half_r, the value named ’load half r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 611: `load_final_r <= load_row_r == rows_r - 4'd2;` This makes load_final_r, the value named ’load final r’ in this block, equal to ‘load_row_r == rows_r - 4’d2‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_row_r: one output-row position processed by the tensor tile; rows_r: one output-row position processed by the tensor tile; d2: the value named ’d2’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory..

Line 612: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 613: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_X, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 615: `ST_LOAD_W: if (input_stage_valid_r) begin` This is the ST_LOAD_W case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with ‘if (input_stage_valid_r) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 616: `if (input_stage_last_r) config_error <= 1'b1;` This condition selects the following hardware branch only when ‘input_stage_last_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_stage_last_r: the AXI-Stream marker for the final beat of a packet or command payload. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 617: `if (!load_half_r) load_half_r <= 1'b1;` This condition selects the following hardware branch only when ‘!load_half_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_half_r: the value named 'load half r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 618: `else if (load_final_r) begin` This condition selects the following hardware branch only when ‘load_final_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_final_r: the value named 'load final r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 619: `load_row_r <= 4'd0;` This makes load_row_r, one output-row position processed by the tensor tile, equal to ‘4'd0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 620: `load_half_r <= 1'b0;` This makes load_half_r, the value named 'load half r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 621: `load_final_r <= rows_r == 4'd1;` This makes load_final_r, the value named 'load final r' in this block, equal to ‘rows_r == 4'd1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are rows_r: one output-row position processed by the tensor tile; d1: the value named 'd1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 622: `state <= ST_LOAD_DY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_LOAD_DY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_DY: the value named 'st load dy' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 623: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 624: `load_row_r <= load_row_r + 1'b1;` This makes load_row_r, one output-row position processed by the tensor tile, equal to ‘load_row_r + 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_row_r: one output-row position processed by the tensor tile; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 625: `load_half_r <= 1'b0;` This makes load_half_r, the value named 'load half r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 626: `load_final_r <= load_row_r == inputs_r - 4'd2;` This makes load_final_r, the value named 'load final r' in this block, equal to 'load_row_r == inputs_r - 4'd2'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_row_r: one output-row position processed by the tensor tile; inputs_r: the value named 'inputs r' in this block; d2: the value named 'd2' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory..

Line 627: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 628: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_W, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 630: `ST_LOAD_DY: if (input_stage_valid_r) begin` This is the ST_LOAD_DY case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'if (input_stage_valid_r) begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 631: `if (input_stage_last_r != (load_half_r && load_final_r)) begin` This condition selects the following hardware branch only when 'input_stage_last_r != (load_half_r && load_final_r)' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_stage_last_r: the AXI-Stream marker for the final beat of a packet or command payload; load_half_r: the value named 'load half r' in this block; load_final_r: the value named 'load final r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 632: `config_error <= 1'b1;` This makes config_error, the value named 'config error' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 633: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 634: `if (!load_half_r) load_half_r <= 1'b1;` This condition selects the following hardware branch only when '!load_half_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_half_r: the value named 'load half r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 635: `else if (load_final_r) begin` This condition selects the following hardware branch only when 'load_final_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are load_final_r: the value named 'load final r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 636: `result_row_r <= 4'd0;` This makes result_row_r, one output-row position processed by the tensor tile, equal to '4'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 637: `column_group_r <= 1'b0;` This makes column_group_r, one output-feature position processed in parallel, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 638: `reduction_group_r <= 1'b0;` This makes reduction_group_r, the value named 'reduction group r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 639: `state <= ST_LOAD_COMMIT_DRAIN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_LOAD_COMMIT_DRAIN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_LOAD_COMMIT_DRAIN: the value named 'st load commit drain' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 640: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 641: `load_row_r <= load_row_r + 1'b1;` This makes load_row_r, one output-row position processed by the tensor tile, equal to 'load_row_r + 1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_row_r: one output-row position processed by the tensor tile; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 642: `load_half_r <= 1'b0;` This makes load_half_r, the value named 'load half r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 643: `load_final_r <= load_row_r == rows_r - 4'd2;` This makes load_final_r, the value named 'load final r' in this block, equal to 'load_row_r == rows_r - 4'd2'. It updates after the active clock edge together with other nonblocking assignments. The important operands are load_row_r: one output-row position processed by the tensor tile; rows_r: one output-row position processed by the tensor tile; d2: the value named 'd2' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory..

Line 644: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 645: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_DY, the machine stores incoming operands into local FPGA memory.; it has no arithmetic value of its own.

Line 647: `// The final dY payload has reached the commit registers. One` Design intent: The final dY payload has reached the commit registers. One This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 648: `// dedicated cycle lets its row-local write land before the DSP` Design intent: dedicated cycle lets its row-local write land before the DSP This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 649: `// operand-selection logic is allowed to read that bank.` Design intent: operand-selection logic is allowed to read that bank. This comment anchors the surrounding logic in the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

Line 650: `ST_LOAD_COMMIT_DRAIN: state <= ST_MULTIPLY;` This is the ST_LOAD_COMMIT_DRAIN case branch, which stores incoming operands into local FPGA memory. The same-cycle action begins with 'state <= ST_MULTIPLY;'; context is the clocked process that updates registers only on a rising clock edge Within state ST_LOAD_COMMIT_DRAIN, the machine stores incoming operands into local FPGA memory..

Line 652: `ST_MULTIPLY: begin` This is the ST_MULTIPLY case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase..

Line 653: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase..

Line 654: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 655: `for (int reduction_lane = 0;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase..

Line 656: `reduction_lane < REDUCTION_LANES;` Within the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are reduction_lane: one parallel arithmetic element within a vector or tensor datapath; REDUCTION_LANES: one parallel arithmetic element within a vector or tensor datapath.

Line 657: `reduction_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are reduction_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 658: `multiplier_left_r[result_lane][reduction_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are multiplier_left_r: the value named 'multiplier left r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 659: `<= multiplier_left[result_lane][reduction_lane];` Within the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are multiplier_left: the value named 'multiplier left' in this

block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 660: `multiplier_right_r[result_lane][reduction_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are multiplier_right_r: the value named 'multiplier right r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 661: `<= multiplier_right[result_lane][reduction_lane];` Within the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are multiplier_right: the value named 'multiplier right' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 662: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 663: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 664: `state <= ST_REGISTER_OPERANDS;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_REGISTER_OPERANDS'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_REGISTER_OPERANDS: the value named 'st register operands' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase..

Line 665: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_MULTIPLY, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 667: `ST_REGISTER_OPERANDS: begin` This is the ST_REGISTER_OPERANDS case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_REGISTER_OPERANDS, the machine performs the named control phase..

Line 668: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_REGISTER_OPERANDS, the machine performs the named control phase..

Line 669: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_REGISTER_OPERANDS, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 670: `for (int reduction_lane = 0;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_REGISTER_OPERANDS, the machine performs the named control phase..

The important operands are reduction_lane: one parallel arithmetic element within a vector or tensor datapath; REDUCTION_LANES: one parallel arithmetic element within a vector or tensor datapath.

Line 687: `reduction_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are reduction_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 688: `product_r[result_lane][reduction_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are product_r: the value named 'product r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 689: `<= multiplier_product[result_lane][reduction_lane];` Within the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are multiplier_product: the value named 'multiplier product' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; reduction_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 690: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 691: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 692: `state <= ST_PAIR;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_PAIR‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_PAIR: the value named ’st pair’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT, the machine performs the named control phase..

Line 693: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PRODUCT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 695: `ST_PAIR: begin` This is the ST_PAIR case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_PAIR, the machine performs the named control phase..

Line 696: `state <= ST_REDUCTION_SUM;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_REDUCTION_SUM‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_REDUCTION_SUM: the value named ’st reduction sum’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_PAIR, the machine performs the named control phase..

Line 697: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_PAIR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 699: `ST_REDUCTION_SUM: begin` This is the ST_REDUCTION_SUM case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_REDUCTION_SUM, the machine performs the named control phase..

Line 700: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_REDUCTION_SUM, the machine performs the named control phase..

Line 701: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_REDUCTION_SUM, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 702: `reduction_sum_r[result_lane] <=` This statement continues through source line 706; the explanation uses the complete expression rather than only the first visual fragment. This makes reduction_sum_r[result_lane], the value named ’reduction sum r’ in this block, equal to ‘{pair_sum_r[result_lane][0][32], pair_sum_r[result_lane][0]} + {pair_sum_r[result_lane][1][32], pair_sum_r[result_lane][1]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are pair_sum_r: the value named ’pair sum r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_REDUCTION_SUM, the machine performs the named control phase..

Line 703: `{pair_sum_r[result_lane][0][32],` This is continuation line 2 of the 5-line logical statement that begins at source line 702. Its exact fragment is ‘{pair_sum_r[result_lane][0][32],‘. The important operands are pair_sum_r: the value named ’pair sum r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes reduction_sum_r[result_lane], the value named ’reduction sum r’ in this block, equal to ‘{pair_sum_r[result_lane][0][32], pair_sum_r[result_lane][0]} + {pair_sum_r[result_lane][1][32], pair_sum_r[result_lane][1]}‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are pair_sum_r: the value named ’pair sum r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_REDUCTION_SUM, the machine performs the named control phase..

Line 704: `pair_sum_r[result_lane][0]}` This is continuation line 3 of the 5-line logical statement that begins at source line 702. Its exact fragment is 'pair_sum_r[result_lane][0]}'. The important operands are pair_sum_r: the value named 'pair sum r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes reduction_sum_r[result_lane], the value named 'reduction sum r' in this block, equal to '{pair_sum_r[result_lane][0][32], pair_sum_r[result_lane][0]} + {pair_sum_r[result_lane][1][32], pair_sum_r[result_lane][1]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are pair_sum_r: the value named 'pair sum r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_REDUCTION_SUM, the machine performs the named control phase..

Line 705: `+ {pair_sum_r[result_lane][1][32],` This is continuation line 4 of the 5-line logical statement that begins at source line 702. Its exact fragment is '+ {pair_sum_r[result_lane][1][32],'. The important operands are pair_sum_r: the value named 'pair sum r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes reduction_sum_r[result_lane], the value named 'reduction sum r' in this block, equal to '{pair_sum_r[result_lane][0][32], pair_sum_r[result_lane][0]} + {pair_sum_r[result_lane][1][32], pair_sum_r[result_lane][1]}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are pair_sum_r: the value named 'pair sum r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_REDUCTION_SUM, the machine performs the named control phase..

Line 706: `pair_sum_r[result_lane][1]};` This is continuation line 5 of the 5-line logical statement that begins at source line 702. Its exact fragment is 'pair_sum_r[result_lane][1]};'. Line 723: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_REDUCE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 724: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_REDUCE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 725: `state <= ST_COMMIT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_COMMIT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_COMMIT: the value named 'st commit' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_REDUCE, the machine performs the named control phase..

Line 726: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_REDUCE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 728: `ST_COMMIT: begin` This is the ST_COMMIT case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 729: `if (!reduction_group_r && reduction_count > 4'd4) begin` This condition selects the following hardware branch only when ‘!reduction_group_r && reduction_count > 4'd4‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are reduction_group_r: the value named 'reduction group r' in this block; reduction_count: an integer count retained for control or measurable telemetry; d4: the value named 'd4' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 730: `reduction_group_r <= 1'b1;` This makes reduction_group_r, the value named 'reduction group r' in this block, equal to ‘1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 731: `state <= ST_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_MULTIPLY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MULTIPLY: the value named ’st multiply’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 732: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 733: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 734: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 735: `if (result_column_index[result_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_column_index: an integer selecting one tensor element, lane, bank, or state entry; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 736: `< result_column_count) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_column_count: one output-feature position processed in parallel.

Line 737: `if (accumulate_result_r) begin` This condition selects the following hardware branch only when ‘accumulate_result_r‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are accumulate_result_r: the value named ’accumulate result r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 738: `selected_accumulator_r[result_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are selected_accumulator_r: a widened running sum that prevents intermediate overflow; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 739: `<= accumulator_bank_read_data` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are accumulator_bank_read_data: a widened running sum that prevents intermediate overflow.

Line 740: `[result_lane];` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 741: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 742: `selected_accumulator_r[result_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are selected_accumulator_r: a widened running sum that prevents intermediate overflow; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 743: `<= 47'sd0;` Within the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are sd0: the value named 'sd0' in this block.

Line 744: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 745: `commit_lane_valid_r[result_lane] <= 1'b1;` This makes commit_lane_valid_r[result_lane], the producer's statement that its current payload is meaningful, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 746: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 747: `selected_accumulator_r[result_lane] <= 47'sd0;` This makes selected_accumulator_r[result_lane], a widened running sum that prevents intermediate overflow, equal to '47'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 748: `commit_lane_valid_r[result_lane] <= 1'b0;` This makes commit_lane_valid_r[result_lane], the producer's statement that its current payload is meaningful, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 749: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 750: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 751: `state <= ST_ADD_ACCUMULATOR;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_ADD_ACCUMULATOR'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ADD_ACCUMULATOR: a widened running sum that prevents intermediate overflow. Context: the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase..

Line 752: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_COMMIT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 768: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase..

Line 769: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 770: `if (commit_lane_valid_r[result_lane]) begin` This condition selects the following hardware branch only when 'commit_lane_valid_r[result_lane]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are commit_lane_valid_r: the producer's statement that its

current payload is meaningful; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase..

Line 771: `rounding_value_r[result_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 772: `<= saturate_s47(accumulated_wide_r[result_lane]);` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are saturate_s47: the value named 'saturate s47' in this block; accumulated_wide_r: the value named 'accumulated wide r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 773: `rounding_negative_r[result_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_negative_r: the value named 'rounding negative r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 774: `<= accumulated_wide_r[result_lane][47];` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are accumulated_wide_r: the value named 'accumulated wide r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 775: `if (accumulated_wide_r[result_lane][47]` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are accumulated_wide_r: the value named 'accumulated wide r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 776: `!= accumulated_wide_r[result_lane][46]) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are accumulated_wide_r: the value named 'accumulated wide r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 777: `config_error <= 1'b1;` This makes config_error, the value named 'config error' in this block, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase..

Line 778: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 779: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 780: `rounding_value_r[result_lane] <= 47'd0;` This makes rounding_value_r[result_lane], the value named 'rounding value r' in this block, equal to '47'd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named 'd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase..

Line 781: `rounding_negative_r[result_lane] <= 1'b0;` This makes rounding_negative_r[result_lane], the value named 'rounding negative r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase..

Line 782: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 783: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 784: `reduction_group_r <= 1'b0;` This makes reduction_group_r, the value named 'reduction group r' in this block, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase..

Line 785: `state <= ST_ROUND_MAGNITUDE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_ROUND_MAGNITUDE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ROUND_MAGNITUDE: the value named 'st round magnitude' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase..

Line 786: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_ACCUMULATOR, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 788: `ST_ROUND_MAGNITUDE: begin` This is the ST_ROUND_MAGNITUDE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase..

Line 789: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase..

Line 790: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 791: `if (rounding_negative_r[result_lane]) begin` This condition selects the following hardware branch only when 'rounding_negative_r[result_lane]' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are rounding_negative_r: the value named 'rounding negative r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase..

Line 792: `{rounding_carry_r[result_lane],` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_carry_r: the value named 'rounding carry r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 793: `rounding_value_r[result_lane][23:0]} <=` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 794: `{1'b0, ~rounding_value_r[result_lane][23:0]}` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are b0: the value named 'b0' in this block; rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 795: `+ 25'd1;` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are d1: the value named 'd1' in this block.

Line 796: `end else rounding_carry_r[result_lane] <= 1'b0;` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 797: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 798: `state <= ST_ROUND_MAGNITUDE_HIGH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_ROUND_MAGNITUDE_HIGH'. It updates after the active clock edge together with other non-blocking assignments. The important operands are ST_ROUND_MAGNITUDE_HIGH: the value named 'st round magnitude high' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase..

Line 799: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 801: `ST_ROUND_MAGNITUDE_HIGH: begin` This is the ST_ROUND_MAGNITUDE_HIGH case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase..

Line 802: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase..

Line 803: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 804: `if (rounding_negative_r[result_lane]) begin` This condition selects the following hardware branch only when ‘rounding_negative_r[result_lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are rounding_negative_r: the value named ’rounding negative r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase..

Line 805: `rounding_value_r[result_lane][46:24] <=` This statement continues through source line 807; the explanation uses the complete expression rather than only the first visual fragment. This makes rounding_value_r[result_lane][46:24], the value named ’rounding value r’ in this block, equal to ‘(~rounding_value_r[result_lane][46:24]) + rounding_carry_r[result_lane] It updates after the active clock edge together with other nonblocking assignments. The important operands are rounding_value_r: the value named ’rounding value r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; rounding_carry_r: the value named ’rounding carry r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase..

Line 806: `(~rounding_value_r[result_lane][46:24])` This is continuation line 2 of the 3-line logical statement that begins at source line 805. Its exact fragment is ‘(~rounding_value_r[result_lane][46:24])‘. The important operands are rounding_value_r: the value named ’rounding value r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes rounding_value_r[result_lane][46:24], the value named ’rounding value r’ in this block, equal to ‘(~rounding_value_r[result_lane][46:24]) + rounding_carry_r[result_lane] It updates after the active clock edge together with other nonblocking assignments. The important operands are rounding_value_r: the value named ’rounding value r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; rounding_carry_r: the value named ’rounding carry r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase..

Line 807: `+ rounding_carry_r[result_lane];` This is continuation line 3 of the 3-line logical statement that begins at source line 805. Its exact fragment is ‘+ rounding_carry_r[result_lane];‘. The important operands are rounding_carry_r: the value named ’rounding carry r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes rounding_value_r[result_lane][46:24], the value named ’rounding value r’ in this block, equal to ‘(~rounding_value_r[result_lane][46:24]) + rounding_carry_r[result_lane]‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are rounding_value_r: the value named ’rounding value r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; rounding_carry_r: the value named ’rounding carry r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase..

Line 808: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 809: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 810: `state <= ST_ROUND_BIAS;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_ROUND_BIAS‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ROUND_BIAS: an additive learned offset applied after accumulation. Context: the clocked

process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase..

Line 811: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_MAGNITUDE_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 813: `ST_ROUND_BIAS: begin` This is the ST_ROUND_BIAS case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase..

Line 814: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase..

Line 815: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 816: `{rounding_carry_r[result_lane],` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_carry_r: the value named 'rounding carry r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 817: `rounding_value_r[result_lane][23:0]} <=` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 818: `{1'b0, rounding_value_r[result_lane][23:0]}` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are b0: the value named 'b0' in this block; rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 819: `+ {1'b0, rounding_bias_r[23:0]};` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are b0: the value named 'b0' in this block; rounding_bias_r: an additive learned offset applied after accumulation.

Line 820: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 821: `state <= ST_ROUND_BIAS_HIGH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_ROUND_BIAS_HIGH'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ROUND_BIAS_HIGH: an additive learned offset applied after accumulation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase..

Line 822: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 824: `ST_ROUND_BIAS_HIGH: begin` This is the ST_ROUND_BIAS_HIGH case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS_HIGH, the machine performs the named control phase..

Line 825: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS_HIGH, the machine performs the named control phase..

Line 826: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS_HIGH, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 827: `rounding_value_r[result_lane][46:24] <=` This statement continues through source line 830; the explanation uses the complete expression rather than only the first visual fragment. This makes rounding_value_r[result_lane][46:24], the value named 'rounding value r' in this block, equal to 'rounding_value_r[result_lane][46:24] + rounding_bias_r[46:24] + rounding_carry_r[result_lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; rounding_bias_r: an additive learned offset applied after accumulation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS_HIGH, the machine performs the named control phase..

Line 828: `rounding_value_r[result_lane][46:24]` This is continuation line 2 of the 4-line logical statement that begins at source line 827. Its exact fragment is 'rounding_value_r[result_lane][46:24]'. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes rounding_value_r[result_lane][46:24], the value named 'rounding value r' in this block, equal to 'rounding_value_r[result_lane][46:24] + rounding_bias_r[46:24] + rounding_carry_r[result_lane]'. Read together, the complete operation is: This makes rounding_value_r[result_lane][46:24], the value named 'rounding value r' in this block, equal to 'rounding_value_r[result_lane][46:24] + rounding_bias_r[46:24] + rounding_carry_r[result_lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; rounding_bias_r: an additive learned offset applied

after accumulation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS_HIGH, the machine performs the named control phase..

Line 831: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 832: `state <= ST_ROUND_SHIFT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_ROUND_SHIFT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ROUND_SHIFT: the value named 'st round shift' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS_HIGH, the machine performs the named control phase..

Line 833: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_BIAS_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 835: `ST_ROUND_SHIFT: begin` This is the ST_ROUND_SHIFT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SHIFT, the machine performs the named control phase..

Line 836: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SHIFT, the machine performs the named control phase..

Line 837: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SHIFT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 838: `rounding_value_r[result_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SHIFT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 839: `<= rounding_value_r[result_lane] >> result_shift_r;` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SHIFT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; result_shift_r: the value named 'result shift r' in this block.

Line 840: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SHIFT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 841: `state <= ST_ROUND_SIGN;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_ROUND_SIGN'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ROUND_SIGN: the value named 'st round sign' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SHIFT, the machine performs the named control phase..

Line 842: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SHIFT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 844: `ST_ROUND_SIGN: begin` This is the ST_ROUND_SIGN case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase..

Line 845: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase..

Line 846: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 847: `if (rounding_negative_r[result_lane]) begin` This condition selects the following hardware branch only when ‘rounding_negative_r[result_lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are rounding_negative_r: the value named ’rounding negative r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase..

Line 848: `{rounding_carry_r[result_lane],` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_carry_r: the value named ’rounding carry r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 849: `rounding_value_r[result_lane][23:0]} <=` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_value_r: the value named ’rounding value r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 850: `{1’b0, ~rounding_value_r[result_lane][23:0]}` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are b0: the value named ’b0’ in this block; rounding_value_r: the value named ’rounding value r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 851: `+ 25’d1;` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are d1: the value named ’d1’ in this block.

Line 852: `end else rounding_carry_r[result_lane] <= 1’b0;` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 853: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 854: `state <= ST_ROUND_SIGN_HIGH;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_ROUND_SIGN_HIGH‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_ROUND_SIGN_HIGH: the value named ’st round sign high’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase..

Line 855: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 857: `ST_ROUND_SIGN_HIGH: begin` This is the ST_ROUND_SIGN_HIGH case branch, which performs this explicitly named phase. The same-cycle action begins with ‘begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase..

Line 858: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase..

Line 859: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 860: `if (rounding_negative_r[result_lane]) begin` This condition selects the following hardware branch only when ‘rounding_negative_r[result_lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are rounding_negative_r: the value named ’rounding negative r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase..

Line 861: `rounding_value_r[result_lane][46:24] <=` This statement continues through source line 863; the explanation uses the complete expression rather than only the first visual fragment. This makes rounding_value_r[result_lane][46:24], the value named ’rounding value r’ in this block, equal to ‘(~rounding_value_r[result_lane][46:24]) + rounding_carry_r[result_lane] It updates after the active clock edge together with other nonblocking assignments. The important operands are rounding_value_r: the value named ’rounding value r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; rounding_carry_r: the value named ’rounding carry r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase..

Line 862: `(~rounding_value_r[result_lane][46:24])` This is continuation line 2 of the 3-line logical statement that begins at source line 861. Its exact fragment is ‘(~rounding_value_r[result_lane][46:24])‘. The important operands are rounding_value_r: the value named ’rounding value r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes rounding_value_r[result_lane][46:24], the value named ’rounding value r’ in this block, equal to ‘(~rounding_value_r[result_lane][46:24]) + rounding_carry_r[result_lane] It updates after the active clock edge together with other nonblocking assignments. The important operands are rounding_value_r: the value named ’rounding value r’ in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; rounding_carry_r: the value named ’rounding carry r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase..

Line 863: `+ rounding_carry_r[result_lane];` This is continuation line 3 of the 3-line logical statement that begins at source line 861. Its exact fragment is '+ rounding_carry_r[result_lane];'. The important operands are rounding_carry_r: the value named 'rounding carry r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath. Read together, the complete operation is: This makes rounding_value_r[result_lane][46:24], the value named 'rounding value r' in this block, equal to '(~rounding_value_r[result_lane][46:24]) + rounding_carry_r[result_lane]'. It updates after the active clock edge together with other nonblocking assignments. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath; rounding_carry_r: the value named 'rounding carry r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase..

Line 864: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 865: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 866: `state <= ST_SATURATE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_SATURATE'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SATURATE: the value named 'st saturate' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase..

Line 867: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_ROUND_SIGN_HIGH, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 869: `ST_SATURATE: begin` This is the ST_SATURATE case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase..

Line 870: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase..

Line 871: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 872: `if (result_column_index[result_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_column_index: an integer selecting one tensor element, lane, bank, or state entry; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 873: `< result_column_count) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_column_count: one output-feature position processed in parallel.

Line 874: `if (input_gradient_lane_r[result_lane]) begin` This condition selects the following hardware branch only when ‘input_gradient_lane_r[result_lane]‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are input_gradient_lane_r: the signed loss derivative used to update a learned parameter; result_lane: one parallel arithmetic element within a vector or tensor datapath. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase..

Line 875: `saturated_result_r[result_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are saturated_result_r: the value named 'saturated result r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 876: `<= saturate_s32($signed(` Within the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are saturate_s32: the value named 'saturate s32' in this block.

Line 877: `rounding_value_r[result_lane]));` Within the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 878: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 879: `saturated_result_r[result_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are saturated_result_r: the value named 'saturated result r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 880: `<= saturate_s24_extended($signed(` Within the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are saturate_s24_extended: the value named 'saturate s24 extended' in this block.

Line 881: `rounding_value_r[result_lane]));` Within the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are rounding_value_r: the value named 'rounding value r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 882: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 883: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 884: `saturated_result_r[result_lane] <= 32'sd0;` This makes saturated_result_r[result_lane], the value named 'saturated result r' in this block, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase..

Line 885: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 886: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 887: `state <= ST_STORE_RESULT;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_STORE_RESULT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_STORE_RESULT: the value named 'st store result' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase..

Line 888: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SATURATE, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 890: `ST_STORE_RESULT: begin` This is the ST_STORE_RESULT case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 891: `for (int result_lane = 0; result_lane < RESULT_LANES;` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 892: `result_lane++) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 893: `if (column_group_r) begin` This condition selects the following hardware branch only when 'column_group_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are column_group_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 894: `result_row_buffer_r[result_lane + RESULT_LANES]` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_row_buffer_r: local storage that decouples producer and consumer timing; result_lane: one parallel arithmetic element within a vector or tensor datapath; RESULT_LANES: one parallel arithmetic element within a vector or tensor datapath.

Line 895: `<= saturated_result_r[result_lane];` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four

signed DSP array. The important operands are saturated_result_r: the value named 'saturated result r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 896: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 897: `result_row_buffer_r[result_lane]` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are result_row_buffer_r: local storage that decouples producer and consumer timing; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 898: `<= saturated_result_r[result_lane];` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are saturated_result_r: the value named 'saturated result r' in this block; result_lane: one parallel arithmetic element within a vector or tensor datapath.

Line 899: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 900: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 902: `if (!column_group_r) begin` This condition selects the following hardware branch only when '!column_group_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are column_group_r: one output-feature position processed in parallel. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 903: `column_group_r <= 1'b1;` This makes column_group_r, one output-feature position processed in parallel, equal to '1'b1'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 904: `state <= ST_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to 'ST_MULTIPLY'. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MULTIPLY: the value named 'st multiply' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 905: `end else if (suppress_output_r) begin` This condition selects the following hardware branch only when 'suppress_output_r' is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are suppress_output_r: the value named 'suppress output r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 906: `column_group_r <= 1'b0;` This makes column_group_r, one output-feature position processed in parallel, equal to '1'b0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 907: `if (result_row_r == result_row_count - 1'b1) begin` This condition selects the following hardware branch only when ‘result_row_r == result_row_count - 1’b1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_row_r: one output-row position processed by the tensor tile; result_row_count: one output-row position processed by the tensor tile; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 908: `if (compute_mode_r == MODE_INPUT_GRADIENT` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are compute_mode_r: the value named ’compute mode r’ in this block; MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter.

Line 909: `&& mode_r == MODE_BOTH) begin` Within the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase., this exact statement contributes to the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array. The important operands are mode_r: the value named ’mode r’ in this block; MODE_BOTH: the value named ’mode both’ in this block.

Line 910: `state <= ST_SWITCH_DW;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_SWITCH_DW‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_SWITCH_DW: the value named ’st switch dw’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 911: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 912: `completed_tiles <= completed_tiles + 1'b1;` This makes completed_tiles, the value named ’completed tiles’ in this block, equal to ‘completed_tiles + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are completed_tiles: the value named ’completed tiles’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 913: `state <= ST_DONE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_DONE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DONE: the value named ’st done’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 914: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 915: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 916: `result_row_r <= result_row_r + 1'b1;` This makes result_row_r, one output-row position processed by the tensor tile, equal to ‘result_row_r + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_row_r: one output-row position processed by the tensor tile; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 917: `state <= ST_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_MULTIPLY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MULTIPLY: the value named ’st multiply’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 918: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 919: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 920: `output_word_r <= 2'd0;` This makes output_word_r, the value named ’output word r’ in this block, equal to ‘2’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 921: `if (compute_mode_r == MODE_INPUT_GRADIENT) begin` This condition selects the following hardware branch only when ‘compute_mode_r == MODE_INPUT_GRADIENT‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are compute_mode_r: the value named ’compute mode r’ in this block; MODE_INPUT_GRADIENT: the signed loss derivative used to update a learned parameter. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 922: `state <= ST_OUTPUT_DX;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_DX‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DX: the value named ’st output dx’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 923: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 924: `state <= ST_OUTPUT_DW;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_OUTPUT_DW‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_OUTPUT_DW: the value named ’st output dw’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase..

Line 925: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 926: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 927: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_STORE_RESULT, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 929: `ST_OUTPUT_DX: if (m_axis_tready) begin` This is the ST_OUTPUT_DX case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘if (m_axis_tready) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 930: `if (output_word_r == 3) begin` This condition selects the following hardware branch only when ‘output_word_r == 3‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_word_r: the value named ’output word r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 931: `output_word_r <= 2'd0;` This makes output_word_r, the value named ’output word r’ in this block, equal to ‘2’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 932: `column_group_r <= 1'b0;` This makes column_group_r, one output-feature position processed in parallel, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 933: `reduction_group_r <= 1'b0;` This makes reduction_group_r, the value named ’reduction group r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 934: `if (result_row_r == rows_r - 1'b1) begin` This condition selects the following hardware branch only when ‘result_row_r == rows_r - 1’b1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_row_r: one output-row position processed by the tensor tile; rows_r: one output-row position processed by the tensor tile; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 935: `if (mode_r == MODE_BOTH) state <= ST_SWITCH_DW;` This condition selects the following hardware branch only when ‘mode_r == MODE_BOTH‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are mode_r: the value named ’mode r’ in this block; MODE_BOTH: the value named ’mode both’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 936: `else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 937: `completed_tiles <= completed_tiles + 1'b1;` This makes completed_tiles, the value named ’completed tiles’ in this block, equal to ‘completed_tiles + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are completed_tiles: the value named ’completed tiles’ in this block; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 938: `accumulator_valid_r <= 1'b0;` This makes accumulator_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 939: `state <= ST_DONE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_DONE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DONE: the value named ’st done’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 940: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 941: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 942: `result_row_r <= result_row_r + 1'b1;` This makes result_row_r, one output-row position processed by the tensor tile, equal to ‘result_row_r + 1’b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_row_r: one output-row position processed by the tensor tile; b1: the value named ’b1’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 943: `state <= ST_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_MULTIPLY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MULTIPLY: the value named ’st multiply’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure..

Line 944: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 945: `end else output_word_r <= output_word_r + 1'b1;` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 946: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DX, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 948: `ST_OUTPUT_DW: if (m_axis_tready) begin` This is the ST_OUTPUT_DW case branch, which presents computed results under valid/ready backpressure. The same-cycle action begins with ‘if (m_axis_tready) begin‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 949: `if (output_word_r == 2) begin` This condition selects the following hardware branch only when ‘output_word_r == 2‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are output_word_r: the value named ’output word r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 950: `output_word_r <= 2'd0;` This makes output_word_r, the value named ’output word r’ in this block, equal to ‘2’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 951: `column_group_r <= 1'b0;` This makes column_group_r, one output-feature position processed in parallel, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 952: `reduction_group_r <= 1'b0;` This makes reduction_group_r, the value named 'reduction group r' in this block, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 953: `if (result_row_r == inputs_r - 1'b1) begin` This condition selects the following hardware branch only when ‘result_row_r == inputs_r - 1'b1‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are result_row_r: one output-row position processed by the tensor tile; inputs_r: the value named 'inputs r' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 954: `completed_tiles <= completed_tiles + 1'b1;` This makes completed_tiles, the value named 'completed tiles' in this block, equal to ‘completed_tiles + 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are completed_tiles: the value named 'completed tiles' in this block; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 955: `accumulator_valid_r <= 1'b0;` This makes accumulator_valid_r, the producer's statement that its current payload is meaningful, equal to ‘1'b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 956: `state <= ST_DONE;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_DONE‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_DONE: the value named 'st done' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 957: `end else begin` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 958: `result_row_r <= result_row_r + 1'b1;` This makes result_row_r, one output-row position processed by the tensor tile, equal to ‘result_row_r + 1'b1‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are result_row_r: one output-row position processed by the tensor tile; b1: the value named 'b1' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 959: `state <= ST_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_MULTIPLY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MULTIPLY: the value named 'st multiply' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure..

Line 960: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 961: `end else output_word_r <= output_word_r + 1'b1;` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 962: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_OUTPUT_DW, the machine presents computed results under valid/ready backpressure.; it has no arithmetic value of its own.

Line 964: `ST_SWITCH_DW: begin` This is the ST_SWITCH_DW case branch, which performs this explicitly named phase. The same-cycle action begins with 'begin'; context is the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 965: `for (int row = 0; row < LANES; row++) begin` This generate/procedural loop repeats the following operation across lanes or entries. In synthesizable RTL, a fixed loop is expanded into parallel or scheduled hardware rather than executed by a CPU. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 966: `result_row_buffer_r[row] <= 32'sd0;` This makes result_row_buffer_r[row], local storage that decouples producer and consumer timing, equal to '32'sd0'. It updates after the active clock edge together with other nonblocking assignments. The important operands are sd0: the value named 'sd0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 967: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 968: `compute_mode_r <= MODE_WEIGHT_GRADIENT;` This makes compute_mode_r, the value named 'compute mode r' in this block, equal to 'MODE_WEIGHT_GRADIENT'. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_WEIGHT_GRADIENT: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 969: `input_gradient_lane_r <= {RESULT_LANES{1'b0}};` This makes input_gradient_lane_r, the signed loss derivative used to update a learned parameter, equal to '{RESULT_LANES{1'b0}}'. It updates after the active clock edge together with other nonblocking assignments. The important operands are RESULT_LANES: one parallel arithmetic element within a vector or tensor datapath; b0: the value named 'b0' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 970: `compute_result_row_count_r <= inputs_r;` This makes compute_result_row_count_r, one output-row position processed by the tensor tile, equal to 'inputs_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are inputs_r: the value named 'inputs r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 971: `compute_result_column_count_r <= outputs_r;` This makes compute_result_column_count_r, one output-feature position processed in parallel, equal to 'outputs_r'. It updates after the active clock edge together with other nonblocking assignments. The important operands are outputs_r: the value named 'outputs r' in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 972: `compute_reduction_count_r <= rows_r;` This makes compute_reduction_count_r, an integer count retained for control or measurable telemetry, equal to ‘rows_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are rows_r: one output-row position processed by the tensor tile. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 973: `result_shift_r <= dw_shift_r;` This makes result_shift_r, the value named ’result shift r’ in this block, equal to ‘dw_shift_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are dw_shift_r: the value named ’dw shift r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 974: `rounding_bias_r <= round_bias(dw_shift_r);` This makes rounding_bias_r, an additive learned offset applied after accumulation, equal to ‘round_bias(dw_shift_r)‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are round_bias: an additive learned offset applied after accumulation; dw_shift_r: the value named ’dw shift r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 975: `accumulator_mode_r <= MODE_WEIGHT_GRADIENT;` This makes accumulator_mode_r, a widened running sum that prevents intermediate overflow, equal to ‘MODE_WEIGHT_GRADIENT‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are MODE_WEIGHT_GRADIENT: a learned coefficient multiplied by an activation. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 976: `accumulator_rows_r <= inputs_r;` This makes accumulator_rows_r, a widened running sum that prevents intermediate overflow, equal to ‘inputs_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are inputs_r: the value named ’inputs r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 977: `accumulator_columns_r <= outputs_r;` This makes accumulator_columns_r, a widened running sum that prevents intermediate overflow, equal to ‘outputs_r‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are outputs_r: the value named ’outputs r’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 978: `result_row_r <= 4'd0;` This makes result_row_r, one output-row position processed by the tensor tile, equal to ‘4’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 979: `column_group_r <= 1'b0;` This makes column_group_r, one output-feature position processed in parallel, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 980: `reduction_group_r <= 1'b0;` This makes reduction_group_r, the value named ’reduction group r’ in this block, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 981: `output_word_r <= 2'd0;` This makes output_word_r, the value named ’output word r’ in this block, equal to ‘2’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 982: `state <= ST_MULTIPLY;` This makes state, the finite-state-machine phase retained in flip-flops, equal to ‘ST_MULTIPLY‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are ST_MULTIPLY: the value named ’st multiply’ in this block. Context: the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase..

Line 983: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_SWITCH_DW, the machine performs the named control phase.; it has no arithmetic value of its own.

Line 985: `ST_DONE: state <= ST_IDLE;` This is the ST_DONE case branch, which raises completion for one cycle and returns control to idle. The same-cycle action begins with ‘state <= ST_IDLE;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_DONE, the machine raises completion for one cycle and returns control to idle..

Line 986: `default: state <= ST_IDLE;` This is the default case branch, which performs this explicitly named phase. The same-cycle action begins with ‘state <= ST_IDLE;‘; context is the clocked process that updates registers only on a rising clock edge Within state ST_DONE, the machine raises completion for one cycle and returns control to idle..

Line 987: `endcase` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge Within state ST_DONE, the machine raises completion for one cycle and returns control to idle.; it has no arithmetic value of its own.

Line 989: `if (clear_counters) begin` This condition selects the following hardware branch only when ‘clear_counters‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are clear_counters: a hardware telemetry register that accumulates measured events. Context: the clocked process that updates registers only on a rising clock edge.

Line 990: `completed_tiles <= 32’d0;` This makes completed_tiles, the value named ’completed tiles’ in this block, equal to ‘32’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 991: `active_cycles <= 32’d0;` This makes active_cycles, the value named ’active cycles’ in this block, equal to ‘32’d0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are d0: the value named ’d0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 992: `accumulator_valid_r <= 1’b0;` This makes accumulator_valid_r, the producer’s statement that its current payload is meaningful, equal to ‘1’b0‘. It updates after the active clock edge together with other nonblocking assignments. The important operands are b0: the value named ’b0’ in this block. Context: the clocked process that updates registers only on a rising clock edge.

Line 993: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 994: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 995: `end` This structural keyword opens or closes the branch/process scope described as the clocked process that updates registers only on a rising clock edge; it has no arithmetic value of its own.

Line 997: `initial begin` This opens simulation initialization. In a testbench it drives starting values and stimulus; project synthesis does not rely on this block as a replacement for explicit reset behavior.

Line 998: `if (LANES != 8) begin` This condition selects the following hardware branch only when ‘LANES != 8‘ is true. Both branches exist as gates; the condition controls a multiplexer rather than making software jump. The important operands are LANES: one parallel arithmetic element within a vector or tensor datapath. Context: the module’s structural declarations.

Line 999: `$fatal(1, "neuraedge_linear_backward8 currently requires LANES=8");` This is a simulation check or diagnostic. It can stop a failing test and print evidence, but it is not part of the synthesized PYNQ circuit.

Line 1000: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 1001: `end` This structural keyword opens or closes the branch/process scope described as the module’s structural declarations; it has no arithmetic value of its own.

Line 1002: `endmodule` This closes the current hardware definition; no circuit behavior is attached to the keyword itself.

Line 1004: `‘default_nettype wire` This SystemVerilog preprocessor line controls compilation of the block that computes exact tiled linear-layer input and weight gradients with a reusable four-by-four signed DSP array.

14 rtl/neuraedge_log_softmax.sv

Role in the complete system: implements power-of-two integer softmax normalization without floating-point exponent hardware.

14.1 Beginner architecture map

Dataflow responsibility The engine buffers logits, finds their maximum, converts bounded negative differences to power-of-two terms, sums the denominator, divides each term into a fixed probability scale, and streams normalized outputs without a floating-point exponential unit.

What becomes FPGA hardware Vivado elaborates module(s) neuraedge_log_softmax into physical nets and primitives. The source declares 9 input-port lines, 11 output-port lines, 1 clocked process(es), and 1 combinational process(es). Clocked assignments become retained state; combinational assignments become gates, arithmetic, and multiplexers.

Cycle-level control The named control phases include ST_EXPONENT_ACCUMULATE, ST_EXPONENT_CLAMP, ST_EXPONENT_DIFFERENCE, ST_EXPONENT_LATCH, ST_EXPONENT_QUANTIZE, ST_EXPONENT_READ, ST_EXPONENT_SHIFT, ST_IDLE, ST_LOAD, ST_OUTPUT_HOLD, ST_OUTPUT_LATCH, ST_OUTPUT_MULTI ST_OUTPUT_OPERANDS, ST_OUTPUT_PRODUCT_ADD, ST_OUTPUT_READ, ST_OUTPUT_ROUND, ST_RECIPROCAL_START, ST_RECIPROCAL_WAIT. A state is a binary value held in flip-flops. On each rising edge, accepted valid/ready handshakes and current state determine the next state and which memories or output registers update.

Connections to other blocks This source instantiates neuraedge_udivider as u_divider, unique as case. Port-map lines connect actual parent wires to each child's named ports; no data is copied merely by naming a connection.

How to debug it In a waveform, place clock and reset first, then each interface's valid, ready, data, and last signals together. A transfer exists only on an edge where valid and ready are both one. Add state, address/index, accumulator, and error signals to explain why the interface advanced or stalled.

The important operands are input: the value named 'input' in this block; rst_n: the active-low synchronous reset. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 10: `input wire start_valid,` This is continuation line 6 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'input wire start_valid,'. The important operands are input: the value named 'input' in this block; start_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 11: `output logic start_ready,` This is continuation line 7 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic start_ready,'. The important operands are output: the value named 'output' in this block; start_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 12: `input wire [8:0] item_count,` This is continuation line 8 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'input wire [8:0] item_count,'. The important operands are input: the value named 'input' in this block; item_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 13: `input wire [4:0] difference_shift,` This is continuation line 9 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'input wire [4:0] difference_shift,'. The important operands are input: the value named 'input' in this block; difference_shift: the value named 'difference shift' in this block. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input

wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 14: `input wire score_valid,` This is continuation line 10 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'input wire score_valid,'. The important operands are input: the value named 'input' in this block; score_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 15: `output logic score_ready,` This is continuation line 11 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic score_ready,'. The important operands are output: the value named 'output' in this block; score_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 16: `input wire signed [SCORE_BITS-1:0] score_value,` This is continuation line 12 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'input wire signed [SCORE_BITS-1:0] score_value,'. The important operands are input: the value named 'input' in this block; SCORE_BITS: the value named 'score bits' in this block; score_value: the value named 'score value' in this block. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 17: `input wire score_last,` This is continuation line 13 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'input wire score_last,'. The important operands are input: the value named 'input' in this block; score_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 18: `output logic probability_valid,` This is continuation line 14 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic probability_valid,'. The important operands are output: the value

named 'output' in this block; probability_valid: the producer's statement that its current payload is meaningful. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 19: `input wire probability_ready,` This is continuation line 15 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'input wire probability_ready,'. The important operands are input: the value named 'input' in this block; probability_ready: the consumer's statement that it can accept a payload this cycle. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 20: `output logic [15:0] probability_q15,` This is continuation line 16 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic [15:0] probability_q15,'. The important operands are output: the value named 'output' in this block; probability_q15: the value named 'probability q15' in this block. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 21: `output logic [8:0] probability_index,` This is continuation line 17 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic [8:0] probability_index,'. The important operands are output: the value named 'output' in this block; probability_index: an integer selecting one tensor element, lane, bank, or state entry. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 22: `output logic probability_last,` This is continuation line 18 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic probability_last,'. The important operands are output: the value named 'output' in this block; probability_last: the AXI-Stream marker for the final beat of a packet or command payload. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 23: `output logic config_error,` This is continuation line 19 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic config_error,'. The important operands are output: the value named 'output' in this block; config_error: the value named 'config error' in this block. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 24: `output logic [31:0] cycle_count,` This is continuation line 20 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] cycle_count,'. The important operands are output: the value named 'output' in this block; cycle_count: an integer count retained for control or measurable telemetry. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 25: `output logic signed [SCORE_BITS-1:0] debug_maximum_score,` This is continuation line 21 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic signed [SCORE_BITS-1:0] debug_maximum_score,'. The important operands are output: the value named 'output' in this block; SCORE_BITS: the value named 'score bits' in this block; debug_maximum_score: the value named 'debug maximum score' in this block. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 26: `output logic [23:0] debug_denominator,` This is continuation line 22 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic [23:0] debug_denominator,'. The important operands are output: the value named 'output' in this block; debug_denominator: the value named 'debug denominator' in this block. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 27: `output logic [31:0] debug_reciprocal_q31` This is continuation line 23 of the 24-line logical statement that begins at source line 5. Its exact fragment is 'output logic [31:0] debug_reciprocal_q31'. The important operands are output: the value named 'output' in this block; debug_reciprocal_q31: the value named 'debug reciprocal q31' in this block. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready,

output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 28: `);` This is continuation line 24 of the 24-line logical statement that begins at source line 5. Its exact fragment is ');'. The expression is a literal or structural operator and has no hidden software state. Read together, the complete operation is: This fixes MAX_ITEMS to 256, parameter int SCORE_BITS = 24) (input wire clk, input wire rst_n, input wire start_valid, output logic start_ready, input wire [8:0] item_count, input wire [4:0] difference_shift, input wire score_valid, output logic score_ready, input wire signed [SCORE_BITS-1:0] score_value, input wire score_last, output logic probability_valid, input wire probability_ready, output logic [15:0] probability_q15, output logic [8:0] probability_index, output logic probability_last, output logic config_error, output logic [31:0] cycle_count, output logic signed [SCORE_BITS-1:0] debug_maximum_score, output logic [23:0] debug_denominator, output logic [31:0] debug_reciprocal_q31) during elaboration. Vivado uses that constant to shape or simplify the generated circuit; MAX_ITEMS denotes the value named 'max items' in this block.

Line 29: `typedef enum logic [4:0] {` This begins a named finite-state-machine type. The encoded bits are stored in flip-flops, while symbolic names make each cycle-level phase reviewable.

Line 30: `ST_IDLE = 5'd0,` This assigns a fixed binary encoding to state ST_IDLE, which waits for a new operation and does not consume payload data. The encoding is visible in waveforms even though the source uses the readable name.

Line 31: `ST_LOAD = 5'd1,` This assigns a fixed binary encoding to state ST_LOAD, which stores incoming operands into local FPGA memory. The encoding is visible in waveforms even though the source uses the readable name.

Line 32: `ST_EXPONENT_READ = 5'd2,` This assigns a fixed binary encoding to state ST_EXPONENT_READ, which identifies one explicit control phase. The encoding is visible in waveforms even though the source uses the readable name.
